The current research attempts to enhance our understanding of the role of humor in advertising by examining the moderating role of a viewer's prior evaluation of the advertised brand. The latter was considered to be a variable of significant importance both from a conceptual as well as a managerial perspective. It was believed that while the presence or absence of humor in a message would affect the extent of cognitive elaboration associated with the message (i.e., humorous ads would lead to more cognitive responses than corresponding serious versions), the nature of an audience's prior evaluation of the advertised brand would determine the directionality of the cognitive elaboration. That is, a favorable prior evaluation would increase the persuasiveness of humor, while a negative prior evaluation would yield no improvement over a neutral version. Further, such effects were expected to persist over a period of time and hence be of managerial relevance.

THE STUDY

Using a between-subjects design, subjects' prior evaluation of the target brand was first manipulated through product trial. Next, subjects saw either a humorous or a non-humorous ad. The effects of these two independent factors on ad attitude, brand attitude, purchase intent, and choice behavior were examined after a week's delay.

RESULTS

Results show that the effect of humor in advertising is contingent on the subjects' prior attitude towards the brand. As hypothesized, when a consumer's prior brand evaluation is favorable, a humorous ad is more effective in enhancing brand attitude and choice behavior, in comparison to the corresponding non-humorous ad. When a consumer's prior brand evaluation is unfavorable, the converse

was found to be true. That is, the non-humorous ad was more effective in enhancing consumer attitudes and choice behavior compared to the humorous version. The above interaction was observed a week after subjects' exposure to the ads, thereby supporting our premise that the effects are persistent over time and warrant managerial attention.

Parallel Processing Models of Consumer Information Processing: Their Impact on Consumer Research Methods

Dawne Martin, University of Calgary
Pamela Kiecker, Texas Tech University

ABSTRACT

Current models of consumer information processing assume that processing occurs in a serial, or sequential fashion. However, new models of parallel distributed processing (PDP) have been developed in the fields of cognitive science and artificial intelligence. These new models assume massively parallel processing in the human brain, and have implications for marketers' research on consumer information processing. Parallel models are introduced and underlying assumptions of serial and parallel models are compared. The impact of accepting parallel processing models on the development of consumer research methods and analysis of results is discussed.

INTRODUCTION

When the study of cognition became popular in the 1960s, it was generally assumed that the human information processing system functioned much like a von Neumann computer. Processing was viewed as serial, consisting of a sequence of discrete operations. Memory was viewed as a set of separate stores. Serial processing models, originally introduced in 1936 by English logician Alan Turing, are the foundation of current models of human information processing used in marketing. The most basic assumption of serial processing models, as delineated by Newell and Simon's (1972) theory of problem solving, requires that only one information process occur at a time. This view has prospered for many years, with more recent models and theories, including frames (Minsky 1975), schemata (Bobrow and Norman 1975), scripts (Schank and Abelson (1977), knowledge assembly (Hayes-Roth 1977) and Bettman's information processing theory of consumer choice (1979), incorporating serial processing. This fact has not only influenced development of human information processing theory, but has directed researchers' selection of research methods used in the study of consumer information processing, particularly process tracing methods.

Evidence from neurobiology suggests that the brain does not operate in a serial manner (Shepherd 1979, Crick and Asanuma 1986). This evidence shows that the human brain is massively parallel, capable of processing a large number of relatively complex cognitive tasks simultaneously. Researchers in a variety of fields have now begun to develop models of human information processing based on this evidence of parallel processing (McClelland, Rumelhart and the Parallel Distributed Processing (PDP) Research Group 1986, Anderson and Hinton 1981). This work has led to a reconceptualization of memory structure and knowledge representation (Anderson 1976, Feldman 1985, Rumelhart and Norman 1981). Testing these

new models requires research methods that are not, necessarily, tied to the basic assumption of serial processing. If selection of either serial or parallel processing models determines how consumer research is conducted, effects of the respective models become a fundamental issue for researchers.

This paper has three objectives: (1) to introduce the concept of parallel processing; (2) to compare specific assumptions underlying serial and parallel processing models; and (3) to address implications of replacing serial processing models with parallel processing models for consumer research. In particular, the appropriateness of current research techniques used by consumer researchers are evaluated in light of parallel processing models.

PARALLEL PROCESSING MODELS

Parallel processing models have grown out of research in cognitive science. Cognitive science is interdisciplinary, drawing on expertise from a variety of fields, including neurobiology, cognitive psychology, mathematics and computer science. Much of the work in this area has been conducted under the rubric of artificial intelligence (AI). The major focus of AI is to develop methods of replicating human intelligence in a computer environment. These attempts at replication of human intelligence have suggested a need for reevaluation of serial processing models. Now, in increasing numbers, researchers are exploring a different framework for thinking about cognitive processes. These researchers generally accept the computer metaphor as a useful approximation of the macrostructure of human thought, however, they have come to feel that an alternative framework may be more appropriate for characterizing its microstructure.

This alternative is suggested in various parallel processing models appearing in the literature over the past fifteen years. The models are referred to variously as Connectionist Models (Feldman 1981, Feldman and Ballard 1982), Parallel Distributed Processing (PDP) Models (McClelland, Rumelhart and the PDP Research Group 1986) and Parallel Models of Associative Memory (Anderson and Hinton 1981). The term "Connectionist Models" is the most general. It is used to refer to a class of information processing models that consist of a network of simple processing units interacting via a series of connections. PDP models are a type of Connectionist Model that stress the notion that processing activity results from processing interactions occurring among rather large numbers of processing units (Johnson-Laird 1988). Connections allow for interactions between units. Each specific Connectionist Model will make assumptions about the number of units and the

pattern of connections between units. The set of units and their connections is typically called a network.

According to the Connectionist view, the human information processing system is a network operating under a set constraints. Each unit, which may be a neuron or some network of neurons, operates through connections with other units. The number and type of connections define the constraints imposed on the network. Units take on activation values based on a weighted sum of their inputs from the environment and from other units. The connections are also weighted--either positively or negatively--so that a particular input will either excite or inhibit the unit that receives it, depending on the sign of the weight.

The strength or weakness of the constraints is determined by the weight of the connection. Learning is a function of changing existing constraints through modification of weights, or introducing new constraints through new connections. In parallel models units do not represent complex concepts, such as those associated with schemata (Rumelhart, et al. 1986). Rather, units are relatively simple, and "schemata emerge at the moment they are needed from the interaction of large numbers of much simpler elements all working in concert with one another" (Rumelhart, et al. 1986, p. 21).

This brief description suggests that parallel models are substantially different from conventional serial models of human information processing. Parallel models begin with neurophysiological evidence, then build on this evidence to describe the cognitive functions of human thought, learning and intelligence. The assumptions underlying parallel models are also very different from those underlying serial models. The next section discusses two important assumptions that distinguish parallel from serial models.

ASSUMPTIONS OF PARALLEL AND SERIAL MODELS

There are numerous assumptions, beginning at the most basic levels and continuing through complex cognitive designs, which differ significantly between parallel and serial models of information processing. Johnson-Laird (1988) considers each of several aspects of an information processing system, describing the general assumptions parallel models make about these aspects. In this section, only two assumptions which appear to have a direct impact on the appropriateness of different research methods currently designed to evaluate human information processing are reviewed. These assumptions are the most general and cover the nature of (1) the processing model and (2) memory structure. Each is reviewed in turn.

The Nature of the Processing Model

Perhaps the most important assumption distinguishing parallel processing models from serial processing models concerns that nature of the

model. Contrary to Newell and Simon's (1972) suggestion that there are central control units or "executives" required to oversee the operations of various programs or production systems, in parallel processing models the human information processing system is seen to be capable of complex global goal directed processing (Rumelhart and Norman 1985).

Representations in parallel models are patterns of activation over the units in the network. The representations are truly active, in the sense that they give rise to further processing activity directly without any need for a central processor that examines them and takes action on the basis of the results of this examination. Knowledge is stored in the connections between processing units. This assumption works together with assumptions about representations. An active representation of a set of units, together with the knowledge stored in connections, will give rise to new patterns of activation on the same or other units. While the concept of executives was developed for serial models in order to address the need to have some control over the sequencing of the serial processes assumed in the models, parallel models do not require this type of control mechanism.

Neurobiological evidence, as mentioned in the preceding section, strongly suggests that the brain is massively parallel. Parallel models assume that this neurophysiological reality is the basis for construction of memory and, consequently, of knowledge representation (Rumelhart and Norman 1981). In contrast, Newell and Simon (1972) recognize evidence for parallel processing, but contend that "it is possible for an IPS [information processing system] to be parallel for two activities, but not parallel for three or more, since the processor may be capable of carrying along only two independent control sequences" (p. 797). Thus, Newell and Simon's imposition of a control system (a characteristic of serial processing models) excluded the possibility of parallel processing at higher levels of cognition.

Another response to the evidence for parallel processing is that the "computation devices" (e.g., neurons) should not have an impact on how concepts are encoded in memory. However, the underlying configuration of the neurons does impact the way information is processed. The way that computational devices operate influences how higher-level cognitive structures are created and operate. For instance, frames (Minsky 1975) and scripts (Schank and Abelson 1977) employ passive data structures which require explicit default values to explain the creation and operation of higher-level cognitive structures. Any variation in operation of passive data structures would alter the conceptualization of memory structure and knowledge representation (Norman 1986).

The Nature of Memory Structure

The second assumption to be addressed is that of memory structure. In parallel models, information is not stored in a "place." Rather, it is

represented by the relationship among units, and each unit may be involved in the storage of multiple memories (Rumelhart and Norman 1981). Thus, memory is distributed across relationships, rather than associated with a particular place in long-term or short-term memory. Accessing memory requires tracing the relationships or connections between units. This conception of memory allows traces to interact, with the result that memory tends to focus on the commonality of information or experiences. Therefore, individuals are capable of forming generalizations from previous experiences when faced with new circumstances.

In contrast, serial models assume that information is stored in a particular place, distinct from the storage of other information. Retrieval of information from memory requires "addresses" or "pointers" to describe the place where information is stored. Retrieval is characterized by finding the information stored in memory, finding the right schema, or following the appropriate links in semantic networks.

Another major difference between serial and parallel models is the categorization of memory as long-term and short-term. Serial models, which require a problem space and short-term storage of information to be manipulated by the production system, focus on short-term memory. In these models, short-term memory is very small, able to hold only five to seven chunks of information (Newell and Simon 1972). The size of the short-term memory places a major constraint on human information processing capacity. This idea of limited processing capacity has generated the notions of information overload (Jacoby, Speller and Kohn 1974, Malhotra 1982, Jacoby 1984, Malhotra 1984) and distraction (Nelson, Duncan and Frontczak 1985, Petty, Wells and Brock 1976, Venkatesan and Haaland 1968, Wright 1974).

In contrast, parallel models do not make any assumptions regarding divisions in memory. What is termed short-term memory in serial models is essentially the electrical activation of the network of relationships that represents the information. Since short-term memory is based on activation, it decays rapidly and may be rather limited (Feldman 1985). However, it is not specifically limited to between five and seven chunks as cited by Newell and Simon (1972). What appears as long-term memory in serial models involves the actual changing of weights in the relationships between units in parallel models (Feldman 1985).

In summary, the conception of memory in parallel models does not call for separate "places" for short-term and long-term memory. Instead, these types of distinctions are a function of the basic processes occurring in the brain (Anderson 1976, Feldman 1985). Furthermore, the assumptions underlying memory in parallel models are not as restrictive as those for serial models with respect to processing capacity. As the above discussion emphasizes, important differences exist between serial and parallel models of human information processing with respect to the nature of the

processing models and the structure of memory. These differences underlie other substantive differences in the way the models address higher levels of cognitive activity, such as learning, inferences and choice. The differences also impact decisions with respect to the research techniques used in the investigation of consumer information processing. The appropriateness of many current techniques used by consumer researchers studying information processing needs to be evaluated in light of evidence supporting parallel models.

IMPACT OF ASSUMPTIONS ON RESEARCH TECHNIQUES

Process tracing techniques have become dominant in research aimed at describing actual consumer choice behavior (Slovic, Fischhoff and Lichtenstein 1977). A basic objective of the research has been to find alternative models or heuristics that take into account consumers' mental representations of information upon which decisions are based (Tversky and Kahneman 1981). However, these techniques have been criticized on two particular accounts: (1) their static nature (Jacoby, Szybillo and Busato-Schach 1977) and (2) their focus on overt, voluntary behavior (Lynch and Srull 1982). In addition to these criticisms, serial processing is assumed when these techniques are used. More importantly, use of process tracing techniques actually *forces* subjects into describing processing in a serial fashion.

Process tracing techniques include protocol analysis, information monitoring, and eye movement analysis. The assumptions underlying serial processing models are evident in each of these process tracing techniques. Both the task and the output of the techniques reflect serial processing by their very design. The output from the consumer, whether in terms of a verbal protocol or selection of information from a display board, is *restricted* to a serial task. Only one thing can be done at a time, by the design of the research. Consequently, the techniques themselves force participants into a serial processing mode, or at least require them to *represent* their decision processes as serial.

In reference to protocol methods, Bettman (1979) states that "...the subject is theoretically verbalizing thoughts as they occur in the course of problem solving" (p. 195). Thus, research assumes that the subject is thinking in a serial manner. The decision net method of analyzing protocols also assumes seriality by imposing a branching structure and rule-dominated method of judgment. Parallel models, in contrast, would assume that comparisons between attributes are made in parallel, based on global constraint satisfaction rather than application of specific rules (Rumelhart et al. 1986).

Information monitoring methods were originally used in the study of consumer processing by Jacoby (1975). Information display boards, for example, are designed in such a way that subjects must choose one piece of information at a time. This information generally relates to an attribute of a particular brand. The process requires subjects to

make a serial inspection of the information. The researcher then assumes that the sequential selection of information represents the consumer's information processing and choice strategy.

Bettman's (1979, p. 197) analysis of this technique reveals several shortcomings that may be due to the basic assumption of serial processing. First, the external information gathering task may not represent the internal processing of the information. Second, the technique does not investigate the effects of internal information which may affect the search and processing of the chosen information. In contrast, parallel models propose that the subject is activating memory relationships that allow for generalizations between past experience the current tasks (Rumelhart, et al. 1986).

Eye movement analysis (Russo and Rosen 1975) is another process tracing method that needs to be reevaluated in light of parallel processing models. The pattern and sequence of eye movements are assumed to represent information examination and are used to infer details of internal processing. In eye movement analysis, like protocol analysis and information monitoring, the subject is forced into a serial mode of search, this time by the physical separation of the articles to be inspected. Eye movement analysis has been designed to "...guard against ambiguous interpretations due to the subjects' use of peripheral vision (Bettman 1979, p. 197). As a result of this design, subjects are restricted from taking in more than one piece of information at a time.

In contrast to the above process tracing methods, experimental techniques are being developed which allow for examination of parallel processing. Much of this research has utilized computer simulation to assist in development of computational theories of human information processing. For instance, Marr and Poggio's (1976) attempt to model human vision led to the need to incorporate interconnections between processing units in order to explain human vision capabilities. However, some research has adapted more conventional experimental techniques to test parallel models.

For example, response time analysis has already been used to investigate the nature of processing (Jacoby, Speller and Kohn 1974). This method assumes that mean response time is an indication of the amount of processing required for a particular task. Traditionally, researchers have tended to assume serial processing in their analysis of response time results. However, discrete response times, combined with accuracy measures, have been used to investigate parallel versus serial models in sentence perceptions (Marslen-Wilson 1975). The interaction of speed and accuracy in restoration of disrupted words was investigated for various levels of disruption in semantic and contextual constraints. Results showed that "sentence perception is most plausibly modeled as a fully interactive parallel process" (Marslen-Wilson 1975, p. 226).

Another experimental technique, one that has been used in reading research, entails presenting two words to subjects, each located at different sides of the eye fixation (Mozer 1983). The words contain two letters which are the same, such as sand and lane. Through counterblocks of trials the duration of the word display is adjusted to provide a fixed rate of whole word response errors. Errors in the subject's ability to reproduce the specified word are analyzed based on error types produced. This analysis determines the level of connection that exists between the current input, or two word pair, and knowledge structures the subject possesses.

A similar procedure might be used to provide evidence of parallel processing in information display boards and eye movement analysis. For example, information display boards could be reproduced using video terminals. The subject would be shown multiple attributes of various brands for a very short duration, after which the subject would be asked to make a purchase decision. The outcome of this choice might then be compared to a choice made when the subject was able to view attributes or brands in a sequential manner. In the case of eye movement analysis, the researcher might reduce the physical separation of the articles to be inspected. The results of this eye movement analysis might then be compared to the results of the conventional eye movement analysis. There is some evidence to suggest that focusing attention on separate places can be accomplished within a single eye fixation, without eye movement (Posner 1978, Triesman and Gelade 1980, Feldman and Ballard 1982).

In summary, it appears that many research techniques used in consumer information processing are based on the underlying assumptions of serial processing models. Process tracing methods, in particular, have been tied to serial models. Researchers also tend to analyze data gathered from other methods, like response time analysis, under the rubric of serial processing. However, there are similar research methods that do not assume serial processing and, therefore, may be more appropriate.

CONCLUSIONS

This paper has introduced the concept of parallel processing. It has presented some of the differences in assumptions between parallel and serial processing models. The comparisons have been limited to two assumptions: (1) the nature of processing, and (2) the nature of memory structure. In light of these differences, it is suggested that some research techniques used to study consumer information processing may need to be reevaluated. In particular, process tracing methods have been shown to be explicitly tied to serial processing models. Some alternative methods, based on parallel processing models, are suggested for future research. Consideration of parallel processing models in research design and theory or model development may alter the way consumer researchers conceptualize important issues, including issues related to consumer choice strategies.

While research appears to support parallel processing models, there are some distinct problems with this approach. Most of these problems are a result of the relatively short history of research in Connectionist or Parallel Distributed Processing Models. The major problems which will impact consumer researchers are associated with the current level of development of the models. Specifically, research on parallel processing models has been focused on lower levels of cognition. Questions of inference, for example, have yet to be fully addressed. However, the models do provide some insight into problems tied to serial models of information processing. For that reason, parallel models warrant further investigation in the context of consumer research.

The Effect Of Imagery Processing And Imagery Content On Behavioral Intentions

Paula Fitzgerald Bone, West Virginia University
Pam Scholder Ellen, Georgia State University

ABSTRACT

Imagery processing has been recognized as superior to discursive (or verbal) processing and thus has become an important tool in designing advertising. Evidence suggests that imagery-producing ads result in superior recall and more positive attitudes toward the product. However, there has been limited examination of the relationship between imagery and behavioral intentions. We investigate this latter relationship going beyond other research in the area by examining imagery content. Specifically, we report the results of an experiment which tests the effects of three message-relevant factors on behavioral intentions: (1) self-relatedness, (2) plausibility, and (3) distinctiveness.

INTRODUCTION

Consumer researchers have long recognized the advantage of imagery processing over verbal processing. While imagery has traditionally been linked to visual stimuli, i.e., "thinking in pictures" (Fodor 1981; Lutz and Lutz 1978), MacInnis and Price (1987) point out that imagery processing can entail all of the senses. One can imagine the song of a bird, the crunch of a Dorito, the feel of sandpaper, and the taste of a lemon just as vividly as one can mentally picture these objects. Therefore, consistent with MacInnis and Price (1987), we define imagery as an information processing mode which uses one or more of the five senses.

Several studies have shown that imagery processing can improve recall and enhance attitude toward the brand (see Lutz and Lutz 1978 and MacInnis and Price 1987 for a review). There is even some evidence of a positive relationship between imagery processing and behavioral intentions (BI) (cf., Anderson 1983; Gregory, Cialdini, and Carpenter 1982). Yet, only Gregory, Cialdini, and Carpenter (1982) have shown this relationship to exist in a marketing context. In a personal selling situation, Gregory, et al. (1982) found that individuals who were asked to imagine themselves enjoying the benefits of cable TV had greater intentions to subscribe to the cable service than did individuals who were simply told about these benefits.

In this investigation, we empirically examine the relationship between imagery and BI in an advertising context. In addition, we identify and test the effects of several message factors which may differentially affect imagery's relation to BI.

Why should imagined sensory experiences result in more positive BI? Two prominent theories may explain these effects: (1) the availability/valence hypothesis (Anderson 1983; Gregory, Cialdini, and Carpenter 1982; MacInnis and Price

1987; Mowen 1980; Tversky and Kahneman 1973) and (2) the semantic network theory (Mitchell 1983). Availability/valence hypothesis states that the information which is most available to an individual when making a judgment has the greatest impact on that individual's judgment. Many researchers (Anderson 1983; Gregory, Cialdini and Carpenter 1982; Mowen 1980) have hypothesized that imagery results in more concrete scenarios and greater information elaboration than does discursive processing (i.e., verbal processing). This, in turn, makes information "spring to mind" more easily when judgments are made. These judgments will be positively (negatively) influenced if the available information is favorable (unfavorable).

Semantic network theory (Mitchell 1983) augments availability/valence theory by considering specific elements of the imagined scene, rather than only the valence of the scene. According to this theory, an individual's long-term memory (LTM) is made up of links and nodes. Links represent relationships (positive or negative; strong or weak) and nodes represent concepts (e.g., products, persons, emotions, tastes, sounds). Imagery content may determine which concepts are linked together in LTM. For instance, an ad which asks a consumer to imagine his/her spouse driving a Volkswagen could create links between the consumer's spouse and the Volkswagen in LTM. This direct link may cause the consumer to perceive a greater chance that her/his spouse would purchase the Volkswagen.

It appears that combining availability/valence theory and semantic network theory can aid us when examining the imagery/BI relationship. These theories are not presented as competing explanations of imagery effects, but rather as theories that work hand-in-hand to help explain this potentially important relationship. Based on these two theories, we make the following proposition:

P1: Imagery processing will create greater BI than discursive processing.

Additionally, it is likely that the imagery/BI relationship is affected by many message factors. We discuss a few of these variables in the following section.

FACTORS INFLUENCING THE IMAGERY/INTENTIONS RELATIONSHIP

Extant literature suggests several variables which may affect the imagery/BI relationship. We have classified these variables into two groups: (1) message elements that facilitate imagery processing, and (2) message elements that differentially affect the relationship between imagery and BI. The first

group consists of message elements which researchers have used to "manipulate" imagery processing. These include the use of (1) pictures, (2) concrete words, and (3) instructions to imagine (Lutz and Lutz 1978; MacInnis and Price 1987).

The second variable set is expected to differentially affect BI when imagery processing occurs. In this study we examine three such variables: self-relatedness, plausibility, and distinctiveness. We chose to investigate these variables because several researchers have alluded to their importance (cf., Anderson 1983; Carroll 1978; Lutz and Lutz 1978; MacInnis and Price 1987) and because these variables have direct implications for designing marketing communications.

Self-Relatedness

Self-relatedness deals with the focal character in the imagined scenario (Anderson 1983; MacInnis and Price 1987). A scenario is self-related when the main character is the consumer exposed to the ad. A scenario is other-related if the main character is *not* the consumer him/herself. Semantic network theory argues that direct links will be made between the self and the product advertised when the consumer is the subject of the imagery processing. This link should make the prospect of future interaction with the product seem more likely. If another person (e.g., friend, relative, celebrity) is the focal character of the imagery experience, there will be no direct link between the consumer and the product. Consequently, the relationship between imagery processing and BI may not be as strong.

Anderson (1983) found that self- vs. other-relatedness does indeed affect the relationship between imagery and BI. In a clinical context, he demonstrated that subjects asked to imagine and draw themselves in various scenarios formed BI consistent with the scenarios. However, no changes in BI were found when subjects were asked to draw scenarios involving other people. This leads us to the following proposition:

P2: Self-related imagery will create more positive BI than other-related imagery.

Plausibility

The plausibility of the imagined scenario should affect imagery's relationship to BI (Anderson 1983; Carroll 1978). A plausible situation is one that is consistent with a consumer's lifestyle--a situation in which a consumer could reasonably expect to participate. BI should be greater for plausible situations since links are formed in LTM between the product and a realistic personal situation. Thus, a plausible context should enhance availability of the brand name and increase the consumer's perception that s/he is likely to purchase the product.

For example, an advertisement for a new line of elegant paper plates could ask an individual to imagine him/herself in a multimillion dollar home, using the paper plates while entertaining international dignitaries and movie stars--an

implausible situation. Alternatively, it could ask him/her to imagine using the plates at home while entertaining a few close friends. The latter, more plausible situation, should create direct links in the consumer's LTM which relate the product to a personal situation, thus making future interaction with the product seem more likely. Therefore, we propose that:

P3: Imagery which contains plausible scenarios will create more positive BI than imagery which contains implausible scenarios.

Distinctiveness

A final factor expected to affect the imagery/BI relationship is situational distinctiveness (Lorayne and Lucas 1974; Lutz and Lutz 1978). Distinctiveness takes into account the imagined scenes' uniqueness. It is bounded at the lower end by mundane and at the upper end by bizarre.

Presenting a product in a mundane situation is unlikely to enhance the relationship between imagery and BI. When a consumer has numerous associations with a situation (which is highly possible with a common situation), the association between the brand and the situation may be drowned out and unavailable (Nisbett and Ross 1980). For example, a consumer asked to imagine him/herself waking up, getting dressed, and making a cup of Folger's coffee is likely to have many different images associated with this mundane event. It is possible that the image of drinking Folger's coffee may be drowned out by other images associated with getting ready for the day.

Evidence suggests that bizarre situations (ones with very high distinctiveness) positively influence advertisement and brand recall (Lutz and Lutz 1978). Yet, semantic network theory suggests that marketers should create links between the product and a situation which could actually occur in the consumer's life. This theory implies that a bizarre situation is unlikely to enhance the relationship between imagery and BI.

Note that plausibility and distinctiveness are inherently confounded since a bizarre product-usage scenario is almost certainly implausible whereas a mundane event would be quite plausible. Thus, these two factors, plausibility and distinctiveness will be considered together and lead to:

P4: Imagery which is plausible and moderately distinctive will create greater BI than imagery which is plausible and indistinctive or implausible and highly distinctive.

In the next section of this paper we discuss an empirical test of the following hypotheses. The specific proposition(s) upon which each hypothesis is based is noted in parentheses.

H1. High-imagery ads will create greater BI than the low-imagery control ad. (Proposition 1)

H2. High-imagery self-related ads will create greater BI than high-imagery other-related ads. (Proposition 2)

H3. High-imagery, moderately distinctive, and plausible ads will create greater BI than either high-imagery, indistinctive, and plausible ads or high-imagery, highly distinctive, and implausible ads. (Propositions 4)

EXPERIMENT

Seven radio advertisements were created in order to investigate the effects of imagery, self-relatedness, plausibility, and distinctiveness on BI. Radio was selected as the experimental medium because self-generated imagery should have a greater effect than other-generated imagery (Lorayne and Lucas 1974; Lutz and Lutz 1978). If a consumer is forced to create his/her own images, the mental processing is at a deeper level than if the images are created for him/her.

Focus interviews indicated that popcorn could serve as the experimental product. Its consumption abounds with high sensory experiences (e.g., aroma, texture, taste, sound), and it is popular with the subject population (college students). A fictional brand name was used to control for familiarity with particular brands.

A 3 (plausibility/distinctiveness) by 2 (self/other-relatedness) design with a low-imagery control group was used in this experiment. The first factor incorporates several combinations of plausibility and distinctiveness to create three different situational scenarios. The independent manipulation of these two factors is impossible because they are inextricably confounded.

The first scenario was plausible and indistinctive. Subjects assigned to this treatment listened to an ad which asked them to imagine someone (self or other) lying on a couch, watching TV, and getting a craving for popcorn. The second scenario was still plausible and moderately distinctive. This ad asked subjects to imagine someone (self or other) cooking out on the beach while on vacation and getting a craving for popcorn. The final scenario was implausible and highly distinctive. In this scenario, subjects were asked to imagine someone (self or other) walking through a dark, dusty hall in a haunted house with Scooby-do and Shaggy, the cartoon characters. Pretesting showed that all scenarios were perceived as intended and that subjects held positive attitudes toward all three scenarios.

The self/other factor was manipulated by having students imagine themselves or an eccentric chemistry professor as the focal character in one of the three scenes described above. We chose someone very different from the student subjects so that they would not identify with the "other."

Pretesting showed that subjects were imagining the intended character.

Fully crossing the two main characters with the three situational scenarios resulted in six high-imagery cells. All six ads used concrete words, actionable sentences, present tense, and instructions to imagine to facilitate imagery. Importantly, each ad described the focal person interacting with the product (Lutz and Lutz 1978). The following is a segment of the self-related, plausible, and indistinctive ad:

Imagine this. It's late Sunday night and you're lying on the couch watching TV. Your stomach is growling--you get a craving that only light, fluffy popcorn will satisfy. You go to the kitchen, turn on the stove and grab a shiny silver package of Pop-quick popcorn from the cabinet. You swirl the pan over the red-hot burner. Suddenly, you hear one kernel pop, then another and another until there is a thunderous drumroll of bursting kernels. Imagine ripping open the package--the steam dampens you face. You smell the unmistakable buttery aroma.

The other two situational scenarios used the same popcorn imagery but the first few sentences were changed to incorporate the different scene.

The introduction to the other-related, plausible, indistinctive ad shows how the self/other manipulation was incorporated into the ads:

Imagine this. It's late Sunday night and an eccentric chemistry professor is lying on his couch watching TV. His stomach is growling--he gets a craving that only light, fluffy popcorn will satisfy.

The seventh cell, the low-imagery control ad, differed significantly from the six high-imagery ads. This ad used passive tense, more complex sentence structure, more abstract terminology, and no instructions to imagine. In addition, there was no situational context and no focal person in the ad. Care was taken to ensure that the information given about the product was equivalent in all seven ads and that the brand name was used the same number of times. Pretesting showed that the control ad created less imagery than did the six experimental ads.

Procedures

College students received extra credit in an introductory marketing course for participating in the experiment. Each of the 25 experimental sessions was randomly assigned to one of the seven advertisements. One hundred and forty-two students participated with cell sizes ranging from 17 to 23.

After completing consent forms, subjects were told that they were to evaluate three different radio announcers. This guise was used to account for the three repetitions of the same ad needed for sufficient exposure to the ad. Subjects then listened to one of the seven experimental ads recorded by

three different professional male radio announcers (i.e., three repetitions of the same ad). A questionnaire booklet was distributed and subjects completed questions about the three radio announcers to lend credibility to the guise. Subjects completed imagery, distinctiveness, plausibility, and self-relatedness manipulation checks, then completed BI items. Attitude toward the ad and attitude toward purchasing the brand measures were also taken. Approximately one week later, subjects were orally debriefed.

Measures

Our study differs significantly from previous marketing investigations of imagery in that imagery processing was measured, rather than assumed to occur. Eight items were used to measure imagery processing (three items based on those used by Cartwright, Markes, and Durrett 1978; five items developed for this study). Prior to responding to these eight items, subjects were provided a clear definition of imagery. The first imagery item was a simple yes/no response to, "Did you experience any imagery?" If the subject did, s/he then completed a seven-item imagery scale. The first item stated, "The imagery from the ad was aroused" and was anchored with "great difficulty" and "with great ease." The second stated, "The imagery from the advertisement was" and was anchored with "not at all vivid, a very vague image almost like nothing at all," and "very vivid, image was almost like a real experience." The final five items were seven-point Likert-type items such as, "I had no difficulty imagining the scene in my head," and "All sorts of pictures, sounds and smells came to my mind while I listened to the ad." Coefficient alpha for the seven items was 0.87.

Several items were used to check the message manipulations. The self-relatedness measure was an open-ended question asking, "Who was the main character(s) in the scene that YOU imagined?" Plausibility was measured on two correlated ($r=0.82$), seven-point items which asked subjects whether the situation in the ad could really happen and how likely it was that a typical person might find him/herself in that situation. Distinctiveness was measured as the sum of two moderately correlated ($r=0.44$) items. The first item asked whether the situation in the ad was an ordinary event, and the second asked whether the situation was a special event.

Attitude toward the ad was measured using the sum of seven four-point items ($\alpha=0.90$). Subjects stated the degree to which the ad made them feel good, happy, cheerful, pleased, amused, soothed, and warm. Attitude toward purchasing the brand was measured as the sum of six semantic differential items similar to those used by Ajzen and Fishbein (1980; $\alpha=0.82$).

Three items were standardized and summed to measure BI ($\alpha=0.89$). First, an eleven-point item asked subjects to estimate the probability that they would purchase the advertised brand. Scale responses ranged from "virtually certain, (99 in

100)" to "no chance, (0 in 100)." Subjects indicated the likelihood of their purchasing the advertised brand the next time they bought popcorn using a five-point item anchored with "definitely will buy" to "definitely will not buy." The final item was a seven-point Likert-type item stating, "The next time I purchase popcorn, I will buy the brand in the advertisement."

Manipulation Checks

The three different scenario manipulations were effective. One-way ANOVAs and individual contrasts indicated significant differences in the predicted direction for both the plausibility and distinctiveness manipulations.

Only subjects who experienced some imagery processing responded to the self-relatedness manipulation check. On the surface, the self-relatedness manipulation appears effective ($\chi^2=12.25$, $p<0.01$); however, over half (29 out of 49) the individuals in the self-related treatment did not imagine themselves during the ad. The manipulation was not as strong as we would have liked.

The six high-imagery groups did not experience more imagery than the low-imagery control group. The yes/no item showed no significant differences ($\chi^2=9.60$, $p=0.14$) nor did the ANOVA for the seven-item scale ($F=1.89$, $p=0.09$). Individual contrasts showed no differences between the low-imagery control group and any of the six high-imagery groups. Possible explanations for this result are provided in the discussion.

While the imagery and self-related manipulation checks indicated that these treatments did not create the desired effects in each cell, differences across individuals did occur. Therefore, rather than conducting the hypothesis tests using the experimental cells as planned, we used an internal analysis to explore these hypotheses (Carlsmith, Ellsworth, and Aronson 1976). In an internal analysis, individuals are grouped by their actual responses to the treatment as indicated by manipulation checks rather than by their cell assignment. While this procedure reduces the ability to make causal statements, it does allow researchers to explore some basic relationships.

Hypotheses Tests Using Internal Analysis

H1 was based on the proposition that imagery processing will create greater BI than discursive processing (P1). To test this relationship, subjects were divided into three imagery processing groups based on their responses to the imagery manipulation checks. Subjects reporting no imagery evoked by the ad were assigned to the no-imagery group. Those experiencing some imagery, but scoring below the mean of the summed imagery scale ($M=35.24$, $SD=7.61$) were assigned to the low-imagery group, and subjects scoring above the mean were assigned to the high-imagery group.

A one-way ANOVA was used to analyze the results, with imagery group serving as the

independent variable and BI serving as the dependent variable. The ANOVA showed a significant difference between the three groups ($F=6.78$, $p<0.01$, $M_{\text{high-imagery}}=0.76$, $M_{\text{low-imagery}}=-0.88$, $M_{\text{no-imagery}}=-1.05$, $\omega^2=0.10$). These results support H1; however, it appears that the degree of imagery processing (e.g., high vs. low) facilitates the effect rather than the simple presence or absence of imagery.

H2 was based on Proposition 2 which states that self-related imagery creates more positive BI than other-related imagery. Only subjects experiencing some imagery were included in this analysis. Subjects who indicated that they had imagined themselves were placed in the self-related group; all remaining subjects were assigned to the other-related group. A one-way ANOVA in which BI served as the dependent variable and self/other-relatedness served as the independent variable showed significant differences between the two groups ($F=9.84$, $p<0.01$, $M_{\text{self-related}}=1.53$, $M_{\text{other-related}}=-0.34$, $\omega^2=0.08$). This finding clearly supports H2.

H3 was based on Proposition 4 which states that the plausibility and distinctiveness of the imagined scenario should affect the imagery/BI relationship. We explored this hypothesis using the three scenario manipulations since these manipulations were effective; however, we only included subjects who experienced imagery in the analysis.

A one-way ANOVA in which BI served as the dependent variable and the three scenario manipulations served as the independent variable showed no statistically significant differences ($F=0.16$, $p=0.85$, $M_{\text{TV scenario}}=0.33$, $M_{\text{beach scenario}}=0.05$, $M_{\text{haunted house scenario}}=-0.04$). Thus, H3 is not supported.

After finding that imagery and self/other-relatedness did affect BI, we investigated these two factors further. First, we examined whether the effect of imagery on BI was direct or indirect, i.e., a result of imagery's effect on attitudinal variables. It could be that imagery creates more positive attitudes toward the ad or attitudes toward the product, which, in turn, creates BI effects (cf., Ajzen and Fishbein 1980). A MANOVA model which used attitude toward the ad, attitude toward the product, and BI as the dependent variables and the three imagery groups as the independent variable tested the issue at hand. The overall MANOVA model was significant ($F=6.98$, $p<0.01$), and the univariate F-tests showed significant effects for each dependent variable. A Roy-Bargman stepdown F test was used to assess whether the observed BI effects were direct or indirect. The stepdown F takes into account the causal relationship between the dependent variables and tests for an incremental effect on each dependent variable by controlling for the causal effects of previous dependent variables. This test detected differences in attitude toward the ad, but not attitude toward the brand or BI. Therefore it appears that the observed imagery effect on BI is indirect, a result of imagery's impact on attitude toward the ad.

Could this also be true for self/other relatedness? Could it be that consumers like ads about themselves better than ads about others and that this change in attitude toward the ad creates differences in BI? We explored this question with a second MANOVA model in which attitude toward the ad, attitude toward the brand, and BI were the independent variables and self/ other-relatedness served as the dependent variable. Again, the overall MANOVA model was significant ($F=3.47$, $p=0.02$), but the only univariate test which showed significant differences was the BI test. The step-down F test also detected a difference in BI, but not in the attitude variables. This suggests that a direct relationship exists between the imagery's focal character and BI, as predicted by semantic network theory.

DISCUSSION

This study provides evidence that imagery processing in and of itself can affect attitudes toward the advertisement which, in turn, affect attitude toward the brand and BI. Furthermore, the significant effect of the self/other factor suggests that the content of the imagined experience is important and can directly influence a consumer's BI. While these results are correlational due to the use of internal analysis, they are encouraging and indicate that research in the area should continue.

Why didn't subjects in the six high-imagery cells experience more imagery than subjects in the low-imagery control cell? Recall that we did get significant differences in pretesting, so the experimental situation itself may have reduced imagery processing. Subjects in the experiment (but not the pretest) were asked to listen to the ads in order to evaluate the radio announcers. MacInnis and Price (1987) point out that imagery processing is enhanced when subjects are told to relax and concentrate on imaging. Our subjects processing set was on evaluating the announcers which may have interfered with imagery generation.

There are many directions in which this research could proceed. First, richer marketing-oriented measures of ad-evoked imagery need to be developed. Recall that this study is the first to specifically measure ad-evoked imagery, rather than the propensity to use imagery (e.g., Style of Processing Questionnaire; Childers, Houston and Heckler 1985) or the ability to imagine (e.g., Betts Questionnaire Upon Mental Imagery; Betts 1909; Sheehan 1967). A reliable and valid measure is needed. Another measurement issue is whether imagery is a unidimensional or multidimensional construct. We are currently developing items to tap three potential imagery components--ease, vividness, and quantity. Finally, given the encouraging results from the self-relatedness factor, it appears that consumer researchers may wish to investigate other message characteristics which could directly or indirectly affect recall, attitudes, and/or BI when imagery processing occurs.

Style of Information Processing Differences in Relation to Products, Shopping and Self-Consciousness

Stephen J. Gould, Rutgers University

ABSTRACT

Style of processing information, as measured by the Style of Processing Scale (Childers, Houston and Heckler 1985), was assessed in relation to several product involvement variables, shopping visualization, three self-consciousness variables, and gender. The sample was divided into four groups on the basis of the scale score: "Low Processors," "High Verbals," "High Visuals" and High Processors." Results indicated that there were clear style of processing differences in relation to most of the tested variables. The strategic and research implications of these results are discussed.

As interest in mental imagery has grown, researchers have found individual differences in consumers' preferred styles of information processing, i.e., verbal versus visual processing (Holbrook, Chestnut, Oliva, and Greenleaf 1984; Smith, Houston, and Childers 1984; Childers, Houston, and Heckler 1985). This paper seeks to extend that work by looking at style of processing in relation to products, shopping plans, and various aspects of self-consciousness (Fenigstein, Scheier, and Buss 1975), all of which have salient visual or verbal elements. It will also provide a further test of the usefulness and nomological validity of the Style of Processing Scale (Childers, Houston, and Heckler 1985).

STYLE OF PROCESSING

Interest in style of processing has developed from at least two main streams of research in psychology and consumer behavior. These are (1) mental imagery research and (2) the information processing paradigm. Within each of these areas, research has found that there are individual differences which have an impact on dependent variables within their domain (MacInnis and Price 1986; Childers, Houston, and Heckler 1985). Mental imagery research has assessed the processing of information in a variety of modes including auditory, olfactory, gustatory, and kinesthetic, but most especially the visual mode (MacInnis and Price 1986). A number of aspects of imagery processing have been studied which are conducive to the extrapolation of individual differences including imagery vividness, imagery control and imagery style (Childers, Houston, and Heckler 1985). Of interest here is the assessment of imagery style which Childers et al. define as "the individual's willingness to habitually engage in imaginally versus verbally oriented processing." In order to assess imagery style, they adapted the Style of Processing (SOP) scale from the widely used VVQ scale (Richardson 1977) and demonstrated its reliability and validity.

It has been found in looking at mental imagery and information processing together, that

there is a positive relationship between preference for visual imagery processing and visually oriented print ads (Rossiter and Percy 1978), that the use of pictures in ads which may stimulate mental imagery can make a difference in information processing (Kisielius and Sternthal 1984), and that schematics (experienced consumers) will use mental imagery more than aschematics (inexperienced consumers) (Smith, Houston, and Childers 1985). Childers, Houston, and Heckler (1985) find that differences in individual information processing may stem from two factors: (1) cognitive ability to process information and (2) preferred strategies or styles of processing, i.e., verbal versus visual.

In light of previous research, the present study was conducted in order to further investigate individual differences in style of processing and to see how this might affect some product areas of interest. It is hypothesized that individuals more verbal in style will be more involved with verbal products, such as books and magazines, while highly visual individuals will be more involved with media, such as television, or products which are visually oriented, such as clothes. Music is explored on a more exploratory basis although it is tentatively hypothesized that music will be associated with the visual mode since both have been related to right brain processing (Hansen 1981). Radio is included on an exploratory basis as well, since it may be used for verbal purposes by some, musical entertainment by others, and since, it may involve the use of imaginative imagery by some but not all users.

Self-consciousness (Fenigstein, Scheier and Buss 1975) is also to be considered. With respect to self-consciousness, it was especially felt that one of its three sub-components, public self-consciousness, would be important. Public self-consciousness has been previously used in consumer behavior contexts to assess an individual's awareness of and concern with his or her self-image and self-appearance in public (Burnkrant and Page 1981; Gould and Barak 1988; Stern, Gould, and Barak 1987). In this regard, it was predicted that visually oriented individuals would be more publicly self-conscious, i.e., self-appearance conscious, than others because of the highly visible nature of self-appearance. Social anxiety, which concerns an individual's degree of anxiety in interacting with others, is more tentatively hypothesized to follow public self-consciousness, as is private self-consciousness, which concerns an individual's degree of focus on his/her own thoughts and feelings (Fenigstein, Scheier, and Buss 1975). Finally, it was hypothesized that high visuals would tend to report more visualization in planning for a shopping trip than would low visuals. Gender was included on an entirely exploratory basis.

METHODOLOGY

Subjects

The sample consisted of 138 adults. They were administered the questionnaire by students in a consumer behavior class, who received class credit. The sample was a quota sample in that at least 2 of the subjects, per student, were required to be over 50 years old and at least two were required in the 35-50 range in order to insure a wide spectrum of ages. Verification was obtained by telephone calls of approximately 5% of the sample, by debriefing of the student interviewers, and by inspection of the surveys, themselves. No problems were encountered. The study was conducted in the Northeastern part of the U.S.

Measures

The following measures were used in the survey:

Independent Measure

The Style of Processing Scale (SOP). The SOP is a 22-item scale which assesses the degree to which an individual uses a verbal or visualizing style of information processing (Childers, Houston, and Heckler 1985). An example of a verbal item is "I enjoy learning new words." An example of a visual item is "When I'm trying to learn something new, I'd rather watch a demonstration than read how to do it."

Dependent Measures

Involvement with product measures. The first eleven items were adapted from the Personal Involvement Inventory of Zaichkowsky (1985) to measure the involvement an individual had with the following products: television, radio, magazines, books, clothes, cameras, and music. These products were selected because of their sensual orientation, particularly with respect to the visual sense, (e.g., camera), or because they reflected a relatively verbal orientation (e.g., books).

Shopping visualization. A single question assessing the use of visualization in making a shopping list or planning a shopping trip was also asked as follows: "When I make a shopping list or plan a shopping trip, I usually visualize what I'm going to buy."

The Self-Consciousness Scale (SCS). The SCS assesses the trait of self-consciousness which concerns the degree to which a person focuses on him/herself or on the external environment (Fenigstein, Scheier, and Buss 1975). The 23-item scale, according to its creators, actually consists of the following three subscales: (1) private self-consciousness which looks at degree of internal focus (e.g., "I reflect about myself a lot"), (2) public self-consciousness which concerns the degree to which someone is conscious of his/herself as a public person with an impact on others (e.g., "I'm very self-conscious about the way I look") and (3) social anxiety which measures the degree to which someone is anxious about social interactions with

others (e.g., "I feel anxious when I speak in front of a group").

RESULTS

Style of processing was assessed by taking each of two subscales of the SOP, the verbal and visual subscales, dividing them at the median and combining them to create four categories for consideration: (1) "Low Processors"- low verbal/low visual on the SOP (n = 34), (2) "High Verbals"- high verbal/low visual on the SOP (n = 37), (3) "High Visuals"- low verbal/high visual on the SOP (n = 33) and (4) "High Processors"- high verbal/high visual on the SOP (n = 34). Reliabilities for the two measures using Cronbach's alpha were .67 for the visual component and .77 for the verbal component. This resulting variable is designated "VERBVIS." While Childers, Houston, and Heckler tend to prefer to use the SOP as a single scale, they also point out that the value of using the scale in its two component form was worthy of further research. In fact, most of the items of the scale assess only one or the other component (e.g., "I enjoy learning new words"- verbal style; "I like to "doodle" "- visual style) while just a few actually force a choice between verbal and visual styles (e.g., "I generally prefer to use a diagram rather than a written set of instructions"). Here, it was deemed appropriate to use the scale by assessing the two components, separately, because some individuals are likely to be either more or less active in both the verbal and visual modes together, and also because some product use often reflects the involvement of both modes of processing (e.g., magazines). This approach is analogous to the fact that while many individuals are either more left brain or more right brain, there are some who are less specialized and more whole brained (Hansen 1981; Kosslyn 1987). It is also similar to sex role research in which various types are identified by combinations determined from scores on two separate scales: masculinity and femininity (Bem 1981). This approach allows for the clear identification of types both for researchers and managers.

A multivariate analysis of variance was run to test for an overall effect of the independent variable, the four-level classification by the SOP, i.e. VERBVIS. Results, using the Hotelling-Lawley Trace statistic, indicated that there was such an effect ($F = 2.46, p < .0001$). Next, the univariate analyses for each of the dependent variables were assessed as follows (see Tables 1 and 2):

Product Variables: There were significant univariate effects for these product variables: television, magazines, and books. When the means are examined for television, High Verbals, group 2 and High Processors, group 4, report being less involved with television than others. Based on planned comparisons, High Verbals differ from both Low Processors ($p < .0138$) and High Visuals ($p < .0018$) while High Processors differ from High Visuals ($p < .0291$). Verbal orientation seems to be most salient. Interestingly, Low Processors had the

second highest involvement with television possibly for the following reasons: (1) they are clearly low in preference for verbal processing which seems to be most salient in reducing television involvement and (2) it is also possible that they have a tendency to be involved with television in some way not assessed here, such as keeping it on for the sound or for 'company.'

In the case of magazines, individuals who are High Processors tended to report being more involved with magazines than individuals who are High Verbals (p < .0072) or High Visuals (p < .0026), alone. Thus, people who are highly

responsive to both visual and verbal cues are most involved with magazines, very likely reflecting the dual visual and verbal nature of magazines. With books, as with television, verbalness seemed to be salient although in the other direction as both High Verbals and High Processors claimed more involvement with books than others. High Verbals were significantly more involved with books than were Low Processors (p < .0075) and High Visuals (p < .0001) while High Processors were more involved than both of these other groups (p < .0001 for both). The effect sizes for these three product categories, as indicated by R², were .10, .09, and

.24, respectively. These are very reasonable effects considering that there is only one independent variable, i.e. VERBVIS. Finally, none of the other product involvement findings were statistically or behaviorally significant, although camera involvement was in the right direction in that both High Visuals and High Processors were more involved with cameras- indicating at least a probable degree of visual salience.

Shopping Visualization. Results indicated that shopping visualization was clearly related to visualization style as both High Visuals and High Processors were more likely to visualize or plan a shopping trip than were others ($p < .0001$). High Visuals were significantly more likely to visualize their shopping in advance than were Low Processors ($p < .0099$) and High Verbals ($p < .0040$). The same was true for High Processors who reported more shopping visualization than the other two groups ($p < .0005$ and $p < .0001$, respectively). The R^2 for this relationship was .14 which again is very reasonable for one independent variable.

Self-Consciousness Variables. There were significant results for all three self-consciousness variables: private self-consciousness ($p < .0007$), public self-consciousness ($p < .0009$) and social anxiety ($p < .0013$). Examination of the means reveals that, in general, High Visuals and High Processors reported being most publicly and privately self-conscious- the contrasts of groups 3 and 4 with groups 1 and 2 were found to be all be significant ($p < .05$ or better). However, for social anxiety the results varied in that only group 2, the High Verbalizers, differed from High Visualizers and High Processors ($p < .0001$ and $p < .0222$, respectively). The effect sizes, as indicated by the R^2 , were .12 for public self-consciousness, .13 for private self-consciousness, and .11 for social anxiety. Altogether, these results evidence a relationship between visualizing style and self-consciousness which seems to indicate a process of self-visualization. Thus, it is likely that High Visuals and High Processors will tend to visualize themselves more than others when focusing on their self-concept, the target of self-consciousness, as well as being more self-conscious in general.

Gender. An interesting result was obtained when gender was crosstabulated with VERBVIS as shown in Table 3. Women tended to report being more active processors than men ($p < .017$). Particularly striking was the result in which 32.91% of women were High Processors to only 13.56% of the men while just the opposite result was found for Low Processors- 35.59% of men to 16.46% of women. However, about the same percentage of High Verbals and High Visuals occurred among both men and women. These results provide a marker for at least a partial demographic identification of style of processing differences, and also a strong impetus for further gender-related research in this area.

DISCUSSION AND CONCLUSIONS

The results of this study give an indication of the effects of processing style on some relevant

marketing variables and point the way to further research in this area. Several findings emerge on the basis of the present data. First, in general, this study provides further support for the usefulness and nomological validity of the SOP scale, particularly when the four processing groups are considered. The scale has been shown to be related to several consumer-related variables.

Second, the results have indicated that involvement with media types of products has links to style of processing. Although not measured in this study, it is likely that the frequency of media use and within media choice differences (e.g., the choice of magazines, such as *People* versus *Scientific American*) are related to style of processing as well.

Third, style of processing is related to visual planning for shopping which may only be a tip of the iceberg in assessing: (1) how visually-oriented consumers may use mental imaging in the search for, purchase, and use of products, and (2) how verbally-oriented consumers function and make decisions in the same situations. The planning of a shopping trip and list involves the visualization of a future event out of the processing and recall of previous shopping experience. For example, High Visuals and High Processors may form cognitive maps of their shopping trips as they picture their purchases in advance in their minds. This suggests a need for marketers and retailers to develop imagery cues in their advertising, store and mall layouts, and store displays which are likely to stimulate mental imagery in the minds of these visually-oriented consumers as they make shopping plans. On the other hand, High Verbals are likely to respond more strongly to the use of verbal cues, such as store and brand names or key appealing terms (e.g. new, free, unique), although more research is needed to identify what they seek in the way of specific mental cues in planning and engaging in shopping.

Fourth, applying the work of Robertson (1987) in looking at brand names in terms of imagistic content, High Processors are likely to be the most responsive of all the groups to store and brand names laden with imagery (e.g. "White Dove"); High Verbals may respond most strongly to abstract, less imagistic names when forming shopping lists (e.g. such as "EXXON" originally was when it was a new name). However, further research is needed to determine whether imagery laden brand names are still more effective for all groups, including High Verbals, in line with the findings of Robertson, or whether individual differences are strong enough to moderate those findings. Low Processors may respond more strongly to other types of cues altogether, such as sound or kinesthetics, which they recall when putting together their shopping plans. Research into various types of cues in the context of style of processing should be undertaken.

Finally, and perhaps most interesting is the finding that mental imaging seems to be related to self-consciousness. This seems to indicate that the self-concept for visually-oriented individuals has a

high image content which marketers and advertisers may want to study and address in the future. In other words, when people focus on themselves, reflecting their private self-consciousness, they may literally see themselves in their mind's eye more than others who are not as inclined to engage in such self-focusing. Self-image research and application may take on whole new dimensions not previously considered. For example, in assessing self-image in marketing research through administering semantic differential and Likert scale type questions, it might be useful to have respondents sit in front of a mirror so they can see themselves while they answer the questions- a technique which is often used in self-awareness research to obtain self-focus and attention (Fenigstein, Scheier, and Buss 1975). In the market research situation, seeing oneself in a mirror might stimulate the visually-oriented person to concentrate on self-relevant visual cues although both High Verbals and Low Processors would probably be less affected. For instance, the verbally-oriented person, although being less self-conscious in general, might be better stimulated in self-imagery evaluation relative to the visually-oriented person if asked to write or verbalize something about his or her self-image. On the other hand, Low Processors may respond to other self-relevant cues not considered here. Finally, High Processors might best respond in terms of inducing self-focus to both the types of cues (mirror and verbalizing), administered simultaneously.

Similar techniques might be used for inducing or tapping into public self-consciousness which can be affected by the presence of other people (Fenigstein 1979). Market researchers might want to evoke public self-consciousness to create an audience effect even though they are only surveying or interviewing one person at a time (e.g. investigating product use in social settings such as when a person throws a party). Or they may just need to be aware whether certain types of questions

may induce public self-consciousness effects. In such cases, visually-oriented people are likely to respond to mental cues with visual imagery (e.g. "Imagine an audience in front of you") while verbally-oriented people, although less publicly self-conscious or socially anxious, should respond best to cues which evoke thinking (e.g. "Write down what others think about you"). As with private self-consciousness, the picture is less clear with respect to Low Processors except that they are less publicly self-consciousness than visually-oriented individuals. More research is needed to investigate them and how they function with respect to processing information about self-relevant cues.

In addition, more research with respect to the self-consciousness construct is needed to work out how people develop and recall self-relevant imagery and concepts. Such research might also consider how people link their self-image to product image, concept, and use, if at all. For example, it is more likely that highly visually-oriented and self-conscious people will visualize themselves throughout the prepurchase and actual consumption phases of interaction with products than will less visually-oriented individuals. Such self-visualization may take the form of seeing oneself possessing products, using them, and displaying, and showing them off in a way which reflects the individual's public self-consciousness and social anxiety. Understanding of this self-visualization process can lead to better insight for both copy creation and product positioning. However, for both High Verbals and Low Processors, themes which play less on self-image and appearances may need to be developed.

In moving beyond the dependent variables considered here, future research should extend and elaborate these results by also considering style of processing in relation to other areas of interest, such as media use, other product areas (e.g. fashion), schema (Smith, Houston, and Childers 1985),

attitudes, advertising involvement and response, hemispheric processing and other brain subsystem processing (Hansen 1981; Kosslyn 1987), and the Elaboration Likelihood Model (Petty, Cacioppo, and Schumann 1983). Thus, style of processing is likely to be built into a whole network of these constructs which ultimately can be used to predict advertising and behavioral response. Particularly intriguing would be to investigate how products, and/or particular attributes of products, such as shapes, colors, and names are related to processing style and subsequently to purchase and use. We need to consider whether there are certain product designs or advertising modes, portrayals or themes which appeal to a person of one processing style or another. Likewise, we might consider whether brand differentiation and positioning messages involve the selective perception of cues by people of different processing styles and therefore are amenable to explicit marketing efforts addressing those differences. There also may be situational differences in processing style which vary by setting (e.g. time pressure, more expressive types of situations such as gift giving) that need to be addressed. Future research might also extend the SOP scale to consider other sense modalities: olfactory, auditory, gustatory, and kinesthetic (see Sheehan 1967 for a short version of the Betts' Questionnaire which assesses these modalities).

Studies in Imagery, Styles of Processing, and Parallel Processing Need Realtime Response Measures

G. David Hughes, University of North Carolina

The three papers in this session provide stimulating contributions to our knowledge of consumer information processing. Ways that each paper could be strengthened are discussed. But these papers have the same limitation: they focused on a static concept, recalled, processed information, not the dynamics of information processing. An example from realtime response research illustrates how these limitations can be overcome.

IMAGERY EFFECTS ON BEHAVIORAL INTENTIONS

Bone and Ellen (1990) make a genuine contribution to the literature in their finding that the degree of self imagery determines attitude toward a radio advertisement, which, in turn, determines subjects' behavioral intentions (BI) regarding the purchase of the advertised hypothetical brand of popcorn. The original hypotheses are well grounded in the current literature to explore the question, "Why should imagined sensory experiences result in more positive BI?" The availability/valence hypothesis and the semantic network theory are very relevant. Their design would have been strengthened, however, by including Heider's balance theory in the semantic network theory (Hughes 1971). It would have provided a very testable model for the examination of attitudes toward self, attitudes toward advertisements, and attitudes toward a brand.

They state their hypotheses clearly and use appropriate rigor in their statistical analysis. But, between these two points, there is considerable ambiguity regarding their working definitions and their measurement procedures, as will be detailed below.

When the authors found that their treatments did not induce the expected imagery effects, they abandoned their causal design and sorted subjects into groups according to their degree of imagery. They were careful to limit their conclusions to those of correlation, not causation.

At this point, however, it would have been helpful to know why individuals differed in their ability to create mental images. Do the authors have any demographic or psychographic profile data that would reveal insightful significant differences between high and low imagers? Perhaps this distinction is a matter of right hemisphere or left hemisphere information processing. The concepts of visual and verbal processors (Gould 1990) could contribute to an investigation of high and low imagers. Or perhaps the low imagers watch more television and have never developed imaging skills. An older group of subjects, raised on radio, may have higher imaging skills. Knowing more about people with low and high degrees of imaging skills is a prerequisite to applying the authors' findings to advertising strategies.

AMBIGUITIES IN DEFINITIONS AND MEASUREMENTS

Sorting out the definitions, variables, scaling techniques, and the hypothesized relationships was difficult. A flow diagram would have been very helpful. The original design was modified halfway into the paper with the addition of the concept of attitudes toward the advertisement. This addition was made without the benefit of relevant citations, so it is not clear why it was added. Some of the ambiguities and recommendations for improvements follow.

Message Elements. The authors examined the impact of three message elements--self relatedness, plausibility, and distinctiveness--on the imagery-behavioral intentions relationships. Self relatedness (not to be confused with self congruity) deals with whether the main character in the imagined scene is the consumer him/herself or someone else. Advertisements that build on self imagery were found to create more positive behavioral intentions (BI).

Plausibility is defined as an imagined scenario that is consistent with the consumer's lifestyle. This concept is different from believability, which is frequently used to test television advertisements. It would be useful to do a study to see if subjects understand the difference and if the difference is relevant to communications strategies.

Distinctiveness is defined as the imagined scenes' uniqueness, which lies between the outer bounds of mundane and bizarre. This definition overlaps their definition of plausibility, and caused problems. These two concepts were then combined into a single treatment, with insignificant results. Because the similar concepts of believability and comparative advantage have produced significant results in commercial testing, it is unfortunate that these concepts were combined. Perhaps a definition of distinctiveness that required a brand choice would have yielded significant results. The authors' design gave no choices of brand, only whether the subject would buy the test brand or not. An information processing design would measure before-and-after changes in brand choice.

Independent Variables. Image processing was measured by first asking subjects if they experienced imagery. If they did, they then answered two semantic differential questions dealing with ease and vividness of the imagery. They also answered five Likert-type scales on the difficulty of imagining. No reasons were given for using two scaling techniques.

Attitude toward the ad was the sum of seven items--good, happy, cheerful, pleased, amused, soothed, and warm--that had been measured along a four-point scale. Even though some of these items have been studied by other researchers, no citations were given in support of their inclusion. It would

have been useful to see how these affect dimensions and their cognitive dimension of plausibility were linked to imagery, to attitude toward the ad, and then to behavioral intentions. The findings could support or refute the arguments that cognition does not need to precede affect (e.g., Zajonc, 1980).

Self relatedness was measured with an open-ended question that asked who the main character was in their imagery. Plausibility used two seven-point scales that asked if the event could happen. Distinctiveness was the sum of two scales that asked if the event was ordinary or special. No reasons were given for the variety in scaling techniques. One can only wonder if the variations in measuring techniques contributed to the insignificant findings regarding plausibility and distinctiveness.

Behavioral intentions were the sum of three standardized measures. One was an eleven-point scale of the probability of purchasing the advertised brand. The second scale used a five-point likelihood of purchasing. The third scale used a seven-point Likert-type scale in response to "The next time I purchase popcorn, I will buy the brand..." No reason for the three scales or their summation was given. It is not clear why attitudes toward purchasing the brand were measured, how these differed from behavioral intentions, and where they fit into the analysis.

The authors could enhance their contribution to the literature by reanalyzing their data with more precisely defined variables. Instead of combining measures that used various scales, they should examine them independently so that they can recommend to other researchers the most appropriate scales and then use them across all concepts. Using a uniform scaling technique can facilitate the selection of statistical methods and reduce respondent confusion.

Because plausibility and distinctiveness were combined in their design, these concepts cannot be separated. But the authors did measure plausibility and distinctiveness for manipulation checks. Perhaps the data from the subjects who were not in the plausibility and distinctiveness cells could be analyzed with these manipulation check variables to determine if future research would benefit from a sharper definition of these two concepts.

The authors could enhance their contribution first by explaining why they used so many different scaling techniques and then by developing more parsimonious measurement methods to facilitate replication by them and other researchers. Such replications are necessary for a field of study to claim that it is a science.

But none of these recommendations overcomes the fact that this research is not measuring consumer information processing. It is, at best, measuring recalled information that was processed. And recall is subject to errors in memory, variations in attending to the stimuli, and a problem that has been called backward filtration, which occurs when a dominant stimulus appears at the end of the stream of stimuli (Hughes, 1990). This late, dominant stimulus overshadows earlier

stimuli. (This effect should not be confused with recency effects.) Finally, subjects' attempts to recall information processes can be influenced by the experimental design either by interrupting the process with a questionnaire or revealing the purpose of the study. The latter could have occurred in this study because the subjects completed imagery, distinctiveness, plausibility, and self-related manipulation checks before completing the behavioral intentions scales. Perhaps the subjects guessed the intent of the study.

To measure consumer information processing we must have methods for realtime response research. A procedure with examples will be shown briefly at the end of this paper.

STYLE OF INFORMATION PROCESSING

Gould (1990) explores the relationships between styles of information processing and involvement with selected products, shopping visualization, and self-consciousness. While Gould's design does not assure directions of causality, the findings provide new insights into processed consumer information and suggest ways to answer questions raised in the Bone and Ellen paper.

For his independent variable Gould used the mental imagery literature and an existing scale that identified verbal and visual processors. He assigned subjects to one of four cells--low processors (low verbal and low visual), high verbals (high verbal and low visual), high visuals (low verbal and high visual), and high processors (high verbals and high visuals). The median scores were used to assign the 138 subjects to one of the cells. The median values and the number of subjects were not reported, which makes it difficult to replicate the study.

The dependent measures included involvement with seven products (television, radio, magazines, books, clothes, cameras, and music), shopping visualization (making shopping lists and visualizing what will be bought), and self consciousness (private-public self consciousness and social anxiety). Gould used existing measuring instruments for these variables.

Because the hypotheses are not stated, the results and discussion are guided by the relationships that were significant. Consequently, the combined "Discussion and Conclusions" section is very difficult to follow and sometimes is not well supported by the findings. But the results are interesting. For example, high verbals and high processors report being less involved with television. Perhaps these individuals like to create their own images. Bone and Ellen may want to add a visual-verbal processing measure to help explain why some persons image and some do not.

There is considerable face validity in the findings. High verbals were more involved in books. High visuals and high processors were more likely to visualize or plan a shopping trip. High visuals and high processors also may tend more to visualize themselves when they focus on their self concept. While the support for this conclusion is

not clear, it could be relevant to the conclusions of Bone and Ellen that self-related imagery creates a more positive behavior intention. The finding that women tend to be high processors could be relevant to copy and media strategies.

This study can also be criticized for not being a study of information processing, but a study of recalled processed information.

PARALLEL PROCESSING

Martin and Kiecker (1990) step back from the details of information processing research and conclude that current approaches assume that the consumer thinks like an old computer, in a serial or sequential fashion, while evidence from neurobiology suggests that the human brain is a massive parallel processor. Evidence of parallel processing requires new definitions of memory structures and knowledge representation, which, in turn, require new means for measuring consumer information processing.

Parallel Distributed Processing (PDP) models stress the concept that information processing amounts to changes in connections between networks of neurons. Information will change the weight and/or sign of these connections as well as create new connections. Thus, information is stored in the form of connections throughout the network, not at a single location to be addressed by a central processor. This model helps to explain how a consumer can combine previous experience and new external information to reach a decision. The authors conclude that information processing research that uses methods such as protocol analysis, information monitoring, and eye movement, restrict the subject to the limited serial task.

Those of us who have been dissatisfied with the present information processing research would like to consider testing parallel processing models, but the paper is limited in its suggestions for implementing the concept. It refers to a study on vision, one on analysis of response times, and one on reading research, all of which assumed a parallel model. It suggests displaying multiple attributes of various brands on a video terminal for a short duration and then asking for a purchase decision. This seems to be a modern variation of threshold research that used a tachistoscope. This design could be implemented very easily with realtime response research technology. It could be done on individuals and groups, which would make it easier and cheaper than the eye movement design that is proposed by the authors. In realtime response research the computer would measure each individual subject's response time, which would be a proxy for the amount of processing that was done.

REALTIME RESPONSE RESEARCH

These three papers share a common need for realtime measures while the subjects are processing the information. The first realtime system was developed at CBS in the mid 1930s to measure audience reactions to programs. It consisted

basically of a rheostat for each subject. When dialed, these rheostats controlled pens over a continuous paper strip, like an EKG. Within the last few years new developments in microcomputer and video technology have made it possible to have portable systems that measure responses in a fraction of a second and superimpose the results over the stimulus videotape. This discussant has developed four generations of these systems since 1984 and has conducted hundreds of realtime research projects. His second and third generation response devices were a seven-position dial that had many limitations (Hughes, 1990). The fourth generation subject response device has a 1-100 dial, a full alpha numeric keypad, and a screen that gives subjects immediate feedback as they dial. The system is called SpeedBack(sm). An example will illustrate how realtime measurements can improve on the research that has been reported in this session.

Bone and Ellen had difficulty in defining and measuring variables that reduced to affect and cognitions. Can subjects distinguish between these concepts? Figure 1 shows the results of a small test that was conducted just for this session.

Twelve MBA students watched six television commercials twice. The first time they dialed for affect along a scale of unfavorable(0)-favorable(100). The second time they dialed for useless(0)-useful(100). The California Raisin commercial that featured Ray Charles and used the claymation technique went above 80 in favorability, but dropped to 30 in uselessness. The next commercial, "Living Well," promoted a St. Patrick's Day Special at a local health club. The responses were straight down for both measures. (The company went bankrupt.) Sudafed, a decongestant medicine, hardly moved off neutral (50) for favorability, but ended on a strong up trend in usefulness when clinical proof was mentioned. The First Response Pregnancy Test had a downward trend in favorability, was slightly above neutral in usefulness at the midpoint, but ended on a sharply negative trend at the end. The Pontiac and local Ford dealer advertisements were downward sloping on both dimensions, but the usefulness curve was higher because both ads discussed discounts and some of the subjects were planning to buy a car in the near future.

Each of these patterns can provide useful insights for generating strategies. We are studying the relationships between these types of patterns and successful advertisements to answer questions such as, "Should an advertisement end on an upward trend?" We have noted that the most successful advertisements are not always rated favorably, but they do need to have useful or believable information. When these patterns were played back, the subjects had reasonable explanations. For example, the Sudafed commercial ended with a reference to clinical studies showing that it was effective in 30 minutes, so the useful information measure went upward. Some subjects were about to buy a car, so they found information about discounts useful even though they did not like the commercial.

FIGURE 1
FAVORABILITY VS. USEFULNESS (12 MBAs)

Because we measure in realtime, and in very fine and fast measures, we are able to see patterns of individual styles of processing. We see several different response patterns. We call some subjects "chunkers" because they wait for a chunk of information before making a decision, while the "averagers" respond to every stimulus when it comes. An example of each style of processing appears in Figure 2. The upper curve for the California Raisin commercial is the averager who made small incremental changes with each new stimulus. The chunker happened to go negative, so that is the lower curve. We do not presently know why these two types occur. In some cases we have noted that people who have no need for the product advertised chunk negative quickly and then go flat. Thus, they seem to tune out the commercial. We plan to examine levels of attending in future tests.

We are just beginning to study the individual differences between these two response styles. We will certainly consider the verbal and visual scales that Gould used.

The Martin and Kiecker paper stimulates us to examine the time between the stimulus and the subject's response to see if we can identify parallel

processing. This will be a very easy task with the SpeedBack(sm) system. The response time of the system is very fast because of the smooth, continuous 1-100 dial and the sampling rate of 1/5 of a second. Realtime response research would also make their information display board design a very simple task.

Figures 1 and 2 illustrate another advantage of fast, realtime response research. It is an excellent tool for small group diagnostic studies. A researcher can start with small groups and, if the results are stable, add additional groups, combine data, and use analytical techniques that require a larger sample. We have replicated the shapes of the curves in these figures with other groups of 12 to 20 subjects.

Realtime response research is like clinical studies in medicine in that it should be used early in the research process. It is not instant polling or a substitute for survey research (Hughes 1990). Conversely, in clinical research the subject becomes his/her own control over time, so we know that differences are due to the stimuli. The fine and fast measures allow us to detect subtle, small differences, such as a single word. We have found that we can

FIGURE 2
PROCESSING STYLES -- AVERAGER/CHUNKER

get stable results with sample sizes as small as 40 subjects.

Persons who are concerned about small samples for diagnostic research should refer to articles in the medical journals. During the period from October, 1987, to October, 1989, there were 35 citations in the *Drug Newsletter* that used a single test group of fewer than 20 subjects. Eleven had 5 or fewer subjects, 11 had 6 to 10 subjects, 7 had 11 to 15 subjects, and 6 had 16 to 20 subjects. Included in these publications were prestigious journals such as the *British Medical Journal*, the *Journal of Clinical Psychiatry*, and the *New England Journal of Medicine*.

In conclusion, while there are many ways that these authors could refine their research, we must

acknowledge that theirs were exploratory studies. I hope that these comments will help them to further analyze the data from these studies and to develop more precise approaches in future studies. Realtime research measures can help them in that regard. Their ideas and findings will stimulate new directions for those of us who are researching consumer information processing.

ABSTRACT

This paper reports the results of a content analysis of articles on tobacco and tobacco related products appearing in *Time*, *Reader's Digest*, *Life*, *New Yorker* and *Saturday Evening Post* from 1930 through 1960. As a percentage of articles published, the issue of smoking and health was most prominent in the 1930s and from 1950 through 1960. On an absolute basis, the number of articles concerned with smoking and health were greatest from 1950 through 1960. The content of articles mentioning smoking and health evolved over time. In the 1930s such articles were concerned with symptoms of health effects (e.g., coughs), while in the 1950s the focus changed to more serious effects such as cancer.

INTRODUCTION

When did smokers first learn that cigarettes were unhealthy? What and when did they learn specifically about the effects of smoking on their health? It is, of course, impossible *ex post* to provide definitive answers to these questions. This is so, despite knowing that conventional wisdom has long held that cigarettes are unhealthy, e.g., the term "coffin nails" dates from early this century (Calfee 1985). A partial answer can be obtained, however, by examining what the popular press was reporting throughout the period when scientific evidence about the effects of smoking on health was first being accumulated and disseminated. By examining what the press was reporting, inferences can be drawn about what the public was being exposed to, if not learning.

The purpose of this paper is to trace what was written in the popular press about cigarettes from the period 1930 through 1960 in order to learn what the American public was being told about the effects of smoking on health. This is of more than academic interest because it is often alleged in cigarette product liability suits that the plaintiff was unaware of the potential adverse effects of smoking on health (Green vs. American Tobacco Co. 1962, Cipollone vs. Liggett Group, Inc. 1984). Others, (Calfee 1985, 1986; Ringold and Calfee 1989), argue that knowledge of the harmful effects of smoking was so widespread some cigarette manufacturers capitalized on the fears of smokers by advertising their product as "less-unhealthy-than" competitive offerings.

Calfee (1985, 1986) and Ringold and Calfee (1989) have shown that claims of the less-unhealthy-than variety appeared in the late 1920s and 1930s, remained fairly stable during the 1940s and increased in frequency in the 1950s. Ringold and Calfee (1989) have also shown that the type of health information being communicated in advertising changed over time. In the 1930s

concerns about the health effects of smoking were reflected in information about symptoms such as sore throats and coughs. By the 1950s this information was concerned with more serious and longer term effects, e.g., lung cancer.

Underlying the Calfee (1985, 1986) and Ringold and Calfee (1989) research is the notion that cigarette advertisers were responding to, rather than initiating, smoker's concerns about the health consequences of smoking. If Calfee and Ringold are correct, information published in the popular press should show the same pattern of dissemination, i.e., articles on smoking and health will be relatively frequent as early as the 1930s, and during the 1930 to 1960 time period, the content will change from mentions of symptoms to mentions of more serious consequences.

METHODOLOGY

We performed a content analysis of all articles published in five popular magazines between 1925 and 1960 and cited in the *Readers Guide to Periodical Literature* under the headings "tobacco," "cigarettes," "smoking" and all related sub-headings. The five magazines were *Time*, *Life*, *Saturday Evening Post*, *Reader's Digest* and the *New Yorker*. Although no articles from these magazines on tobacco, smoking or cigarettes were cited in the *Reader's Guide* between 1925 and 1929, one hundred and thirty-five separate citations were found under those headings for the 1930 to 1960 time span. All 135 articles were located and photocopied. For purposes of this study an "article" is defined as any citation in the *Reader's Guide*.

Codes were developed following an examination of over one-half of all tobacco related titles listed in the *Reader's Guide* from 1950-1960. In addition, all such articles appearing in *Time* between 1950 and 1960 were examined. The coding form was intended to capture general and specific information about the content of the article as well as other descriptive information such as article source, date and length. General information regarding content was measured with eight codes summarizing the "most prominent theme" (MPT) of the article, e.g., agriculture, marketing, regulation, health, etc. This was the only variable in the coding scheme that forced the coders to make decisions that went beyond noting the mere presence or absence of information or other routine categorizations, e.g., percentage of the page occupied by the article.

The MPT information was supplemented with 207 specific codes concerning such potential topics as agricultural methods, crop sizes, quality of crop, product liability suits, smoking and athletes, smoking and children, figures for tar, irritation of eyes linked to smoking, irritation of nasal passages

TABLE 1
Distribution of Tobacco Articles by Periodical and Decade

Periodical:		1930-39	1940-49	Time Period: 1950-55	1956-60	Total
Time	n	8	14	29	26	77
	%	10.4	18.2	37.7	33.8	100.1
Reader's Digest	n	4	6	9	8	27
	%	14.8	22.2	33.3	29.6	99.9
Life	n	0	3	5	3	11
	%	0.0	27.3	45.5	27.3	100.1
New Yorker	n	0	7	5	3	15
	%	0.0	46.7	33.3	20.0	100.0
Saturday Evening Post	n	0	2	2	1	5
	%	0.0	40.0	40.0	20.0	100.0
Total	N	12	32	50	41	135
	%	8.9	23.7	37.0	30.4	100.0

linked to smoking, smoker's hack or cough, quitting smoking, calls to ban the promotion of cigarettes, etc. Consistent with Kassarijian (1977), the sole objective of the 207 specific codes was to categorize the topics contained in the article. A complete list of the codes is available from the authors.

Two training sessions were held with the two student coders to review and explain the coding instructions and to give the coders an opportunity to practice on a set of articles appearing after 1960 in *Time*. Thus, the articles used in the data set were not used in the practice coding. Each coder worked independently through all 135 articles. When the coding was completed, a third trained student coder went through each article resolving coding differences.

The overall inter-rater reliability was .62, which was lower than anticipated. An analysis of the source of coding differences revealed that almost all were due to coding omissions rather than to coding disagreements, i.e., one of the coders found something in an article that the other did not. When a random sample of one-quarter ($n = 34$) of all the articles was examined to determine the source of coding disagreements, 91 percent (261/288) were omissions. It appears that the complexity of identifying the complete content of articles, coupled with the task of assigning the content to 207 specific coding categories, was a difficult task. (By way of comparison the IRR's for the MPT coding was .72 and was .96 for the "type of article" coding.) Because of the low overall IRR, we carefully reviewed the reconciliation results of the third judge. Based on this review, we are quite confident that the final coding was successful. That is, we believe the final set of codes accurately reflects the content of the 135 articles.

FINDINGS

We begin with information describing the 135 articles, including when and where they were published and their main topics. Next, we summarize results regarding the details of the articles including, for example, the specific effects of smoking on health. The key questions are, of course, when did health related information about cigarette smoking begin appearing in the popular press and what specific health effects were mentioned?

Overview of the 135 article data set. Table 1 provides the distribution of articles by four time periods for the five target periodicals. The data are displayed in decades for 1930-39 and 1940-49, while the last eleven year period was split at 1956. The 1950 to 1960 time frame has been divided in an attempt to capture three effects: First, during the early 1950s the first widely disseminated scientific evidence about the health effects of smoking started appearing. Second, it was also during this time that the FTC cigarette advertising guidelines went into effect, (i.e., 1954-55). Third, *Reader's Digest* began publishing tar and nicotine figures in the latter half of the 1950s, setting off the 1957-59 so-called "tar derby." Thus by dividing the analysis at 1956, it was anticipated that the coding scheme would capture changes in the specific health effects being mentioned.

Two points from Table 1 stand out: First, there were very few articles about tobacco, cigarettes and smoking before the 1950s. Overall, of the 135 articles in the data set, approximately two-thirds appeared between 1950 and 1960, slightly less than one-quarter were published in the 1940s and less than ten percent appeared between 1930 and 1939.

TABLE 2
Most Prominent Theme and Whether Health Mentioned by Decade

Most Prominent Theme:		Time Period:				
		1930-39	1940-49	1950-55	1956-60	Total
Agriculture	n	1	5	2	0	8
	%	8.3	15.6	4.0	0.0	5.9

Total	N	12	32	50	41	135
	%	100.0	100.0	100.0	100.0	100.0
Percentage of Articles <i>Not</i> Mentioning Health:						
	%	33.3	68.5	44.0	14.6	40.0
	n	4	22	22	6	54
	N	12	32	50	41	135

Second, *Time* and *Reader's Digest* account for the vast majority of these articles. In fact, *Time* alone accounted for 57 percent (77/135) of all the articles with *Reader's Digest* contributing an additional 20 percent of the citations. It might be noted that in terms of issues per article, *Time* a weekly publication averaged one smoking related article every 7.4 issues while *Reader's Digest*, a monthly, averaged one every 4.9 issues. Taken as a group, the other three publications, all weeklies, averaged one article every 55 issues.

Besides publishing smoking information more frequently than the other periodicals, *Reader's Digest* also published longer articles. All 135 articles were trichotomized into one-third of a page or less, more than one-third but less than a full page and a full page or more. Twenty-six of the 27 articles published in *Reader's Digest* were more than one full page in length. By contrast, 49 of the 77 published in *Time* were one-third of a page or less and only three were more than one page. (Remember, however, *Time* has larger pages than does *Reader's Digest* so the difference in number of words per article is likely to be less dramatic.) For the entire data set, 42 of the 135 articles (31 percent) were more than one page and 55 (or 41 percent) were one-third of a page or less. Length of

article did not vary across the five publications by time period.

The overwhelming percentage of articles were concerned with cigarettes rather than with other tobacco-related topics (e.g., the tobacco crop, tobacco prices, etc). Overall 83 percent (or 112 of 135) articles were concerned with cigarettes. To determine whether there was a trend to cigarette-related articles versus other tobacco-related articles over time, we developed a two-by-two matrix of time period (1930-49; 1950-60) by topic of article (cigarettes; other tobacco-related). The obtained chi-square of 7.20 was significant at beyond alpha = .01 and indicated that there was a shift to cigarette-related articles between 1950 and 1960; i.e., 81 of the 91 articles (89 percent) appearing between 1950-60 were concerned with cigarettes compared to 31 of 44 (or 70 percent) before 1950.

Table 2 classifies the most prominent theme of the article by time period. The theme receiving the most attention by far in the 135 articles was health, (slightly over one-third of all articles), followed by marketing (22 percent) and articles on smoking initiation or cessation (13 percent). The theme of "regulation" accounted for less than ten percent of all articles overall, but was important in two time periods. Regulation was the main theme in five articles (15 percent) between 1940 to 1949,

TABLE 3
Content of Tobacco Articles by Decade

Article Content:	Time Period:				Total
	1930-39	1940-49	1950-55	1956-60

¹pmms = production, manufacturing, marketing or sales,

²mms = manufacturing, marketing or sales.

(but only one of these articles concerned the FTC cases against Lucky Strike, Camel, Old Gold and Philip Morris regarding health claims). Regulation was the most prominent theme in another five (or ten percent) of the articles published between 1950 and 1955; (three of these were concerned with FTC regulation of advertising and another reported on the FTC's advertising guidelines). In the other time periods articles on regulation were rare, as was regulation itself.

After 1949, articles concerned principally with the health effects of smoking accounted for a substantive percentage of all tobacco related articles: 32 percent (or 16 articles) between 1950 and 1955 and 58 percent (or 24 articles) of those published between 1956 and 1960. During the 1930s four of the twelve articles mainly concerned health, while in the decade of the 1940s only two of 32 articles had health as the most prominent theme.

The trend underlying these data becomes even more apparent when the percentage of articles *not* mentioning health are examined (see lower portion of Table 2). In the 1940s over two-thirds of the thirty-two articles published did not mention anything about tobacco and health. In the 1950-55 time period, this figure fell to 44 percent and in 1956-60, it fell again to less than 15 percent. When attempting to identify trends by time period, we must be careful to distinguish the absolute number of health citations from the relative number. During the 1930s two-thirds of the articles on smoking mentioned smoking and health, compared to less than one-third in the 1940s. On an absolute basis, however, this translates into eight articles mentioning health in the 1930s versus ten articles in the 1940s. Thus, readers were exposed to more

health-related content in the 1940s, although the percentage of articles mentioning the health effects of smoking was lower than in the 1930s.

An examination of the eight articles from the 1930s that mentioned health effects of smoking indicates these issues concerned respiratory problems (3), eye irritation (2), negative effects with regard to olfaction (2), fatigue (4), addiction (4) and quitting smoking (5). They did not usually concern more serious health issues such as cancer (1) or early mortality (2).

Overall, these findings are generally consistent with Ringold and Calfee (1989). That is, citations to smoking and health were relatively frequent in the 1930s and the 1950 to 1960 time period. During the 1940s we found that smoking and health was mentioned in more articles, but was mentioned relatively less frequently than during the 1930s.

Reader's Digest was the most consistent in providing information about tobacco and health. In the 1940s five of the six articles it published on tobacco mentioned health and in the 1950 to 1960 time period sixteen of the seventeen *Reader's Digest* articles mentioned health issues associated with tobacco. By comparison, a smaller percentage of articles in *Time* mentioned health in every time period, i.e., health was mentioned in 21 percent of the articles published in the 1940s, 52 percent of those published in 1950-55 and 88 percent of those published between 1956-60.

Content of the 135 articles. Table 3 shows the content of the data set by time period. To aid interpretation the 207 specific categories were aggregated into eight broader groups. Overall 1,466 specific types of content were coded; an average of

TABLE 4
Health Effects Content of Tobacco Articles by Decade

Other health effects from Smoking.	17.1	14.0	10.6	7.8	10.8
Total	100.0	100.0	100.0	100.0	100.0
N	35	57	169	141	402

slightly less than eleven content citations per article. Health related citations and cigarette manufacturing, marketing and sales citations, each accounted for over slightly one-quarter of the codes. Regulation of cigarette advertising and discussions of research results, calls for more research and discussions of research methodology, accounted for eleven and thirteen percent of the specific citations, respectively. Information about the composition of cigarette smoke represented slightly less than eight percent of the codes. All other categories accounted for five percent or less of the codes. Consistent with data presented earlier on the number of articles published by time period, almost 70 percent, (i.e., 1,019/1,466) of all content citations occurred between 1950 and 1960.

The specific content of the articles over time mirrored the findings presented above regarding the "most prominent theme." That is, health effects were mentioned relatively frequently in the 1930s, infrequently in the 1940s and more frequently than any other topic area from 1950 through 1960. Citations to research results and methodology and other research topics tracked quite closely with the pattern for health effects citations, as did mentions of the composition of cigarette smoke.

The specific types of health effects cited in these articles are shown in Table 4. The most apparent result in Table 4, i.e., that different types of health effects were prominent at different times, is perhaps the least surprising. Of more relevance is that the potentially fatal health effects of smoking specifically, links of smoking to cancer and effects

on the circulatory system (e.g., heart attacks), did not account for a substantive portion of content citations until the 1950 through 1960 time period.

In the 1930s the popular press made reference to smoking and fatigue, addiction and quitting, allergic reactions and the like. During the 1940s smoker's cough and other respiratory effects accounted for 35 percent of the health effect citations. Other health issues of prominence in the 1940s concerned effects of smoking on the circulatory system, (12 percent of cites) and addiction, (14 percent of cites). Interestingly, one of the most prominent health effects of current concern, harm done to the fetus by a mother who smokes, was mentioned hardly at all from 1930 through 1960.

Table 5 breaks down content by periodicals. Because of our focus on health related information, that category is displayed in more detail than the others. In addition, *Life*, *New Yorker* and *Saturday Evening Post*, have been aggregated in Table 5 because each had so few smoking-related citations. As shown in the last line of Table 5, the latter three publications had both the lowest percentage of (18 percent), and fewest health citations. Instead, over 50 percent of the citations in the latter three publications were concerned with production, management, marketing and sales of cigarettes and other tobacco products.

The last line in Table 5 indicates that *Reader's Digest* averaged 7.5 health content mentions per article compared to 2.1 in *Time* and 1.4 in the aggregation of *Life*, *New Yorker* and

²mms = manufacturing, marketing or sales.

Saturday Evening Post. Table 5 also shows that over 40 percent of the items coded from *Reader's Digest* were health related, compared to slightly over 20 percent in *Time*. Also, more of the citations in *Reader's Digest* were concerned with the composition of cigarette smoke (10.5 percent) and with mentions of research results or research methodology (15.8 percent) than in *Time*. In addition, there were fewer mentions of cigarette manufacturing, marketing and sales (14.4 percent) in *Reader's Digest* than in *Time* (31.7 percent) or as noted above in the grouping of the three other periodicals.

Regarding specific health effects of smoking, 9.0 percent of the health citations in *Reader's Digest* were to circulatory problems associated with smoking, 8.9 percent were to smoker's cough and respiratory problems and another 2.5 percent were to early mortality. The corresponding percentages for *Time* were 3.2 for circulatory problems and 1.6 for early mortality due to smoking. Conversely, 6.7 percent of the content citations in *Time* were to the link between cancer and smoking, compared to 3.9 percent in *Reader's Digest*.

The information on the specific content of articles in Tables 3, 4 and 5 can be summarized as follows. The health effects of smoking accounted for a substantial percentage of all content citations in the 1930s and the 1950s. Health content in the 1930s was mainly about smoker's cough, fatigue and other such symptoms of health effects. It was not until the 1950s, especially 1956-1960 that health effects such as cancer and circulatory system effects became the modal health content categories. *Reader's Digest* articles mentioned the health effects of smoking to a much greater extent than did the other periodicals.

CONCLUSIONS

This paper reported the results of a preliminary study of the prevalence of tobacco related articles and of the content of those articles in five widely circulated popular periodicals from 1930 through 1960. Our findings are generally consistent with those reported by others (Calfee (1985, 1986, Ringold and Calfee 1989) regarding the prevalence

and content of health-related information in cigarette advertising in the 1930 through 1960 time period.

The nature of the health content changed in each decade. Broadly speaking, during the 1930s the content was not about the potentially fatal effects of smoking but about less serious effects such as smoker's cough, irritations, allergies and the like. A much higher percentage of all smoking and health content citations from the 1950s articles were by contrast concerned with cancer and the effects of smoking on the circulatory system.

What Would Happen if Cigarette Advertising and Promotion Were Banned?

John E. Calfee, University of Maryland
Debra Jones Ringold, University of Baltimore

We cannot answer to anyone's satisfaction the question raised in the title to this paper. Rather, we have two more limited objectives. First, we hope to demonstrate that a realistic inquiry into the probable effects of banning cigarette advertising is essential before pursuing a ban as public policy. This imperative arises from history, particularly the series of disappointments encountered in past interventions in the cigarette market and in many other markets. Much of this disappointment, we believe, stems from the failure to think in concrete terms about what outcomes the proposed intervention is likely to bring. Second, we will summarize what we think are the most likely results of a comprehensive cigarette advertising ban, in view of the record of the past fifty years of increasingly regulated marketing of cigarettes.

BACKGROUND

Early in 1970, Congress prepared to enact a ban on broadcast advertising for cigarettes. This was regarded as a nearly certain means for reducing smoking because broadcast advertising was the main promotional device for the dominant brands of the day. The special beauty of the ban lay in the appeal that broadcast advertising has for teenagers, who (then as now) watch too much TV and read too little. But support for the broadcast ban was far from universal, and in fact public opinion polls at the time showed only minority support (Roper Center 1970). A particularly interesting dissent came from psychologist Eugene Levitt, a researcher into youthful behavior who served on the board of directors for the Indiana section of the American Cancer Society. In a trenchant 1970 article, Levitt asked a troubling question: why did anyone expect a broadcast ad ban to reduce youth smoking, in view of the universal finding of behavioral research that young persons' decision to smoke was associated primarily with peer and parental influence, plus a short list of other factors, none of which were cigarette advertising? (Also see Levitt and Edwards 1970). Levitt was especially hard on the Federal Trade Commission, which supported the ban without offering any evidence beyond pure intuition as to the likely effects of the ban. Worse, the broadcast ban would also bring to an end the millions of dollars' worth of anti-smoking messages that broadcasters had been required to subsidize under the current version of the FCC's Fairness Doctrine. Levitt thought it likely that the impact of these anti-smoking messages on young persons exceeded the extremely limited impact of cigarette advertising.

The broadcast ban was no sooner implemented than doubts emerged on a larger scale. Industry support for the ban, little noticed before the law passed, became increasingly meaningful to those who wished to limit smoking. By 1977, even a

task force at the Department of Health, Education and Welfare (home of the Surgeon General's office) recommended lifting the ban, at least for low tar and nicotine cigarettes (Warner 1979). That the broadcast ad ban failed in its purpose is now all but an article of faith among students of the cigarette market and of advertising restrictions (Warner 1979; Doron 1979a/b). Numerous studies have failed to show that the partial ban brought a substantial dampening of demand, and most studies have concluded that a substantial increase in demand arose from the end of subsidized anti-smoking messages (Warner 1979; McAuliffe 1987). Commentators have also noted that the ban probably aided the cigarette industry financially (Doron 1979a/b; Schuster, et al. 1987), a conjecture that received support in the one study to address this topic in a rigorous manner (Mitchell and Mulherin 1988).

Other major federal interventions in the cigarette market also regulated information. Most prominent have been the mandated health warnings, which were required on labels by a 1965 law, required in ads by FTC action in 1972, and then reformulated in 1984 legislation as a rotating set of four more specific warnings. Each step has met with disappointment, a declaration that no good had been achieved, and often, plans to improve the method (Drew 1965; FTC 1981; Blum 1988; Richards et al. 1988). As Wilkie pointed out in 1985, even the most recent change, the rotating warnings strongly recommended by the FTC, was undertaken with no particular goal as to consumer awareness. Less prominent regulatory interventions have been received with similar dismay. The 1954-55 FTC Cigarette Advertising Guides probably helped the industry survive the first cancer scare by banning claims that suggested the physical effects of smoking (*Business Week*; *Fortune* 1953 and 1963; Calfee 1985, 1986; McAuliffe 1988). The 1960 FTC ban on tar and nicotine claims encountered severe criticism from such anti-smoking groups as *Readers Digest* and the American Cancer Society and, later, from federal health agencies including the Public Health Service and the Interagency Committee on Smoking and Health (*The New Republic* 1966; *Time* 1966; Miller and Monahan 1966). The 1966 FTC decision to allow tar and nicotine claims was generally applauded (except by the industry) but the FTC's 1972 decision to make tar and nicotine figures mandatory was criticized as conveying no additional market benefit (Posner 1979; Calfee 1985).

WHAT ARE THE GOALS THIS TIME?

The central problem now remains the one so well articulated by Levitt in 1970: a shortage of specific goals that an ad ban is expected to achieve. Several analysts (e.g., Warner et al. 1986) have noted that possible goals fall roughly into two categories: (a) improved consumer understanding of

the health effects of smoking, and (b) reduced smoking. In both cases, possible gains must be balanced against possible losses.

Consider health information first. In 1980, the Surgeon General laid out a series of benchmarks for consumer awareness of smoking and health, to be achieved by 1990. These benchmarks included awareness by 85% of consumers that smoking is a factor in chronic obstructive lung disease, 90% for lung cancer and certain other cancers, and 85% for heart disease. A recent report from the federal Office of Smoking and Health, reviewing survey data collected in 1985, concluded that "in general . . . the 1990 objectives concerning the populations's knowledge of the health consequences of cigarette smoking have been met" (Shopland and Brown 1987). We must ask ourselves what further improvements could be expected from a ban on cigarette advertising. One cannot reasonably require absolute awareness levels exceeding the ones laid out in 1980 for broad illness categories (cf. Jacoby and Hoyer 1982 on "baseline" miscomprehension). Presumably, goals are narrower. One possible goal is to increase awareness of more specific relationships such as those involving smoking and gallstones or cancer of the bladder. Another possible goal, perhaps more interesting, is to increase the degree to which smokers "personalize" information on health effects (Fishbein 1977; Cohen 1989; FTC 1981), but it is not clear what standards would be appropriate for this kind of awareness. Or one could think in terms of increased awareness by young persons of health effects, but young people already have greater awareness of these matters than the population at large (Shopland and Brown 1987).

Thus when we consider consumer information, we are in effect asking, will the ban make things get even better, or more precisely, get even better even faster? A realistic appraisal would advance evidence on how advertising adversely affects these goals, and would take note of what has been achieved in other markets. How do consumer awareness levels in the cigarette market compare with those in markets in which consumers are thought to be reasonably well informed? In the absence of such evidence, one must be cautious in claiming that an ad ban will bring substantial improvements to a market in which awareness of health effects has already surpassed most standards set by the Office of Smoking and Health.

Now consider goals in terms of behavior. Per capita cigarette sales have been declining in this country at roughly one to two percent per year for about fifteen years (FTC, 1967 and later; U.S. Public Health Service 1989). Few large industrial nations, with or without advertising, match this record of reduced smoking (Boddewyn 1986; New Zealand 1989). Would a ban accelerate this rate of decline, or perhaps increase the decline here relative to declines in nations that leave cigarette advertising untouched? Perhaps the ban would suppress smoking initiation among teenagers. To do so, however, the ban would have to improve upon the

strong reduction in teen smoking already seen in the last decade and a half, during which the percentage of graduating high school seniors who smoke daily declined from 27% to 20% between 1975 and 1985 (NIDA 1984 and 1985). Yet the evidence linking advertising and youth smoking remains as weak as it was when Levitt wrote in 1970 (U.S. Public Health Service 1979; Krohn, et al. 1986; Moschis 1989.)

Given this history and current situation, one must ask what if any favorable changes a ban is likely to bring, beyond what is already occurring.

REASONABLE EXPECTATIONS

How is a ban on cigarette advertising and promotion likely to affect consumer information and smoking behavior? We begin by noting the importance of market incentives. One must look beyond the bald fact that cigarette manufacturers wish their advertising to sell cigarettes. When a product is enveloped in adverse health information, sellers have an incentive to emphasize this adverse information in advertising, in order to increase market shares. A substantial body of evidence suggests that such a "fear"-based strategy has often been employed in the cigarette market (Hanley 1929; *Business Week*; *Consumers Report* 1957; Schelling 1978; Calfee 1985, 1986; Ringold and Calfee 1989; McAuliffe 1988). The impulse to follow this strategy moderates or overcomes the offsetting desire to reassure smokers. This impulse, combined with the presence of mandatory health warnings and tar and nicotine information, and stringent regulatory control over positive claims in cigarette advertising, means that it is far from clear that when one eliminates cigarette advertising, one eliminates a factor that suppresses health information about smoking (Schelling 1978). Recent content analysis has in fact found that most specific messages in current cigarette advertising consist of mandated warnings, mandated tar and nicotine information, and voluntary emphasis on tar and nicotine content (Ringold and Calfee 1989).

We offer only a few words on the complex issue of whether cigarette advertising distorts media coverage of smoking and health. It is common to suppose that elementary economic intuition indicates cigarette advertisers are in a position to distort health information in the press, particularly in news magazines (Warner 1985; Weiss and Burke 1986; Whelan 1981). But individual sellers have an incentive to advertise even when the advertising helps subsidize adverse health information about smoking. This is because the adverse health information hurts the entire industry, whereas the advertising aids mainly the brand paying for the advertising. This fact greatly decreases the credibility of threats to withhold ads systematically from publications that report on smoking and health. Thus it is no surprise that cigarette firms continued to advertise in the late 1960s even though their ads subsidized anti-smoking messages that were widely regarded as having a major role in the contemporaneous decrease in smoking. In fact, the industry wished to bring such advertising to an end,

but competitive pressure to advertise was sufficiently strong so that only concerted action (which would violate antitrust laws) could achieve a voluntary ban on broadcast advertising (Schneider, et al. 1982). It is equally unsurprising that advertising continues today on a vigorous scale in major daily newspapers and the dominant news weeklies, precisely the outlets that provide the most comprehensive information on smoking and health. Overall, it seems unlikely that inherent economic forces cause the cigarette industry to have more than the slightest effect on market-wide reporting on smoking and health.

A large literature suggests that advertising plays a weak role in expanding long-term industry demand for mature products (Assmus et al. 1984). This in turn suggests that eliminating advertising is unlikely to have a negative effect on sales in a market that is the embodiment of maturity. Of particular significance is econometric analysis of advertising and sales, analysis that is probably more extensive for this market than for any other. Econometric results suggest little if any negative effect on sales from small decreases in advertising, and similarly find little or no change from huge decreases such as occurred when broadcast advertising was banned in the U.S. (Hamilton 1972; Warner 1979; McAuliffe 1987 and 1988; U. S. Public Health Service 1989, chap. 7). International data are largely consistent with this view. Hamilton's 1975 survey and Boddewyn's 1986 comparison of nations with and without bans, and nations before and after bans, finds little apparent effect from bans. A more recent study by the New Zealand Toxic Substances Board (1989) unintentionally provides supporting data showing little difference between countries with and without advertising bans. A recent study by the federal Office on Smoking and Health of smoking prevalence in six Western nations provides little reason to think that the comprehensive ad ban in Norway has brought smoking reductions exceeding those in less regulated countries (Pierce 1989).

All this strongly suggests that a cessation of cigarette advertising would have little effect on sales. Indeed, it is entirely possible that present-day cigarette advertising, with its plethora of health warnings and incessant reminders that tar and nicotine should be avoided, dampens rather than increases overall sales (Schelling 1978). Moreover, there are reasons to believe that advertising supports a mix of cigarette types substantially lower in tar and nicotine than would be the case without advertising. The history of tar and nicotine advertising in this country is punctuated with both prohibitions of, and governmental support for such advertising. This record strongly indicates that advertising hastens and helps maintain acceptance of lower yield cigarettes (Calfee 1985, 1986). The health benefits of lower tar cigarettes are clear in the case of lung cancer, in the sense that epidemiological evidence linking smoking and lung cancer also manifests a progressively weaker link for lower yield cigarettes (Stellman and Garfinkel

1986; Peto 1985 and references therein).

Correlational evidence on smoking and heart disease does not display a similarly strong link between cigarette yield and heart disease (Kaufman, et al., 1983), but this finding is inconclusive in view of the fact that controlled intervention studies have thus far generally failed to support correlation-based predictions linking smoking and heart ailments (Rose, et al. 1982; Hjermand, et al. 1981; Multiple Risk Factor 1982). Leading experts on smoking and health continue to recommend world-wide use of lower yield cigarettes (Peto 1985; Participants 1985). We believe it likely that an end to advertising would bring a regression in the market toward the much higher yield cigarettes of former years, just as happened when tar and nicotine advertising was temporarily halted during 1955-57 and in the early 1960s (Miller and Monahan 1966; Calfee 1985).

However doubtful the proposition that a comprehensive ban would reduce sales, the immediate effect of such a ban on the financial health of the industry seems clearer. Promotional expenditures would almost certainly decrease substantially, as happened in 1971. Prices are likely to remain stable or increase because the ban would remove the main competitive tool for lower-cost "generic" brands. Thus a ban would probably increase industry profits, as apparently happened after the broadcast ban. Yet the industry opposes the ban, apparently in all sincerity. This is probably accounted for by the fact that a blanket ban on promotion could be the harbinger of more stringent constraints on smoking itself, especially if, as seems likely, the ban itself brings no visible improvement in the market.

One other aspect of the movement to ban cigarette advertising bears mention. Congressional attention has recently turned to the notion of limiting cigarette advertising to "tombstone" ads, i.e., ads that contain brand name, tar and nicotine content (perhaps) and the Surgeon General's warnings. This is not the place for an extended analysis of this approach. But many of the same caveats continue to apply. Whether the tombstone plan could accomplish any well-articulated goal is unclear. If a total ban is unlikely to dampen sales, the same may apply to a ban of all but tombstone advertising. Regulatory history is not encouraging; much the same kind of regulation has been attempted in advertising for stocks and bonds, with extremely dubious effects on the market (Stigler 1964; Jarrell 1981; Shoeman 1986). The long history of affirmative disclosure requirements in FTC advertising regulation is similarly unencouraging (Wilkie 1982). Moreover, tombstone advertising would provide little support for lower-yield cigarettes, because advertising for lower-yield brands must persuade smokers that a given brand offers a favorable trade-off between flavor and yield. This cannot be done through tombstone ads. The resulting constraints on promoting low-yield cigarettes would remove most market emphasis on the advisability of avoiding tar and nicotine. In

general, there seems little reason to think the tombstone device would be superior to what we have now.

Overall, then, we expect that a ban on cigarette advertising and promotion would bring: (a) little if any improvement in consumer information on health effects of smoking, particularly in the many areas in which consumer awareness has already reached nearly the highest imaginable level; (b) little if any change in recent downward trends in smoking behavior, absent striking new health information, exceptionally vigorous anti-smoking campaigns, or major changes in cigarette taxes; (c) some regression toward higher tar and nicotine yield; (d) a possibility of higher cigarette prices; (e) higher industry profits; and (f) possibly, encouragement for greater legislatively created restrictions on smoking itself.

CONCLUSIONS: THE DANGER OF DIFFUSE GOALS

That a total ban on cigarette advertising would be a fateful restriction on freedom can hardly be denied. Such a step calls for persuasive reasons to believe the results would resound decisively to the benefit of smokers and the population generally. Yet one can hardly claim that the benefits of a ban would outweigh its subtle and far-reaching costs without at least specifying approximately how the ban would alter those observable quantities that are routinely invoked when explaining why the cigarette market has failed so completely as to call for extreme measures. What is needed is not a detailed set of predictions, but merely a set of goals and forecasts sufficiently concrete to allow a rough assessment of what is at stake in the ban proposal.

Articulating goals forces one to confront difficult questions. What does cigarette advertising really do (as opposed to what sellers would like it to do)? Is a logical extension of measures tried before likely to produce results strikingly different from those obtained in the past? Are the real goals of a ban even confined to advertising matters—that is, is the ban proposed for what the ban itself will do, or mainly as a prelude for other measures that have nothing to do with advertising and promotion? After all, we are all familiar with regulations designed for one purpose but used for another (see, e.g., "Antitrust and Economic Efficiency," 1985).

The proposal to ban cigarette advertising and promotion has all the signs of high hopes undiluted by realistic assessment. As such, it is likely to bring both disappointment and pressure for progressively "tougher" measures, also unaccompanied by concrete expectations. Those who advocate a ban usually do so without specifying concretely what the ban would do, instead seeing the ban as but one part of a "comprehensive" strategy to reduce smoking (e.g., Warner 1987; Cohen 1989). Such an outlook seems to suggest that expectations for a ban can be held in abeyance until after the ban is achieved and society can move on to other measures. One must ask whether there are specific goals for the ban when considered in conjunction

with other components of this strategy, or is the entire plan supported primarily by good intentions? To suggest embarking on an ad ban without any concrete expectations at all is to invite bad legislation. If the ban were enacted, powerful restrictions would have been imposed on markets without any means for judging whether the restrictions were necessary or even beneficial.

Banning Cigarette Advertising: A Cure That Will Aggravate the Disease

Paul N. Bloom, University of North Carolina at Chapel Hill

I think banning cigarette advertising is a bad idea. I have a variety of reasons for holding this belief, none of which have to do with any emotional or financial ties to cigarettes or the cigarette industry. Indeed, I have never smoked, have always hated being around cigarette smoke, and have never taken a penny from the cigarette industry (or from any anti-smoking groups, for that matter). Moreover, I dislike the idea of an ad ban even though I am convinced that cigarette advertising *does* help to persuade people -- especially young people -- to smoke who would have not done so otherwise. I simply cannot accept the argument that all those millions are being spent merely to take market share away from one another.

So why do I want to permit something to continue that I feel contributes to serious public health problems? Essentially, I dislike an ad ban because I think it is the wrong remedy for the problem. And what bothers me about this remedy goes much deeper than a simple concern about its potential infringement on freedom of commercial speech. Frankly, I don't think the First Amendment protects sellers from saying things that can harm people -- and the courts have recently affirmed this. Instead, what bothers me about an ad ban is that, at best, I think it will have a negligible effect on smoking behavior, while, at worst, it could contribute to significantly higher levels of nicotine addiction worldwide. Let me elaborate on why I reach these conclusions and then present several ideas for alternative remedies that I think would be more effective.

My basic view is that flaws in how consumers process information about cigarettes permit cigarette advertising to help in persuading people to begin smoking. I feel that two kinds of flaws predominate. These are:

1. Some consumers are influenced to value or weight certain attributes of cigarettes like "makes you look sophisticated" or "helps you relax" relatively more than they value health and safety attributes.
2. Some consumers find information about the health and safety attributes of cigarettes confusing, difficult to comprehend, and costly to acquire. They therefore develop inaccurate beliefs about the health and safety attributes of cigarettes.

Young consumers seem most likely to experience these flaws and I doubt whether banning advertising would do much to protect these people from their occurrence.

A ban on advertising would certainly reduce the opportunity for consumers to see and hear messages that tell them directly or indirectly that

they should value attributes other than health and safety. But it would also reduce the opportunity for them to see the current warning disclosures, which may help somewhat in getting consumers to at least keep health and safety a consideration. On balance, the current system clearly tilts things strongly toward valuing sophistication, relaxation, and so forth over health and safety. However, I fear a system without advertising would tilt things even more. Young consumers would decide how to value attributes based on watching peers, admired adults, celebrities, and everything else in the world. I worry that some young people will only be exposed to pro-smoking values, and I also worry about how the cigarette companies might be able to use non-advertising forms of promotion to make a good part of everything else in the world (e.g., sporting events, movies, in-store-displays) be a pitch for pro-smoking values. With the economic incentives for the cigarette companies as great as they are, I don't think we can underestimate how ingenious they might be in finding alternative ways to communicate their values through non-advertising channels.

Let me also stress that the current warning disclosures contain accurate information about health and safety hazards which would not be as readily available to consumers with an advertising ban. Thus, I think there is a good chance that consumers would possess both more pro-smoking values and more inaccurate beliefs about the health and safety hazards of cigarettes under an advertising ban.

An ad ban would also insulate the major cigarette companies from a certain amount of competitive pressure. They would be protected from any upstart company being able to enter the market with a big splash by advertising a truly "safer" cigarette. And they would be protected somewhat from beating on each other. In a sense, an ad ban would cause a truce to their advertising arms race and allow them to pocket millions of dollars while settling into a cozy shared-monopoly situation. Who knows where they would put all this money? Perhaps it would allow them to be even more aggressive in promoting the pleasures of smoking throughout the developing world.

The bottom line could very well be a lot more smokers around the world -- and in the U.S. -- and a lot less revenues for U.S. media. The big winners in all this, other than the cigarette companies, could be the overseas media. But I wonder, if we are so interested in helping the foreign media, why don't we simply leave things the way they are now and provide them with some nice foreign aid grants? Certainly, the cost of this would be lower than the increased health care expenses in the U.S. and elsewhere that I think our government would have to pay for if the ad ban went through.

What would I do instead of an advertising ban to remedy the situation? Maybe I'm a dreamer, but my inclination would be to pursue two policy

directions: better warning disclosures and stronger antitrust enforcement. I think improved and larger warning disclosures in the advertisements can't hurt, unless they actually would encourage the cigarette companies to call a truce on their own and stop advertising altogether. But to prevent this from happening, I think it would be helpful to break the giant companies of this industry into smaller companies. Then they would be less able to capitalize on their old brand equity and be forced to use advertising and other differentiation tools -- including trying to develop safer cigarettes -- to try to build new forms of brand equity. The new, smaller companies might be less efficient than the old ones, and their prices might be higher, but these higher prices might even encourage a few addicts to quit or cut down. This approach would not be the "quick fix" that people are seeking from an advertising ban, but I feel it would work much better in the long run.

The Regulation of Cigarette Advertising in the United States: Some Alternatives

Edward T. Popper, Bryant College

ABSTRACT

Currently, U.S. Policy makers are considering proposals that could ban all advertising for cigarettes in the United States. A ban is the most severe regulatory action that can be taken with regards to a product's advertising. Before it can be imposed there should be no question that it is the most viable option available. To add clarity to the debate, this paper will examine the role of cigarette advertising (or more precisely, the conflicting roles described by the industry's critics and defenders) in today's marketplace. Next, the need for affirmative disclosure in cigarette advertising will be addressed as well as the effect of those informational remedies already in place. The paper will then propose a set of regulatory objectives to address the public policy concerns regarding cigarette marketing. Finally, a range of alternative solutions will be proposed in terms of those objectives.

INTRODUCTION

There can be little argument that the regulation of cigarette advertising and promotion is one of the most controversial issues currently facing marketers and public policy makers. Defenders of cigarette marketing vigorously assert that there are no harmful consequences to that product's advertising and marketing and that these programs have no effect on the aggregate demand for cigarettes (e.g. Ward, 1989). The critics of the industry's marketing practices point to the nearly \$3 Billion U.S. cigarette manufacturers spend on cigarette advertising and promotion and argue that it is naive and unrealistic to believe that these massive expenditures have absolutely no effect on total cigarette sales (e.g. Warner, 1986).

The debate over proposals to ban or restrict cigarette advertising and/or promotion provides a focus for this controversy. A ban is the most severe regulatory action that can be taken with regards to a product's advertising. Before it can be imposed there should be no question that it is the most viable option available. To add clarity to the debate this paper will, first, examine the role of cigarette advertising (or more precisely, the conflicting roles described by the industry's critics and defenders) in today's marketplace. Next, the need for affirmative disclosure in cigarette advertising will be addressed as well as the effect of those informational remedies already in place. The paper will then propose a set of regulatory objectives to address the public policy concerns regarding cigarette marketing. Finally, a range of alternative solutions will be proposed in terms of those objectives.

THE ROLE OF CIGARETTE ADVERTISING & PROMOTION

At the heart of the current controversy is the role that cigarette advertising plays in the marketplace. Representatives of the tobacco industry have argued that there is no evidence to support the contention that advertising of cigarettes has any effect on the total size of the U.S. market for cigarettes. The support for this argument ranges from econometric studies that show little effect or no effect of advertising on aggregate cigarette demand (e.g. Schmalensee, 1972) to behavioral studies that suggest children's smoking behavior is a function of peers' and parents' smoking attitudes and behavior (e.g. Ward, 1986; Blackwell, 1986). The most extreme advocates of cigarette advertising even argue that the current decline in cigarette consumption among children and teenagers "confirms...that advertising is *not* [emphasis in original] a significant influence on the decision of children to start smoking (Boddewynn, 1989).

Critics of cigarette advertising reject these arguments vigorously. In the words of a founder of FCB Advertising:

"[T]he cigarette industry has been artfully maintaining that cigarette advertising has nothing to do with total sales...[T]his is complete and utter nonsense. The industry knows it's nonsense...I am always amused by the suggestion that advertising, a function that has been shown to increase consumption of virtually every other product, somehow miraculously fails to work for tobacco products (Foote, 1981)".

Others argue that it makes no financial sense for cigarette manufacturers to advertise only for brand share shifts (Tye, Warner & Glantz, 1987) citing industry data that indicates brand shifting is only 10% annually (Marketing and Media Decisions, 1985). At the extreme, the critics of cigarette advertising argue, for example, that "Most cigarette advertisements are deceptive, and many violate the tobacco industry's own code of ethics (Tobacco and Youth Reporter, 1989)."

The actual role of cigarette advertising and promotion falls somewhere in the middle of these extremes. A review of the econometric studies examining the effect of tobacco advertising on aggregate demand for tobacco (Toxic Substances Board, 1989) reveals that many of the studies do show advertising for cigarettes increases aggregate demand. This same conclusion was also suggested by the U.S. Surgeon General who reported "...evidence makes it more likely than not that advertising and promotional activities do stimulate cigarette consumption (U.S. Department of Health and Human Services, 1989)." Further, all of these

studies are likely to underestimate advertising effects since they ignore promotional expenditures and the effect of "quitters" leaving the cigarette market.

The funding of promotional programs has grown to over half of all cigarette marketing communications expenditures in the 1980's (FTC, 1986) while advertising expenditures have remained relatively flat (in constant dollars). Thus, econometric studies that examine only advertising are omitting what has become the predominant form of marketing communications used in this industry and underestimating spending for marketing communications. The task confronting those marketing communications is also underestimated in these studies since they examine aggregate demand without accounting for the effect of substantial numbers of smokers leaving the market. For example, if aggregate demand was level over a period of years but a substantial number of smokers had left the market, the only way demand could have been level would have been for either average consumption level (among the retained smokers) to increase or for new consumers to enter the market (In fact, government data indicate that new smokers are entering the market every year, albeit, at a declining rate. U.S. Department of Health and Human Services, 1989). Those econometric studies that are based on aggregate demand ignore this market replenishment which, absent the high quitting levels, would actually result in increased aggregate consumption.

Aside from increasing aggregate demand, advertising that results in brand switching may be targeting (either explicitly or implicitly) youth. The 1989 Surgeon General's Report (U.S. Department of Health and Human Services, 1989) indicates that most current smokers, started using cigarettes while they were teenagers. The cigarette industry's own data indicate that new smokers switch between brands for the first year they smoke before crystallizing on a chosen brand (MARPLAN, 1957). Given the low rate of brand switching referenced above (10% per year) it is clear that a substantial portion of that switching occurs among teens. Thus, if the function of cigarette advertising is, as the companies insist, to promote brand switching a target of that advertising must be those teens who are new smokers.

A final role for cigarette advertising is a defensive one. Some cigarette advertising presents alternatives for smokers who are considering leaving the market. That advertising presents brands that claim lower levels of tar and nicotine. While such claims could be considered simply to be statements of product construction (as some researchers have claimed), the only relevance the claims could have is if consumers inferred (perhaps incorrectly) that the products were safer and healthier because of the lower tar and nicotine. Aside from claims of low tar and nicotine content, for consumers who are not actively considering quitting smoking, brand image advertising also plays a defensive role reinforcing the product images that are the bases for some smoker's brand loyalty.

In summary, cigarette advertising increases the market for cigarettes, promotes brand switching among both adults and youths, and provides both reasons and alternative products to keep smokers in the cigarette market.

AFFIRMATIVE DISCLOSURE

While there is near unanimous belief in the medical community that cigarettes are remarkably toxic and addictive (U.S. Department of Health and Human Services, 1989) consumers are less unanimous in their awareness of the product's risk. While the majority of consumers are aware of some of the health risks of smoking, a significant portion are unaware. This portion is even higher for smokers (ibid). Thus, many current and potential cigarette smokers are approaching this product category uninformed.

There can be little doubt that information about the health risks of using a toxic product is important and material to a consumer. Using this logic the FTC, in 1981, recommended that more effective cigarette warnings (both on packages and in advertisements) be adopted (Myers, et al., 1981). While, as is the case for most disclosure programs (Wilkie, 1985), there were no objectives formally set for the new disclosures, some objectives can be inferred.

As stated above, the rationale for proposing new disclosures (in format, content, and number) was the relatively low consumer awareness of the risks of smoking. Thus, at the very least, the disclosures were intended to increase consumer information about the risks. If that was the objective, the current cigarette disclosures are unsuccessful.

The 1989 Surgeon General's Report (U.S. Department of Health and Human Services, 1989) indicates that significant numbers of adults continue to underestimate the health risks of cigarette smoking. Further, there is rising evidence that even the current in-ad cigarette warnings are ineffective (Fischer, et al., 1989; Davis and Kendrick, 1989). These studies suggest that the non-warning content of cigarette advertising is the attention focus of the advertising targets. Conversely, there is no research that demonstrates that smokers note the warnings (either on pack or in-ad) or recall them. This would indicate that for the inferred informational objectives discussed above to be achieved either the warnings or the advertising itself must be changed.

How the warnings could be changed to increase their communications effectiveness is unclear. Obviously, increasing the size of the warnings would, at some point, result in increased attention. However, if the size of in-ad warnings is increased by as much as 50%, they still will not increase the warning's communications level (Popper & Murray, 1989). That same research indicated that moderate changes in the warning format are also unlikely to increase communication. Thus, while the warning could be changed to increase communication, the magnitude of change necessary might be so substantial that the warning dominates the ad.

TABLE 1
Proposed Regulatory Objectives

Eliminate Advertising and Promotion that Leads to the Expansion of the Cigarette Market
Eliminate Advertising and Promotion that Would Inhibit Smokers from Quitting
Communicate the Health Risks of Smoking at a Level at Least Equal to the Communication of the "Benefits" of Smoking
Prohibit Advertising Targeted to Youth
Prohibit Deceptive Advertising

An additional issue is the potential for interaction between the warning disclosure and the advertiser's selling message. If the warning is attended to and believed it presents a health problem to a smoker (current or potential). An implied health claim in the advertiser's selling message (such as a statement about low tar and nicotine) presents what could be perceived (inappropriately) as a solution to that problem. Thus, even an effective disclosure could have harmful consequences for the smoker.

Disclosure has been a component of cigarette communication for the past twenty five years. The very presence of the disclosures provides an indication of the policy makers' belief that disclosure is required. That the disclosures are ineffective or have unintended consequences suggests that the underlying policy must be reconsidered. The following section will propose a set of regulatory objectives to be considered when evaluating policy alternatives.

PROPOSED REGULATORY OBJECTIVES

It is a stated public health objective of the United States to achieve a totally smoke free (i.e. no cigarettes used) country by the year 2000 (U.S. Department of Health and Human Services, 1989). Any regulatory objectives should be consistent with that goal. At the same time, no one is realistically proposing a ban (or prohibition) on the *sale* of cigarettes. Thus, the regulatory objectives effecting advertising must be consistent with the joint goals of eliminating smoking and not prohibiting cigarette sales. This results in the following set of objectives (Table 1):

Eliminate Advertising and Promotion that Leads to the Expansion of the Cigarette Market

Obviously expansion of the cigarette market is inconsistent with the policy objective of eliminating smoking. Thus, any marketing program or activity that expands the market for cigarettes is contrary to the stated national public health policy and must be eliminated. Since cigarette

manufacturers argue that none of their advertising and promotion leads to market expansion they should accept this regulatory objective without reservation. Further, given that market expansion would be a violation of public policy, the burden of proof should be on the cigarette marketers themselves to demonstrate (perhaps from the research they already conduct on all of their marketing programs) that their programs (taken separately or as a campaign) have no market expansion effects.

Eliminate Advertising and Promotion that Would Inhibit Smokers from Quitting

Given the public health goal to eliminate smoking, for a company to employ marketing practices that keep people smoking is contrary to that objective. Thus, to be consistent with that public health goal, the regulatory objective must be the elimination of marketing programs that either encourage smokers to keep smoking or inhibit them from quitting. As above it should be the responsibility of the marketers themselves to demonstrate that their advertising and promotion programs neither have the intent nor effect of keeping people in the cigarette market.

Communicate the Health Risks of Smoking at a Level at Least Equal to the Communication of the "Benefits" of Smoking

A basic problem facing disclosures is defining a standard of adequacy. Common sense should dictate that a disclosure designed to modify a claim or a marketer's message have equal "visibility" to the message it modifies (Popper, 1988). This is particularly appropriate when the disclosure deals with a substantial, indeed, mortal health risk. Thus, it naturally follows that information (in cigarette marketing communications) that presents the health risks of smoking (i.e., mandated health disclosures) have the same level of communication as the attribute/benefit information in the ad. Once again, it should be the cigarette marketer's responsibility to demonstrate that parity of communication as a

TABLE 2

natural outgrowth of their ongoing advertising, communications, and marketing research.

Prohibit Advertising Targeted to Youth

The cigarette manufacturer's own Advertising Code prohibits advertising to youth. This objective would simply give their self regulatory standard the regulatory force. To the extent that the self regulatory standard is adhered to, the industry could have no objection to this objective.

Prohibit Deceptive Advertising

This final objective simply reinforces existing regulatory authority. It puts cigarette manufacturers on notice that policy makers expect them to be non-deceptive in their advertising. If a deceptive ad is one that misleads a consumer, acting reasonably, to his or her detriment, than any cigarette advertisement that claims health or benefits (either implicitly or explicitly) without evidence to substantiate the health claim would be deceptive. Given the FTC's guidelines on advertising substantiation (the presence of a claim in an ad requires the advertiser to have proof of the accuracy of that claim *before* it can be included in an advertisement), cigarette manufacturers would be required to have proof (in this case, medical proof), prior to advertising (either explicitly or implicitly) relative health benefits of a cigarette.

This set of potential objectives results in a number of regulatory alternatives.

ALTERNATIVE SOLUTIONS

A wide range of policy alternatives are available to achieve the objectives discussed above. Given that any of the alternatives will represent a constraint on commercial speech, they should only be implemented if there is no less restrictive method to achieve the same policy objective. The following are a range of policy alternatives in

reverse order of severity to achieve those policy objectives (Table 2):

Increased Mandatory In-Ad Disclosure

Obviously this is closest to current practice. It would entail increasing the number, explicitness, size or colors of the disclosures required to appear in cigarette advertisements. One alternative for developing these warnings would be to have them written by regulators or legislators (as is the case for *all* disclosures currently required mandated for any product). Another approach would be to require in-ad disclosures that would be attention demanding (as determined by consumer research rather than regulatory fiat) as well as including the health risk information determined, designed by public health experts, in order to fully inform smokers.

In many ways this alternative is similar to what was actually proposed by the FTC in 1981 (Myers, et al., 1981) but not enacted by the U.S. Congress. It is unclear, however, if such communications-effective disclosures were introduced whether cigarette manufacturers would continue to advertise. Much as they withdrew from television in the face of the fairness doctrine advertisements in the late 1960s (Warner, 1986), faced with powerful and required in-ad anti-smoking disclosures the cigarette manufactures might withdraw their advertising voluntarily.

Increased Mandatory In-Ad Disclosure With Performance Standard

This proposal is similar to the previous one except it acknowledges the historical inability of regulators to craft effective disclosures. Instead, it places the responsibility for disclosure design in the hands of the cigarette companies themselves (whose success in crafting effective communications is unquestionable).

Under this alternative regulators would only define the medical/health risk information that needs

to be communicated. They would not define the manner or even specific wording for communicating this information. The cigarette manufacturers would then be required to demonstrate that the health risk information (disclosures) are communicated as effectively (using predetermined criteria and measures) as are the selling or image messages of the advertisement (i.e. a performance standard). It is likely, for the same reasons described above, that such a requirement would also result in the manufacturers voluntarily withdrawing their advertising.

Counter Advertising Funded By Additional Cigarette Tax

As Warner (1986) demonstrates, the counter advertisements run under the fairness doctrine ruling in the late 1960s, were particularly effective in communicating the health risks of smoking and reducing per capita cigarette consumption in the U.S. This proposed alternative would fund a similar series of anti-smoking messages. Run in paid media (as opposed to PSA placement, as are most current counter advertisements) in high viewership/readership slots and developed according to rigorous (DAGMAR) standards, including copy testing, these messages could be expected to have impacts similar to those that achieved by the fairness doctrine mandated anti-smoking commercials of the 1960s.

Funding anti-smoking commercials with additional cigarette taxes serves two goals. First, the messages are both self-funding and self adjusting. The funding is a function of the level of sales. As the market declines, the need for the messages declines, and the funding declines according. Further, since cigarette consumption has been demonstrated to be price elastic (Toxic Substances Board, 1989), a "Counter Advertising Tax" (a type of user fee) would have the added benefit of reducing consumption in furtherance of the nation's Public Health Goal.

Tombstone Advertising Requirement (Image Ad Ban)

This alternative would limit advertisers to including only product attributes in their cigarette advertisements. It is based on the premises that "image" advertising plays a role in youths' determining which brand to adopt at the end of their introductory "trial" period (MARPLAN, 1957) and that image maintenance is among the reasons why smokers resist quitting.

Given the objectives described above, if the attributes included in these tombstone advertisements represented health claims (either explicit or implicit) the cigarette advertisers would be required to provide prior data supporting the medical validity of their health claim(s).

Total Advertising Ban

This proposal would extend the current ban on broadcast cigarette advertising to all media. While the broadcast advertising ban had an initial

impact on cigarette sales, the cigarette manufacturers quickly increased their expenditures in other media. After just a few years, the level of advertising expenditures (in constant dollars) reached its pre-broadcast ban level. When the broadcast ban was enacted, broadcast advertising represented the overwhelming share of cigarette advertising. The expected effect would, presumably, have been to dramatically reduce cigarette advertising. In turn, this would suggest that the implied regulatory objective of the broadcast ad ban was to dramatically reduce cigarette advertising. This proposal simply extends the current ban to accomplish the ends sought by the broadcast ban.

The experience with the broadcast ban further suggests that if the regulatory objective is to reduce the overall level of marketing communications for cigarettes it is insufficient to merely ban the currently dominant form(s) of marketing communications. Instead, the regulation or legislation has to be crafted to cover potential marketing communications media (perhaps including media that do not yet exist).

The obvious concern over this advertising ban (or the bans proposed below) is that it might not be permissible under the first amendment to the U.S. Constitution. Obviously, this is a precise question of law appropriately left to the courts. However, there is an indication that the U.S. Supreme Court Decision in *Posadas de Puerto Rico v. Tourism Company of Puerto Rico* provides specific support for a ban on cigarette advertising (Devore, 1988).

Total Promotion Ban

An alternative to banning cigarette advertising is to ban consumer promotion (to include sampling, couponing, event sponsorship, premiums, etc.). Currently cigarette manufacturers' promotional expenditures exceed their advertising expenditures (FTC). This reflects a general trend in marketing towards promotion, away from advertising, due to the action-inducing benefits of promotion. Further, cigarette advertising is so intensive that the marginal return for incremental advertising expenditures is declining.

By banning promotion those devices which are most likely to result in youthful trial of cigarettes (such as free sample distribution, concert sponsorship, and sports sponsorship) would be removed. Further, the elimination of sports sponsorship would eliminate the linkage of cigarettes to sports performance (e.g. the Virginia Slims Tennis series), which is, itself, a violation of the industry's own advertising code. This would also remove the opportunity cigarette company's currently have to circumvent the broadcast ad ban through their own sponsorship of events, performers and competitors.

Total Advertising & Promotion Ban

Obviously, the most draconian of steps, this proposal should only be taken if the actions of the cigarette companies violate the objectives presented

above and all other alternatives are either rejected or ineffective.

RESEARCH OPPORTUNITIES

This paper has only presented some of the alternatives available to regulators and suggested some of the relevant issues. It presents no evidence regarding the potential effect of these programs if implemented in the U.S. market. That is because no such evidence is available. While the gravity of the health risks presented by cigarettes is such that the U.S. government may well decide to take action, all parties would clearly benefit from research that evaluates the potential impact of any and all of these programs.

Some of the alternatives available to regulators are dramatically more restrictive than others. To impose a more restrictive policy when a lesser one would accomplish the public policy objectives violates both the spirit and the letter of the Central Hudson guidelines for constraints on commercial speech. Thus there is an opportunity --- indeed, an urgent need --- for researchers to test the effects of these alternatives.

The Effect of Framing on the Choice of Supermarket Coupons

William D. Diamond, University of Massachusetts

Abhijit Sanyal, University of Massachusetts

ABSTRACT

One of the most interesting implications of Prospect Theory is that choices are affected by whether the alternatives are framed as gains or as reduced losses. The framing of sales promotions should affect whether they are chosen by consumers. This paper presents the results of a field experiment demonstrating that supermarket shoppers presented with redeemable coupons were significantly more likely to choose a test promotion if it were framed as a gain than if it were framed as a reduced loss. Other factors affecting the desirability of sales promotions are discussed.

INTRODUCTION

If consumers evaluated sales promotions in the straightforward way described by multiattribute attitude models (Sawyer and Dickson, 1984), they would ignore the details of the presentation of promotional offers, and concentrate on the computed values of the offers. Two coupons offering identical amounts off of the same purchase would not be evaluated differently. Yet decision making in other domains is affected by variations in the format of the information presented (Payne, 1982). It would be surprising if the evaluation of coupons and other promotions were not affected by presentational factors.

Prospect theory (Kahneman and Tversky, 1979; 1984) is one of the most important descriptive theories of choice under risk. One of prospect theory's interesting consequences is that people's choices of risky alternatives are affected by how the alternatives are framed. When alternatives are framed as gains subjects make less risky choices than when the alternatives are presented as reduced losses.

Kahneman and Tversky originally used civil defence problems to demonstrate framing effects. Subjects took fewer risks when the alternatives were presented as lives saved (framed as gains). They took more risks when the same alternatives were presented as reductions in lives lost. Prospect theory's value function allows the prediction that a gain of 200 lives (saved) feels like it makes more difference than a reduced loss from 600 to 400 deaths.

The framing of alternatives affects choices in other domains. McNeil, Pauker, Sox and Tversky (1982) showed that the framing outcomes in terms of probability of survival or dying affected the hypothetical medical treatments chosen by physicians and their patients. Levin and Gaeth (1988) showed that whether meat was described in terms of percent fat or percent lean made a difference in whether it was chosen by consumers.

Over the past few years, consumer researchers have adopted part of this theory to hypothesize consumer preferences. Thaler (1985) first used

pieces of prospect theory to predict that consumers would prefer segregated gains to reduced losses in their buying decisions. Thaler argued that rebates were valued because the rebate check, separated physically and temporally from the purchase process, was perceived to be a gain rather than a reduction in cost. Thaler also argued that the car purchaser had hedonic motives for thinking of the rebate check as a separate gain. (Consumers may have now learned to integrate rebates with the original price of the item, especially since many retailers emphasize the cost of the item after rebate.)

If we adopt Thaler's perspective, it is straightforward that if two sales promotions have the same monetary value, the promotion which is framed by the consumer as a gain will "feel" more valuable than a promotion framed as a reduced loss. There are no published tests of this hypothesis. The purpose of this paper is to present evidence, from a study of consumers in a shopping situation, that sales promotions framed as gains are chosen more often than promotions framed as reduced losses.

It is not obvious what makes consumers frame a particular promotion as a gain or as a reduced loss. For instance, in early 1989 Payday candy bars were promoted by a message on the wrapper stating "free 5 cents inside". (We can verify that a nickel was included with the candy bar inside the wrapper.) It is our intuition that consumers are more likely to perceive the nickel as a gain than they would be to perceive a promotion offering 5 cents off the regular purchase price. Sweepstakes may also be perceived as (potential) gains rather than mere reductions of the the purchase price of the product.

One factor which has been robust in affecting the framing of sales promotions is whether the promotion is monetary or nonmonetary (Diamond and Campbell, 1988; Campbell and Diamond, 1989). Diamond and Campbell found that subjects in a laboratory simulation integrated monetary promotions (such as discounts) with the reference price to modify the reference price. Nonmonetary promotions (such as free goods or extra amounts of the product) were segregated from the reference price of the product and did not affect it. Campbell and Diamond's subjects rated nonmonetary promotions as making them feel that they are "gaining something extra". In contrast, subjects rated monetary promotions as making them feel that they were "losing less than usual". In short, nonmonetary promotions are framed as gains and monetary promotions are framed as reduced losses. Several other researchers (Klein and Oglethorpe 1987; Monroe and Chapman 1987; Puto 1987; Rowe and Puto 1987) have studied the effects of framing on different aspects of consumer information processing. These researchers do not consider the

implications of differences in the framing of sales promotions.

To determine whether framing affects the choice of sales promotions, it would be useful to test two versions of the same promotion. In one version, the promotion would be described as a monetary promotion (framed as a reduced loss); in the other version the promotion would be described as nonmonetary (framed as a gain). Our hypothesis is stated as follows:

If consumers are given the choice between a test promotion and some other promotion, the test promotion is more likely to be chosen when it is framed as a gain than when it is presented as a reduced loss.

EXPERIMENTAL STUDIES

Experimental Setting and Subjects

To maximize external validity, we conducted the study in a field setting with nonstudent subjects. Subjects were shoppers in an independent supermarket in a college town in the northeast. Subjects in different experimental conditions were asked to choose between different pairs of store coupons and allowed to keep and redeem the coupons they chose.

Stimuli

To understand the stimuli, it is important to consider several variables which could confound the effects of framing. If the nonmonetary promotions chosen utilized extra amounts of product, the offer might be disliked because subjects might not wish to inventory a larger amount of the product; because of concerns for product freshness; or because of boredom with consuming added quantities of the same brand or product. These problems have nothing to do with framing. Similarly, if a nonmonetary promotion utilized a premium, the value of the offer could be diminished if subjects did not value the particular premium. It is not plausible that all subjects would like *all* premiums of a given magnitude more than an equivalent discount (who wants free cat food if they don't own a cat?). Finally, a subject with a tight budget might use the heuristic "maximize cash flow" to evaluate promotions. This would lead subjects to prefer monetary promotions regardless of how promotions are framed.

To remove these potential confounds, we used two versions of a single promotion (see Figure 1). Throughout this paper, this promotion will be referred to as the *test* promotion. In the nonmonetary (framed as gain) version of the test promotion (Figure 1A), the subject obtains a free can of Campbell's soup with the purchase of Prego spaghetti sauce. In the monetary (framed as reduced loss) version of the test promotion (Figure 1B), the subject receives a discount at the cash register with the purchase of *both* the spaghetti sauce and the soup. Shoppers redeeming the two versions of the test promotion spent identical amounts of money, obtained identical amounts of the same products, and

were given identical pricing information. The retail prices of the items, marked on the coupons, were the actual store prices of the items.

The Comparison Offers

Many informally run pilot subjects comparing the two versions of the test offer in Figure 1 rapidly realized that they were equivalent offers. People aware of this were usually indifferent between the two (although they did express how they "might feel" if they had to choose an offer). Therefore, to see if the forms of the offer affected preference, we asked subjects to choose between *one* version of the test offer, and a different offer consisting of a cash discount on Prego spaghetti sauce. These offers will be referred to as *comparison* offers. One comparison offer is presented in Figure 1c.

Preliminary work.

This study was conducted in the lobby of a local independent supermarket. 33 shoppers, who had been paid \$1 for answering a short questionnaire (a different study), chose between two coupons. They were told that they could keep and redeem the coupon they chose.

The study was a two group experimental design. Subjects were randomly assigned to see one of the two versions of the test offer. This was the only experimental manipulation. Subjects were asked to choose between this version of the test offer and a comparison offer consisting of a 35 cent discount on Prego spaghetti sauce. The experimental conditions are diagrammed in Figure 2.

Results and Discussion of the Preliminary Work

Despite the fact that the percentage saving was slightly greater for the test offer (20.6%) than for the 35 cent discount presented in the comparison offer (18.5%), an overwhelming majority (28 of 33 subjects) chose the discount offered in the comparison offer. Not enough subjects chose the test offer to analyze the importance of framing in affecting choice. While the experimenters did not solicit reasons for the choice, the usual reasons spontaneously given were a preference for cash over Campbell's Tomato and Rice Soup, and a dislike of the soup.

According to the theory presented above, the 35 cent discount would be framed as a reduced loss. However, it was chosen far more than the test offer regardless of how the test offer was framed. These preliminary results were consistent with the ideas discussed above, that monetary offers are valued and that the specific premium may affect desirability as much or more than the framing of an offer.

The Main Study

To be able to detect differences in preferences resulting from the framing of the test offer, we "tuned" the stimuli in the preliminary study by reducing the value of the comparison offer from 35 cents to 25 cents. Again, subjects were randomly

assigned to choose between one version of the test offer and the 25 cent discount in the comparison offer. The procedures of the study were otherwise unchanged.

Results of the Main Study

Seventy three shoppers made a choice between a version of the test offer and the comparison offer. Table 1 presents the choices of the subjects in the different experimental conditions.

Different proportions of subjects chose the test offer and the comparison offer in the different experimental conditions, $\chi^2(1) = 6.13$, $p < .05$. More than half of the subjects seeing the test offer framed as a gain chose the test offer rather than the comparison offer. Almost three quarters chose the comparison offer when the test offer was framed as a reduced loss.

DISCUSSION

The framing interpretation of the results.

Kahneman and Tversky presented framing as a factor affecting choice. Here, choices of sales promotions were determined by how they were framed. The results presented here are consistent with the theory that framing affects the desirability of sales promotions. Formally, the two versions of the test offer were equivalent, both in terms of the utility of the coupon and in terms of the information presented to the consumer. Yet the offer apparently felt more desirable and was chosen more often when it was presented as a potential gain in the form of a free good.

Other interpretations of the results. There are other possible reasons why the nonmonetary version of the test promotion was chosen more than the monetary version. One reason invokes an information processing perspective. A second alternative cause of the results is reactance theory.

Both versions of the test promotion contained identical information. To use an information processing perspective to explain why one version was preferred more than the other, one would have to posit reasons why the information had different salience in the two experimental conditions. For instance, one might reason that consumers are most likely to use simple heuristics for evaluating sales promotions in some situations.

One analogy which may help to explain this is Kahneman and Tversky's (1979) description of the "certainty effect". This may be seen as a heuristic leading to the increased preference for risky alternatives with probability 1. Of course, certainty is as good a probability as you can have--it is at the top of the bounded interval from zero to one. Similarly, free goods are at the upper boundary of possible discounts. Therefore, consumers may invoke the simple heuristic that "if something free is offered, the promotion must be good." The explicitly free can of soup offered in the nonmonetary version of the test promotion might trigger this heuristic; the monetary version would not.

This explanation is only subtly different than the hypothesized effects of framing described in this paper. The heuristic might be described as a evaluating the free good positively because it is a clear gain. Johnson, Payne and Bettman (1988) argue that when choice alternatives are complex looking or difficult to process, people are more likely to employ simple decision heuristics for evaluation or choice. Because it may be more difficult to integrate a premium with the reference price than it is to integrate a discount with a reference price, consumers offered a premium may be more likely to employ simple heuristics which positively evaluate the promotion.

TABLE 1
Subject Choices in the Experiment

	Test Offer	Comparison Offer
Test Offer Framed As Gain (Free Soup)	20	16
Test Offer Framed As Reduced Loss (Buy Both)	10	27

Reactance theory (Lessne and Notarantonio, 1988) posits that people become very stubborn and rebellious if they believe that they are being coerced or that their freedoms are threatened. If consumers felt that the nonmonetary version of the test promotion was forcing them to purchase two products in order to get a discount, they might feel reactance and reject the promotion without thoroughly evaluating it. This would not occur as readily when the free can of soup was given with the purchase of a single item. Verbal protocol data might provide a good test of the degree to which reactance causes the results seen in this study. In general, protocol data could be used in future studies to clarify the heuristics which consumers use to evaluate sales promotions.

CONCLUSION

Two conclusions may be drawn from the research reported here. First, sales promotions which are framed as gains do appear more desirable than those framed as (merely) reduced losses. Secondly, the desirability of a sales promotion is determined by factors other than how it is framed. After all, the coupon offering a 25 cent discount on Prego spaghetti sauce offered a substantially smaller percent off than either version of the test offer; and was a "reduced loss" according to the criteria described in this paper. Yet it was chosen more than 50% of the time by the subjects in the main study. It will be of interest and value to determine the strategies and heuristics which consumers use to evaluate sales promotions, and whether different groups of consumers use different heuristics.

There would be value in extending this research by determining other factors which lead consumers to frame promotions as gains or losses. Some determinants of framing, like the nickel packaged with the Payday bar or the sweepstakes discussed earlier, might be the attributes of the promotion itself. Other factors might be motivational or situational. We suspect that when the consumer frames the promotion as a gain, he or she will perceive real value in the offer, and be most satisfied with the purchase.

The Framing of Sales Promotions: An Approach to Classification

William D. Diamond, University of Massachusetts

Robert R. Johnson, College of William and Mary

ABSTRACT

Research on sales promotions has been hindered by the absence of a theoretical approach to categorizing promotions. In this paper, the case is made for categorizing promotions by whether they are framed as gains or as reduced losses. A "cost/benefit" approach suggests that non-monetary promotions are most likely to be framed as gains whereas discounts and rebates will be framed as reduced losses. A perceptual map of promotions, derived from the similarity judgments of two groups of consumers, is consistent with this categorization. Attribute judgments show some heuristics subjects use to evaluate promotions.

INTRODUCTION

Promotions take many forms including coupons, rebates, reduced shelf price, and premiums. Behavioral theories tend to differentiate promotions on the basis of their magnitudes alone. A few of these theories have implications which could distinguish forms of promotion, but these implications have not been explored.

One reason for this is the absence of constructs providing rationales for differentiating promotions. As a result, behavioral researchers have tended to either confine empirical work in this area to one type of promotion at a time or select promotions atheoretically. The tendency toward very narrow categorization of promotions has been reflected in recent articles which deal with only a single type of promotion, such as couponing (e.g. Henderson 1985; Irons, Little, and Klein 1983; Narasimhan 1984; Neslin and Shoemaker 1983; Schindler and Rothaus 1985).

We argue here that a taxonomy based upon theory and consumer perceptual data will be useful in the application and extension of the behavioral theories of sales promotions. There is a close link between theory and practicality in this area.

The first section of this paper outlines a theoretical approach to the categorization of sales promotions. This approach is derived from prospect theory (Kahneman and Tversky 1979, 1984). Specifically, sales promotions can be categorized by whether they will be framed as gains or as reduced losses. This section concludes by discussing how behavioral theories apply differently to promotions framed in different ways.

The second part of the paper sets forth a perceptual map of promotions based upon the judgments of two consumer groups. This provides a taxonomy which is very similar to the theoretical categorization. By labelling the stimulus space with attribute judgments, we explore the heuristics that people use in evaluating types of promotions.

A THEORETICAL CATEGORIZATION OF SALES PROMOTIONS

Prospect Theory and Framing

Recent research (Kahneman and Tversky 1984; Puto 1987; Thaler 1985) shows that when alternatives are presented as gains, subjects choose and judge them differently than when equivalent alternatives are presented as reduced losses. Thaler (1985) argued powerfully that promotions may be framed as gains or losses. The promotion framed as a gain will have benefits which are segregated from the original purchase price, whereas the promotion framed as a loss will be seen as merely reducing the initial purchase price. Thaler presented automobile rebates as a case where a promotion could be perceived as a separate gain rather than a mere reduction of the purchase price. In Thaler's language, a separate "mental account" may be established for the rebate. According to Thaler, an equivalent saving resulting from a sale offer should be seen as a reduced loss rather than a gain. Thaler used the shape of the prospect theory value function to deduce that a promotion framed as a segregated gain should be perceived as more valuable than one framed as a reduced loss. Although several other researchers (Klein and Oglethorpe 1987; Monroe and Chapman 1987; Puto 1987) have studied the effects of framing on consumer information processing, these researchers have not considered the implications of differences in the framing of sales promotions.

Predicting the Framing of Sales Promotions

There are several ways of hypothesizing whether a particular promotion will be framed as a segregated gain or as a reduced loss. One of Thaler's assumptions was that the physical or temporal separation of a rebate check from the price quotation leads to the framing of the rebate as a gain. He did not test this hypothesis.

Thaler and Johnson (1986) hypothesized that situations would be framed in accordance with a hedonic mechanism. Gains would be either segregated from or integrated with losses depending on which form would produce the most happiness for the subject. The general principle of hedonic framing led Thaler and Johnson to postulate several rules of framing. Because sales promotions are small gains presented in the context of a larger loss (the purchase price), the same rule should apply to all of them. This rule, known as the "silver lining effect" is to segregate small gains from larger losses. Accordingly, most promotions should be seen as gains rather than as reduced losses. This principle does not distinguish among types of sales promotions.

A third approach to predicting framing utilizes a "cost/benefit principle" (Beach and Mitchell 1978; Payne 1982). Beach and Mitchell posit that decision makers are motivated to choose the strategy which requires the least investment to achieve a satisfactory solution. From this perspective, the relatively unimportant problem of whether to take advantage of a sales promotion may not be allocated very much attention. The "cost/benefit" approach to predicting framing stems from the amount of effort necessary to integrate gains with losses in different situations.

Tasks are more complex when different pieces of information about an alternative are in different units which may not be commensurable (Abelson and Levi 1985). Klein and Oglethorpe (1987) suggest that it should be more difficult to integrate multiple attributes of purchases if these attributes are in different metrics.

Adapting this to the domain of sales promotions, one might hypothesize that when promotions are in the same units as pricing information, they will be more easily integrated with the price. The promotion will then be framed as a reduced loss. Conversely, when promotions are in units other than money, they will be more difficult to integrate with the price. The consumer may not expend the effort required to integrate these noncommensurable promotions into the price paid, and such promotions should be more often considered as separate gains.

This reasoning presents theoretical grounds for the dichotomy between reduced-cost and value-added promotions recently discussed by Sawyer and Dickson (1984). Price-off promotions, including rebates, are expressed in the same units as price and are most likely to be framed as reduced losses. Value-added promotions, including either bonus amounts of the same product or other products as premiums, are in units other than price. These promotions are most likely to be framed as gains. Thus, the two classes of promotions should have fundamentally different properties if the consumer does not have the time, inclination, or ability to "recode" the nonmonetary benefits of a premium or purchase as a saving on the original product.

It is likely that other factors will influence the framing of sales promotions. For instance, continuity programs like frequent flier programs may be framed as gains because the promotion sets up very obviously separate "mental accounts" for the purchase price and for the promotional benefits. Similarly, promotions where money is contributed to a charity or worthy organization may be seen as gains because of the large segregation of the promotional benefit from the purchaser and the purchase price. The context of the promotion--whether other brands are being promoted--may well affect whether a particular offer is seen as a gain or a reduced loss. Finally, the various aspects of the presentation of a promotion may affect whether it is perceived as a gain or a reduced loss.

Implications of Framing for Behavioral Theories of Promotion

Once sales promotions are categorized in terms of how they are framed, it is possible to extend previous theories of sales promotions. We will examine the implications of this classification for two behavioral approaches to promotion: price perception theories and noncognitive theories of induced behavior.

Price perception theories include theories of reference price and theories of the acceptability of promotions of different sizes. Reference prices, generally, are the amounts consumers expect to pay or will pay for a product or brand. The foundation for most theories of reference price is adaptation-level theory (Helson 1964; Klein and Oglethorpe 1987). The theory posits that consumers integrate all the pricing information they have seen to form adaptation-levels or reference prices. Consumers evaluate a specific price by comparing it with a reference price.

Monetary promotions, which are in the same units as price, are most likely to be framed as reduced losses. These promotions are likely to be integrated with reference price, leading to a downward modification of reference price. Inferences of reduced quality, which may result from a lower reference price (Monroe and Chapman 1987), should more likely result from promotions in monetary units than from promotions in nonmonetary units.

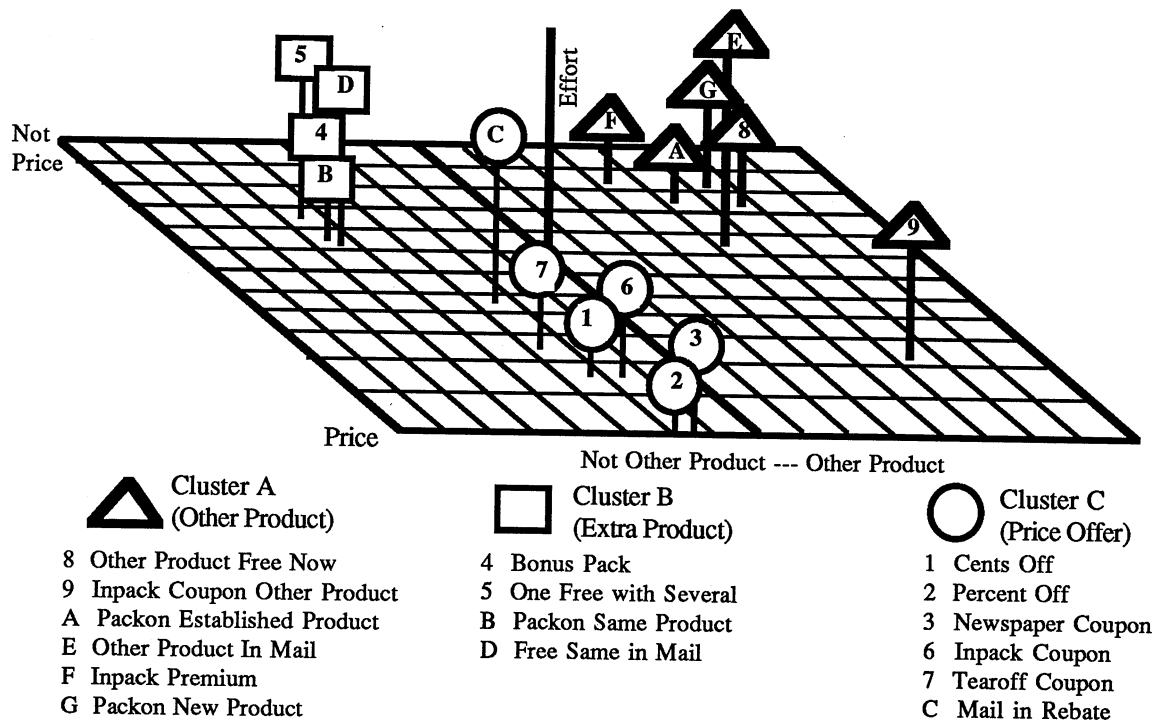

Diamond and Campbell (1988) tested the effect of different promotional forms on reference price in a laboratory simulation. Subjects were exposed to 20 weeks of the pricing and promotional information on a fictitious brand. Discounts, but not nonmonetary promotions, lowered the reference price of the product.

Campbell and Diamond (1989) hypothesized that because nonmonetary promotions are less likely to be compared with the original price of the product, large nonmonetary promotions should be more likely to be within the consumer's "latitude of acceptance" than large monetary promotions. Data from two experiments confirmed this hypothesis.

Sawyer and Dickson (1984) call a second set of behavioral theories of promotion "noncognitive theories of induced behavior." The best known of these is behavioral shaping or operant conditioning. Rothschild and Gaidis (1981) and Peter and Nord (1982) conceived of promotions as rewards or reinforcements, but did not differentiate among promotions. Promotions perceived as separate gains (rather than reduced losses) may be most readily perceived as rewards for a purchase. If this is so, nonmonetary promotions would be the most effective reinforcement, and would be the most effective at increasing purchase rates through operant conditioning.

As the preceding discussion shows, a classification of sales promotions based on framing can have significant implications for hypotheses regarding the effects of promotions on consumers. We now consider whether such a classification is

FIGURE 1
Perceptual Map of Sales Promotions

consistent with the manner in which consumers actually differentiate promotions.

METHOD

The plan of the study was to develop stimulus and subject weight spaces using a weighted multidimensional scaling of similarity judgments of sales promotions. The universe of sales promotions was developed by adding categories found in area supermarkets to those found in previous taxonomies. No references to specific products or prices were made in the sentence-long descriptions of the promotions. This approach has advantages and disadvantages. Specifics are very important determinants of whether a particular promotion is an effective incentive. However, our purpose was to explore the heuristics which people use to classify and evaluate general types of promotions. If the perceptual map were developed from a set of specific promotions, the dimensions of the promotions might be heavily dependent on the specifics of the stimulus set. The effects of specific promotional and contextual attributes on the evaluation of promotions must be examined in subsequent research.

To reduce the number of judgments subjects had to make, and to keep the stimulus space simple, we eliminated sweepstakes and contests from the preliminary list of stimuli. Sweepstakes and contests are complex phenomena which can not be

be described with a simple stimulus. The final list consisted of 16 "generic" sales promotions. Abbreviated descriptions of these promotions (which were not presented to subjects) are listed at the bottom of Figure 1.

Twenty students and twenty non-student women judged the similarities of all pairs of the promotions. Such a small sample size has precedents in the literature. Green and Rao (1971) used 30 matrices to evaluate scaling programs. Jones and Young (1972) used the similarity judgments of 31 subjects to describe the longitudinal development of a social environment. Green and Carmone (1969) used the similarity and preference judgments of four different groups, each ranging from 15 to 20 in size, to scale business school images. These methodological studies generated interesting stimulus configurations with small sample sizes.

The students were juniors and seniors at a northeastern state university. The sample of non-student women was a diverse convenience sample. They ranged in age from 21 to 65 with a median age group of 35-39 years. The subjects were paid \$8.

A personal computer presented all pairs of stimuli in random order to each subject and recorded similarity judgments. Subjects rated the paired promotions from 1 (very similar) to 7 (very different). The similarities data were analyzed using the ALSCAL procedure in SPSS^X. A weighted

^AStimuli classified by experimenters

^BStimuli rated by Subjects

multidimensional scaling (INDSCAL) model provided stimulus and subject weight spaces.

A second group of twenty undergraduates rated the promotions on 12 attributes. The 16 promotions were presented in random order on a personal computer. The experimenters also classified the promotions according to two criteria suggested by the theory developed earlier in this paper. Promotions were distinguished by whether

the benefits were monetary or nonmonetary and by whether they used another product as a premium. The criteria for classification are presented in Table 1.

RESULTS

At 2, 3, and 4 dimensions, the S-Stress describing the fit of the solution was .351, .282, and .244, respectively. The fit improved far more

from 2 to 3 dimensions than from 3 to 4 dimensions. The three dimensional solution is the most interpretable of these solutions, and is very consistent with the classification based on framing. Therefore, the three dimensional solution is presented in Figure 1.

Attribute Ratings

To label the stimulus configuration, we regressed the mean attribute ratings upon the dimensions of the stimulus space (Kruskal and Wish 1978). These regression results are presented in Table 1. Two types of information must be used to interpret this table. First, the multiple correlation between an attribute ratings of the various promotions and the coordinates of the stimulus space (perceptual map) must be high. For instance, the multiple correlation between the attribute "other product as premium" and the coordinates of the stimulus space is .99. This means that the position on the perceptual map virtually perfectly reflects whether a promotion does or does not use another product as a premium. The second important piece of information is the regression weight of an attribute expressed as a direction cosine. The closer this number is to 1.0 or -1.0, the closer one of the three dimensions of the stimulus space reflects the ratings of the promotions on a particular attribute. The direction cosine of "Other Product as Premium" is nearly 1.0 for the first dimension. Therefore the first dimension almost perfectly reflects whether the promotion uses another product as a premium or not.

The first dimension of the stimulus space correlates most highly with the objective rating of whether or not the promotion utilizes another product (a premium) as an incentive. The second dimension is most correlated with the attribute distinguishing monetary promotions (including discounts and rebates) from all other offers (including extra amounts of product and other product as premiums). The multiple correlations between each of the objective attribute ratings and the positions of the promotions in the stimulus space were greater than .95.

The attributes leading to the easiest interpretation of the third dimension were the ratings of the time and effort required to utilize the promotional offer. This dimension distinguishes promotional incentives which are immediate and low-effort from delayed and high-effort incentives such as rebates and mail-in offers.

The attribute ratings cast light on the subjects' stereotypes toward promotions. Most prominently, the subjects were not fond of rebates or other mail-in offers. Dimension 3 was negatively correlated with liking of promotion, feelings of savings and value, feeling that the promotion is a reward, and ratings that the promotion is for young people.

The attribute ratings also provide evidence about how promotions are framed. Subjects rated promotions on a 7-point scale from "makes me feel that I am losing less than usual" to "makes me feel that I am gaining something extra." Promotions

framed as gains should be rated on the high end of the scale. The regression coefficient relating dimension 3 (high time and effort) and framing showed indicated that promotions perceived as requiring much time and effort were rated as reduced losses ($t(12)=3.6$, $p<.01$). The regression coefficient relating dimension 2 (monetary/nonmonetary) and the perception as a gain was also significant ($t(12)=2.7$, $p<.05$). Nonmonetary promotions (including extra amounts of products and premiums) tended to be perceived more as gains than monetary promotions.

Cluster Solution

To aid in interpretation, the points in the stimulus space were clustered using the centroid method. The dimensions were weighted by the average squared subject weights. The coefficient representing the distance within clusters has the values .52, .23, .16 and .13 for one, two, three and four clusters. The three-cluster solution appears to be helpful in interpreting the stimulus space.

Cluster A (triangles in Figure 1) comprises the promotions which use another product as a premium. Cluster B (squares in Figure 1) contains promotions which provide an extra quantity of the promoted product. Cluster C (circles in Figure 1) includes the price-off or cash rebate offers. Thus, the three-cluster solution distinguishes promotions on the basis of the units of benefit: whether these units are monetary, extra amounts of the promoted product, or units of another product as a premium. (If the two-cluster solution is adopted, the two non-monetary clusters collapse into one cluster. The two remaining clusters, monetary units vs. nonmonetary promotions, is equivalent to the framing distinction presented earlier.)

DISCUSSION

In this paper, we have developed a theoretical classification of sales promotions. This classification is not fundamentally different than some classifications which have been used by managers. However, the theoretical foundation of the present distinction may lead to elaboration and extension of behavioral theories of sales promotions.

The classification is based on the hypothesis that since nonmonetary promotions are more difficult to integrate with the cost of the product, they are more likely to be framed as separate gains. Nonmonetary promotions include extra amounts of the promoted product and premiums using another product. The logic of this hypothesis derives from Thaler's (1985) work on mental accounting.

Consumer similarity judgments produced a perceptual map which strongly resembles the theoretical classification. Subjects did discriminate between monetary and nonmonetary promotions. Unexpectedly, promotions which offered extra amounts of the promoted product were seen as different than promotions offering premiums. Moreover, subjects discriminated and evaluated

promotions on the basis of whether they required much effort and time.

Ratings of the promotions support the basis for the classification based on framing. Subjects tended to rate nonmonetary promotions as gains and monetary promotions as reduced losses. Our research thus supports Thaler's approach. However, it differs in the classification of rebates. Thaler hypothesized that rebates would be framed as segregated gains if they were physically or temporally segregated from the purchase price quotation. Our research found that subjects considered monetary rebates to be reduced losses. This may be due to consumers' increasing familiarity with such offers or the increasing practice of expressing prices as "after rebate." The framing of rebates as gains might re-emerge in future research, when the specifics and context of the promotions are described in more detail.

Other attribute ratings suggest some of the subjects' stereotypes toward promotions. For instance, nonmonetary promotions and immediate incentives were rated as more appropriate for young people. These were also rated as feeling the most like a reward, and may be the most appropriate for behavioral shaping (Rothschild and Gaidis 1981). It may be rewarding to investigate these and other connotations of sales promotions.

Future research in this area should address two limitations of the present work. First, these promotions were "generic." Consumer reactions to promotions may depend on the specifics of the products being promoted, and the magnitude and type of the incentives. Secondly, the samples used here were not large, nor were they necessarily representative of specific populations. The generalizations from these groups must be considered exploratory.

Despite these limitations, we believe that the correspondence between a classification of promotions based on framing and the empirical results reported here is sufficient to encourage the study of the different behavioral properties of promotions the consumer frames as gains and those the consumer frames as decreased costs.

Overestimating Salesperson Truthfulness: The Fundamental Attribution Error

Robert Baer, Bradley University¹

ABSTRACT

This study examined consumers' susceptibility to the fundamental attribution error--the tendency to overestimate the importance of internal causes while underestimating the significance of external causes. The results showed that a short product line caused subjects to overestimate the extent to which the salesperson's product claims reflected their true beliefs about the product. Yet, a sales commission prompted subjects to underestimate the extent to which the sales message reflected the salesperson's genuine beliefs.

One of the more pervasive problems encountered in marketing is to establish the perceived trustworthiness of marketing messages. Trustworthiness refers to the extent to which the source is perceived as intending to communicate valid statements about the product. Trustworthy statements are perceived to be objective and furthering no vested interest of the source. The more trustworthy a source, the more believable and effective are his or her persuasive communications. In conjunction with expertise (perceived knowledge regarding the product category), trustworthiness creates the perception of credibility. An untrustworthy source, on the other hand, is one who is insincere, dishonest and is perceived as having a vested interest in the claim. When a source's self-interest can be obviously furthered by acquiescence to his or her's persuasive communication, a target should discount what is said.

Marketing trustworthiness and credibility can be considered from an attributional perspective (Settle and Golden, 1974; Hansen and Scott, 1976; Calder and Burnkrant, 1977). Attribution theory is a collection of theories (Bem 1965; Kelley 1967; Jones and Davis 1965) that seek to explain the cognitive processes involved when an individual infers the causes of another person's behavior. Within the past ten years there have been two major reviews of attribution theory and consumer research. Mizerski, Golden and Keenan (1979) provided an overview of four major attributional theories and reviewed the relevant consumer behavior research from 1971 to 1978. Folkes (1988) has summarized the relevant consumer behavior research since then and has concluded that "attribution theory is a rich and well-developed approach that has a great deal to say about a wide range of consumer behavior issues" (p. 548).

Studies of attribution have dwelt on the conditions which determine whether a behavior is

attributed to inner traits, beliefs or dispositions (internal attribution) or to prevailing social and environmental pressures (external attribution). Consumers are typically confronted with just such an attributional problem. For example, given an opinion expressed by a salesperson, the customer must decide whether the act (stated opinion) was caused by (1) the salesperson's true beliefs about the product (internal attribution) or (2) variable situational contingencies such as the desire to make the sale, the reward for making the sale or the role requirements of the job (external attribution). An attribution to the external situation means that the customer believes that most salespeople would behave in the same way. By contrast, an internal attribution indicates that the customer is assigning traits and opinions to the salesperson that are more important than the situational pressure surrounding the salesperson's behavior.

However, it is not always easy to discern whether a salesperson's verbal statements were caused by internal or external reasons. The cause will be more ambiguous and therefore less revealing about his or her true beliefs to the extent that external pressure exists. For example, customers who encounter a friendly salesperson should not make an internal attribution (i.e., this is a friendly person) because friendliness is perceived to be an important part of an individual's role as a salesperson. In this case, the external constraint (job requirements) can quite easily account for the observed behavior (friendliness). Thus, under these circumstances, it is logical for consumers to regard the sales message with caution (Sparkman, 1982).

However, one of the more significant consequences that has emerged in the investigation of attributional processes is the discovery that people do not always make attributions in this logical fashion. Rather, the attributional process is plagued by a number of systematic errors and biases that distort the judgmental process (Nisbett and Ross, 1980). One of the more common errors is that people are generally biased toward making internal attributions. That is, they tend to see the dispositions of a person as causing that person's behavior. Several investigators (Jones, 1979; Miller, 1976; Ross, 1977) report that people tend to infer that an individual's actions are congruent with their beliefs even when the individual *clearly* had no choice in his or her actions. Logically, observers should discount the diagnosticity of behavior when the person has little or no control over their behavior. Their failure to do so is widely regarded as attributional error in the direction of personal causation.

Although it has been the exploration of attribution error which has shaped much of the attribution research in other disciplines, attributional error has had little impact on the field

¹The author thanks Rustan Kosenko and four anonymous reviewers for their helpful comments. This research was partially funded by The Caterpillar Fellows Program.

of consumer behavior. The present study examined the extent to which consumers were prone to make internal attributions. A bias toward internal attributions would cause consumers to overestimate the extent to which salespeople believe their own product claims. Since consumers are cognizant of the fact that salespeople operate in a highly constrained environment and that they are not often free to express their true beliefs about the product, one might expect that consumers would be exempt from this error. However, attributional research has shown that the error is a pervasive tendency in the perception of other people. In fact, the error is so impermeable to change that it is often referred to as the "fundamental attribution error" (Ross, 1977).

The purpose of the present study was to determine whether consumers in a sales situation were vulnerable to the fundamental attribution error. Attribution research leads one to speculate that since the error is so robust, consumers too should commit the error, i.e., they should underestimate the extent to which the salesperson's word is a reflection of their job requirements and should be somewhat inclined to take the salesperson's word at face value. This is a rather startling prediction that runs counter to prevailing thought which depicts consumers as highly sensitive to the salesperson's vested interest in the sale and cautious about his or her motives. In this study, a sales situation was chosen to examine the fundamental attribution error because it is *not* a neutral environment. Rather, consumers are likely to question the salesperson's motives and are not likely to automatically assume that the salesperson is trustworthy. Thus, the present study created a stringent test of the fundamental attribution error.

The present study investigated two different variables (length of product line and sales incentive) that could mediate the perception of salesperson trustworthiness. Salespersons who have the luxury of a long product line or who are known to not make a commission from the sale, may be perceived as having more freedom to convey their genuine beliefs about the product than salespersons with a short product line or who make a sales commission. Those with the long product line or no commission may be perceived as having less stake in any single product item, and, as a result, their word may be considered more trustworthy. In the case of a short product line or a sales incentive, the external constraint can quite easily account for the salesperson's behavior. Under these circumstances, it would be logical for the customer to be cautious about trusting the salesperson's expressed opinion.

In this study, it was hypothesized that: (1) When the message was not constrained by external factors (no sales commission or a long product line), consumers would assume that the salesperson's true beliefs about the product were congruent with their verbally expressed beliefs. Thus, a salesperson who speaks highly about the product should be perceived as genuinely believing in that product more than one who speaks unfavorably about the product. (2) Subjects would commit the fundamental attribution error in the no choice conditions (short

product line or sales incentive) by attributing an attitude toward the salesperson that was consistent with their publicly expressed beliefs. A significant difference between the beliefs attributed to a salesperson who speaks favorably versus unfavorably about the product in the no choice conditions would be indicative of attributional error. (3) The same pattern of results was expected when the salesperson's constraint was manipulated by either the length of the product line or by the sales incentive. However, it was predicted that attributional error would be diminished in the sales incentive compared to the product line condition. Knowledge about a sales incentive for sales personnel heightens consumer sensitivity about the salesperson's vested interest which, in turn, diminishes perceptions of salesperson trustworthiness.

METHOD

Overview

The experimental conditions provided for two levels of the salesperson's expressed beliefs toward the product (favorable versus unfavorable), two levels of product line length (long-choice versus short-no choice) and two levels of sales incentive (no incentive-choice versus incentive-no choice). The design was not fully crossed. Subjects were assigned to only one of the levels of either the product line or sales incentive conditions.

Participants

The participants were 49 male and 61 female undergraduate business students who volunteered to participate in the study. Participants were run in small groups ranging in size from eight to fourteen. Participants were randomly assigned to one of the eight cells in the experimental design as they appeared for their experimental session. Sixty-two subjects were assigned to one of the four cells in the product line length condition while 48 subjects were assigned to one in four cells of the sales incentive condition.

Procedure

Stimulus materials were presented in booklet form. Independent variables were manipulated by asking subjects to take the role of observers while reading written scenarios portraying an automobile salesperson's behavior. The cover page of the booklet described the experiment as an investigation of the way in which people make judgments about products and salespeople with limited information. Subjects were asked to imagine a potential customer who had come to an automobile dealership inquiring about the "Austin automobile or, perhaps, some other car of medium price."

Sales Message

Persuasive messages pertaining to the sale of an automobile were composed. The messages were adopted from sets of persuasive messages reported by Pratkanis, Greenwald, Ronis, Leippe and

Baumgardner (1983). The messages were used in 11 previous studies published by those authors and have been found to produce strong, immediate persuasion effects that tend to dissipate quickly.

The sales messages consisted of a brand name and a description of the product attributes. For the brand name, a fictitious name (Austin) was randomly selected from a list of the 72 most common six-letter names in the United States (U.S. Social Security, 1964). The same brand name was used in all experimental conditions. To create a description of the product attributes, paragraphs based on articles appearing in *Consumer Reports* were composed. Three attributes (durability, safety and handling) were chosen because different automobiles should vary among these characteristics. Each sales message contained a separate statement about durability, safety and handling. These product attribute statements provided general information about the meaning and importance of the attribute. The product attribute statements were identical for all experimental conditions.

Independent Variables

Salesperson's Expressed Beliefs.

Salespersons expressed a belief about the Austin that was either favorable or unfavorable. The belief consisted of one sentence for each of the three product attributes that assigned a value of either "poor" (unfavorable) or "excellent" (favorable) to each of the three attributes. In addition, salespersons in the favorable condition began their sales message with an overall excellent assessment of the Austin and concluded by recommending its sale. Salespersons in the unfavorable condition began with a poor evaluation and concluded by not recommending its sale.

Length of Product Line. Subjects in the short product line (no choice) condition were told that there was a short product line of medium-priced cars. In fact, these subjects were told that the Austin was the only medium-priced car on the lot. Because of the short product line, it was emphasized that salespersons were not free to sell the models in which they most believed. If these salespersons thought that the Austin was not a good car, they were not free to express their opinion to the customer.

Subjects in the long product line (choice) condition were told that there was a long product line, i.e., that there were 11 medium-priced cars in addition to the Austin. Subjects in this condition were told that salespersons were permitted by their supervisor to sell any medium-priced car that they wished to sell. These sales persons were described as free to choose models to sell that they saw fit. If the salespersons thought that some models were better than others, they were free to say so to the customer.

Sales Incentive. Subjects in the sales incentive condition (no choice) were told that salespersons received special incentives to sell the Austin. That is, these subjects were told that salespersons would receive a much larger

commission for selling the Austin than would result from selling other cars in its price range. These subjects were told that salespersons were pushed by their supervisor and if they did not think that the Austin was a good car, they were not free to express that opinion.

Subjects in the no sales incentive condition (choice) were told that salespersons were given no special incentives to sell the Austin, i.e., that salespersons received the same commission for selling any medium-priced car. Thus, these salespersons were described as free to choose models to sell as they saw fit. If salespersons thought that some models were better than others, they were free to say so to the customer.

Manipulation Check

In order to assess the effectiveness of the constraint (choice) manipulation, subjects were asked, "How much free choice did the salesperson have to express his or her true opinions about the Austin?" Subjects responded on a 9-point rating scale, 1 = very little choice, 9 = very much choice.

Dependent Measures

As the major dependent measure, subjects attributed an attitude to the salesperson. Subjects were asked, "What do you think is the salesperson's deepest and most genuine belief about the Austin?" (1 = extremely poor car, 9 = extremely good car). The degree of confidence in their attitude attribution was also assessed. Perceptions of the salesperson were measured on 9-point bipolar scales (1 = very little, 9 = very much). Finally, subjects were asked to estimate the monetary worth of the Austin.

RESULTS

Results were analyzed by two 2x2 ANOVAs. Manipulated variables were length of the product line (short versus long), sales incentive (incentive versus no incentive) and the salesperson's expressed beliefs toward the product (favorable versus unfavorable). Since subjects were assigned to one of the levels of either the product line length or sales incentive conditions, separate 2x2 ANOVAs were performed on the product line length and sales incentive data.

Attitude Attribution

First, consider the results for the subjects in the product line length conditions. A significant main effect for expressed beliefs, $F(1,58) = 24.60$, $p < .01$ was obtained. These results indicated that salespersons who spoke favorably about the product were perceived as having more favorable attitudes ($M = 5.09$) towards the product than those who spoke unfavorably ($M = 3.83$). In terms of the central questions of this research, however, the data are best understood in terms of the product line length (constraint) x expressed beliefs interaction, $F(1,58) = 104.84$, $p < .01$. The means are shown in the left-hand panel of Table 1. These results indicated that in the choice condition (long product line), attitudes were attributed in line with the direction of

TABLE 1
Attitude Attribution Mean Scores and (Standard Deviations)^a

Salesperson's Expressed Beliefs	Product Line		Sales Incentive	
	Long (Choice)	Short (No Choice)	No Incentive (Choice)	Incentive (No Choice)
Favorable	6.06 (1.88)	5.47 (1.20)	6.58 (1.62)	4.25 (1.29)
Unfavorable	2.20 (1.42)	4.13 (1.30)	2.00 (1.13)	4.92 (1.31)

^a"What do you think is the salesperson's deepest and most genuine belief about the Austin?" (1 = extremely poor car, 9 = extremely good car).

sales message, i.e., salespersons who spoke favorably about the product were perceived as having more favorable attitudes than those who spoke unfavorably. These results support hypothesis 1. Although this difference was diminished in the no choice condition (short product line), subjects still tended to infer attitudes that were consistent with the direction of the sales message. That is, salespersons who gave favorable messages were perceived as more favorable toward the product ($M = 5.47$) than those who spoke unfavorably ($M = 4.13$), $F(1,29) = 13.94$, $p < .01$. This significant difference in attitudes attributed to targets who spoke favorably or unfavorably in the no choice condition is widely regarded as attributional error in the direction of personal causation and supports hypothesis 2.

The right-hand panel of Table 1 shows the results for the sales incentive conditions. A main effect for expressed beliefs, $F(1,44) = 46.02$, $p < .01$ was obtained. Salespersons who spoke favorably about the product were perceived as being more favorable ($M = 5.42$) about the product than those who spoke unfavorably ($M = 3.46$). However, a constraint (sales incentive) \times expressed beliefs interaction, $F(1,44) = 82.69$, $p < .01$, indicated that this was true only in the choice condition (no sales incentive) thus supporting hypothesis 1. In the no choice condition (sales incentive), a reversal occurred. Salespersons in those conditions were attributed with attitudes in the *opposite* direction for the sales message. Salespersons who spoke favorably about the product were perceived as less in favor ($M = 4.25$) than salespersons who spoke unfavorably ($M = 4.92$), $F(1,22) = 3.67$, $p < .05$. No other effects were significant.

The constraint \times expressed beliefs interaction provided only partial support for hypothesis 2 and 3. As predicted, subjects exposed to the sales incentive conditions were less likely than product line length subjects to commit the fundamental attribution error. However, unexpectedly, a different pattern of results was obtained in the sales incentive condition. Attitudes correspondent to the direction

of the sales message were not attributed to these salespersons. In fact, sales incentive subjects attributed beliefs toward the product opposed to the direction of the sales message. This effect has been observed in previous studies (e.g., Jones, Worchel, Goethals and Grumet, 1971 and Miller and Rorer, 1981) when the extremity, quality and persuasiveness of the constrained behavior has been weak. When a person acting under pressure does a poor job, observers infer that the person holds an attitude in the opposite direction. Weak or ambivalent behavior under no choice conditions is perceived as "foot-dragging" and it signifies that the person is acting under pressure. As a result, perceivers do not believe the spokesperson and they make attributions that are less consistent with the expressed beliefs.

Confidence

Subjects rated their degree of confidence in their attitude attribution (1 = very little confidence, 9 = very much confidence). There was no difference in the amount of confidence that subjects in the different product line length conditions expressed (all means ranged from 4.40 to 5.13). However, for subjects in the sales incentive conditions, a main effect for sales incentive, $F(1,44) = 32.49$, $p < .01$, indicated that subjects were more confident of their attitude attribution when no sales incentive was available to the salesperson ($M = 6.54$) than it was not available ($M = 3.46$).

Salesperson Characteristics

Subjects rated the salesperson's trustworthiness, credibility, believability, sincerity and eagerness to help on 9-point rating scales (1 = not at all, 9 = very much). Results for the product line length and sales incentive conditions were very similar. For the product line length case, subjects in the choice compared to the no choice condition rated the salesperson as more trustworthy ($M = 4.93$ vs. $M = 2.97$), $F(1,57) = 21.50$, $p < .01$, more credible ($M = 4.50$ vs. 3.29), $F(1,57) = 7.38$, $p < .01$, more believable ($M = 4.87$ vs. $M = 3.84$),

TABLE 2
Perceived Product Value Means^a

Salesperson's Expressed Beliefs	Product Line		Sales Incentive	
	Long (Choice)	Short (No Choice)	No Incentive (Choice)	Incentive (No Choice)
Favorable	\$11,094	\$10,726	\$8,950	\$7,790
Unfavorable	\$ 9,020	\$ 9,662	\$8,686	\$8,866

^a"Estimate how much you think that a new Austin automobile is worth?"

$F(1,57) = 4.35$, $p < .05$, more sincere ($M = 5.27$ vs. $M = 3.13$), $F(1,57) = 20.03$, $p < .01$ and more eager to help ($M = 4.32$ vs. $M = 2.08$), $F(1,57) = 6.53$, $p < .01$. No other effects were significant.

Similarly, for the sales incentive treatments, subjects in the choice compared to the no choice condition rated the salesperson more trustworthy ($M = 6.04$ vs. $M = 3.42$), $F(1,44) = 43.04$, $p < .01$, more credible ($M = 6.0$ vs. 3.29), $F(1,44) = 33.36$, $p < .01$, more believable ($M = 5.60$ vs. 3.05), $F(1,44) = 47.24$, $p < .01$ and more sincere ($M = 5.68$ vs. $M = 3.21$), $F(1,44) = 28.80$, $p < .01$. No other effects were significant.

Estimated Product Value

The results for estimated product value are shown in Table 2. A constraint x expressed beliefs interaction was obtained for the product line treatment, $F(1,57) = 3.96$, $p < .05$. The results indicated that in the choice conditions, the estimated value of the product was consistent with the direction of the sales message, i.e., the product was seen as more valuable when the salesperson spoke favorably ($M = \$10,175$) than unfavorably ($M = \$8,871$). Although this tendency was diminished in the no choice condition, subjects in the no choice condition still tended to infer that the product was of greater value when the salesperson spoke favorably ($M = \$10,726$) than unfavorably ($M = \$9,662$).

For subjects in the sales incentive treatment, a constraint x expressed beliefs interaction, $F(1,44) = 4.21$, $p < .05$, indicated that in the choice condition (no sales incentive), the product was perceived as more valuable when the salesperson spoke favorably ($M = \$8,950$) rather than unfavorably ($M = \$8,686$). However, a reversal effect occurred under no choice conditions (sales incentive). The product was seen as more valuable when the salesperson expressed unfavorable beliefs ($M = \$8,866$) than favorable beliefs ($M = \$7,790$).

DISCUSSION

The present study was designed to assess consumers' tendencies to commit the fundamental attribution error. The error is a well-documented

phenomenon whereby observers attribute attitudes or dispositions to another person, even when that person's behavior appears to have been facilitated by strong situational pressures. Researchers manipulating the saliency of situational constraints have had to go to extraordinary lengths to decrease this bias (Miller, 1976; Snyder and Jones, 1974). Yet, even when subjects are aware of powerful situational constraint operating, they are still prone to make internal attributions.

Prior to this study, the fundamental attribution error has never been investigated in a marketing context. A sales environment is one in which the powerful constraints on the salesperson seem quite apparent. In fact, it is reasonable to assume that customers approach this situation with a bias opposed to the fundamental attribution error. They expect to doubt the salesperson's word and expect to regard the sales message as caused by the external situation rather than by the salesperson's genuine beliefs about the product.

These considerations notwithstanding, the present study found evidence for the fundamental attribution error in the product line conditions. Although attributions were consistent with the direction of the sales message in the choice conditions, subjects tended to infer attitudes consistent with the sales message even when the salesperson's lack of choice was emphasized in the experimental instructions. This finding is even more surprising given subjects' perceptions of the salesperson. In all cases, subjects in the no choice conditions perceived the salesperson as less trustworthy, credible, believable, sincere and eager to please than subjects in the choice conditions. In the no choice conditions, subjects explicitly acknowledged that the salesperson's word should be regarded with caution. Yet, an attitude consistent with the salesperson's expressed beliefs were attributed to them by subjects.

Having committed the fundamental attribution error, subjects' perceptions of the product value were compatible with the error. Even when the salesperson clearly had no choice in the views that he or she expressed, subjects inferred that the

product was more valuable when the salesperson spoke favorably compared to unfavorably.

These results suggest that consumers are not exempt from the fundamental attribution error. Although they are more conservative in the attitudes that they attribute to salespersons under no choice conditions, there is still a tendency to think that the salesperson believes what he or she says. Marketers can capitalize on this bias with manipulations that emphasize that the salesperson's behavior is voluntary.

In the sales incentive conditions, salespersons who expressed beliefs in favor of the product were actually perceived as less in favor than those who expressed beliefs against the product. As noted above, this effect has been found in previous studies when the behavior is weak or ambivalent. In the present study, however, the sales message in all experimental conditions was identical in terms of wording, length, quality, extremity and persuasiveness. Only the brand evaluations at the end of the sales message differed. Subjects' perceptions of the message quality ($M = 3.88$), extremity ($M = 5.27$) and persuasiveness ($M = 4.94$, all on 9-point rating scales) were weak to moderate and did not differ from condition to condition. Thus, the reversal effect can not be explained by assuming that the sales message in the sales incentive condition was weaker than the message in the product line condition.

Furthermore, a manipulation check that asked subjects "How much free choice did the salesperson have to express his or her true opinions about the product?" yielded similar perceptions of constraint in the product line ($M = 4.26$) and sales incentive ($M = 4.65$), $F < 1$, conditions. Further subjects in the no choice-product line length condition perceived a similar amount of salesperson free choice in the favorable ($M = 1.80$) and unfavorable condition ($M = 1.40$), $F < 1$. Yet, there was a significant difference between the attitude attributions in these two conditions. Similarly, subjects in the no choice - sales incentive condition perceived the same amount of salesperson free choice in both the favorable ($M = 2.25$) and unfavorable condition ($M = 2.0$), $F < 1$. Yet, significant differences in attitude attribution occurred.

The reversal effect cannot therefore be accounted for by assuming greater constraint in the sales incentive condition. Apparently, then it took a mild sales message combined with subjects' awareness of the salesperson's incentive that yielded perceptions of "foot-dragging." These results indicate that an ineffective salesperson runs the risk of being perceived as untrustworthy. A less than convincing performance under constraining circumstances prompt consumers to think that the salesperson does not believe his or her verbal statements. This perceived "foot-dragging" phenomenon elicits attitude attributions opposed to the verbal statements.

Halloween: An Evolving American Consumption Ritual

Russell W. Belk, University of Utah

Halloween is a little studied consumption holiday that is in several significant respects a mirror image of the other major American consumption holiday: Christmas. In the contemporary American Christmas celebration adults wear costumes (of Santa Claus) and extort good behavior from children with threats that rewards of durable goods will be withheld (Belk 1987, 1989). In contemporary Halloween celebrations, American children wear costumes (often of "evil" beings) and extort treats of nondurable goods from adults with threats of property destruction. In Christmas rituals the extended family meets for a day of feasting (on wholesome foods) with a traditionally religious focus. In Halloween rituals children leave home and family to join other children for an evening of pranks in order to obtain unwholesome sweets in a decidedly nonreligious atmosphere. In Christmas rituals gifts are exchanged within the family and each is personally and lovingly acknowledged. In Halloween rituals non-family members provide gifts to masked and anonymous children who pose a vague menace. What accounts for this opposing symbolism? What is Halloween all about? How is it changing? What do Halloween costumes and iconography represent? And what do contemporary celebrations of this holiday tell us about consumer behavior.

In this paper I attempt to answer such questions using a combination of secondary data and both qualitative and quantitative primary data. The paper is a work in progress and is based on primary data collected over the past two Halloweens in a city of one million people in the western United States. Participant observation was used to study a variety of child and adult Halloween practices including fairs, parades, costume contests, trick-or-treating, parties, dances, and a race for costumed runners. Depth interviews were conducted with both children and adults and a written questionnaire was administered to undergraduate university students. The observations and interviews were recorded both verbally (fieldnotes, journals, tape recording) and visually (photography, videotaping). A variety of secondary sources were consulted in popular literature and the literatures of a variety of social sciences. Relevant topics in these literatures include fears, nightmares, play, games, children's stories, sex role socialization, rites of passage, liminality, mysticism, magic, masks, costumes, decoration, legends, myths, fairy tales, horror movies, performance, drama, Halloween history, American holidays, the ritual calendar, and related holidays in different cultures.

Besides relying on multiple sources of evidence, a deliberate attempt was made to avoid a priori theorizing and to continuously cycle between the primary and secondary sources as new interpretive themes emerged. Beginning with participant observation and emersion in Halloween

celebrations, the project has developed via an interactive and continuous process of theory formulation, application, modification, and expansion (see Belk, Wallendorf, and Sherry 1989). What began as a simple investigation of the solicitation, acquisition, and consumption of candies by children, soon became an investigation of the mysteries of a rich and evolving social ritual involving children, adults, and community.

AN HISTORICAL ACCOUNT

Certain aspects of Halloween can be traced, through surviving remnants, as far back as prehistoric Celtic celebrations of Samhain (variants: Saman, Samain, Semuin, Samhuinn). Winkler and Winkler (1970) suggest that Samhain celebrated the harvest and was influenced by Egyptian and Babylonian harvest festivals, but Frazer (1959; original 1890) argues that Samhain was instead a pastoral festival marking the time of bringing the herds back from pastures to their winter stalls. In addition to being a seasonal harvest or herding festival, Samhain was a Celtic new year's festival and a day of the dead involving Celtic ancestor worship (Ward 1981). Samhain was the Lord of the Dead (the term also means "summer's end") and sacrifices made to him included human sacrifice by the Celt's Druid priests (Myers 1972). A survival of this Halloween practice in Europe substituted black cats to be burned in the wicker cages that would have contained criminals or captives before the Romans banned human sacrifices in 61 A.D. (Linton and Linton 1950). On Samhain night the ghosts of the dead emerged and visited their old homes. Witches and hobgoblins with more orgiastic, mischievous, or malevolent intent also roamed the earth. Fires were lit, in part to scare these ghosts and witches away with their purifying flames (Myers 1972). These associations with spirits, the dead, debauchery, and evil remain attached to contemporary Halloween celebrations.

There may also have been precedents for trick-or-treating and Halloween costumes in Samhain celebrations. James (1961) reports that in Gallic celebrations of Samhain, the skins of slaughtered animals were worn as a disguise to invoke the spirits of sacred animals and that this masquerade feature continues to survive in the Scottish Highlands. According to Myers (1972) banquet tables were prepared for visiting ghosts and after the feast the ghosts were led out of town by costumed villagers. Harvest beggars are also thought to have asked for food and traces of a masked procession that asked for contributions in the mysterious name of "Muck Olla" survived into historic periods (Linton and Linton 1950, Ward 1981). In Christian times, this practice became transmuted into souling (in which special soul-cakes were solicited) and eventually into children's begging "a penny for the

Guy" (Fawkes) in England and trick-or-treating for candy in the U.S..

Jack-o'-lanterns are another practice that derives from Irish customs and perhaps those of their ancient Celtic forbearers. Irish children have long hollowed out potatoes, turnips, and rutabagas, made carved faces on them, and placed lighted candles inside (the pumpkin appears to be an American modification). The related folktale involves a trickster figure: a miserly drunkard Irishman named Jack. He twice tricked the Devil into promising not to take his soul. The first time he told the Devil he would accompany him to Hades if he could have sixpence to enjoy one last drink first. The Devil obliged by turning himself into sixpence which Jack immediately pocketed. He only let the Devil out when he promised not to claim his soul for ten years. At the end of ten years he asked the Devil if he would retrieve an apple from a tree for him before they departed for Hell. When the Devil climbed the tree, Jack used his knife to carve a cross on the trunk, thus barring the Devil from descending. This time Jack let the Devil down only after he promised never to claim his soul again. When Jack did die and was barred from Heaven, he appeared at the gates of Hell, only to be refused admittance and doomed to wander the world forever (as an undead figure). As he was leaving, the Devil threw him a live coal which he placed inside the turnip he had been eating, making the first jack o' lantern (Tuleja 1987).

Despite the rise of Christianity, Samhain practices continued for hundred of years in the British Isles. Eventually the Christian church realized that it was more effective to try to take over pagan holidays than to oppose them. In order to co-opt the festival of the dead, in 835 Pope Gregory IV designated November 1st, Samhain, as "All Hallows" ("All Saints") Day. "After all, the saints themselves are dead people" (Sterba 1948). The church also imitated the masquerading by encouraging parades in which people dressed as their favorite saints (Myers 1972). However, this attempt to quash Samhain failed and led to the addition of "All Souls" Day on November 2nd (first created by Abbot Odilo of Cluny in 998) to the Catholic calendar by Pope John XIX in 1006. While more successful, since other dead besides the saints could then be celebrated, remnants of Samhain can still be seen on October 31st, Hallows' Evening or Hallowe'en.

Halloween was known by American colonists, but wasn't celebrated in the United States until after 1840 when the great Irish potato famine resulted in a large number of Irish immigrants (Santino 1983). Some of the Halloween games of the Irish such as bobbing for apples have survived, while others such as roasting nuts and fortune telling have largely disappeared. Linton and Linton (1950) trace the origin of pranks to the Irish belief that the "little people" come out to do mischief on this night and place the height of Halloween vandalism in the late 1800s (similar patterns appear in part of Canada--Walden 1987). They also suggest that Halloween

has since become a degenerate holiday that has lost much of its original significance, a view echoed by Rook (1985). Stone (1959) questions whether the holiday has *any* meaning for children and suggests it may be more for the amusement of adults.

The historical precedents of Halloween explain some icons and historical vestiges of the holiday, but they do not explain why it continues to be a popular American and North American holiday, despite its lack of clear meanings to participants. Nor do these historical precedents seem to account for some of the recent changes in Halloween celebrations. One of the most dramatic of these changes is the curtailment of trick-or-treating due to tales of poisoned candy, razor blades in apples, and hallucinogenic drugs placed in treats (e.g., Ainsworth 1973, Wemhaner and Dodder 1984). In the past two decades such fears have caused parents to prohibit or limit their children's trick-or-treating, have led hospitals to offer free x-rays of Halloween goodies, and has led Brian Sutton-Smith (1983) to suggest that instead of edible sweets, Halloween treats be restricted to "small gifts, small toys, personal parcels, or greeting cards." And yet, such stories of razor blades, poison, broken glass, and pins are urban legends with no basis in fact (Grider 1984, Best and Horiuchi 1985). These tales are spread both orally and by the media (Best 1985), and are fervently believed. But with the exception of one father who was convicted of killing his eight-year-old son by feeding him trick-or-treat candy laced with cyanide, other reports of contaminated treats turn out to be hoaxes and rumors. Best and Horiuchi (1985) found that such stories in the popular press peaked in 1969-1971 and again in 1982. They suggest that the first peak is a reflection of displaced U.S. anxiety due to the Vietnam war and domestic riots, and that the latter was clearly a result of widely reported poisoned Tylenol murders in the Chicago area that year. Besides lessening Halloween trick-or-treating, these rumors may also be causing an increase in institutionalized (i.e., controlled) substitute activities such as parties and "spook houses" (Crader and Wentworth 1984, Magliocco 1985). Beginning with the 1978 John Carpenter film, *Halloween*, several dozen horror films have been produced that attract particularly big audiences and rentals just before and during Halloween. These too represent another institutional alternative or addition to prior American Halloween traditions.

Although an estimated 93% of U.S. households with children under age 12 still participated in trick-or-treating last year (Neuharth 1988), another trend in Halloween celebrations is a shift to more adult activities (Demarest 1983, USA Today 1988). Costume shops report a rapidly growing market for adult Halloween costumes. Clubs, bars, hotels, museums, and other institutions are beginning to sponsor large parties for costumed adults, and Halloween is reported to be the second biggest U.S. adult party night after New Year's Eve. Washington, D.C.'s Georgetown closes down its streets for a wild adult Halloween celebration and

New York's Greenwich Village Halloween Parade draws hundreds of thousands of adult participants and spectators (Miller 1987, New Yorker 1988). Parades like the Greenwich Village and San Francisco Polk Street Halloween events draw substantial participation from the gay community who turn out in drag and flamboyant costume (O'Drain 1986).

Why is the U.S. Halloween changing in these ways? Why does a holiday that seems detached from its historical rationale continue to be celebrated? What functions does Halloween serve and does it serve different functions for males and females, children and adults, and children of different ages? What is the role of Halloween in the family, neighborhood, and larger community? Why costumes, and why particular types of costumes? Why do we frighten ourselves with "Halloween movies?" To begin to answer these questions, it is useful to first consider some of the primary data of this study.

STUDY 1: THE GHOSTS OF HALLOWEENS PAST AND PRESENT

The first study sought descriptive data on Halloween activities from U.S.-born senior undergraduate business students (64 males and 64 females). These students were asked to describe how they spent the most recent Halloween (the data were collected in January), how they spent Halloween when they were teenagers, and how they spent Halloween as pre-teenagers in grade school. There is no room to present verbatim responses (although see others in Ainsworth 1973, Hunter 1983, McDowell 1985, and Mook 1969), but these responses were coded into categories as summarized in Figures 1, 2, and 3 for the three age periods involved in the questions.

Pre-teenage Halloween activities by these students showed little variation. Eighty-five percent of females and 87% of males reported trick-or-treating as their primary activity. Another 7% of each sex reported that they went to parties primarily. And the remaining 8% (females) or 6% (males) reported either no activity or one of a variety of other activities (scary movies, pranks, costume parade, making Halloween decorations, or participating in Halloween activities at school) as the major focus of their Halloweens. As seen in Figure 2, this pattern changed considerably during teenage years. Only 14% of females and 18% of males reported trick-or-treating and only 4% and 6% respectively reported being in costume in some other context. For both sexes partying and drinking alcohol were the dominant activities. Pranks were slightly more common among males (16%) than females (13%) and watching scary movies was slightly more common among females. Less than 10% of the sample reported no Halloween activities. Among the prominent "other" activities (mostly by females) were passing out candy at home, hayrides, visiting "spook houses," and telling ghost stories. For the present period of these young adult's most recent Halloweens, there is another dramatic shift in activities. About one-fourth of each sex now do

nothing special for Halloween. Trick-or-treating, which lingered into teenage years, is almost non-existent among these young adults (but see Hunter 1983 for accounts of adult trick-or-treating for alcoholic drinks). More than one-fifth of females and one-third of males still report partying and drinking, and significantly more than during teenage years--26% of females and 13% of males--report costumed activities. Unlike students on some other college campuses, those studied had no local tradition of street partying. Smaller numbers now give out candy or take children (their own or their siblings) trick-or-treating, and pranks are virtually non-existent. Thus, while some young adults "drop out" of Halloween participation, the majority continue in some way, supporting secondary data of more active adult participation in Halloween. The functions of these activities will be considered in the interpretation section.

STUDY 2: HALLOWEEN COSTUMES

An observational study was conducted of children's and adult's Halloween costumes, with photographs taken of 196 people: 30 below the age of 6, 102 ages 6 to 11, 32 ages 12 to 17, and 32 ages 18 and older. Sex was approximately evenly balanced in each group. The sites in which these costumes were photographed included trick-or-treaters in an upper middle class neighborhood, a costume contest in a middleclass mini-mall, a rural small town Halloween parade, a Halloween running race, and several adult private clubs. Costumes were classified into 40 categories that were collapsed into the 9 shown in Figure 4.

Sex differences were prominent. Females were much more likely to be dressed as a witch/wizard, an inanimate object (e.g., pumpkin, pizza, doll, star) or as a stereotypical female role character (e.g., nurse, Snow White, harem girl, cheerleader, ballerina). Males were much more likely to be dressed as a superhero (e.g., Superman, Batman), monster (e.g., Dracula, Freddy Krueger, zombie), a stereotypical male role character (e.g., hobo, sports player, cowboy), or as a scary animal (e.g., dragon, lion, leopard).

It can readily be seen that these costumes correspond to culturally stereotyped sex roles. The youngest (under age 6) group's costumes were most often chosen by parents who dressed them either in "cute" costumes or in animal costumes (as if the child were a doll or a pet). Girls start at this age to be dressed in "feminine" outfits, while "masculine" outfits for boys become common in grade school. Males of grade school age also begin to wear the aggressive outfits of fierce animals. At older ages they are more likely to be superheroes. Females on the other hand continue in grade school in "feminine" outfits and as witches. As older adolescents (12 to 17) and adults they become inanimate objects or adopt minority ethnic roles (e.g. Gypsy, Chinese coolie). It should be noted however that these data were gathered in a region where traditional sex role stereotyping remains especially strong. Nevertheless, the extent to which

Costumes Chosen by Males and Females

children identify with the roles implied by these costumes may be seen in the following quotes from interviews asking other children "What are you going to be for Halloween?"

WM 6--I want to be a wizard 'cause they can do magic like make bats and have their own castles.

WF 5--A fairy princess, because I didn't like the costume that my Mom gave me...a pumpkin all stuffed with towels and not comfy.

WM 3--A bumblebee because the penguin is too big for me to wear.

WF 7--I'm going to be Lady Lovelylocks. It's this girl who has pixie-tails in her hair; she's really beautiful.

WM 6--Dracula...because I like him because he's scary and cool. I like scary things.

WF 5--A bride--because it makes me happy.

BM 3--A dinosaur, because it's on TV. A big dinosaur-Rex. It has sharp teeth.

WF 8--I'm going to be a skeleton. I like them.

INTERPRETATIONS

Some Rejected Prior Interpretations

As has already been noted, historical explanations of Halloween no longer seem very applicable to the American Halloween. In a largely urban society, celebrating harvest and the return of the flocks no longer have much meaning even as nostalgic anachronisms. Halloween is also no longer our New Year celebration as it was for the Celts and has remained for some Celtic descendants until very recently. It could still be that Halloween marks a seasonal change, but it is a quarter-day and not an equinox or a solstice. Furthermore other temporal markers such as Labor Day, the start of School, and Christmas or New Year's are closer to marking seasonal changes and these changes are also less important in a largely industrial society.

Several psychoanalytic explanations of Halloween have also been offered that seem less than compelling. In one view Halloween enacts our repressed fear of death by symbolically sacrificing our children in order to mollify the spirits of the dead (Sterba 1948). While the first part of this argument, that Halloween involves a repressed fear of death, may have some merit, it is not as plausible

that we offer our children as symbolic sacrifices by sending them out dressed in various death masks such as skeletons, ghosts, and zombies. Parents play the greatest role in selecting costumes for preschool children, and are much more likely to select cute or animal costumes than death motifs. In addition, when "real" death threats to these children are perceived, as with the poison candy and razor-blade-in-the-apple legends, parents attempt to protect their children from these threats.

Another set of psychoanalytic interpretations have been offered by Fraiberg and Fraiberg (1950). They suggest that Halloween is a symbolic totem feast which enacts the Oedipal killing and eating of the father by the brother horde. The products of the harvest are sacrifices at this feast and their consumption also represents the possession of the women by the brothers. Another part of their Oedipal interpretation involves the symbolism of the door, at which treats are sought, as a symbolic vagina, the windows that are soaped as symbolic eyes for voyeuristic fetishism, and Halloween pumpkins as pregnant bellies. Even if there were not more plausible explanations for these elements of Halloween celebrations, it seems strange that Oedipal conflicts with parents would be enacted with strangers outside the house.

Emerging Interpretations

The Nature of Contemporary Halloween Celebrations. Caplow, et al. (1982) note that Halloween is in several ways the antithesis of other U.S. holidays. If the witch is the central figure of the holiday, she may be considered the inversion of the American mother figure. Her sex, ugliness, age, nocturnal preference, and malevolence also stand in opposition to the traits of Santa Claus, Cupid, and the Easter Bunny who reign during other major U.S. holidays. They also suggest that Halloween is an *anti-festival* that burlesques Easter by replacing the resurrection with ghosts and skeletons and burlesques Thanksgiving by turning the edible pumpkin pie into a horrific jack-o'-lantern. While Thanksgiving and Christmas celebrate family, Halloween mocks it. Caplow, et al. (1982) conclude that "...at Halloween, nonpersons imitating nonbeings demand and receive nonmeals from nonrelatives in a nonneighborly way" (Caplow, et al. 1982, 232-233). Thus Halloween is an anti-festival, and is specifically anti-home, anti-family, anti-nourishment, and anti-religion.

The only part of this characterization that might be questioned is the "nonneighborly" quality of Halloween. While the pranks believed to be characteristic of Halloween in the late 19th century and the vandalism associated with Devil's night in the Detroit area are indeed nonneighborly, Stone (1959) found that trick-or-treating youngsters had little intention of delivering tricks and indeed did not know what constituted a trick. While the current data suggest some incidence of pranks during teenage years, the extent and severity of these tricks were generally quite limited. While there remain some elements of mischievousness in Halloween

celebrations, it cannot be said that treats are truly extorted from those whose houses are visited. Rather, in an opposite sense, trick-or-treating and neighborhood holiday decoration provide a sense of community (Brown and Werner 1985) and demonstrate to children that the world outside the immediate family is kind and acts as a quasi-family. As Sutton-Smith (1983) observes:

We say to our children, in effect, that your neighbors are to be trusted. They are nice people. If you go up to their scary door along their scary path dressed up as a scary person, nevertheless they will treat you nicely and give you candy and food (p. 64).

As one informant (WM 10) put it, "If we bring up all those scary things at least once a year, maybe they won't scare us as much." Freud (1961; original 1920) also suggested that children use games that involve the things they fear most in order to gain some control of these terrors. Horror movies may serve much the same function.

Functions of Halloween for Young Children.

There is also another sense in which a feeling of community prevails for the child at Halloween. It derives from the adventure of the child leaving family and joining masked friends for a dark foray in search of candy treasure. The spirit of liminality is enhanced because "a touch of sin and evil seems to be necessary tinder for the fires of *communitas*" (Turner 1969, 183). Turner notes that child trick-or-treaters occupy a position betwixt and between the living and the dead and their masks and disguises provide them with the anonymity needed for a rite of reversal in which the weak become powerful, like the highwaymen whom they sometimes imitate. Shallek (1973, p. 16) suggests this reversal is necessary to relieve pressure because children remain the one repressed group that has not yet rebelled in our society. But Turner's brief application of his liminality formulation to Halloween fails to note several additional elements of the process: the chaos of Halloween as anti-structure, the liminal Halloween season bridging summer and winter and allowing witches and demons to slip between this seam (Ward 1981), the archetypal struggle between light and darkness at this time of year (Burland 1972), trick-or-treating with comrades as a pilgrimage and a self-imposed rite of passage, children--like gays, hippies, and freaks--as marginal people, and the adolescent as nonperson hovering betwixt and between childhood and adulthood.

The essential liminal nature of the trick-or-treat pilgrimage is recounted by Ann Mesko (Hunter 1983)--I have added liminal characteristics specified by Turner (1972) in brackets:

Group members were allowed to examine treats between stops, but it was frowned upon to sample them [asceticism]. Members were allowed to remove their masks while in transport because of the discomforts of breathing through them, but were not allowed

to remove the essential costume [uniform clothing]. Facial disguises had to be replaced before entering a householder's property [transition; ritual preparation]. Under no circumstances were members to reveal their true identity to the householder when in his presence [anonymity; obedience]. And the group had to travel as a unit; that is, the male members were not allowed to move ahead of the females [equality; absence of rank; unselfishness]. All of the rules served to reaffirm group solidarity and to ensure an orderly progression through the itinerary [communitas; ritual] (p. 40).

For the young child Halloween may thus be seen largely as a sacred pilgrimage. An implicit function served by children's jointly going out into the night, is mastery of fear. It might seem strange that children would dress up as scary monsters and visit spook houses in order to master fears, but this is the very way these fears are met (Balter 1988; Magliocco 1985). In these contexts fears are met in a controlled situation with safety highly likely; they are bracketed in time and space. For preschool children, both fear mastery and costume-imparted sex roles are generally supervised by parents or older siblings, making the initial experience a pilgrimage with guides.

Functions of Halloween for Adolescents. For adolescent children, one social function of the trick-or-treat ritual is to socialize children to acquisitiveness, possessiveness, and gluttony. One informant (WM 12) explained his Halloween procedures this way:

Get all the candy you can when trick-or-treating. Take the candy home, and dump it all onto the table or floor. Separate the good candy bars (Snickers, Mars, Three Musketeers) into separate piles from the rest. Also separate the other candy into suckers, gum, etc.. Examine everyone's candy and the one with the most good candy has won. Eat the good candy first, and protect your stash from others.

The ethos expressed here was fairly common, especially among grade school age males. Younger children showed confusion between Halloween and Christmas and sometimes spoke of Halloween trees with candy under them and leaving treats out for spirits in the evening (seemingly inspired by leaving treats for Santa, rather than similar Samhain practices, as even older children had only vague and often mistaken ideas about the origins of Halloween). Stone (1959) has also noted this consumer (rather than producer) orientation of Halloween.

Another function of Halloween for adolescent children is to aid in exploring sexuality. While prepubescent children may properly regard themselves as children and postpubescents properly regard themselves as adults, children going through

puberty and menarche are uncertain. One interpretation of the horror films popular in this age group at Halloween is that these films help express these feelings of confused identity (Evans 1975, Hogan 1986). As Evans observes:

The adolescent finds himself trapped in an unwilling change from a comparatively comprehensible and secure childhood to some mysterious new state which he does not understand, cannot control, and has some reason to fear. Mysterious feelings and urges begin to develop and he finds himself strangely fascinated with disturbing new physical characteristics--emerging hair, budding breasts, and others--which, given the forbidding texture of the X-rated American mentality, he associates with mystery, darkness, secrecy, and evil (1975, 126).

Fiedler (1978, p. 28) adds that children wonder "whether they are beasts or men: little animals more like their pets than their parents." With such a view it becomes more understandable that the half-human/half-animal form of monsters like the wolfman and Frankenstein's monster should hold a special fascination as their bodies are contorted and transformed. Similarly, the special fondness of Dracula for blood has been seen as symbolizing menstruation. The monthly timing of these attacks (at full moon) offers further support of this interpretation. Another interpretation that ties more closely to the teenage horror films of the 1970s and 1980s involves cautions against sexual promiscuity. In films like *Halloween*, the heroine/survivor is a teenage female virgin, while those who die are sexually active (Neale 1984).

Besides their sexual significance, horror films evoke Halloween through the use of masks. Adolescents then adopt these same masks and costumes for their own Halloween masquerade--e.g., Michael from *Halloween*, Freddy Krueger from *Nightmare on Elm Street*, Jason from *Friday the 13th*, *The Phantom of the Opera*, and others. The films also involve the boundaries between wakefulness and sleep, fantasy and reality, human and nonhuman--all of which have liminal parallels in both nightmares and Halloween (Hartmann 1984). Horror is also created by creatures that violate taboos through pollution, dirt, ambiguous forms, and other threats to an ordered and clearly categorized world (Prince 1988). The chaos and inversion of these films is very parallel to the chaos and inversion of Halloween, so that the fascination of these films during Halloween (but not during "purifying" holidays like Easter) is not at all surprising. The functions served by these movies are not unlike those more prominently served by fairy tales and ghost stories in the past--they express the collective anxieties of adolescents (e.g., Bettelheim 1976).

Functions of Halloween for Adults. For adults, the increased participation in Halloween celebrations appears to serve still different

functions. The mask and carnival atmosphere of Halloween that allow children to invert the power structure, master fears, and try on different identities, allow the adult to transcend normal rules of propriety and relieve the normal tensions of social order. Some historical carnival celebrations have disappeared or substantially changed their character including the Roman Saturnalia, Hilaria, and the fetes of Kalends, the medieval feast of fools, and Christmas mumming in various locales (e.g., Abrahams and Bauman 1978, Davis 1982, MacGowan and Rosse 1923). Surviving carnival festivals besides Halloween include New Year's Eve celebrations, Carnival in Brazil, Trinidad, and several other predominantly Catholic areas, Mardi Gras in New Orleans, Shrovetide in Finland, St. Peter festival in Columbia, and St. Martin's Day in parts of Denmark and the Netherlands. Reversal rites also survive in certain activities like "monster" car-crushing trucks and demolition derbies (Jewett and Lawrence 1978). There appears to be a widespread and longstanding need for such a festival. The symbolic inversion of carnivals may involve debauchery, drunkenness, homosexuality, transvestism, and generally a spirit of play, tricks, and taboo-breaking rule violation (Babcock 1978, Da Matta 1984, Huizinga 1970 [original 1955]). These traits accord well with the gay drag parades, the adult parties, and the drinking activity associated with the contemporary Halloween.

A part of the license for such activity is granted by the use of costume and mask. The power of masks is to some degree shaped by the audience who assume that the wearer suspends all identity but that of the role (e.g., Hickey, Thompson, and Foster 1988). Although Abrahams and Bauman (1978) note that participants may be those given to bawdiness at other times as well, the mask, the presence of co-celebrants, and the tolerance and sometimes encouragement by the community all enhance such activity during the Halloween carnival.

What remains to be understood is why the current U.S. Halloween celebration seems to be shifting in emphasis from children to adults. Some clues may be found by returning to the razor-blade-in-the-apple legend and the Halloween horror films of the past two decades. Best and Horiuchi (1985) suggest that the poisoned Halloween treat rumors have actually flourished because we felt surrounded by unactionable threats with the U.S. loss in Vietnam, the Arab oil embargo, increased crime, the Tylenol poisonings, and increased reports of various forms of child abuse. By confining our fear to a narrower target (the Halloween sadist) and a single day of the year, the threat is contained and parents are able to take action against it by controlling their children's trick-or-treating. But why the increase in adult Halloween activities? Noting some of U.S. society's other reactions to a felt loss of control, Wood (1986) argues that the resurgence of horror films in the 1970s and 1980s is both an enactment of and a cathartic response to increased political, religious, and sexual repression due to the rise of conservatism, religious fundamentalism, and

AIDs during this period. It seems likely that these same forces could account for the increased adult emphasis on Halloween as carnival release. While these interpretations remain tentative, they are also compatible with the earlier increase in horror films during the Great Depression and accounts that Halloween pranks were also much more in evidence during this period (e.g., Stone 1959).

If these interpretations are correct, the evolving course of the U.S. Halloween celebration may be tied to social forces that are quite volatile. Similar shifts in holiday control due to social forces have been detected in Brazilian carnival (Taylor 1982) and Philadelphia mumming (Davis 1982). Other U.S. holidays also evolve and change (e.g., Belk 1987, 1989), although they may have better articulated mythologies to anchor them, and thus change somewhat more slowly. While current emphasis is shifting in favor of adults, Halloween is multivocal and because of its ambiguity is able to serve children, adolescents, and adults in different ways and with different meanings. Its attractiveness is also shown in its recent infusion into the pre-Columbian Mexican Day of the Dead (El Dia de los Muertos) ritual (Hernandez and Hernandez 1979). It seems clear that with several thousand years of lineage, Halloween is not about to disappear, even though other holidays have taken over some of its earlier functions. As the major non-family holiday, Halloween retains unique characteristics that can not be co-opted.

Toward Improving Household Consumption Behavior Research: Avoidance of Pitfalls in Using Alternative Household Data Collection Procedures

Alvin C. Burns, Louisiana State University
James W. Gentry, University of Nebraska - Lincoln

BACKGROUND

This Special Session of the 1989 Association for Consumer Research Conference responds to a need expressed by the participants of the ACR Household Consumption Behavior Session held as part of the 1988 ACR Conference. The 1988 Forum Session relied on a Delphi investigation and revealed critical issues inhibiting research in this area. The only documentation of this session exists in the form of a summary prepared by James Gentry. To help the reader comprehend the issues, views, and general conclusions of this two-consecutive session forum, we have appended the summary to this article. (While parts of the summary are written in jocular fashion, its underlying concern for advancing this area should not be minimized.)

During both sessions, and addressed more explicitly in the second session, participants agreed that the vast majority of household consumer behavior research suffers from cross-sectional survey, positivist methodology bias. It was agreed that since most participants had little experience with alternative methodologies, a sharing of knowledge about them was a logical first step toward resolution of this bias and the ultimate advancement of our understanding of household consumption behavior.

OBJECTIVES OF THE 1989 FORUM

To this general end, the current special session was organized with the following three specific objectives in mind:

1. To provide for knowledge exchange on alternative research methodologies;
2. To create a forum for debate on alternative methodologies; and ultimately,
3. To encourage a broadening of methodological approaches to overcome the positivist methodology bias inhibiting household consumption behavior research.

The general orientation of the special session was intended to be educational. Throughout, it was assumed that intimate experience with an alternative methodology had generated a wealth of invaluable knowledge which needed to be communicated to household consumer behavior researchers who might consider using the methodology. Moreover, because of the special problems of household research (e.g., multiple respondents, divergent perceptions, joint consumption, shared resources, etc.), it was reasonable to believe that pitfalls exist, and that potential users of a method should be made aware to them.

PARTICIPANTS AND THEIR PRESENTATIONS

While the session was intended to be a dialogue between those who have learned the pitfalls of an alternative methodology and those who would consider applying that approach to their own research agendas, this *Advances in Consumer Research* contains abstracts of the various presenters' major points. The participants are listed below as they presented at the 1989 ACR Conference Program.

"Methodological Problems in Survey and Experimental Research on Family Choice Processes"

Kim P. Corfman, New York University

"Pitfalls in Obtaining Family Purchase Research Data"

Ellen R. Foxman and Patriya S. Tansuhaj,
Washington State University

"A Simulation Game as A Family Research Paradigm"

James W. Gentry, University of Nebraska-Lincoln

Jeffery J. Stoltman, Wayne State University

"Information Integration Theory Approach to Husband-Wife Decision Making"

James Shanteau, Kansas State University
C. Michael Troutman, Charles, Charles and Associates

"Longitudinal Methods for Family Consumer Research"

Alladi Venkatesh, University of California, Berkeley

Integrators:

William J. Qualls, Massachusetts Institute of Technology

Michael D. Rielly, Montana State University

The following pages contain abstracts of the various presenters' points. There are some variations from the original slate of presenters apparent with these abstracts. In a few cases, the presenters added co-authors who may or may not have been present at the forum, but who made important contributions to the presentations and abstracts.

APPENDIX

Summary of the 1988 ACR Household Consumption Behavior Sessions

October 14, 1988
Honolulu, Hawaii

Co-Chairs

Al Burns, University of Central Florida
Jim Gentry, University of Nebraska-Lincoln

**SUMMARY OF SESSION ONE:
DOMAIN ISSUES**

The intent of the session was to broaden the research perspectives held by household/family researchers. Given the disparate views espoused by the audience (summarized below), this goal was accomplished. On the other hand, another goal was to reach a consensus as to whom we should study and what topics most need study -- no such closure was reached.

The session started with the question "Why do we have families?" and quickly evolved into discussion about the differences between family and household. Eric Arnould cited Netting, Wilk, and Arnould, *Households* as a source of the dimensions that delineate kinship relationships: co-residence, pooling of resources, transmission of values, reproduction, and production and consumption functions. Becky Holman stressed that the key underlying variable is "relationships," noting that there are dysfunctional families as well as extremely close non-kinship relationships. Liz Wilson (and later C. W. Park) suggested that we incorporate models from small group decision-making and organizational behavior areas. Rich Lutz noted that we should let the phenomena determine our conceptualizations. Mike Reilly pointed out that the basic premise of the family consumer behavior area is that family decision-making processes are quite distinct from those incorporated in general interpersonal influence settings.

Another topic raised is whether we should study "decision making" or "choice." Russ Belk (and later Rich Lutz) argued strongly that the focus should be "choice," as many outcomes are not the result of a decision making process. Russ gave the example of organ donation, which studies at the University of Minnesota indicated really involved "decision avoidance" -- as options for the loved one become more negative sequentially, the family becomes backed into a corner and finally agrees to donate the organ. Mike Reilly mentioned his hypothesis that the "rationality" of the decision process is curvilinearly related to involvement; as involvement becomes very high, the "emotional afterburners" turn on.

A point that followed the choice/decision discussion was that we need to study sequences of choices. Cross-sectional approaches looking at single decisions somehow need to capture prior interactions within the family. Jeff Stoltman earlier had maintained that the construct of role specialization would be sufficiently rich to be used across a wide variety of household types; Becky Holman mentioned that such an emphasis might help capture the household members' expectations

and choice history leading to the current choice task.

Other points raised:

--C.W. Park mentioned that we rely on our spouses as an additional memory bank, thus making our internal information search within the family a joint rather than individual process.

--Russ Belk pointed out that joint decision making is becoming less prevalent, as choices within the family are being made more and more individually.

--Mike Reilly mentioned the importance of shared consumption (as one item differentiating families from other groups). In a truly surprising gesture, Rich Lutz acknowledged that Mike had made an excellent point and encouraged the study of shared consumption as a direction for future research.

--Sandy Grossbart stressed the changing nature of role players in choice events across one's life. These people are often outside the nuclear family and can have major influence on choices; however, the players change over time.

--Bill Qualls suggested that we develop a categorization scheme for households, using "relationship" as one dimension. Al Burns had developed a couple of such schemes, plus a delineation of types of households in the session handout. Sandy Grossbart pointed out that the homeless are a household type not covered in the Burns' diagrams.

Session Two: Methodological Issues

There seemed to be agreement as to the need for longitudinal research on multiple household respondents involving choice sequences using multiple methodological approaches. The focus of the discussion was on how to achieve some of these goals given time and financial constraints. Unfortunately, no quick and dirty yet sufficient approaches were generated. Of the participants, only Venky Venkatesh was currently conducting a longitudinal household study.

Other issues concerned how to obtain the type of observation data that was being promoted repeatedly in the sessions. In the first session, Russ Belk had suggested that respondents could be asked to "tell stories." Don Granbois' suggestion in the Delphi process that we consider using focus groups was raised as a possible means of collection data from the family about choice sequences. Jeff Stoltman and Kim Corfman raised cautionary notes, discussing the potential for conflict (and even physical violence) that can occur as issues which the family typically chooses to lie dormant suddenly surface.

The last part of the session focused on where we should go from here. Al Burns presented his Blue Skies ideas and discussion followed in terms of what might be feasible. Jim Gentry volunteered to continue to develop a list of CB-oriented family researchers in order to improve communication among people in the field. For example, Benny Regaux-Bricmont used the list to announce the Fall 1990 special issue of *Recherche et Applications en Marketing*--the official journal of the French Marketing Association--on family decision making. Ellen Foxman offered to initiate a communication network via BITNET. Jim and Ellen will develop a questionnaire about interest in the area so that we can provide a summary of the sub-areas of household consumer behavior which people in the field are currently studying. The intended outcome will be a crude newsletter going to people in the field and, eventually, the development of a BITNET network for the dissemination of information, questionnaires, data bases, a family/household bibliography, etc.

Al Burns volunteered to work with the ACR hierarchy to increase the likelihood of having a special session at next year's conference that will focus on those issues stressed as being most critical in the current sessions.

Venky Venkatesh offered to try to arrange a Household Consumption Behavior Conference/Workshop at UC-Irvine in early 1990.

METHODOLOGICAL PROBLEMS IN SURVEY AND EXPERIMENTAL RESEARCH ON FAMILY CHOICE PROCESSES

Kim P. Corfman, New York University

Research on families in sociology and marketing has a long history of experimentation with a variety of methods for collecting data. Numerous observations have been made concerning the weaknesses of many of these approaches. This paper is an attempt to gather together the pitfalls associated with using surveys and experiments in the investigation of family choice processes.

SURVEY METHODS

Survey research makes use of reputational methods of measuring influence in decision-making. One or more family members are asked for reports on aspects of their joint decision-making through interviews, questionnaires, or diaries.

Because choice processes vary from one occasion to the next due to variations in the topic, the timing and the people involved, researchers tend to restrict their focus to particular types of decisions (Ferber and Lee 1974; Munsinger, Weber and Hansen 1975). While this limits the ability to generalize it does help justify conclusions that are drawn about the chosen topic. When survey methods are used, limiting investigation to specific types of choices makes data collection more difficult. Only a small subset of the typical sample is likely to have engaged in the activities selected, recently enough that they can reasonably be asked to report on them.

Because families make many decisions over the course of their existence some researchers have taken a longitudinal approach and examined the impact of choices made in the past on subsequent choices (Corfman and Lehmann 1987). When this is attempted in the context of a survey, all of the usual panel problems of attrition and reporting error apply.

Most of the problems associated with survey research are related to the fact that subjects are providing influence *perceptions* which may not conform to reality. The norm until very recently, despite 20 years of warnings against it (Bokemeier and Monroe 1983; Safilios-Rothschild 1970; Wilkening and Morrison 1963), was to ask a single family member for information on family members' influence in decision-making. Usually the wife (Blood and Wolfe 1960; Green and Cunningham 1975; Haberman and Elinson 1967) and sometimes the child (Herbst 1952, Hoffman 1960, Straus 1962) was selected for convenience, on the assumption that this individual would provide reasonably accurate data. More recent studies have demonstrated that when more than one family member is questioned there is often considerable disagreement among them (Burns and Hopper 1986; Davis 1970, 1971; Wilkes 1975). In a recent study, Monroe et al. (1985) demonstrated that 24 percent of the couples in their sample would have been substantially misrepresented had only one spouse been questioned. The degree of incongruence and inaccuracy depends upon many factors including the decision topic, the specificity of the question and the actual involvement of the subject, but it can generally be concluded that influence perceptions are biased and should be used with care. Bokemeier and Monroe (1983) reviewed 80 articles on family power drawn from 48 different professional journals from 1965 to 1978 and found that many researchers extended conclusions to family members other than the one(s) from whom the data were collected. At the very least caution should be exercised if generalizations are applied to family members not questioned in the survey.

Few studies have explicitly addressed the sources of error in reporting on relative influence, but several may be hypothesized (Corfman 1989; Davis 1970; Safilios-Rothschild 1970). First, it may be difficult to infer from past encounters and their outcomes who had more influence. Family members do not always enter into joint decisions with completely formed preferences or strong commitments to them. When you add this to the likelihood that both individual and joint learning has occurred in the process of making a choice, it may not be at all clear who was more influential. Second, perceptual and reporting biases may operate. Perceptual biases are likely to result from the desire to preserve a self-image (e.g., dominant, expert, flexible, supportive). Reporting biases occur when a family member wishes to give an inaccurate impression. For example, social norms that dictate right to authority, appropriate family roles and the importance of equality in the relationship may affect

the way a subject perceives or chooses to represent his or her family's choice processes. Finally, even when perceptions are accurate and subjects wish to report them, memories are far from perfect.

Another problem with survey research is related to the specificity with which questions are asked. It has been shown that more specific questions that concern individual decision topics or aspects of those decisions produce more congruence and probably more accuracy than global questions (Davis 1971; Munsinger, Weber and Hansen 1975; Turk and Bell 1972; Wilkes 1975). This is probably related to the issues of validity with respect to global measures. Can families be categorized according to influence patterns or decision-making roles as the use of global measures implies, or is influence specific to the type of decision, the aspect of the decision, the family and other contextual factors such as timing and proximity of potential influencers? The bulk of research in the consumer behavior of families argues for the latter. This means that global measures are not indicators of who always has more influence, but of who, on average, is more influential. Further, abstracting from many specific instances to a global statement is not an exercise to which subjects are likely to be accustomed and it involves the compounding of subjective judgments from many past decisions. Both are likely to result in error.

Experimental Methods

While experimental methods avoid many of the pitfalls associated with survey research, they present another set of problems. Most of these problems fall into the following categories of issues: convenience, task realism, experimental behavior, and situation volatility.

Convenience. Experimental research is considerably less convenient to conduct than survey research. Because the subject burden is greater it is more difficult to conscript a representative sample of family units. Further, because the unit of observation includes more than one individual, the logistics of getting the relevant parties together with the experimenter are complex. (As with survey research, identifying these parties is also an important and non-trivial task.) Once these problems have been addressed, the experimental session imposes a greater burden of effort and time on both the subjects and the experimenter than most surveys.

Task realism. When a similar experiment is being performed on all family units, the appropriateness of the decisions to each unit must be assessed to ensure that conclusions are not drawn from a family's behavior in making a decision they would not normally make. For example, researchers who use interaction-based measures have tended to present contrived situations to their subjects. Kenkel's (1965) method asks couples to decide how to spend an imaginary \$300 and Strodbeck's (1951) method asks family members to resolve differences in values revealed through their answers to a questionnaire. Although studies of consumer

behavior tend to use more concrete tasks, they also run the risk of asking subjects to make unrealistic decisions.

The timing of experimental decisions is also necessarily artificial. Therefore, even if the decision is one the family might reasonably make, the members have not chosen to make it, nor have they chosen the time at which to make it. When a family is asked to make a sequence of decisions the condensed time frame adds an additional element of artificiality. Also related to the issue of timing is the observation that, in their natural settings, families often face several problems concurrently (Davis 1976). When an experimenter presents one clearly defined task at a time, the choice situation is unrealistically simplified.

Further complicating this is the nature of the decisions that tend to be included in an experimental sequence. Even if some effort is made to present a variety of topics, they are not likely to represent the range of decisions families make in a typical day or week. If it is hypothesized that the outcomes of past decisions affect future processes and outcomes, it is important to ask what "counts" as part of a family's decision history. Do all decisions play future roles or are they only relevant to decisions on similar subjects?

Another element of artificiality is imposed by the requirement often made or inferred by subjects that they must make decisions. A very popular option in "real life" is not to decide. Decisions are often put off temporarily or indefinitely. Finally, families participating in experiments face the same unrealistic conditions faced by all experimental subjects. They are working under ideal conditions meaning, among other things, that they are likely to have higher energy levels and face fewer distractions than they would in their natural environments (Davis 1976).

Experimental behavior. A number of researchers have hypothesized that people behave differently when they are being observed than when they are alone (Corfman and Lehmann 1987; Karlsson 1964; Olson 1969; Safilios-Rothschild 1970). One clear reason for this is that in public people prefer conform to social norms and exhibit the behavior they believe is socially acceptable. This may result, for example, in fewer uses of threats and coercion, fewer displays of anger and frustration, and greater assumption of authority by traditional husbands. While some kinds of behavior may be socially acceptable in other settings, they are not appropriate in the presence of an unfamiliar third party (an experimenter or observer). For this reason such potentially influential intimate behavior as displays of affection and sexual negotiations are less likely to be exhibited in experimental settings. The gender of the experimenter may also influence the effect. Kenkel (1961) found that when observers were female, wives were more active and powerful. Conducting experiments in families' own homes may reduce the artificiality. O'Rourke (1963) reported more disagreement, more activity, less decision-making efficiency, and less emotionality when

decisions were made in the lab than when they were made at home. Subjects may also behave differently in experiments because some influence techniques are not available to them within the lab or the limited time frame. Family members cannot wait for the right moment or mood to press for acquiescence. They cannot engage in many reward or bribe activities such as giving gifts and cooking meals. Nor can they nag intermittently over a long period of time. Finally, regardless of the potential importance of the choice topics presented to subjects, they rarely lose sight of the fact that they are participating in an experiment in which they cannot be held to their choices. The result is that preferences are often less intense and positions defended less vigorously.

Volatility of situation. A final problem that may arise in experiments with the potential for conflict is that the session may become more emotionally intense that the observer is equipped to handle. The presence of an observer and the experimental setting reduce this probability (and make responses less representative). However, experimenters should be prepared to redirect or terminate discussions.

PROBLEMS IN COMMON

In addition to those discussed above, survey and experimental methods have a number of problems in common. The following affect the legitimacy of generalizing from the results of one study to other families and situations.

Family researchers tend to use nonprobability samples, especially convenience samples. As observed by Kitson et al. (1982), convenience samples are inexpensive and convenient, but volunteers may have special characteristics or concerns about the topic which make them poor representatives of the population. For example, families who are willing to participate in studies of their choice behavior are likely to be more stable than the average for the population. Convenience samples also tend to omit isolated people who are not tied into social networks. While these samples have obvious shortcomings, they do have value if their limitations are kept in mind. There are ways to reduce the relationship between the topic being studied and subjects' interests and self-selection bias related to the topic. For example, while the task itself should not be misrepresented, the research questions can be obscured until the debriefing. Researchers can also change the reasons for self-selection so that they are not so closely related to the research subject. For example, if large enough financial or gift incentives are offered they will overcome the reluctance of some families to be examined.

Identifying the family members who are involved in the decisions being studied is another difficult task researchers encounter. Involvement varies according to type of decision, product category, decision phase, attribute, time of day, decision history, family characteristics, and probably other factors as well. Most studies focus

on the couple as the relevant unit of observation, although some choices may be made by only one spouse and others may involve children, grandparents, and other members of the extended family.

Even if the involved parties are correctly identified for the particular survey or task, because relative influence (as well as involvement) varies according to the product category, decision phase, attribute, etc., care must be taken not to generalize from the findings to situations which may only appear to be similar.

While the tone of this review is undeniably negative, this does not mean that current methodologies are without value. Despite the many problems associated with doing survey and experimental research on families, awareness of the pitfalls, use of multiple methods, and integration of evidence accumulated over a period of time will undoubtedly lead to interesting and important insights.

THE USE OF TRIAD DATA TO STUDY FAMILY PURCHASE DECISIONS
Patriya S. Tansuhaj, Washington State University
Ellen R. Foxman, Washington State University

INTRODUCTION

Families are the consumption units for many products purchased in the US and elsewhere, and family members clearly affect the purchase of numerous products by and for the sole use of individuals. Further, families are an enduring social unit, and it can be expected that both their influence on individuals and their own distinctive behaviors as consumption units will exist for the foreseeable future. These facts make knowledge of family purchase processes and behaviors a matter of considerable practical utility and theoretical import, and help explain researchers' continuing interest in studying family consumption. What we know (or think we know) about family purchase behaviors, however, is very much affected by how we try to study them. Family researchers often acknowledge potential methodological weaknesses in their studies. The purpose of this paper is to compare and contrast our approach to study design, data collection and analysis with more traditional approaches. The advantages and disadvantages of using triad data (i.e., responses from father, mother and child) to understand family purchase decisions are discussed. This information may help other researchers avoid problems we have encountered and perhaps lead to the development of alternative approaches to the conduct of family research that present more accurate, complete, and integrated pictures of family purchase decisions. The experience of using triad data also raises some interesting research questions for future research to answer.

AN EMPIRICAL STUDY USING TRIAD DATA

Most family studies have focused on purchase roles and influence relationships between husbands and wives. However, there is increasing evidence in the popular press that children now play a significantly more active role in family purchase decisions (Dagnoli 1987; Graham 1989). The broad purpose of our study was to assess children's influence in family purchase decision processes (Foxman, Tansuhaj and Ekstrom 1989). A series of

questions were raised by the decision to include children in studying family purchasing:

- 1) Which children in the family should be questioned? It was felt to be practically impossible to question all children in the family and thus obtain a measure of all children's combined influence in purchase decisions. In the face of this practical limitation, it was decided to use an adolescent child as a respondent. This choice was supported by research on child development. Adolescents are more likely than younger children to have matured cognitively and to be active in a range of family purchase tasks (Elkind 1968; Mussen 1973; Mussen, Conger, and Kagan 1969).
- 2) Which family members should be asked to assess their perception of the adolescent's influence? Because there is ample evidence that spouses can disagree on purchase-related decisions and perceptions, it was felt to be necessary to obtain data from both mothers and fathers, as well as the adolescent child.
- 3) Which types of influence? Most family purchase studies have focused on particular products and services. Numerous studies have found that purchase influence perceptions differ depending on the product under consideration. It was felt, however, that perhaps a more normative dimension of product influence might also be assessed; that is, it might be useful to tap perceptions of family member participation and influence in family purchasing as a whole. As a result, items assessing both product-specific purchase influence and general influence in family decision processes were included in the study.

WHAT WAS DIFFERENT ABOUT THIS STUDY?

The Foxman, Tansuhaj and Ekstrom (1989) study differed from most other marketing family purchase studies in its use of triad data and adoption of a Euclidean distance measure to represent triad influence relationships. These two aspects are discussed separately below.

Use of Triad Data

In a review of fifteen previous marketing studies related to children's influence in family decision making, it was found that mothers were usually asked to rate their children's influence. In two studies of older children (i.e., college students), children rated themselves (Converse and Crawford 1949; Perrault and Russ 1971). Berey and Pollay (1968) and Atkin (1978) included both mothers and small children in their observational studies. Jenkins (1979) was first to ask the fathers in a focus group of husbands and wives about their perception of children's purchase influence.

Belch. et al. (1980; 1985) and our study were the only studies which included influence perceptions from triads of fathers, mothers, and children. In the Belch studies, however, respondents were asked to rate their own and other family members' influence separately using a scale in which 1 meant "no input" and 6 meant "all of input" -- a measurement approach which permitted family members to overstate their influence. The study also combined the influence ratings as the mean of the father, the mother, and adolescent responses.

Our study avoided these problems by utilizing a relative influence scale (for the product influence items) and agree-disagree Likert scales (for the general influence items) -- and by not combining the influence perceptions of triad respondents. This approach made individual influence perceptions more easily discernible but presented analytic problems in summarizing triad influence relationships. These analytical problems are discussed in the next section.

Analytical Issues

The most critical problem stemming from using multiple respondents from each family (i.e., more than two) is data analysis. It is even more complicated when the aim is to arrive at a single household measure of perceived influence.

In our initial approach to understanding family influence relationships, we used a simple multitrait-multimethod analysis to identify agreement and disagreement between father-mother, father-child, and mother-child dyads. We later were able to obtain a single score representing the extent to which triad member influence perceptions converged by calculating the Euclidean distance among the family members' factor scores. It should be possible to construct an index of families based on this household measure of convergence. In our study, we only tried to identify factors that might help explain convergence or a lack of it.

PROS AND CONS OF USING TRIAD DATA

From the aforementioned section, it is clear that the key advantage of using multiple respondents in family studies is that it potentially helps us obtain a more accurate picture of family decision processes. The key disadvantages involve difficulty in collecting and analyzing the data.

Considering data collection for multiple respondents, our study encountered a severe non-response problem in attempting to obtain data from fathers. We asked over 500 junior high school students to fill out the adolescent version of the questionnaire. The actual data set employed in our study consisted of only 161 triads because, while over 400 mothers responded, less than 200 fathers did.

Although we gained additional information by including the father in attempting to more accurately assess children's influence, we actually gained that information from a much smaller number of families. As we consider including more respondents in family studies, we need to remember that the non-response

problem is likely to increase as the size of the set of individuals to be analyzed as a family unit increases.

Considering data analysis, it is clear that the multivariate methods mostly favored in marketing family studies are poorly suited to the analysis of triad or larger-group data. Methods to deal with this type of data are largely undeveloped or unexplored. Consequently, researchers who surmount the problems associated with collecting data from larger numbers of family members still must deal creatively with the question of what to do with that data once it has been obtained.

FUTURE RESEARCH USING MULTIPLE RESPONDENTS

The obvious issues to be resolved in future multiple respondent family research are the data collection and analysis problems discussed above. However, there are additional matters that deserve concern. For example, including the *relevant* respondents in a particular family study is probably more important than including *a lot* of respondents. If it is possible to gain information somehow on which purchases a family member influences, then perhaps it will be possible to exclude them from those studies of decisions in which they do not participate.

The question of who needs to be considered as a family member is also important in both domestic and cross-national or cross-cultural family studies. Marketing studies for the most part consider the family to consist of a father, mother, and one or more children -- the "standard" U.S. nuclear family. Such a family is increasingly less standard in the U.S., and may never have been the standard in some U.S. subcultures or in other cultures. The point is that the relevant family members in family purchase studies may not be part of the nuclear family.

There is also the matter of possible gender effects associated with family purchase data collection. While such effects have been little investigated in marketing studies, there is some evidence that the sex of the interviewer, contact person, sponsor, or observer in a study can affect the data collected for that study in a systematic way (Warren 1980). While it could be relatively easy to control for such an effect in a single-respondent study, controlling for gender interaction effects between researchers and respondents will become increasingly difficult as the number of respondents (presumably of different sexes) increases.

A SIMULATION GAME AS A FAMILY RESEARCH PARADIGM

- James W. Gentry, University of Nebraska-Lincoln
 Jeffrey J. Stoltman, Wayne State University
 Kevin Coulson, University of Nebraska-Lincoln

ABSTRACT

This study discusses the simulation game as a research paradigm. It reviews the general literature

on simulation gaming for research purposes, and then discusses a specific application in which the Bean Game (Yeans and Manning 1984) is used to investigate issues studied previously by Corfman and Lehmann (1987), Davis, Hoch, and Ragsdale (1986), and Park (1982). The game is found to impose an unrealistic structure on the data collection; nonetheless, the paradigm does provide insight into the process issues of interest.

INTRODUCTION

The use of a simulation game as a research paradigm is not a new phenomenon; in fact, Cohen and Rhenman (1961) stated that many of the developers of the early computer simulation games were as interested in using them for research purposes as they were for pedagogical purposes. There are a number of articles available (Bass 1964; Cohen and Rhenman 1961; Nees 1983; Rowland and Gardner 1973) which do a very thorough job of discussing the pros and cons of using a simulation game as a paradigm for investigating substantive issues.

The use of games for family research is relatively rare. While some of the early uses of games in family sociology were for research purposes (Haley 1962; Straus 1966), most of the games in the family area have been used in the area of family counseling/therapy (see Rabin 1983 for an annotated bibliography) or for pedagogical purposes in family economics classes. This paper will discuss the benefits and the methodological weaknesses associated with simulation games in terms of family research.

Advantages. To some extent, the game environment provides a middle ground between laboratory and field research. The simulation provides greater opportunity for control than does field research and yet allows one to study a sequence of decisions over a long period of (simulated) time. The simulation can insure that certain situations occur. The cost of collecting data is far lower in a simulation than in a field study, and the simulated environment removes much of the sensitivity associated with the problem area.

Decision history is extremely important in understanding family processes, with feedback from earlier decisions providing constraints for subsequent decisions. The longitudinal nature of most simulations can enable the researcher to manipulate experimentally a number of situational variables in order to explore the dynamic interaction and impact of these variables on group performance and satisfaction (Rowland and Gardner 1973). The game decision making can be interrupted, dissected, and reconstructed, allowing the researcher to obtain a wealth of information on the decision process itself. Bass (1964) notes that the use of a game provides the ability to replicate studies, a possibility which is lacking in field studies. The game can also provide the stimulus for focused interactive verbal protocols when spouses play the game together.

Disadvantages. A major criticism of games as research paradigms is their artificiality. Tedeschi, Schlenker, and Bonoma (1973) blamed this on the arbitrary rules and trivial outcomes which are provided by the experimenter, thus failing to tap the rich behavioral repertoires of subjects and to elicit powerful motives.

Another disadvantage is that "control" may be largely illusory, as respondent variation will result in vastly different wealth conditions at any given time. Any single manipulation later in the game will be seen differentially because of the different frames of reference generated from prior decision sequences. Consequently, a within-household analysis may be required.

Evaluation of the "Bean Game" as a Family Research Paradigm

We used the "Bean Game" (Yeans and Manning 1984) to investigate spousal decision making in a house buying context. Subjects were required to allocate beans to various housing attributes (individually and then jointly) under varying financial conditions (budgets of 20, 15, and 12 beans).

Purpose. The intent for using the Bean Game in this study was to investigate spousal preference prediction (similar to Corfman and Lehmann 1987; Davis, Hoch, and Ragsdale 1986; Kenny and Acitelli 1988) and the house-buying decision process (similar to Park 1982; Park and Lutz 1982).

Process. Eighteen couples participated in the study. First each individual provided importance ratings for the 18 attributes included in the game and then provided ratings for his/her spouse. Each spouse was then instructed to play the game alone at the 20, 15, and 12 bean levels. The couples then played the game together, making any necessary tradeoffs to arrive at a conclusion satisfactory to both.

Brief Overview of the Analyses. We performed analyses both within and across couples. Within couples, we correlated the spouse's importance ratings with his/her partner's and with the bean allocations in the game. Across couples, we obtained pooled correlations among importance ratings and between the importance ratings and the actual allocations in order to make conclusions as to overall influence. The results support the anchoring and adjustment process suggested by Davis, Hoch, and Ragsdale (1986), as one's predicted ratings are closer to one's own ratings than to one's spouse's ratings. The results also indicate that one can better predict one's spouse's ratings with one's own ratings than with one's predicted ratings for the spouse. In aggregate, it appears that husbands can predict wives' ratings better than wives can predict husbands' ratings. By correlating the differences in the importance ratings with the bean allocations across couples, we were able to see if some were consistently "wife-dominated" while others were consistently "husband-dominated." The majority of the correlations indicated that husbands have relatively more influence.

Park (1982) discussed the relative ease of one spouse's determining the other spouse's preference levels on salient *objective* dimensions as opposed to salient *subjective* dimensions. Further, he suggested that couples would reach early agreement on the salient objective dimensions. Our process allowed us to investigate the relationships between spouses' ratings on the salient objective dimensions. Those objective dimensions rated greater than five on a seven-point scale by at least one spouse were investigated; in general, the correlations on these dimensions were not greater than the correlations on all dimensions. Thus, it would appear that the couples do not come to the task in greater agreement on the critical dimensions than on any other dimensions.

The Bean Game's structure allowed us to examine patterns of individual and joint behavior (in the form of bean allocations) across situations involving different levels of financial constraints. One outcome that could not be observed in the methodologies used by Corfman and Lehmann (1987), Davis, Hoch, and Ragsdale (1986), and Park (1982) is that the joint allocations often were more extreme than either of the individual allocations. For both the 20 and 12-bean conditions, joint allocations for five of the 18 dimensions were more extreme. Further, none of the extreme-shift patterns were the same across the two conditions. Thus the results provide little support for an averaging model, but do support the proposition that situational influences are very important.

Park (1982) also suggested that spouses would make concessions based on preference differences across spouses, a relationship found in the Corfman and Lehmann (1987) study. We investigated those dimensions in which there was a large divergence in the importance ratings within couples, and then looked at the joint allocations. We did not find a pattern of concessions toward the spouse with the higher importance ratings. Further, we found that most couples were largely unaware of the existence of the discrepancies.

OVERALL EVALUATION OF THE BEAN GAME

Our observation is that the Bean Game, while somewhat incomplete in its structure, can be used to provide insight. The data collection process for the game (where couples went through the task in the privacy of their own homes) required far less effort than that in the Park (1982) and Park and Lutz (1982) studies. Had we required subjects to do this in the laboratory and then recorded the process, we would have been able to develop decision nets as in the Park studies. An alternative to obtaining protocols for the whole process (each spouse individually and then the joint data collection) would be to have focused discussions of their predictions of each other's preferences, about those dimensions for which there were discrepancies between their importance ratings, and about the final joint bean allocations.

Tedeschi, Schlenker, and Bonoma (1973, p. 197) noted that "like other experimental paradigms, games constrain what the subjects can do." We found this to be true in terms of the attributes selected for consideration in the selection of a house. The game dealt with 18 such criteria, which did not include commonly considered attributes such as resale value, school district, or size of kitchen. The comprehensive nature of the 18 criteria included in the Bean Game was investigated by having 100 respondents (mostly older students) rate 40 housing attributes which had been compiled from a survey of studies dealing with the home purchase and from discussions with realtors. The attributes were factor analyzed; the results indicated that the game seemed to cover factors such as quality of construction and size quite well, but not factors such as neighborhood and extras. One positive note may be interjected, though. To the extent that the focus of the study is the investigation of the *process* involved, even a somewhat incomplete framework such as the Bean Game seems to provide insight.

The game's structure can also be questioned on other grounds. The game was developed by consumer economists for pedagogical purposes in mind. The resulting normative structure may be bothersome to subjects. The budget is set by the bean level, and subjects are required to allocate all of the beans. The implied notion is to get the best house possible given the constraints. Some subjects, upon realizing that they were going to end up with a disappointing house in any event, might have chosen to spend less than the total number of beans on the house and used the remaining beans for other consumer goods. In other words, tradeoffs outside the housing decision may exist in the real world. Allowing couples to choose between (1) a 20-bean house and their deteriorating car and (2) a five-bean car and a 15-bean house would provide a richer context and allow the study of non-comparable alternatives.

The preliminary study reported here does indicate that the game environment can be used to investigate issues studied earlier through the use of more elaborate procedures. The Park (1982) study required a tremendous amount of effort on the part of the subjects and the investigators. Adding the collection of protocols to the use of the game would have made data collection much more difficult, but it still would have been simpler than the procedures used by Park. Further, the game environment makes it feasible for the subjects to go through the process individually before doing it jointly; dealing with actual consumers did not allow this luxury. As in the study using the information integration methodology used by Troutman and Shanteau (1989), the individual- then-joint process allowed the discovery of instances where the joint decisions were more extreme than either of the two individual decisions, indicating that the simple averaging model may not explain the joint decision-making process.

The bean allocations provide an easily quantifiable dependent measure not available in the

Park (1982) and Corfman and Lehmann (1987) studies. Concessions could be seen on an attribute basis, allowing analysis of more than just a dichotomous (choice-based) measure.

INFORMATION INTEGRATION THEORY APPROACH TO HUSBAND-WIFE DECISION MAKING

James Shanteau, Kansas State University
C. Michael Troutman, Charles, Charles and Associates

ABSTRACT

The approach described in this presentation addresses husband-wife decision making by focusing on the relation between spouses' individual and collective judgments. The purpose is to illustrate a new method for examining how spouses make joint decisions. Before considering the proposed approach, a methodological review is offered of prior approaches to dyadic decision making. This is intended to show the need for an alternative framework. A new perspective is then suggested to examine how spouses make joint decisions. This method is illustrated in three experiments of couples' collective decisions about medical services.

BACKGROUND

Research on family decision making has traditionally focused on the influence that each spouse has on consumer choices (Engel, Blackwell, & Miniard, 1986). Although various research procedures have been used, the measurement of social power has proved difficult (Turk & Bell, 1972). Moreover, there is a fundamental question about the role of social power in couple decision making. A discussion between husband and wife, for example, may involve both power issues and an exchange of information (Park, 1982). Thus, these methods may have been blind to important processes in collective decision making.

When spouses interact to make a decision, the outcome seems simple--they either agree or disagree. Even a casual analysis of husband-wife interaction, however, indicates that matters are more complicated than that. Whether the spouses agree or disagree is not so important in the present view as the sharing of information. To understand how collective decisions are made, it is necessary to examine simultaneously the husband's and the wife's individual decision processes as well as the collective decision processes. In this way, it becomes possible to analyze in detail how joint decisions relate to individual decisions.

ALTERNATIVE APPROACH

The proposed approach derives from Anderson's (1981, 1982) information integration theory (IIT). This theory assumes that there are two fundamental processes involved in making decisions. The first is the evaluation process by which psychological value is attached to information. The second process involves the integration of separate pieces of information into a unitary judgment. The former is reflected in the estimation of weight and scale values, while the latter is reflected in an algebraic integration model.

One advantage of IIT is that it can be applied at the level of a single subject/couple. This means

that both the parameter estimates and the model form can be determined and compared for each individual and/or couple. As shown by Troutman & Shanteau (1989), this provides important advantages over previous approaches (also see Anderson & Armstrong, 1989).

The research described here appears to contradict Sheth's (1974) assertion that the area of couple decision making has been researched sufficiently so that a comprehensive theory can be developed. The present findings suggest that the critical cognitive component remains to be understood.

LONGITUDINAL METHODS FOR FAMILY CONSUMER RESEARCH

Alladi Vankatesh, University of California, Berkeley

INTRODUCTION

Longitudinal analysis is particularly suited for studies that are designed to assess the effects of variables over time. The value of such research addresses issues relating to changes, impacts and cause-effect relationships (Nicosia 1965; Bucklin and Carnan 1967; Eckland, 1968; Crider et al., 1973; Winer 1983). In spite of their appeal, longitudinal designs present several problems which need careful attention (Nicosia 1965; Crider, et al., 1973). In general, the problems may be classified as those relating to (a) attrition of the sampling units; (b) the diminishing relevance of certain research issues over time, (c) response biases and (d) high cost. These problems are in addition to those

faced in the standard cross-sectional survey designs. In this paper, a review of longitudinal methods as appropriate to household research will be presented. The Paper will also include an empirical study of U.S. families conducted during 1984-86 using CATI (Computer Assisted Telephone Interviewing) technique and time diary data collection procedures.

A GENERAL OVERVIEW

Longitudinal studies may be classified in two ways, according to the nature of sampling scheme, or according to the data collection procedures.

Nature of the Sampling Scheme: Based on a survey of different behavioral and social science disciplines, we identify four types of studies: (a) medium-term (1-3 years), qualitative studies of a limited number (about 25-50) of families, (b) long-term (5-10 years), qualitative studies of a limited number of families, (c) multivariate, quantitative studies of a small sample of families (about 50-150), and (d) multivariate, quantitative studies of medium to large sample of families. Types (a) and (b) research are usually undertaken by anthropologists, medical sociologists, applied researchers in family therapy, and development psychologists. Types (c) and (d) studies are found among demographers, family sociologists, applied economists, and marketing researchers.

Data Collection Procedures: We have identified different studies based on data collection procedures. Longitudinal research can utilize primary data or secondary data. Some researchers would add a third category, namely, field experiments or quasi-experiments, to identify the collection of longitudinal context where some type of intervention is examined via a pre-post, or multi-period data collection procedures or measures.

In this paper our major emphasis is on primary data collection as it pertains to household research. Since much of the family research in Economics and Demography uses secondary data, a small section of the paper will be devoted to it towards that end.

SELECTED ISSUES IN FAMILY RESEARCH

An Overview of Longitudinal Family Studies: We find that different disciplines have different orientations in the way they conduct family studies. Some examples are given below.

Family Development research theorists use life cycle models for their research. Most recently, there has been an emphasis on using family life events as markers of family life change. In this type of research, the researchers are less concerned with representativeness of their sampling schemes and more interested in abnormal samples as the basis for theory generation in family development.

Marketing researchers use *panels* of families for studying consumption patterns. Panel studies of purchase behavior of grocery products have undergone revolutionary changes in the last ten years. The Berkeley panel studies of the sixties used extensive time diaries for recording weekly grocery shopping. In the last ten years the scanner data

technology has completely altered the nature of this type of research. The methodological considerations in these two types of research are quite different and there are other interesting issues of contract that need to be reviewed.

Anthropological studies of family behavior are based on developing family ethnographies over a period of time. Because of the intense nature of these studies and the fact that most anthropological research is carried out in cultures other than that of the researcher, there are extensive cost constraints in conducting this type of research. There are also other research issues which do not surface in the standard survey type of research. Ethnographic research involves the use of informants, recording of oral histories, and pursuing of observational techniques. It is not uncommon for anthropologists to return to their sites to observe changes etc., and continue where they left off.

Researchers of time-budget studies perform extensive analysis of family time allocation patterns across different activities. Time-budget studies are carried out in different parts of the world and much comparative data are now available for performing research using a multi-cultural perspective. An important issue in time-budget studies refers to the data collection procedures and the validity of the reported data.

Some Research Issues: In contrast to individual oriented research, research on families presents some special kinds of problems. In typical family research, we are concerned with both structural (e.g. family composition) variables and individual family member variables. Specifically, in longitudinal studies, both the structural issue in family research relates to the definition of a continuing or longitudinal family, taking into account the fact that a family's composition may change from one period to another. The paper will give an example of the Reciprocal Rule Model as a way to determining family composition appropriate for longitudinal studies.

A general problem in longitudinal analysis is the attrition bias, that is, bias due to the dropping out of families from one wave to the next. While replacement of families is a solution, we now have procedures available to estimate biases due to attrition which utilize a combination of probit/OLS techniques.

In typical survey type situations family data are collected from a single member within the family (e.g. husband or wife). Because of the inherent biases in such reporting, researchers have been arguing for collecting data from both husband and wife. Such data are still not accurate because we now have bias from two sources instead of a single source. We will illustrate a method of data collection to minimize dual bias.

AN EMPIRICAL STUDY

For this paper, data collected from a national sample of 614 households, between 1984 and 1986, will be used to provide examples of the issues discussed above. The data pertain to the adoption

and use of personal computers at home. The project was funded by the National Science Foundation.

Message Framing Effects on Product Judgments

Joan Meyers-Levy, Northwestern University
Durairaj Maheswaran, New York University

ABSTRACT

The purpose of this paper is to provide a summary of a special topic session organized to address recent developments in framing research in consumer behavior. The papers presented in this session examined both how and when consumers' judgments vary as a function of the way message information is framed. In addition, they explored the theoretical and empirical implications of such framing effects.

OVERVIEW

Recent research has shown that people's choices and judgments can be influenced not only by the content of communicated information but also by the way the information is described or framed (Kahneman and Tversky 1979; Meyerowitz and Chaiken 1987; Puto 1987; Tversky and Kahneman 1982). Two paradigms have prevailed in framing effect investigations. In consumer research that assumes a decision theory approach, people typically are presented with two discrete options to a problem, one representing a risky outcome and the other a certain outcome. People's choice of option is compared when these same two options are expressed as either as gains or losses (Kahneman and Tversky 1979, 1982; Puto 1987; Thaler 1985).

A second paradigm prevails in research that examines consumers' response to persuasive communications. Here consumers' overall product judgments are examined after being presented with one of several sets of message claims that are alternatively framed by presenting positive versus negative attribute labels (e.g., "ground beef described as "75% lean" or "25% fat", Levin and Gaeth 1988", positive versus negative consequences (e.g., "... women who [do/do not do] breast self examination have an [increased/decreased] chance of finding a tumor in the early, more treatable state of the disease, Meyerowitz and Chaiken 1987", or nonverbal versus verbal descriptions, "35 grams of protein" versus "excellent protein content" Scammon 1977). This session focused on research that pursued this latter approach to investigating framing effects.

Each of the four papers presented in the session report the findings of empirical research which explores the extent to which the effectiveness of alternative message framing manipulations is contingent on situational and/or individual difference variables. Thus these papers add significantly to our theoretical understanding of framing effects by attempting to go beyond just simple demonstrations of framing effects and clarifying when a particular framing effect is likely to be observed, reversed, or eliminated.

The first paper by Gary J. Gaeth, Irvin P. Levin, Deborah A. Cours and Susan Combs explores the interactive effects of personal experience and

framing where framing is manipulated in terms of positively versus negatively phrased product attribute labels. The subsequent framing effect study by Joan Meyers-Levy and Durairaj Maheswaran explores whether some of the conflicting outcomes observed in framing effect studies in the literature can be accounted for by differences in people's use of detailed versus more cursory processing. The study reported investigates how the effectiveness of a message that focuses on either benefits received ("positive framing") or benefits foregone ("negative framing") varies as a function of product risk and personal relevance. A third paper by Nancy Artz examines framing effects of a different sort. The effect of numeric versus verbal message framing is explored as a function of source expertise and individual's predisposition to favor quantitative versus qualitative information. Finally, the last paper by Carolyn Yoon, Joan Meyers-Levy and Alice Tybout investigates yet another type of framing effect. This paper explores the extent to which simply framing a hypothetical event as having occurred in the past or as to take place in the future leads people to engage in alternative search processes in memory and thus results in the generation of event descriptions that vary in the degree of detail they contain and their predictability. More detailed abstracts of the papers provided by the authors are presented next.

ABSTRACTS

Framing of Attribute Information in Product Description

Gary J. Gaeth, Irvin P. Levin, Deborah A. Cours and Susan Combs
University of Iowa

Consumers' evaluation of products are influenced by the manner in which information about key attributes is labeled or "framed". In prior research we found that ground beef was judged to be of higher quality when it was labeled "75% lean" rather than "25% fat". However, the difference in response to "75% lean" and "25% fat" meat was attenuated when consumers actually tasted the meat (Levin and Gaeth 1988). Furthermore, both theory and research suggest that the temporal sequencing of information provided by outside sources (e.g., ads) and information gained from personal experience is a crucial factor affecting consumer impressions.

A recent study in our laboratory extends earlier work by examining the interactive effects of information frame and personal experience within a dynamic and realistic temporal sequence of information acquisition. College students were asked to evaluate the usefulness of a word processing system at different points in the following sequence of information and experience: basic introductory

literature about the system and description of available features; observations of the system in use; hands on experience with the word processor. These three phases were spaced one week apart. Subjects also received a "frame" which was a written summary of the effects of using the word processor on a previous class of students. This information was framed positively (% of students who improved their grade) for some subjects and negatively (% of students who did not improve their grade) for others.

Consistent with prior work, evaluation tended to be more favorable in the positive condition than in the negative condition, but the magnitude of this effect differed depending on when in the sequence the framed information was introduced and how often subjects were required to update their evaluations. When subjects were asked to re-evaluate their opinions following each new phase of information, a transient recency effect was obtained. That is, framed information presented at an early phase affected judgments at that point in time but not judgments made at a later date. By contrast, when subjects were asked to respond only at the end of the sequence of information (in some cases three weeks later), even early information had a long-term effect. This set of findings fits current theorizing on the role of response mode on belief updating (Hogarth and Einhorn 1989).

This study illustrates the value of using a well-established cognitive phenomenon, in this case the information framing effect, for discovering the influence of information introduced at varying times during the formation of product impressions. Our long-term goal is to use studies of this type to develop a comprehensive model of product impression formation based on varying amounts, source and sequences of product-relevant information.

Investigating Message Framing Effects on Consumer Judgments: The Influence of Personal Relevance and Product Risk

Joan Meyers-Levy, Northwestern University
Durairaj Maheswaran, New York University

Research by Meyerowitz and Chaiken (1987) found that positively framed messages, which noted the positive consequences of using a product, were more effective than were negatively framed messages, which highlighted negative consequences. However, Levin and Gaeth (1988) observed reverse framing outcomes when they described a product using positively or negatively phrased attribute labels. The current research attempted to reconcile these disparate findings by positing that the direction of framing effects may depend on whether message information is processed in a detailed or cursory, heuristic manner.

In an experiment, subjects received manipulations intended to vary the degree to which they would use detailed or heuristic processing in comprehending message information that was positively or negatively framed to highlight either benefits gained or benefits foregone by

buying/failing to buy a product. More specifically, subjects were presented with materials that discussed the role of cholesterol in the development of heart disease. The degree to which subjects engaged in relatively detailed or heuristic processing was manipulated in two ways. First, the extent to which concern over cholesterol was portrayed as personally relevant to subjects was varied. Second, the tradeoff of product benefits and risk was varied by informing subjects that the advocated product involved a fairly high risk (i.e., a nine month test of the product by the American Heart Association showed that product use resulted in a significant reduction of cholesterol for 80% of test participants but 20% of participants evidenced enhanced cholesterol levels) or a relatively low risk (i.e., the corresponding percentages were 98% and 2%).

It was expected that detailed processing would be greatest in the high personal relevance/high product risk condition. As a result, negatively framed information, which was highly diagnostic and consequential to subjects, would receive disproportionate weight and impact relative to positively framed information and produce greater compliance. However, heuristic processing would be greatest in the low personal relevance/low product risk condition. Here it was anticipated that subjects might use the valence of the message frame as a heuristic cue for determining their disposition and the result would be greater compliance when the message was positively rather than negatively framed.

Results were consistent with the expectations. Indeed it appeared that negatively framed messages were more effective when people processed the message in a predominantly detailed manner, whereas positively framed messages were superior when the message was heuristically processed.

Individual Differences in Preference for Numeric/Verbal Framing

Nancy Artz, Northwestern University

A variety of researchers (e.g., Holbrook 1978; Scammon 1977; Yalch and Elmore-Yalch 1984) have examined the effects of numeric and verbal advertising claims (e.g., "3 grams of fiber" versus "high in fiber"). The mixed results these researchers observed are difficult to interpret because the numeric and verbal claims were not clearly designed to convey equivalent information. A study was undertaken with numeric and verbal claims that conveyed equivalent information to examine numeric/verbal execution as a framing device.

Subjects were presented either numeric or verbal claims about a cereal from either an expert or novice source. For example, the verbal claim included the phrase "contains average amount of protein" while the corresponding numeric claim was "contains 3 grams of protein average cereal has 3 grams."

Thus the numeric and verbal claims conveyed equivalent information but were framed with either

numeric or verbal execution. Subjects indicated their beliefs about the product's nutritiousness, and these responses served as a dependent measure in an ANOVA.

There was a significant three-way interaction between numeric/verbal frame, source expertise, and an individual difference variable of whether a person's undergraduate training was quantitative or qualitative ($p < .01$). Specifically, source expertise influenced product beliefs only when the numeric claim was presented to quantitatively oriented individuals.

Overall, the pattern of results suggests that there are individual differences in preference for numeric frames and this preference may play a motivational role in message processing. Individuals favorably predisposed to a particular frame appear to process claims using that frame versus the alternative one differently.

Exploring Temporal Perspective Framing Effects

Carolyn Yoon, Duke University

Joan Meyers-Levy, Northwestern University

Alice Tybout, Northwestern University

A somewhat tenuous observation that has emerged in the social cognition literature is that people's descriptions and judgments of hypothetical events differ depending on whether the events are retrospectively framed as having already occurred or prospectively framed as to occur in the future (Bavelas 1973; Webb and Watzke reported in Weick 1979). It appears that when individuals are asked to look backward and describe a hypothetical event, they write longer, more detailed, concrete, and conventional descriptions of it; when they look forward and describe this same event, their descriptions tend to be briefer, more abstract and they mention more unusual, unconventional features.

We hypothesized that such temporal framing effects might occur because of differences in the memory search processes and cognitive elaboration these temporal frames stimulate. Events that are situated in the future are by definition considerably undetermined or uncertain, and such uncertainty may prompt a broad search of memory. This broad search may absorb considerable processing time, thereby leaving less time for writing a description of the event. This broad search also is more likely to uncover unusual, less predictable outcomes that might be associated with the event. By contrast, hypothetical events that are situated in the past may be regarded as more certain, even if they are unknown to the individual. Accordingly, people may engage in a more constrained memory search, focusing on a most likely or representative (Kahneman and Tversky 1982) outcome given the situation. Thus people may report a familiar, prototypical event and this is likely to be elaborated on in considerable detail.

A study was conducted to explore the existence of such temporal perspective framing effects as they might relate to a consumer relevant situation and to investigate the plausibility of the

proposed explanation. Subjects were given a priming task intended to encourage either a narrow or broad search of memory. Then they were asked either to look forward or to look backward in time and describe the purchase behavior and situation that a hypothetical individual will confront/confronted when buying a gift for a parent.

Some evidence supported the prediction that relative to prospective framing, retrospective framing resulted in descriptions that were more detail specific (e.g., greater specification of the gift, more adjectives that described the gift, greater number of brands mentioned, etc.). Some evidence also suggested that such framing effects may stem from the breadth of memory search and elaboration stimulated by the temporal perspective frame.

ACKNOWLEDGEMENT

The session coordinators thank Alice Tybout of Northwestern University for Chairing the session and Chris Puto of University of Arizona for providing valuable comments as discussant.

The Effects of Music in Conditioning Brand Preference: Replication and Extension

Kunal Basu, McGill University
Marvin Goldberg, McGill University
Gerald J. Gorn, University of British Columbia

The role of music in influencing brand preference has been examined in Marketing/Advertising with varying paradigmatic orientations. Of the two dominant approaches, one is based on presumed characteristics of communication processes (i.e., the hierarchy of effects, or information processing), and the other, on classical conditioning. In the first, music is viewed as a peripheral cue in advertising or some brand-related message, and its effects traced through viewers'/customers' information processing stages. The emphasis here is on the potential effects of music on recipients' attention, as well as attitude towards an ad, either by itself, or in combination with other executional aspects.

Classical conditioning approaches, however, focus directly on the impact of music on brand preference or choice, without necessarily examining intervening cognitive mechanisms (i.e., comprehension, elaboration or evaluation). The classical associative relationship between an unconditioned stimulus (e.g., music), and the target conditioned stimulus (i.e., brand) is examined experimentally, focusing on design characteristics that alleviate demand characteristics and allow reliable and valid interpretation of findings.

Despite the potential for such a direct relationship between music and brand preference (Gorn 1982; Nord and Peter 1980; Allen and Madden 1985; McSweeney and Bierley 1984; Shimp 1989), the effect awaits replication and extensions that cover the range of the phenomenon.

STUDY

Subjects were asked to participate in a market research project to evaluate the quality of a boom box. They were exposed to a neutral (i.e., unfamiliar) brand of boom box (conditioned stimulus), in the context of music (unconditioned stimulus) played through its speakers. Four experimental conditions were created, with different musical pieces played to each group, each followed by an ad for an unfamiliar low-involvement product. The musical pieces were pretested to elicit very positive, positive, negative and very negative reactions. It was expected that subjects' evaluations of the speakers would be affected by their level of liking towards the music played on the speakers.

Results of the study were discussed with attention to both persuasion as well as demand assessment indices.

Classical Conditioning of Negative Attitudes

Elnora W. Stuart, Winthrop College
Terence A. Shimp, University of South Carolina
Randall W. Engle, University of South Carolina¹

ABSTRACT

Consumer researchers in recent years have displayed growing interest in the classical conditioning paradigm. Published efforts to this point, however, have focused exclusively on testing positive attitudinal conditioning. The present research program departs from this pattern by examining the possibility of conditioning negative attitudes toward consumer goods. Results from five experiments--all utilizing multiple trials with forward conditioning and random control groups--provide consistent albeit modest support demonstrating the conditionability of consumer goods to negative stimuli.

WHY STUDY NEGATIVE CONDITIONING?

While marketing communications efforts typically are aimed at persuading consumers to purchase a particular brand and thus seek to generate more positive attitudes toward the brand, there also are a number of situations in which marketing activities may be classified as attempts at demarketing. For instance, advertising is frequently used in public service campaigns to dissuade consumers from participating in a variety of activities that are harmful to their health including the use of tobacco, illegal drugs, and the excessive use of alcohol, especially when driving.

In addition to these proactive demarketing campaigns, negative conditioning, or some other form of associative learning, may occur unintentionally in the marketplace when a consumption object (product, brand, or store) finds itself in a contiguous relation with an undesirable stimulus. For example, random advertising placements on television or in a magazine may result in a food product being advertised beside a noncomplimentary item. Or specific brands may be shown in conjunction with revolting, gruesome, or grotesque scenes in movies or television programs. Another form of negative conditioning may occur when the consumer spots an especially unappealing person wearing a particular brand of apparel or using some other product. Rumors represent still another form of negative-like unconditioned stimulus that can wreak untold damage on a brand's reputation and image.

Happenstances in the marketplace are not always kind to the images marketers most prefer for their brands. It is for this reason that negative conditioning--along with negative information in

general (cf. Scott and Tybout 1981; Weinberger, Allen, and Dillon 1981)--is worthy of serious consumer scholarship.

PRIOR RESEARCH

There is ample evidence of negative conditioning in the basic classical conditioning literature. Most notable is the rich line of research into aversive conditioning, especially to taste, through the use of such negative USs as electric shock and nausea induced through chemical injection or radiation. Many may remember the classic film "A Clockwork Orange" in which the conditioned aversion to violence, women, and accidentally to Beethoven's "Ninth Symphony" was so strong that the subject Alex subsequently attempted to end his life rather than listen to the "Ninth."

Studies have supported negative conditioning of attitudes either through the use of electric shock (e.g., Zanna, Kiesler, and Pilkonis 1970) or through pairing with negatively valenced words (e.g., Moore, Moore, and Hauck 1982). Gorn's (1982) seminal conditioning experiments in the marketing literature included one experimental group that was exposed to positively evaluated music from "Grease" and a second group where the CS, a pen, was paired with what amounted to a negative US, i.e., classical Eastern Indian music. Gorn's results, although the research was not designed for this purpose, evidenced negative conditioning: subjects in the undesirable music group selected the color pen shown in the experiments only 30 percent of the time, somewhat less than might be expected by chance.

The current research program includes five experiments that attempt to demonstrate a downward change in attitude through the multiple-trial presentation of negatively valenced unconditioned stimuli. These stimuli are either systematically paired with consumer goods (in a forward conditioning pattern) or, for comparison purposes, are presented the same numbers of times but in random order with respect to the consumer goods that serve as conditioned stimuli. The research paradigm in all five experiments follows successful procedures established previously in our series of positive conditioning experiments, especially the previous Experiment 4 (Stuart, Shimp, and Engle 1987).

EXPERIMENT 1

In adapting Stuart et al.'s (1987) positive conditioning procedures, this initial negative conditioning experiment sought to condition negative attitudes toward fictitious Brand L toothpaste using four distasteful, unpleasant scenes that served as a negatively valenced US composite.

¹Appreciation is extended to the American Lung Association of South Carolina and the Winthrop College Foundation for their financial support.

Method

Brand L toothpaste, the conditioned stimulus (CS), was operationalized by the visual presentation of a green and yellow tube presented via a color slide presentation. The unconditioned stimulus (US) was operationalized similarly through the slide presentation of four unpleasant scenes. These four scenes, selected through pretesting as eliciting strong negative responses included (1) a trash dump with rusty cans, (2) a trash dump with old cardboard boxes, (3) leaking chemical storage drums, and (4) a large black mound of decomposing vegetation.

The experiment included forward-conditioning and random-control groups. The forward-conditioning group received 10 conditioning trials in which a 7.5-second presentation of Brand L toothpaste, the CS, was always followed by a 7.5-second presentation of one of the four unpleasant US scenes. Two seconds of down time (a darkened screen) followed each trial, the purpose of which was to alert subjects to the subsequent trial rather than having each trial merge into the next. Strict timing of all presentations was accomplished through the use of a programmable dissolve unit, a sync-pulse recorder and multiple projectors. Also included in the presentation were filler trials that paired products other than Brand L toothpaste with affectively neutral scenes, the purpose of which was to reduce hypothesis guessing (see Stuart et al. 1987 for further explanation). In comparison to the forward-conditioning group, the random-control group received the same number of presentations of the CS, the US, the down times, and the filler material but in random order with respect to each other. In other words, the relationship between CS and US in the random control group was entirely nonsystematic, hence preventing the formation of a predictiveness relationship between CS and US (Rescorla 1967).

In order to prevent excessive boredom and to maintain attention during all ten conditioning trials, the presentation was broken into three intervals. Following each of the first two intervals subjects completed attitudinal measures pertaining to two filler products (although these results are not of interest). Following the third and final portion of the slide presentation, subjects rated Brand L toothpaste on various attitudinal scale items. Subjects were then advised that a written statement explaining the study would be mailed at a later date, cautioned not to discuss the study, and thanked for their participation.

Measures

Four measures of attitude toward the Brand L toothpaste served as indicators of a conditioned attitudinal response: (1) a summated score of seven 7-point semantic differential items (good-bad, high quality-poor quality, like very much-dislike very much, superior-inferior, attractive-unattractive, pleasant-unpleasant, and interesting-boring); (2) a 7-point global evaluative item ("Overall my feeling about Brand L toothpaste is favorable-unfavorable");

(3) an 11-point measure of purchase intentions ("All things considered, if you were to purchase toothpaste on one of your next several trips to the supermarket, what are the chances in 10 that you would purchase Brand L toothpaste if it were available?"); and (4) a graphic rating scale consisting of a 120-millimeter line on which subjects placed an "X" to indicate their feelings toward Brand L toothpaste from very positive to very negative.

Results

Forty-seven subjects participated in Experiment 1, 24 in the conditioning group and 23 in the random-control group. The Table presents means, standard deviations, and t-values. While the behavioral intentions item is the only one to reach statistical significance ($t = -1.84$; $p < .05$, one-tailed), expected directional differences were evidenced for the other scales as well. That is, for all measures the means of the forward-conditioning group were predictably lower (less positive) than for the random-control group.

It is informative to compare the mean scores in this experiment with scores obtained in our earlier positive conditioning experiments using Brand L toothpaste as the conditioned stimulus (Stuart et al. 1987). The best comparison with the present experiment, due to the use of identical procedures, is the "forward 7.5/7.5" group in Stuart et al.'s Experiment 4. On the semantic differential, overall, behavioral intentions, and graphic rating scales, the positive conditioning (random control) groups in the prior experiment had means of 38.8 (24.3), 5.6 (3.33), 6.76 (2.33), and 94.28 (45.74). These averages compare with the present means (see Table) in the negative conditioning (random control) groups of 18.33 (20.13), 2.29 (2.87), 1.08 (2.13), and 26.83 (32.0). It is apparent that the negatively valenced USs in the present forward conditioning trials had a dramatic impact in reducing attitudes toward Brand L toothpaste in comparison to the positive USs in the earlier experiment. However, as to be expected, the differences in the two experiments between the positive and negative random control groups' mean scores are relatively trivial.

EXPERIMENT 2

A number of different negative scenes were pretested and four of these were selected for inclusion in Experiment 1. However, two of the scenes that had ranked very low (lower, in fact, than three that were included in the first experiment) were not used in Experiment 1 because of their rather gruesome nature. One included a large number of human skulls stacked on a shelf (reminiscent of a scene from the Cambodian killing fields) and the other was of a shrunken human head. Because Experiment 1 exhibited directional effects but did not reach statistical significance for three of the four attitudinal measures, it was felt that the use of these more negative USs might elicit stronger negative results. Thus the US in Experiment 2 included these

*p < .05, one-tailed.

two scenes plus the scenes of the trash dump with rusted cans and the trash dump with boxes. Brand L toothpaste again was the CS.

Method

Forty-five subjects participated in Experiment 2, 23 and 22 respectively in the forward-conditioning and random-control groups. As in Experiment 1, the conditioning group was exposed to 10 pairings of CS followed by US, while the random-control group viewed 10 separate showings of CS and US not systematically paired with one another. The same four measures of conditioned attitude were again obtained in the same three-part fashion.

Results

The Table shows the means, standard deviations, and t-test results for the two groups included in Experiment 2. Again, for all measures the differences between the forward conditioning and random control groups were in the right direction but only the graphic rating scale revealed the conditioning group to have a significantly less favorable attitude toward Brand L toothpaste than did the random-control group ($t = -1.86$; $p < .05$, one-tailed).

EXPERIMENT 3

While the largest amount of conditioning typically occurs during the first few conditioning trials, bringing the conditioned response to asymptote may require a substantial number of trials (Domjan and Burkhard 1985). Therefore, Experiment 3 was designed to replicate Experiment 2 but with 20 instead of 10 conditioning trials. Brand L toothpaste again was paired with the same four affectively negative scenes used in Experiment 2. Experimental conditions and procedures are otherwise identical to those in Experiment 2.

Results

Thirty-six student subjects, 18 per group, participated in Experiment 3. The Table again shows the means, standard deviations, and t-test results for the forward-conditioning and random-control groups. Results present the expected directional differences but none of the four measures of attitude toward the brand reached levels of statistical significance.

EXPERIMENTS 4 AND 5

The first three experiments offered modest demonstration that systematic pairing of a fictitious brand of toothpaste with negatively valenced visual scenes leads to less favorable attitudes toward that brand. However, the inability to obtain stronger effects was possibly due to two aspects of our experimental procedures. First, it may be that the US scenes and the CS object, Brand L toothpaste, may not have been sufficiently similar to engender stronger negative conditioning. There is evidence in the basic conditioning literature (e.g., Schwartz

1989) that CS and US similarity, or belongingness, is a requisite for strong conditioning effects. Conditioned and unconditioned stimuli are said to be similar to one another when they share common physical features or sensory properties. For example, in conditioning experiments with animals, it is fairly simple to condition aversive behavior to taste but more difficult to condition such a response to odor alone (Holder and Garcia 1987). A second possible problem with Experiments 1-3 was the possibility of floor effects. That is, an already unfavorable attitude toward Brand L toothpaste (as evidenced by the random-control groups' low mean scores) would have made it difficult for the conditioning procedure to further attenuate the forward-conditioning group's mean attitude.

Therefore, Experiments 4 and 5 sought to examine negative conditioning using a different CS. It was thought that a cola brand might be more sensitive than toothpaste to the negative visual scenes employed previously as USs. Cragmont Cola, a red and white can of cola possessing no distinctive features other than the somewhat sophisticated-sounding brand name, was selected. Cragmont is a real regional brand of cola that was unknown to our subjects due to its unavailability in the study region. However, in some of our other conditioning experiments (unrelated to the present experiments), we had found that Cragmont is rated very favorably by similar student subjects. Hence, the use of Cragmont Cola prevented the floor-effect problem and also was thought to provide a better "fit" with the unpleasant US scenes. This possibility is purely speculative and remained an empirical issue until the experiments were performed.

The US included in Experiment 4 included the four negatively valenced scenes included in Experiments 2 and 3, that is the shrunken head, shelf with human skulls, trash dump with rusty cans, and trash dump with old cardboard boxes. Experiment 5 was identical to Experiment 4 with the exception that leaking chemical storage drums and a large black mound of decomposing vegetation were substituted for the shrunken human head and shelf with human skulls. To enhance the possibility of obtaining significant results, subjects were exposed to 20 conditioning trials. Again, all experimental sessions included small groups of student subjects and measurement was divided into three separate administrations.

Results

The Table presents means, standard deviations and t-test results for the forward-conditioning and random-control groups included in Experiments 4 and 5. Experiment 4 again reveals the expected directional differences between the two groups but an absence of significant effects for any of the four measures. The differences between the two groups are more pronounced in Experiment 5, but only the overall rating scale obtained statistical significance ($t = -1.80$; $p < .04$, one-tailed).

DISCUSSION

Although statistically significant differences between the conditioning and random-control groups were isolated, the consistent replication of directional results in five separate experiments provides plausible support that attitudes toward consumer goods are susceptible to negative conditioning. Indeed, the replication of results in five separate experiments may suggest far stronger support for theory in general than significant differences found in a single empirical test.

Why our experiments did not evidence stronger results remains problematic. One possibility may lie in the measures used. It has been suggested that positive and negative affect are essentially two separate dimensions (Abelson, Kinder, Peters, and Fiske 1982; Allen and Madden 1985). The use of single adjective scales such as those employed by Abelson et al. (1982) and Allen and Madden (1985) may have provided better measures of negative affect and allowed differences between the conditioning and control groups to reach levels of significance.

A second possible explanation lies in the belongingness between the CS brands and US scenes. As described previously, an important requirement for classical conditioning is that conditioned and unconditioned stimuli be similar or share a belongingness relation (Domjan and Burkhard 1985). This suggests that a variety of appropriate CS-US relationships must be present for an associative mechanism to be activated and thus permit learning to occur (Testa 1974). This is not to say that conditioning is not possible with less related CS-US combinations but that some are learned more easily. Unfortunately, little is known about requirements for CS-US belongingness, only that certain combinations are better. Stronger effects may have obtained had other types of pictures or possibly semantic stimuli, i.e., negatively valenced words, been utilized.

Quite obviously, these modest results warrant caution in concluding that classical conditioning of negative attitudes occurs in actual marketing communications situations. Still, these results suggest that organizations seeking to engage in demarketing activities may consider including the sort of stimuli in their messages which would provide some approximation of negative US-CS pairings. Likewise, advertisers and other marketing communicators must be cautious and avoid, where possible, having their brands shown in conjunction with undesirable objects, events, or people.

Order Effects in Consumer Judgment, Choice, and Memory: The Role of Initial Processing Goals

Frank R. Kardes, University of Cincinnati
Paul M. Herr, Indiana University

ABSTRACT

Consumer information processing is a dynamic process that unfolds over time as information is encountered. However, little research exists on the effects of order of presentation on consumer judgment, choice, and memory. A new procedure was developed to permit the detection of order effects in choice as well as in judgment. The results revealed that strong primacy effects in judgment and choice occur when consumers do not expect a final evaluation or choice task. When the choice task is anticipated, however, these primacy effects are eliminated. The results also indicate that the relationship between judgment and memory depends on the pattern of order effects observed in judgment and memory.

PRIMACY AND RECENCY EFFECTS

The order in which information is encountered has a strong impact on judgments of products. Sometimes information appearing early in a sequence has a stronger effect on judgment than does subsequent information (a primacy effect), whereas at other times, later items dominate earlier items (a recency effect). Although a rather extensive literature exists on order effects (for reviews see Anderson 1981, 1982; Dreben, Fiske, and Hastie 1979; Einhorn and Hogarth 1987; Jones and Goethals 1972; Lichtenstein and Srull 1987; Wyer 1974; Wyer and Carlston 1979), it is still difficult to predict whether primacy or recency will occur in a given situation.

The present experiment differs from previous research in several ways: (1) we focused on judgments of products rather than on judgments of people, (2) a two-object paradigm was employed, (3) recall and judgment were measured in a choice context instead of an impression formation context, and (4) order effects were investigated in choice as well as in judgment. Moreover, the present study is a continuation of a program of research on context effects in judgment and choice (Kardes, Herr, and Marilino 1989).

Jones and Goethals (1972) suggest that judgment primacy effects are likely when new information is integrated with previously encountered information. When this continuous, on-line, judgment-updating process occurs, earlier information is likely to color the way subsequent information is interpreted (the change-in-meaning hypothesis). Judgment recency effects, on the other hand, are likely when new information is processed independently from earlier information (and when an attention decrement over time is unlikely). Hence, when consumers are motivated to integrate information to form a coherent overall impression of a product (an impression set), judgment primacy should occur. In contrast, when the information

integration process is disrupted by instructions to memorize information (a memory set), judgment recency should occur.

It is unclear how a choice set should influence order effects in judgment. Choice processing is complex because it often involves integration and differentiation (Tetlock and Kim 1987). Consumers often integrate information within alternatives and differentiate (e.g., compare and contrast) information between alternatives. Tetlock's (1989) program of research has shown that when people reason about political issues in a cognitively complex fashion, they are less likely to exhibit overconfidence and other judgmental biases (e.g., Kahneman, Slovic, and Tversky 1982; Nisbett and Ross 1980). If a choice set encourages cognitively complex reasoning, and if complex reasoning reduces the magnitude of judgmental biases, then primacy and recency effects in judgment might also be diminished when choice processing occurs.

THE RELATIONSHIP BETWEEN JUDGMENT AND MEMORY

Although primacy or recency tend to occur in judgment, primacy and recency tend to occur in recall (Anderson and Hubert 1963, Dreben et al. 1979, Lichtenstein and Srull 1987). Early items are memorable due to greater levels of rehearsal (Rundus 1971), middle items are poorly recalled, and later items are readily recalled if they are still active in working memory (Wyer and Srull 1986). When judgment order effects differ from recall order effects, weak judgment-recall relationships should be observed. Weak relationships are likely when on-line processing leads to separate evaluation-based and attribute-based representations in memory; strong relationships are likely when judgments are computed on the basis of information retrieved from memory (Hastie and Park 1986; Lichtenstein and Srull 1985, 1987). However, Chattopadhyay and Alba (1988) argue that weak judgment-recall relationships are not observed when sensitive judgment and recall measures are taken in a choice setting. Moreover, they obtained data inconsistent with the two-process model. We examined the judgment-recall relationship using both an unweighted recall index and the Chattopadhyay and Alba weighted recall index.

METHOD

Pretest

Twenty-four undergraduates rated the attractiveness of 28 features of 14-inch color televisions on a scale from 1 (Extremely bad) to 10 (Extremely good). These features were described as features of 14-inch color TVs in general and were

not associated with any one particular brand. The attributes were presented on less than two pages in the questionnaire to minimize order effects. Two sets of 14 attributes (seven favorable and seven unfavorable) were selected to represent Brands A and B in the main experiment. Brand B ($M = 5.53$) was significantly superior to Brand A ($M = 5.21$), $t(23) = 4.00$, $p < .001$. Henceforth, Brand A will be referred to as the inferior brand and Brand B will be referred to as the superior brand.

Procedure

An independent sample of 84 undergraduates participated in the main experiment. Subjects received a booklet containing instructions, attribute descriptions, and measures. Half of the subjects were told that their task was to choose between the two brands (choice set) and half were instructed to memorize the attributes for the two brands (memory set). The attribute information and measures were the same for all subjects.

Each page of the booklet contained descriptions of one inferior brand attribute and one superior brand attribute. Order of presentation was held constant across subjects and subjects were asked to evaluate each attribute on a semantic differential scale ranging from 1 (Extremely bad) to 10 (Extremely good). Subjects rated each attribute after each description before proceeding to the next page.

The early attributes were favorable for the inferior brand and unfavorable for the superior brand. Thus, if primacy effects were found, subjects would actually prefer the inferior brand over the superior brand. Again, this effect should be found in memory-set but not in choice-set conditions even though all subjects received the same information presented in the same order. Favorable (+) and unfavorable (-) attributes were presented in the following order:

Inferior brand: + + + + - - - + + - - -
 Superior brand: - - - + - - + + - - + + +

Imbalanced sequences were used to prevent subjects from detecting the relationship between the two brands. Nevertheless, the favorable-to-unfavorable (inferior brand) and the unfavorable-to-favorable (superior brand) sequences were preserved. This design enables us to examine order effects in choice as well as in judgment.

After completing the attribute ratings, overall evaluative judgments of the two brands were assessed on scales ranging from 1 (Extremely bad) to 10 (Extremely good). Finally, all subjects were asked to choose between the two brands and to freely recall as many attributes as possible.

RESULTS

Order Effects in Judgment

Attitudinal judgments as a function of initial processing goals and brand are presented in Table 1. A 2 (choice or memory set) x 2 (inferior or superior

brand) analysis of variance, with one between-subjects factor (Set) and one within-subjects factor (Brand), was performed on brand attitudes. This analysis yielded a significant Brand main effect, $F(1, 82) = 17.89$, $p < .001$, and a significant Set X Brand interaction, $F(1, 82) = 8.16$, $p < .005$. The set main effect was not significant ($F < 1$). Simple effect tests were used to interpret the Set X Brand interaction while controlling for the compounding of alpha. As Table 1 indicates, in choice set conditions, subjects tended to evaluate the inferior brand more favorably than the superior brand ($M_s = 6.37$ vs. 6.07), but this tendency was nonsignificant ($F < 1$). In memory set conditions, however, more favorable brand attitudes were formed towards the inferior brand than towards the superior brand ($M_s = 6.98$ vs. 5.47), $F(1, 82) = 25.72$, $p < .001$. Even though all subjects received the exact same information presented in the same order, primacy effects were found when subjects were motivated to memorize attribute information but not when they were motivated to select one alternative. Thus, consistent with the hypothesis that cognitively complex reasoning reduces the magnitude of judgmental biases, judgment primacy effects were eliminated in choice set conditions.

Order Effects in Choice

The probability of choosing the inferior brand was .61 in choice set conditions and .81 in memory set conditions. The observed choice probability did not differ from chance in choice set conditions, chi-square = 1.98, *n.s.* In contrast, a strong primacy effect in choice occurred in memory set conditions, chi-square = 16.96, $p < .001$. Primacy effects in judgment and in choice are diminished when choice processing occurs.

Order Effects in Memory

The proportion of attributes correctly recalled as a function of initial processing objectives and serial position is presented in Table 2. Serial position was divided into three categories: the first three items, the middle eight items, and the last three items. As Table 2 indicates, primacy and recency effects in recall were observed across brands and across set conditions. Recall was poorest for the middle items, as predicted.

The Judgment-Recall Relationship

Previous research has shown that the relationship between judgment and recall depends on the manner of judgment formation (Hastie and Park 1986, Lichtenstein and Srull 1985, 1987). When evaluations are formed on-line as judgment-relevant information is acquired, overall evaluations and the specific attribute information used to form overall evaluations are stored independently in memory. Consequently, under these conditions, judgment and recall are not necessarily related. In contrast, when evaluations are formed after information acquisition, the attribute information that is retrieved from memory serves as a direct input for evaluative

TABLE 1
Brand Attitudes

judgments. When recall serves as a direct input for judgment, a strong judgment-recall relationship should be observed.

However, Chattopadhyay and Alba (1988) provide recent empirical evidence that is inconsistent with this model. They maintain that a strong relationship between judgment and recall is always obtained when sufficiently sensitive measures are used. Hastie and Park (1986) and Lichtenstein and Srull (1985, 1987) used the "preferential recall index" (PRI), which is the ratio of the number of positive attributes recalled divided into the number of positive and negative attributes recalled: $P/(P+N)$. Chattopadhyay and Alba (1988) used the more sensitive Luce (1959) index, which is similar to the PRI except that each attribute recalled is weighted by its evaluative rating. Hence, the Luce index contains information about degree of positivity and degree of negativity rather than a

simple tally of the number of positive and negative features recalled. Both indices were employed in the present study.

Judgment-recall correlation coefficients as a function of initial processing goals, brand, and recall index are presented in Table 3. As Table 3 indicates, judgment-recall relationships tended to be stronger in memory set than in choice set conditions. No significant correlations between judgment and recall were found for the superior brand. For the inferior brand, a stronger judgment-recall correlation tended to occur in memory set ($r = .33, p < .03$) than in choice set ($r = .25, p = .12$) conditions when the PRI was used. When the Luce index was used, a somewhat stronger relationship was found in memory set ($r = .31, p < .04$) than in choice set ($r = .28, p < .08$) conditions.

A correlation coefficient between two measures is greatly reduced when the variability in

the two measures is not equivalent. To determine if range restriction can account for the observed pattern of coefficients (see Table 3), standard deviations were examined. Standard deviations in the judgment and recall measures as a function of processing objectives, brand, and index are presented in Table 4. As Table 4 indicates, standard deviations tended to be lower in the recall than in the judgment measures. However, this pattern was consistent across set conditions, brands, and indices. Although a restriction in range partially contributed to the overall low levels of correlation that were observed, range restriction cannot account for the pattern of coefficients found across set conditions, brands, and indices.

DISCUSSION

Several interesting findings emerged from the present study. First of all, strong judgment primacy effects were found in memory set conditions, but these effects disappeared in choice set conditions. Secondly, primacy effects were observed in choice as well as in judgment when subjects' initial processing goal was to memorize attribute information.

However, primacy effects vanished in choice set conditions. Finally, different patterns of serial position effects occurred in judgment than in recall. As a consequence, relatively weak relationships were found between judgment and recall even when the sensitive Luce recall index was employed.

Initial processing goals clearly influence the manner in which information is interpreted and used by consumers. Extensive research has shown that people are often "cognitive misers," and little effort goes into examining, analyzing, and using relevant information (e.g., Alba and Hutchinson 1987; Cialdini 1988; Langer, Blank, and Chanowitz 1978; Petty and Cacioppo 1986). Under these circumstances, important information is often overlooked or underutilized and people are susceptible to a variety of judgmental biases (Kahneman et al. 1982, Nisbett and Ross 1980). In contrast, when involvement is high as opposed to low, more cognitive effort is allocated to analyzing information and the magnitude of these biases tends to be reduced. However, an increase in effort does not always guarantee an increase in accuracy in judgment (Fischhoff 1982, Kruglanski (1989),

Kruglanski and Freund 1983) or in choice (Klein and Yadav 1989; Payne, Bettman, and Johnson 1988).

The results indicate that attribute information is more extensively analyzed in choice set than in memory set conditions. When consumers have an initial processing objective of choosing between two brands, relatively complex comparison and reasoning processes occur. As a consequence, primacy effects, and perhaps other biases as well, are reduced. In contrast, when consumers have an initial processing goal of memorizing attribute information and later receive a surprise choice task, primacy effects occur in judgment and in choice. Hence, the timing of goals is critical. Primacy effects are reduced when a choice set is operating prior to information acquisition (an initial processing goal), but not when consumers switch to a choice set after information acquisition (a final processing goal). This finding suggests that a choice set can *prevent* biases but cannot *reverse* them.

We also tested diverging predictions about the effects of a memory set on sequential information processing. Jones and Goethals' (1972) model predicts that judgment recency effects should occur in memory set conditions (because the integration process is disrupted), whereas Lichtenstein and Srull's (1987) model predicts that judgment primacy effects should occur in memory set conditions. When recalled attribute information is used as a direct input for judgment, primacy effects in memory should lead to primacy effects in judgment. This is precisely what we found.

Finally, the present study addressed an inconsistency in the literature on the relationship between judgment and memory. Hastie and Park (1986) and Lichtenstein and Srull (1985, 1987) argue that weak relationships between judgment and memory should occur in impression set conditions, whereas strong relationships should occur in memory set conditions. Chattopadhyay and Alba (1988) maintain that a strong relationship between judgment and memory should always occur and that measurement problems are primarily responsible for low correlations. The present data are more consistent with the former model, even though the sensitive Luce recall index was used in a choice context. Judgment and recall should not always be strongly related. When different patterns of order effects occur in judgment versus recall, low judgment-recall correlations should be observed. On the other hand, when similar patterns of order effects occur in judgment and recall, strong relationships should be more likely.

In conclusion, the present study demonstrates that initial processing objectives play an important role in determining how information is interpreted and used over time. By influencing the manner in which information is processed, goals affect judgment, choice, memory, and the relationships between these constructs. A clearer understanding of these complex relationships can be achieved only by integrating motivation and cognition.

Selective Attention in Consumer Information Processing: The Role of Chronically Accessible Attributes

S. Ratneshwar, University of Florida
David Glen Mick, University of Florida
Gail Reiting, University of Florida¹

ABSTRACT

Understanding the determinants of selective attention and elaboration in consumer information processing is important since the outcomes are crucial to product evaluation and memory for information which, in turn, impact brand preferences and choice behavior. This study focused on an individual difference factor shown to facilitate information processing, namely the *chronic accessibility* of an attribute in memory. Subjects were classified as "Chronics" or "Nonchronics" based on a card-listing method. They were then presented with attribute information in the context of a product judgment task; two different rates of information presentation were utilized in a between-subjects design. Most importantly, the results showed that in the rapid presentation condition "Chronics," as compared to "Nonchronics," exhibited enhanced recall of target attribute information and made more positive judgments. Implications of the study are discussed and suggestions are made for future research on chronically accessible attributes.

INTRODUCTION

An important issue in consumer information processing is the manner in which environmental information is *selected* for deeper or more elaborative processing from the vast amounts potentially available. On a daily basis, consumers confront a barrage of information about products and brands from media advertising, packaging, point-of-purchase displays, etc. Given the widely accepted model of a capacity-constrained information processor (cf. Bettman 1979), *attention* serves as an important "tuning" mechanism in the active selection of information for additional processing (Bargh 1982; Broadbent 1977; Kahneman 1973; Neisser 1976).

The issue of information selection is particularly significant when one also considers the contexts of everyday information processing. For a variety of reasons, purchase decisions are often made very quickly. Research has shown that as time pressures mount, consumers are likely to reduce the dimensions they consider during brand choice (Wright 1974). Moreover, some information is delivered at rates the consumer cannot control, such as television and radio commercials. Faster rates

have been shown to decrease attention and disrupt cognitive elaboration (Moore, Hausknecht, and Thamodaran 1986). These and other readily conceivable examples underscore the fact that information reception conditions are usually far from ideal. Given this fact, two conclusions may be drawn from a research standpoint. First, understanding the determinants of attention and elaboration processes is critical to a comprehensive theory of consumer behavior. Second, from a methodological perspective, simulating information *overload* experimentally is important for gaining insights into the causal antecedents of attention and elaboration in conditions that parallel real-life information contexts.

Though information overload research in consumer behavior has been controversial, few researchers would deny that the phenomenon can and does occur (Jacoby 1984; Malhotra 1984). In the present context overload occurs when processing capacity is sufficiently strained such that cognitive processes like attention are disrupted or forced to become increasingly selective. Varying information presentation rates and providing subjects with concurrent tasks are two ways that overload has been operationalized (see Bargh and Thein 1985 for related discussion).

A considerable amount of previous research in consumer behavior and advertising has been devoted to studying variables that impact attention and elaboration. One stream of such research has focused on *characteristics of the stimulus* and/or the *local context* in which the stimulus occurs (e.g., vividness, the use of various ad executional elements). Another stream of research has focused on the role of *individual motivational characteristics*, typically in the form of consumer involvement (e.g., Celsi and Olson 1988; Gardner, Mitchell, and Russo 1985; Petty, Cacioppo, and Schumann 1983). A robust finding from these studies has been that higher levels of involvement tend to be associated with more elaborative and systematic processing of central information (i.e., key message arguments).

This paper seeks to contribute to our knowledge of the factors that affect attention and elaboration processes by focusing on individual differences in the *chronic accessibility* of product attributes. We begin by briefly reviewing social cognition research on chronically accessible constructs as applied to person perception. Next, we present an empirical study designed to explore the role of a chronically accessible product attribute in affecting attention and elaboration processes, as observed through attribute information recall and product judgments. Finally, we discuss the

implications of the present work and suggest directions for future research.

CHRONICALLY ACCESSIBLE CONSTRUCTS IN PERSON PERCEPTION

Kelly's (1955) work on the psychology of personal constructs is seminal to recent social cognition research on chronic accessibility. Kelly's thesis was that over a lifetime each individual develops a set of constructs that are applied in a relatively invariant manner to anticipate, structure, and understand environmental information. In a more recent discussion of attention and information processing, Bargh (1984) points out that most contemporary models of social cognition continue to emphasize the interaction between the environmental stimuli that are currently present and the individual's "structural" readiness to perceive some of the stimuli and not others. Thus, informational inputs may be given attentional emphasis not only because of their own characteristics (intensity, vividness, etc.), but also because of the perceiver's "perceptual readiness" (Bruner 1957), based on the activation of relevant constructs or representations in memory. This active perceptual set may be influenced by relatively *temporary* expectancies generated (or experimentally induced) by the task context (cf. Asch's original work on impression formation, 1946; more recently Hastie and Kumar 1979 and Srull 1981). More pertinent to the theme of this paper, however, are the relatively *permanent* or *chronic* constructs that individuals utilize to select information for elaborative processing, i.e., those at the heart of Kelly's original work.

Higgins, King and Mavin (1982) operationalized chronic construct accessibility on the basis of frequency and primacy in traits (e.g., intelligence, honesty) used by subjects to describe different people. These researchers then showed that subjects deleted significantly more *inaccessible* than *accessible* trait-related information in their impressions and in their recall of information about a target person. Using a dichotic listening task, Bargh (1982) demonstrated that information relevant to a trait (e.g., independence) which was central to the self-description schema of a subject was capable of provoking automatic attentional responses. Finally, and most germane to our study, Bargh and Thein (1985) hypothesized that people might be able to engage in elaborative processing even under overload conditions if they possess processing structures for which the informational input is relevant. Their results confirmed that when information about a target person was rapidly presented, impression formation and information recall were influenced by whether or not subjects possessed a relevant chronically accessible construct.

To summarize, previous research in person perception has demonstrated that chronically accessible constructs play a vital role in the selection of information for deeper or more

elaborative processing, based on the reasoning (Bargh and Thein 1985) that such processing occurs when target information is recalled better and is utilized to form evaluative impressions. In addition, such constructs enable people to pick up and process construct-relevant information even when processing resources are taxed. Bargh (1982) points out that the *development* of such constructs is probably illustrative of the general principle of greater cognitive skill arising from greater experience with some particular environmental domain (see also Alba and Hutchinson 1987). Enhanced *accessibility* of a construct in memory is likely to result from both *frequency* and *recency* of activation of the particular construct in encounters with the domain (Bargh 1982; Higgins and King 1981).

PRESENT STUDY

The major objective of our empirical study was to begin building what we see as a potentially insightful bridge between research on chronically accessible constructs in social cognition and the determinants of attention and elaboration in consumer information processing. It appears likely that the functional reason underlying the development of these constructs in social cognition--enabling the capacity-constrained perceiver to cope with a "blizzard of cues" (Bargh and Thein 1985)--is equally applicable to the issue of selective attention in consumer information processing.

Based on the findings in person perception, our major hypotheses were as follows. When information is presented rapidly about a target product, and it contains a target attribute that is chronically accessible in memory to some subjects but not to others, the former will be likely to direct their attention to the target attribute and process it more deeply and/or elaboratively. Thus, they should exhibit enhanced recall for the target attribute. However, when the information presentation rate is relatively slow, differences between "Chronics" and "Nonchronics" in efficiency of processing of the target attribute should not significantly affect its recall. Hence, we predicted an interaction between chronic accessibility of the attribute and information presentation speed on recall of the target attribute. With respect to subjects' attitudinal judgments of the target product, we expected that both in rapid-paced and slow-paced conditions subjects for whom the target attribute was chronically accessible should process the attribute information sufficiently for it to impact their judgments. While nonchronic subjects may process the stimulus attribute information sufficiently in slow-paced conditions, with the attribute not being of primary importance to these subjects, it should not impact their judgments. Hence, we predicted a main effect for chronic accessibility of the target attribute on attitudes toward the target product, i.e., irrespective of the pace of information presentation.

As part of our study we also examined the extent to which an individual dispositional variable, "need for cognition," might influence the processing and subsequent recall of attribute information. The

"need for cognition" scale was developed to distinguish between individuals who tend to engage in and enjoy effortful analytical activity, and those who do not (Cacioppo and Petty 1982). It has been shown that individuals high (vs. low) in "need for cognition," when presented with a persuasive message, subsequently recalled more message arguments and reported expending more cognitive effort in processing the message (Cacioppo, Petty, and Morris 1983). Thus, in our study we expected high (vs. low) "need for cognition" individuals to recall more attribute information, particularly in rapid-paced information presentation conditions. We hoped that this might provide a useful "benchmark" with which the effect size in recall due to chronic accessibility might be compared. We anticipated that the recall effect due to domain-specific individual differences, such as the chronic accessibility of a particular product attribute, should be considerably larger than the effect due to domain-neutral individual differences such as "need for cognition."

METHOD

Subjects

Eighty-one undergraduates in a large public university were recruited for the study and received extra class credit for their participation.

Procedure

Subjects participated in two supposedly "unrelated" studies, with an interval of about three weeks between the two.

The first session used a memory probe in order to elicit chronically accessible attributes from subjects. A modified version of the card-listing method used by Zajonc (1960) and Higgins, King, and Mavin (1982) was employed for this purpose. Subjects were informed that they were participating in a study of consumers' perceptions of different products. Attributes were elicited for several different product categories (e.g., automobiles, banks). For *each* product category, subjects were asked to list on blank cards the attributes or characteristics that came to mind in four different contexts of product affect, namely, "like," "dislike," "seek," and "avoid." For example, on the first page of the booklet they were instructed to "think of the type of automobile that you *like* a lot. What are the characteristics or aspects of such an automobile that come to your mind? Taking one blank card each time from the card pile, please write down these characteristics in the order in which they occur to you." The order of presentation of the various product categories in the booklet was rotated so that subjects had to elicit attributes for several other products in between tasks related to the same product. The order of production of attributes in each task was recorded by the subject. Each attribute was written on a separate card which the subject then turned over and kept face down. Subjects were instructed to complete the tasks without looking back at the cards on which they had already written.

After the attribute elicitation was completed, subjects filled out the 34-item "need for cognition" scale (Cacioppo and Petty 1982). Subjects' responses on the 34 items (scale of +4 to -4) were summed up (after adjusting the sign of reverse scored items) in order to derive their "need for cognition" (NFC) scores.

The attributes produced by the subjects in the above session were analyzed as follows. First, the data were scrutinized with the goal of selecting a target product category and a related target attribute on which subjects revealed a clear pattern of inter-individual differences with respect to attribute accessibility. The category *banks* was selected, with the target attribute *friendly employees*. Next, the attribute data produced by the subjects were analyzed in order to classify them on the basis of whether the target attribute was chronically accessible ("Chronics") or inaccessible ("Nonchronics"). Following the procedures of Higgins, King, and Mavin (1982) and Bargh (1984), attribute accessibility was operationally defined on the basis of both frequency and primacy of attribute production. Synonyms and antonyms of the target attribute were taken into account in the analysis. As mentioned earlier, subjects had produced attributes for the category *banks* in four different contexts of affect. The criterion used to classify a subject as a "Chronic" was that the target attribute should have been listed in either the first or the second serial position in a minimum of two out of the four contexts. Subjects were classified as "Nonchronics" if the target attribute did not occur in the first four serial positions in any of the four contexts. These criteria resulted in 28 subjects being classified as "Chronics" and 21 as "Nonchronics"; the remaining 32 subjects were eliminated from the second study reported below, since they could not be identified as clearly belonging to either of the two categories.

Three weeks later subjects were scheduled for the second session ostensibly concerning their impressions of products under real life conditions where people are often exposed to product information for only brief periods of time, "for example, during a TV commercial or when glancing at an ad while flipping the pages of a magazine." Hence, they were told to expect only a limited amount of time for reading information which was to be presented to them on an overhead screen. While all subjects were provided the same instructions, they were randomly assigned to sessions (average $n = 6$) where either the information presentation time was actually very brief ("Rapid Pace" condition) or relatively ample ("Slow Pace" condition), as described in more detail below.

Subjects were asked to respond with their judgments on eight successive "trials," in each of which attribute information was presented on the screen with respect to a different product category. On each trial, the product category was first identified at the top of the screen for 5 seconds (e.g., "A CALCULATOR"). Next, attribute information was presented below the product category name in one of two manipulated time

conditions - either for 3 seconds ("Rapid Pace") or for 20 seconds ("Slow Pace"). In all trials, the attribute information was in the form of a list of six features displayed simultaneously, one below the other in block letters (e.g., "BRIGHT DISPLAY," "SOLAR POWERED," etc.) On each trial, as soon as the information presentation was over and the screen was empty, subjects recorded their judgments of the product on three bipolar 9-point (- 4 to + 4) scales. These items asked for attitudinal judgments of the target product in terms of how favorable, how good, and how likeable the product was in the opinion of the subject. As anticipated, the data revealed the three items to be highly intercorrelated (average $r = 0.80$), and hence they were summed to form one composite attitude index (range - 12 to + 12).

The target product ("A BANK") was in the fourth position in the above block of eight trials. The first three "dummy" trials served the purpose of familiarizing the subject with the task before responding to the actual stimulus. The last four dummy trials were inserted to ensure that any stimulus attribute information being maintained in short-term memory through rehearsal was cleared out before subjects were administered the free recall task (described later in this section). The attribute information presented to the subjects on the target product included the target attribute ("FRIENDLY EMPLOYEES") in the fourth serial position, along with five attributes (e.g., "ATTRACTIVE LANDSCAPING," "MODERN BUILDING") that were judged nondiagnostic for banks in pretests. Care was taken to ensure that there were no overlaps between the attribute information on the target product and the attribute information on the dummy products.

On completion of the above judgment task, subjects were asked to respond to items in the questionnaire which asked how pleasant was the task, how much effort did the subject put into the task, and how adequate was the time given for reading the product information (all scales - 4 to + 4). Subjects were then asked to rate their English reading ability in terms of speed and comprehension relative to other undergraduate students (scales of 1 to 5 with higher numbers indicating higher ability). After this, subjects were administered a surprise attribute recall task. The experimenter named the product, and the subjects were asked to recall and write down as much as they could remember of the information presented earlier about the product, using the same words as much as possible. The experimenter prompted the subjects with the product names that corresponded to the various trials, and in the same sequence as before. On hearing each product name, subjects recalled the attribute information in a self-paced manner. Subjects' responses with respect to the target product were scored on the basis of whether or not they had recalled the original information in gist form. One judge (blind to condition) scored all the protocols and two other judges scored a random sample. Interjudge agreement was close to 100%. Recall for each subject was scored in terms of whether or not

the target attribute had been recalled, and the total number of other attributes (range 0 to 5) which had been correctly recalled. Finally, on completion of the recall task, subjects were asked to judge, in terms of their personal preferences in banks, how important it was for them that a bank have friendly employees (scale - 3 to + 3).

RESULTS

Attitude toward target product

A 2 ("Chronics" vs. "Nonchronics") x 2 ("Rapid Pace" vs. "Slow Pace") analysis of variance on the attitude index revealed a marginally significant main effect for chronicity, $F(1, 45) = 3.00$, $p < 0.10$. As predicted, "Chronics" had more positive attitudes toward the target product than "Nonchronics," $M_s = 5.54$ vs. 3.29 respectively. Neither the main effect for Pace nor the Chronicity x Pace interaction was significant ($p > 0.50$ in both cases).

Recall of target attribute

In "Rapid Pace" conditions, a significantly higher proportion of "Chronics" correctly recalled the target attribute *friendly employees* as compared to "Nonchronics," 84% vs. 20%, $p < 0.01$ (Fisher's exact test, 2 - tail). However, as anticipated, in "Slow Pace" conditions "Chronics" did not recall significantly more than "Nonchronics," 89% vs. 73%, $p > 0.50$.

Recall of other attributes of target product

A 2 x 2 (Chronicity x Pace) ANOVA was performed on the total number of other attributes correctly recalled by subjects. As anticipated, a significant main effect was found for presentation speed, with subjects in "Slow Pace" recalling more attributes than subjects in "Rapid Pace," $M_s = 3.10$ vs. 2.03 , $F(1, 45) = 11.39$, $p < 0.01$. Neither Chronicity ($p > 0.20$) nor the Chronicity x Pace interaction ($p > 0.17$) had significant effects on the recall of other attributes.

Other measures

2 x 2 (Chronicity x Pace) ANOVAs were performed on subjects' judgments of task pleasantness, effort put into task, adequacy of time, and self-assessed ability in English reading speed and comprehension. These analyses revealed only one significant effect: as anticipated, and in confirmation of our manipulation, subjects in "Slow Pace" conditions judged the time provided for information processing to be more adequate than subjects in "Rapid Pace" conditions, $M_s = 3.35$ vs. 0.76 , $F(1, 45) = 47.34$, $p < 0.001$. All other main effects and interactions in the above variables were nonsignificant, $p's > 0.20$. A similar 2 x 2 ANOVA was also performed on subjects' ratings of their perceived importance of the target attribute. This analysis showed that "Chronics," as compared to "Nonchronics," rated the attribute *friendly*

employees as significantly more important, $M_s = 2.54$ vs. 1.76 , $F(1, 45) = 7.72$, $p < 0.01$.

Effects of "need for cognition"

Subjects were split on the median "need for cognition" (NFC) score into "Low NFC" and "High NFC" groups (median score = 62, range = 14 to 119). Low NFC subjects did not differ from High NFC subjects with regard to recall of the target attribute in either "Rapid Pace" or "Slow Pace" conditions ($p > 0.50$ in both cases). 2×2 (NFC \times Pace) ANOVAs were conducted on the other variables. These analyses revealed that Low NFC subjects did not differ significantly from High NFC subjects in recall of other attributes of the target product, in attitudes toward the target product, in pleasantness ratings, or in effort put into the task (p 's > 0.25). Interestingly, however, High NFC subjects rated their reading speed higher than did Low NFC subjects, $M_s = 3.42$ vs. 2.96 , $F(1, 45) = 3.32$, $p < 0.10$. The former also rated their comprehension ability higher as compared to the latter, $M_s = 3.96$ vs. 3.26 , $F(1, 45) = 6.89$, $p < 0.05$.

DISCUSSION OF PRINCIPAL RESULTS

The results supported our hypotheses about differences in information processing between subjects for whom a target attribute was chronically accessible in memory, and those for whom it was not. In rapid-paced conditions, a significantly higher proportion of "Chronics" (84%) as compared to "Nonchronics" (20%) was able to correctly recall target attribute information. In slow-paced conditions, as anticipated, the difference in recall was not significant because the additional time provided to process the target attribute erased the advantage of processing efficiency that "Chronics" exhibited in the rapid-paced condition. The magnitude of the difference in recall between "Chronics" and "Nonchronics" in rapid-paced conditions is striking. So is the fact that 84% of the "Chronics" recalled the target attribute in the rapid-paced condition, given that (a) they were not instructed to memorize the attributes, (b) they received only three seconds to process information on six attributes, including the embedded target attribute, and (c) the study design included delay and interference before recall was tested. Also noteworthy is the fact that in comparison, the average recall proportion among "Chronics" for the other five non-target attributes in the rapid-paced condition was only 41%.

Consistent with the social cognition literature discussed earlier, the findings in this study are most likely explained by the structural readiness of "Chronics" to process more deeply and/or elaboratively information on the target dimension consequent to the target product category being activated in their memory. "Chronics" did not differ from the "Nonchronics" on recall of the non-target attributes, nor on self-assessed measures of effort put into the task, reading speed, or comprehension.

Therefore, differences in effort or language abilities are unlikely to be implicated in the inter-group difference in attribute recall. The one other possibility is that in rapid-paced conditions instead of *encoding* the presented information better, "Chronics" may have *generated* the attribute in a schema-based manner at the point of test. However, the data on "intrusions," i.e., false recall of items not actually presented in the stimulus, do not support such an alternative explanation. Overall, intrusions amounted to only 8% of the total number of attributes recalled, and "Chronics" did not significantly differ from "Nonchronics" in number of intrusions in rapid-paced or slow-paced conditions (p 's > 0.30).

The results also supported our expectation of a main effect in attitudes due to chronic accessibility of the target attribute. Both in slow-paced and rapid-paced conditions, "Chronics" made more positive judgments of the target product than "Nonchronics." This suggests that even when processing capacity was strained, "Chronics" were able to process the target attribute sufficiently for it to impact their product judgments. (Recall that the non-target attributes, based on pre-tests, were intentionally designed to be nondiagnostic for both "Chronics" and "Nonchronics.")

As anticipated, "Chronics" also judged the target attribute to be more important than "Nonchronics." This raises the following question: are inter-individual differences in attribute importance ratings also associated with differences in recall of the target attribute (as chronic accessibility was shown to be), particularly in the rapid-paced conditions? To assess this possibility, the data were analyzed after conducting a median split of subjects based on their attribute importance ratings ($W \leq +2$ and $W = +3$). Results showed that these two groups of subjects did not differ in recall of the target attribute in either rapid-paced conditions (58% vs. 65%, $p > 0.50$) or in slow-paced conditions (83% vs. 75%, $p > 0.50$). In rapid-paced conditions, target-attribute recall and chronic accessibility were highly associated, while there was negligible association between target-attribute recall and subjects' target-attribute importance ratings (ϕ coefficient = 0.63 vs. 0.07). Hence, whereas target-attribute importance ratings were significantly associated with chronic accessibility classifications (point-biserial $r = 0.37$, $p < 0.01$), unlike chronicity, the ratings were not a reliable predictor of inter-individual differences in target-attribute recall during information overload conditions. However, this result must be viewed with caution since the importance ratings had a skewed distribution.

IMPLICATIONS AND FUTURE RESEARCH

A chronically accessible attribute is likely to have some inherent similarities to one that is particularly important or salient to an individual. Previous researchers have speculated that there may exist a causal relation between attribute importance

and attention to attribute information in advertising (e.g., MacKenzie 1986). While the present work was not an advertising study per se, the findings suggest the possibility of benefit segmentation on the basis of chronic accessibility for product attributes; in particular, those in the "Chronic" segment can be expected to process *relevant* ad information much more efficiently than "Nonchronics." By emphasizing the chronic attribute in a headline and/or visual, and by placing the ad in a medium appropriate to the "Chronic" segment, an advertiser may maximize limited opportunities to communicate in information-cluttered environments. Future research must test the robustness of our findings and their advertising implications, using different overload manipulations, different product classes, different consumer groups, different media, and more ecologically valid advertising stimuli.

From a methodological perspective, we note that there is considerable diversity and a lack of convergent validity with respect to measures of attribute importance (Jaccard, Brinberg, and Ackerman 1986). Our approach to assessing attribute chronicity was taken directly from the social cognition literature where the concept has been studied most. The card-listing technique employed in this study is similar (though not identical) to the free elicitation method (E) used in Jaccard et al. (1986); importance (I) rating measures were identical in both studies except for the number of scale points. Correlations between the E and I measures were considerably lower in Jaccard et al. (1986) than in our study. Moreover, in their factor analyses, the E measure consistently loaded on a separate factor. If the E and I measures do in fact assess different constructs or different dimensions of the same construct, then that may explain why our analyses revealed discrepant findings in predicting target-attribute recall based on chronicity versus attribute importance.

Jaccard et al. (1986, p. 467) go on to speculate that the E measure "appears to measure, albeit imperfectly, factors that people consciously consider in their evaluations." In fact, a free elicitation measure like the card-listing task used to determine attribute chronicity is an *indirect* and less obtrusive measure than the I measure; as such, it can reveal through the order and frequency of elicited attributes which attribute(s) people are most inclined to use in rapid evaluations. Our preliminary conjecture is that, in an attitude judgment context, attribute chronicity is more closely related to the notion of "salience" than "importance" (see Higgins and Bargh 1987 for related discussion). Further, chronically accessible attributes likely enable consumers to efficiently process environmental information in relatively *familiar* product categories. The extent to which such processing may be deemed to be "automatic" or "conscious" are significant theoretical issues, but space limitations preclude their discussion here; however, it appears to us that Jaccard et al. (quoted above) may have prejudged the

issue of consciousness (see Bargh 1984; Janiszewski 1988).

Our present findings may also have implications for choice research, especially choices made under time pressure. Fazio's (1986) research has shown that as the accessibility of an attitude in memory increases (operationalized by decreases in the response latency of an attitudinal judgment), the likelihood that the attitude will influence subsequent overt behavior also increases, i.e., there will be stronger attitude-behavior consistency. By analogy, the more accessible an attribute in memory (increasing chronicity), the more likely it may be that inputs relevant to the attribute will influence choice behavior under rapid information presentation and time-pressured choice scenarios, i.e., where the spontaneous activation of the attribute is needed for consistency between attribute information and choice. Future research could measure attribute chronicity, manipulate brand attribute profiles, manipulate information exposure time, and determine whether systematic variations in brand choices verify a chronicity explanation for attribute-choice consistency.

A potential moderator of chronicity effects is structural variations in the knowledge network in which the chronic attribute resides. The card-listing task employed in this study is a modified form of Zajonc's (1960) card-sorting technique that can yield measures of cognitive complexity, differentiation, unity, and organization of the domain to which the chronic attribute applies. For instance, prior social cognition research has shown that cognitive differentiation has little or no impact on construct-accessibility recall effects, but does substantially influence construct-accessibility attitudinal effects (Higgins, King, and Mavin 1982). Future research should investigate the moderating role of cognitive structure on attribute-accessibility effects in consumer information processing.

CONCLUSION

Drawing from previous research in social cognition literature, this study examined the effects of chronically accessible attributes in selective attention and elaboration during consumer information processing. In particular, it was found that subjects chronic to a target attribute recalled information relevant to the attribute more readily than non-chronic subjects after rapid presentation of product information. "Chronics" also judged the product more positively than "Nonchronics" in both rapid and slow information conditions. Implications of these results were discussed in terms of advertising and choice behavior, including directions for future research.

Multiattribute Judgements Under Uncertainty: A Conjoint Measurement Approach

Amiya K. Basu, The University of Illinois at Urbana-Champaign
Manoj Hastak, The American University

ABSTRACT

A methodology to predict product choice under uncertainty in attribute values is proposed and tested. The methodology consists of (i) estimating the multiattribute utility function of a consumer, and (ii) predicting new product evaluation based on expected utility computed using the estimated utility function. To test the methodology, conjoint analysis is used to estimate a respondent's multiattribute utility function. Next, the respondent is asked to evaluate hypothetical product profiles with uncertain attribute values. The observed evaluations are compared with predictions using the proposed technique and also a naive model which ignores attribute uncertainty. In the sample studied, both the proposed technique and the naive model predicted reasonably well, but neither model performed significantly better than the other.

INTRODUCTION

Multiattribute modeling of consumer choice is a well known paradigm in marketing research. The model rests on the assumption that consumers perceive a product as a 'profile' or combination of attribute values. For example, a television set may be perceived as a combination of its picture quality, longevity, audio quality, etc. The consumer is assumed to integrate information about different attribute values to form an overall evaluation (or assess utility) of each alternative, and to choose the one that maximizes utility subject to budget constraints. Utility is clearly a function of the individual attribute values. The multiattribute approach to choice modeling has enjoyed considerable popularity in the marketing literature. Significant progress has been made in the last twenty years toward the determination of the form and parameters of multiattribute utility functions (see Shocker and Srinivasan 1979, Green and Srinivasan 1978, Wilkie and Pessemier 1973, Anderson 1974). One commonly used and widely accepted model to emerge from this research is the additive conjoint measurement model. The model can be briefly described as follows:

Let (x_1, x_2, \dots, x_n) represent the vector of attribute values for a product with n significant attributes. Then, the overall utility function for the product can be expressed as

$$(1) \quad U(x_1, x_2, \dots, x_n) = \sum_{i=1}^n U_i(x_i)$$

where U_i is the part-worth utility function for attribute i .

Data for the model can be collected through either the 'full profile' or 'pairwise trade-off' methods. In the 'full profile' approach, the consumer is asked to rate or rank order a large number of hypothetical 'product profiles'. These profiles are generated by creating combinations of attribute values across all significant attributes. Parameters of the part worth utility functions are derived from ratings or rank orders provided by the subjects. Once these parameters are available, it is possible to determine the utility of a consumer for any given combination of attribute or values, and hence predict whether the consumer will choose the product over other alternatives. This predictive feature of the model makes it particularly relevant for managerial application and use.

RESEARCH ISSUES

Extant research on multiattribute models in general, and conjoint analysis in particular has rarely involved an explicit consideration of uncertainty in attribute values.¹ This is a serious limitation. Consumers may frequently not know the exact value of a product attribute, but only be aware of it as a random variable with a certain probability distribution. The uncertainty may originate from the consumers' lack of knowledge of attribute values as well as true variation in an attribute value over time or across product units. The effects of uncertainty on product evaluation are most apparent in the case of a new, unfamiliar product. In this instance, the probability distributions for attribute values are likely to be spread out over a large range. Since consumers are generally risk averse, they are likely to avoid products with high attribute uncertainty. As a result, a new product would be more difficult to sell than an established one. Unless the effects of uncertainty on the perceived 'value' of a new product are carefully investigated, utility values computed from conjoint analysis (which uses expected attribute values for new products) would be erroneous and generally overestimate probability of success for the product. A methodology to estimate the effect of attribute uncertainty on choice would improve a manager's ability to set price and design warranty schemes for a new product.

The only systematic attempts to date to incorporate the concept of uncertainty in multiattribute judgment analysis were made by Pras and Summers (1978), and Meyer (1981). Pras and

¹There exists a separate stream of research (see Currim and Sarin, 1983) which focuses on uncertainty regarding which alternative from a set of alternatives a consumer would receive. However, attribute values of each alternative are known with certainty.

Summers performed an individual level analysis of the respondents' evaluation of automobiles. The respondents used a constant sum scale to indicate the importances of the attributes they felt were significant. A separate scale was used next to estimate the risk tolerance of a respondent for a given attribute. Also, the researchers used self-reported data from the respondents to determine subjective probability distributions of attribute values. Integrating the information about attribute evaluation, perceived uncertainty, and stated preference among product alternatives, the researchers demonstrated the effect of attribute importance on risk tolerance by a respondent.

Meyer's analysis involved inference about unknown attributes in the context of conjoint analysis and is closely related to the present study. His approach is based on the assumption that part-worth utility for each product attribute can be separated into two components, (i) the expected value of the attribute, and (ii) the dispersion or variance. This is an interesting approach and it addresses a long neglected area. However, Meyer's approach suffers from the following limitations:

1. Since the 'dispersion' or variance is an additional variable, a very large number of profiles is needed to estimate the utility function using conjoint analysis.
2. In general, the expected part-worth utility of an attribute may not be separable into the mean and the variance of the attribute.

In this paper, we suggest an alternative procedure, described in the following section, which overcomes the limitations of Meyer's technique listed above.

OBJECTIVES

The objective of this paper is to develop a simple procedure which will predict a consumer's evaluation of a product with uncertain attribute values. It is assumed here that the consumer has a well defined utility function for any combination of attribute values. For a given product, the values of different attributes are random variables (x_i), and the expected 'value' or utility the consumer has for the product is given by

$$(2) \quad E [U (x_1, x_2, \dots, x_n)] = \sum_{i=1}^n E [U_i (x_i)].$$

We will henceforth denote this quantity by 'expected utility' or EU. The consumer would choose the product which gives him/her the maximum expected utility, EU.

If instead of using equation (2), the utility of the consumer for the new product is computed at the expected values of the attributes, the 'value' the consumer has for the product will be (erroneously) computed as

$$(3) \quad EV = \sum_{i=1}^n U_i [E (x_i)].$$

If there is no uncertainty about attribute values, equation (2) reduces to equation (3). Also, if U_i is linear in x_i , then $E[U_i(x_i)] = U_i[E(x_i)]$. Otherwise, equation (3) may estimate the expected utility of the consumer for the product incorrectly. The nature of the error can be illustrated using the following example:

Consider a product with a single attribute x . x is a random variable which is uniformly distributed between 0 and 20. $U(x)$, the utility of the consumer for attribute level x , is the piecewise linear function given by:

$$U(x) = x \quad \text{if } 0 \leq x \leq 10, \\ U(x) = 10 + .5(x-10) \quad \text{if } 10 < x \leq 20.$$

Clearly, the expected value of x is 10, and EV , the consumer's utility computed at $x = 10$, is 10. In contrast, the expected utility of the consumer, EU , is given by

$$EU = \frac{1}{20} \int_0^{20} U(x) dx = 8.75$$

noting that the probability density function of the uniform distribution here is $1/20$ for $0 \leq x \leq 20$.

Note that here, the utility function exhibits concavity, i.e. the consumer is risk averse, and he/she strictly prefers a certain value of $x = 10$ over an uncertain scenario where the expected value of x is 10. This also demonstrates that even if we have a piecewise linear approximation to the consumer's utility function, with properly designed uncertain scenarios we should still be able to notice the error in using equation 3 to estimate how a consumer would evaluate a new product.

We propose that the consumer's expected utility for a new product can be determined in two stages as follows:

1. Use conjoint analysis to determine the part worth utility functions U_i . In this step, hypothetical products with certain attribute values are used.
2. Determine the probability distributions for x_1, \dots, x_n for the new product. Compute the consumer's expected utility for the new product using equation (2).

It should be noted that the task involved in (1) above is considerably simpler than estimating a utility function involving means as well as dispersions of attribute values. Also, the model is free from any limiting assumption of separability of effects of mean and dispersion as used by Meyer (1981). Data obtained from conjoint analysis in task 1 eliminate the need to estimate attribute

importance and risk tolerance separately (as done by Pras and Summers, 1978). Finally, the tasks (1) and (2) are mutually independent. If the part worth utility functions are known, the expected utility for any known distribution of attribute values can be computed.

In this paper, we try to examine if the procedure outlined above yields an accurate measure of consumer preference. To achieve that goal, we focused on a simple product which could be presented reasonably well by a small number of search attributes. First, conjoint analysis was performed at an individual level to determine a respondent's partworth utility functions for the attributes of the product. Next, the respondent was presented with product profiles with uncertain attribute values. The actual preferences of the respondent were compared with predictions based on the first stage analysis.

In specific, we studied how the procedure described above performs compared to the naive method where the utility for the new product is computed using expected attribute values. For notational convenience, we will call the method outlined above the 'expected utility model' or 'EU model', and the naive method using expected attribute values will be called the 'expected value model' or 'EV model'.

STUDY DESIGN

56 undergraduate students participated in the study. The product category selected was a rental two bedroom apartment which the subject would share with three other undergraduates. Subjects performed 4 distinct tasks during a 1 hour session in the sequence presented below.

Task 1: Data for estimation of conjoint model.

A full profile approach was used with the following three attributes, each at four levels:

1. x_1 , the distance from classes: 4, 8, 12 or 16 minutes.
2. x_2 , the floor space: 600, 700, 800, or 900 sq. ft.
3. x_3 , the monthly heating bill during winter (to be shared by the four residents): \$40, \$80, \$120, or \$160.

The apartments were identical otherwise.

A 1/4 fractional factorial design was used to collect data for the conjoint analysis. In addition to these 16 profiles to be used in the data analysis, the respondents were provided with two extreme profiles (profiles 3 and 9 in Table 1) which they could use as anchors. Table 1 presents the hypothetical profiles used in the study. The respondent was asked to rank order the eighteen profiles and also rate each profile on a 0-100 scale.

Task 2: Simultaneous evaluation of hypothetical product profiles.

Here the respondent was presented with the eleven hypothetical apartments listed in Table 2. Two apartments (3 and 8 in table 2) had a known (certain) value for each attribute and were included to serve as anchors. Each of the other nine apartments had an uncertain heating bill, and the probability distribution, which was piecewise uniform, was described to the respondent. (We introduced uncertainty in only one attribute to keep the task

simple for the subjects. Heating bill was selected since we felt that it would be easier to justify random variation in heating bills than in either floor space or distance to school. A known heating bill may be conceived of as a fixed addition to the rent.) Following Pras and Summers (1978), the probability distributions of the heating bill were made to differ on the following two characteristics:

- (i) The distribution was either skewed left, symmetric, or skewed right.
- (ii) The variance was high, medium or low.

These nine profiles consisted of the (3x3) combinations of the three levels of these two characteristics. The other two attributes were known with certainty, and their values were randomly varied

from profile to profile. The respondent rank ordered the 11 profiles and also rated each profile on a 0-100 scale.

Task 3: Pairwise comparison of hypothetical product profiles.

The respondent was presented with eight pairs of hypothetical apartments. Each pair consisted of one apartment with known (certain) values for all attributes, and one apartment with known (certain) values of distance and floor space, but uncertainly in heating bill. The known (certain) heating bill was always greater than or equal to the expected value of the uncertain heating bill.²

²This was done since we felt that the respondent would have a negative utility for heating bill.

TABLE 3

APT No.1:	Distance to classes	12 mins.		
	Floor space:	900 sq.ft.		
	Heating bill:	30% chance - between \$40 and \$80. 40% chance - between \$80 and \$120. 30% chance - between \$120 and \$160.		
APT No.2	Distance to classes:	12 mins.		
	Floor space:	900sq.ft.		
	Heating bill:	\$105 (for sure).		
Strongly Prefer APT No.1		Like Both Equally		Strongly Prefer APT No.2
1	2	3	4	5

The uncertain heating bills differed across pairs on the following characteristics:

- (i) The variance was low, or high.
- (ii) The distribution was symmetric, or skewed right (the 'skewed left' case was omitted due to time constraints).
- (iii) The certain heating bill in the pair exceeded the expected value of the uncertain heating bill by a small (\$0-\$5) or a large (\$10-\$20) amount.

The eight pairs consisted of (2x2x2) combinations of the two levels of the three attributes. In four pairs the uncertain case was presented first, and in the other four the certain case was presented first. For each pair, the respondent was asked to indicate on a five point scale how strongly he/she preferred the second apartment in the pair over the first.³

Table 3 presents one pair of apartments used in the study.

Task 4: General information.

Finally, the respondent completed a short questionnaire which obtained background information. It also contained a constant sum scale where the respondent was asked to divide 100 points among four attributes of an apartment: rent, distance from school, floor space and heating bill, according to importance.

The data from task 4 were used to check the nature of the sample and establish face validity for the measurement of part-worth utilities. These were not included in any formal analysis.

DATA ANALYSIS AND RESULTS

The data were analyzed in two stages.

1. *Estimation of part-worth utility functions.* Dropping the two extreme profiles, rankings and ratings obtained for the 16 hypothetical profiles from task 1 were used to estimate the part-worth utility functions for each individual respondent using the dummy variable regression model,

$$(4) Y = \beta_0 + \beta_1 D_1 + \beta_2 D_2 + \beta_3 D_3 + \beta_4 D_4 + \beta_5 D_5 + \beta_6 D_6 + \beta_7 D_7 + \beta_8 D_8 + \beta_9 D_9 + \epsilon,$$

where D_1, D_2 & D_3 corresponds to x_1 (distance) = 8, 12 & 16 minutes, D_4, D_5 & D_6 to x_2 (floor space) = 700, 800 & 900 square feet, and D_7, D_8 & D_9 to x_3 (heating bill) = \$80, \$120, & \$160. The regression estimated four points on each of the three part-worth utility functions.

Using both rankings and ratings, the average R^2 computed over the 56 cases was .95. Also, for each case, we examined if the null hypothesis that only the intercept should be retained could be rejected at $\alpha = .05$ (this corresponded to having $R^2 > .804$). The null hypothesis was rejected in 53 (out of 56) cases using ratings, and 55 cases using rank orders. The insignificant cases were dropped from further analysis.

Since in tasks 2 & 3 there would be uncertainty only in heating bill, the null hypothesis that heating bill is an insignificant predictor of the dependent variable (i.e. $\beta_7 = \beta_8 = \beta_9 = 0$) was tested for each individual using $\alpha = .10$. Once again, the insignificant cases were eliminated from further consideration. 40 cases were retained for the analysis using rank orders, and 39 cases for the analysis using rating scores.

2. *Comparisons of predictions from the EU and EV models.* The estimated conjoint models were used next to compare predictions based on the EU and EV models with the respondents' stated evaluations from task 2 & task 3. Since we

³Note that for four pairs, the heating bill of the second apartment was uncertain, and in the remaining four, it was known with certainty.

	EU model	EV model
\bar{r}_p	.8527	.8508
r_{pooled}	.8311*	.8243*
r_s	.8529	.8475

Notation:

* → p = .0001.

\bar{r}_p = average Pearson correlation of predicted and observed scores.

r_{pooled} = Pearson correlation of predicted and observed scores for the pooled data.

r_s = average Spearman rank order correlation of predicted and observed scores.

estimated only four points on each part-worth utility function, a piecewise linear approximation was used for each function to obtain the predictions. (The Appendix demonstrates how these computations were done.)

Analysis of data from task 2. For every individual, scores for the two extreme profiles were dropped, and EU and EV were computed for each of the nine hypothetical apartments with uncertain heating bills. Next, Pearson correlations and Spearman rank order correlations were computed between the predicted (using the EU and the EV models) and observed scores for each individual. (The rank orders obtained from task 2 were used to compute the Spearman rank order correlations while the rating scores were used to compute the Pearson correlations.) The results are presented in Table 4. It is obvious that both the EU model and the EV model predicted the respondents' evaluation of the hypothetical apartments reasonably well. However, the results did not indicate that either model performed significantly better than the other.

Analysis of data from task 3. The analysis here had two components. The first component was performed at an individual level. For each respondent, for every pair of hypothetical apartments, the respondent's evaluations of apartment 2 and apartment 1 were computed and the difference estimated. Both the EU model and the EV model were used. Next, the Pearson correlation between the predicted difference and the observed preference score of apartment 2 over apartment 1 was computed. Table 5a presents the results of the analysis. Both the EU model and EV model performed better than a naive model where one apartment is randomly chosen. However, the quality

of prediction was unsatisfactory for either model. More significantly, the EU model did not perform better than the EV model.

The second component used pooled data from the entire eligible sample. Only the cases were considered where the respondent indicated strict preference for either apartment,⁴ and the EU and the EV models gave opposite predictions. An analysis of these cases would provide us with a critical test regarding the relative performances of the two models. We could not determine a priori when the EU and the EV models would make opposite predictions. However, we expected that the two models would tend to make divergent predictions when the heating bill known with certainty exceeded the expected value of the uncertain heating bill by a small margin.

The cross-tabulations of the predicted choice using the EU model with the actual choice are presented in Table 5b. Since here the predictions from the EV model were exactly the opposite of those made by the EU model, cross-tabulations using results from the EV model are omitted as redundant.

From Table 5b, it is clear that the null hypothesis of no relationship between predicted and observed choice cannot be rejected here with any reasonable level of confidence. However, the cross-tabulation seems to indicate a weak relationship.

Therefore, we could not establish here that the EU model would predict choice under uncertain attribute values better than the EV model.

⁴A score of 1 or 2 indicated preference for apartment 1 while a score of 4 or 5 indicated preference for apartment 2.

 $p = .689$.SUMMARY OF RESULTS AND
CONCLUSION

To summarize, part-worth utility functions estimated from conjoint data were used to compare the predicted abilities of the EU model and the EV model. Both models predicted consumer choice better than chance. The performance on task 2, where the profiles varied on all attributes, was significantly better than the performance on task 3, where the apartments in a pair differed on heating bill alone.

Also, it was found that the EU model and the EV model performed approximately equally well in tasks 2 and 3. This last result appeared counterintuitive since the EU model should have predicted choice better than the EV model even when a piecewise linear approximation to a nonlinear part-worth utility function was used.

In an attempt to interpret this apparent anomaly, we tried to examine if the part-worth utility functions for heating bill were indeed approximately linear, which could explain the similarity of the performances of the EU and the EV

**APPENDIX
COMPUTING EV AND EU.**

In all the cases considered, distance (x_1) and floor space (x_2) were known with certainty, and their contributions would be identical for the EU and the EV models. Here we will demonstrate how we can compute $E[U_3(x_3)]$ (denoted by EU_3) and $U_3[E(x_3)]$ (denoted by EV_3) where x_3 denotes the uncertain heating bill.

U_3 has been estimated at 40, 80, 120, and 160, and piecewise linear approximation used for intermediate points. For example, if $80 \leq x_3 < 120$,

$$(A1) \quad U_3(x_3) = U_3(80) + (U_3(120) - U_3(80)) \left(\frac{x_3 - 80}{120 - 80} \right)$$

Let $f(x_3)$ represent the probability density function of x_3 .

We will only consider the situation where x_3 has the following piecewise uniform probability distribution over $40 \leq x_3 \leq 160$:

$$(A2) \quad \begin{aligned} f(x_3) &= \frac{P_1}{40} \text{ if } 40 \leq x < 80, \\ f(x_3) &= \frac{P_2}{40} \text{ if } 80 \leq x < 120, \\ f(x_3) &= \frac{P_3}{40} \text{ if } 120 \leq x \leq 160, \end{aligned}$$

where $P_1 + P_2 + P_3 = 1$. This is a generalization of the uncertain heating bills used in tasks 2 & 3. It can be easily seen that

$$P(40 \leq x_3 < 80) = P_1, \quad P(80 \leq x_3 < 120) = P_2, \quad P(120 \leq x_3 \leq 160) = P_3,$$

and $E(x_3) = 60P_1 + 100P_2 + 140P_3$.

(A) *Computing EV_3 .* EV_3 can be computed using simple interpolation. For example, suppose $80 \leq E(x_3) < 120$. Then, EV_3 can be computed as follows:

$$(A3) \quad EV_3 = U_3(80) + \{E(x_3) - 80\} \frac{U_3(120) - U_3(80)}{120 - 80}$$

(B) *Computing EU_3 .* It can be easily shown that in the case considered here,

$$(A4) \quad \begin{aligned} EU_3 &= \int_{x_3=40}^{160} U_3(x_3) f(x_3) dx \\ &= \frac{P_1}{2} \{U_3(40) + U_3(80)\} + \frac{P_2}{2} \{U_3(80) + U_3(120)\} \\ &\quad + \frac{P_3}{2} \{U_3(120) + U_3(160)\} \end{aligned}$$

models, and differences in predictions from the two could be attributed to random error in estimation.

In the cases where the importance of heating bill was found to be significant (39 cases using ratings, 40 using rankings), regression was performed using a model where the contribution of heating bill was restricted to be a linear function.

Using a subset F-test with $\alpha = .10$, the null hypothesis that the contribution of the heating bill was linear was rejected in 10 out of 39 cases using ratings, and in 10 out of 40 cases using rankings.

Considering the entire sample, the null hypothesis that the contribution of heating bill is actually linear for each respondent can be rejected at $\alpha = .01$ using both ratings and rankings.⁵

Unfortunately, the number of cases where the null hypothesis of linearity could be rejected was always too small to conduct a statistically meaningful analysis of these cases alone.

Even though it is possible to reject the null hypothesis that the part-worth utility for heating bill is linear in all cases, the evidence indicates that linearity might indeed have existed in most cases, leading to similar predictions by the EU and the EV models.

Why did that happen? An examination of the estimated ranges of part-worth utilities for distance, floor space and heating bill shows them to be approximately equally important to the respondents on the average. However, an examination of information obtained from task 4 indicates that rent is much more important than any of the three attributes included in the study. This fact might have manifested itself as an approximately linear part-worth utility function for heating bill.

Another reason might be the fact that the heating bill was to be shared by the four residents of an apartment, thereby making the range of the heating bill to be paid by an individual \$10 - \$40 rather than \$40 - \$160. The reduced range might have made the part-worth utility function for heating bill approximately linear.

It is also possible that the respondents' perception of uncertainty in attribute values differed from the uncertainty presented in the questionnaire.

The reasons discussed so far indicate potential limitations of the study performed rather than a failure of the technique proposed. Although these limitations could not be known a priori, it is possible that a future study using an attribute which clearly has a nonlinear part-worth utility function may establish the relative superiority of the EU model.

Finally, it is possible that the lack of success of the EU model here arises from a deeper source, that the estimation of the conjoint model will give us part-worth utilities which will no longer hold when attributes are not known with certainty. Previous research (Currim, Weinberg & Wittink 1981; Wittink, Krishnamurthy & Nutter 1982) has already revealed the fact that the estimated importance of an attribute would depend on the number of levels of the attribute used in the conjoint analysis. Similarly, the presence of uncertainty might affect evaluation by a consumer, and the expected utility given by equation (2) would no longer be valid. Future research should address this question which is of crucial importance to any attempt to incorporate uncertainty in attribute values into conjoint analysis.

⁵Since $\alpha = .10$ is used for an individual level analysis, there is a 10% chance that the null hypothesis of linearity is rejected when in fact it is true. The binomial probability that it would happen for 10 or more out of 39 cases is .007, and that it would occur for 10 or more out of 40 cases is .006.

An Examination of the Effects of Attribute Order and Product Order Biases in Conjoint Analysis

Michael Tharp, Kent State University
Lawrence Marks, Kent State University

ABSTRACT

The effect of perturbing the stimulus structure within conjoint measurement and the effects of product order in a multiple-product conjoint study are examined. Although conjoint measurement has historically been considered quite robust, ordering bias may result in structural unreliability if not measured properly and accounted for sufficiently. The results of the study contribute to the evidence of conjoint measurement's robustness with regard to ordering biases.

INTRODUCTION

The primary reason for the acceptance of conjoint analysis as a research tool in consumer behavior is its capability to convert relatively primitive data into fairly sophisticated information (Johnson, 1975). "Conjoint" is defined as the measuring of relative values of attributes considered jointly, which might be measured inaccurately if calculated individually (Johnson, 1974). Conjoint analysis has been used as a measurement technique in a variety of contexts since its introduction as a research tool by Luce and Tukey (1964).

A full review of the successes and failures of conjoint measurement in analyzing buyer behavior and evaluative criteria usage patterns is beyond the scope of this paper. However, the research which has focused on the problems of data collection, and stability or reliability are of particular importance within the context of the present study. This research includes work on treatment of interactions (Green and Devita, 1975), aggregation errors resulting from the "combining" of individual responses (Curry and Rodgers, 1976), and the use of continuous versus discrete attribute levels (Pekelman and Sen, 1979). In addition, there have been a few studies that have specifically examined conjoint measurement stability and reliability. Parker and Srinivasan (1976) varied the levels in an attribute bundle used to describe health care facilities and found very little change in the results obtained from the conjoint analysis. Both Acito (1977), and McCullough and Best (1979) were in agreement that conjoint analysis had sufficient temporal stability to provide encouragement to researchers using conjoint measurement. Also, Segal (1982) evaluated the two basic methods of conjoint, "two-factor" evaluation and "full-profile" method, and found both to be very reliable with regard to input preference judgments and estimated parameter reliability. In a larger, more comprehensive review of conjoints' robustness, Carmone, Green and Jain (1978) found that orthogonal arrays of only 18 combinations did almost as well in partworth recovery as the full set of 243 combinations from which the array was drawn. In the same review, metric ANOVA was found to perform almost as well as nonmetric

MONANOVA in solution recovery (depending upon the form of input data used). Finally, Reibstein, Bateson and Boulding (1988) investigated the comparative reliability of the three most common conjoint data collection procedures (full profile, trade-off matrix, and paried profile comparison) and found the reliability score was significantly affected by the type of data collection procedure, independent of the type of reliability which they tested. However, their results indicated that the conjoint technique is reliable, in an absolute sense, under a variety of data collection methods and across a number of product categories. The strongest concern raised by their results is that minimal fractional factorial designs appear to provide less reliable results than would be desired.

Most of the conclusions about the reliability, stability, and validity of the results of conjoint measurement appear to be very favorable. However, one potential problem involves the seldom investigated (e.g., Acito 1979) effects of order bias as a hidden influence of error in many full-profile, conjoint measurement studies. Although a standard method of randomizing evaluative criterion is often utilized by researchers to minimize order bias, this "shuffling" technique may make it difficult to measure order bias if it does exist.

HYPOTHESIS DEVELOPMENT

The purpose of this study is to examine the effect of attribute and product order biases in a multi-product conjoint measurement study. As a prelude to hypothesis development, it is necessary first to review a portion of the information processing literature.

In a conjoint study of reasonable complexity, subjects may be asked to consider not only several product attributes, but several types of products as well. Concern may occur in such studies about two potential ordering biases. One potential problem involves the order in which the attributes are presented. The second concern is about the effect of the presentation order of the products.

To begin, it has been found that the order in which information (e.g., product attributes) is presented influences both perception and retention (Klatsky, 1975). Presentation order effects are evidenced by the fact that words at the beginning (primacy) and the end (recency) of a list are better retrieved than words embedded in the middle (Asch, 1952).

The potential effect of the presentation order of the products is of concern because of the possibility of "halo" effects (or general impressions that seep into respondents' usage of attributes) stemming from the level of salience that an attribute had in the previously presented products. Several recent studies have drawn attention to the fact that

conditional approaches to assessing consumers' judgments may be plagued with perceptual distortions such as halo bias (e.g., Holbrook and Huber, 1979; Huber and Holbrook, 1979). For example, in a study involving automobiles, Erickson, Johansson, and Chao (1984) found a halo effect of overall attitudes on beliefs about the cars.

However, research into the effects of primacy and recency does not indicate unambiguously which order is more likely to influence consumers' memory, perceptions, evaluations, and attitudes. In general, elements which occur earlier and later in a message have been found to be better remembered and more influential than those in the middle of the message. But generalizations are very difficult to make because the situation and individual factors interact with the message (Nickles 1984). Topic saliency, familiarity, interest, and level of controversy have been found to influence whether recency or primacy effects will occur (Rosnow and Robinson 1967). Thus, "unfortunately, it is presently impossible to predict which effect will emerge in a particular situation" (Engle, Blackwell, and Miniard 1986, p.221).

It would be difficult to predict the precise effects of the order of information presentation on its processing in a multiple product conjoint analysis. However, a general hypothesis might be that the partworth values for an attribute will be affected by both the order in which the attributes are presented and/or the order in which the products are seen. In the current study, the effects of both of the previously mentioned potential biases are investigated simultaneously. The reasons for this are explained shortly.

HYPOTHESIS

The partworth values for an attribute will differ depending upon the order in which the attribute is presented and/or the order in which the products are presented.

METHODOLOGY

The conjoint measurement used as a focus for this research was part of a larger research project that investigated consumers' use of country-of-origin cues in product evaluations. The design of the parent study allows the testing of the hypothesis as stated. That is, investigation of the simultaneous effects of attribute and product order on partworth values. An alternative approach would be to create two separate hypotheses to be tested by two different studies. In that approach, one study would test for the effect of attribute positioning, the other for the effect of product ordering. If an effect on the partworth values is found, separate studies would provide an indication of which type of bias is the cause. Although the present study cannot differentiate between the two sources of error, it does allow for the assessment of the existence of either kind. If the partworth values are affected, it would be necessary to utilize a two study design to determine the source.

In an effort to improve upon the often used convenience sample of college students, the study utilized 89 respondents that were drawn from a population of the (adult, non-student) friends, family, and co-workers of a group of university students at a mid-sized, Midwestern university. Students were trained to administer the conjoint measurement as part of an optional class assignment. Participation was validated via telephone confirmation for a random sample of the subjects.

Three products were selected for the main study and analyzed using conjoint analysis. Each product, automobiles, furniture, and beer, was measured using the full-profile method with a fractional factorial design chosen for the specific products based on previous studies and such that the fewest possible number of unrealistic attribute level combinations were included (see Appendix 1 for the attribute combinations and levels used.) Each respondent evaluated all three products.

The attribute "country-of-origin" was included in all three of the products' conjoint measurements. For each product, "country-of-origin" was placed in either the first, middle, or last position on the individual attribute combination cards which respondents were asked to rank. Each third of the respondents saw each product with the alternate positioning of "country-of-origin" of first, middle or last. Thus, no one respondent saw any two products with the "country-of-origin" attribute at the same position on the product cards. In addition, each third of the respondents saw the products themselves in a different order from the other respondents. The full design for the experiment (which is a quasi-Latin square design) is presented in Table 1.

ANALYSIS

HYPOTHESIS TESTING: Standardized group partworth values for each product are shown in Table 2. In order to test for significant differences due to attribute positioning and product presentation order an ANOVA was done comparing standardized individual partworth values that represented country-of-origin attribute usage by the respondents (in each product category) for each country position treatment. Thus, the product type was held constant within each subgroup, and any variance in the partworth score could only be caused by either attribute positioning or product ordering.

Individual partworth scores within each group were subjected to an ANOVA and results for each of the products are tabulated in Table 3. No significant differences due to attribute positioning or product ordering (which vary together due to the quasi-Latin square design used in the parent study) are evident within any one group.

However, ANOVA assumptions that the data are normally distributed (from randomly selected groups that have equal variances) have not been checked. Post hoc testing specifically investigating whether the assumptions of the ANOVA procedure were satisfied provided interesting information about the data. The Lilliefors' "test of normality" was used

TABLE 1
Multi Product-Multi Attribute Positioning Conjoint Measurement Randomization Design

<u>SUBJECTS</u>					
1-30		31-60		61-89	
Product Order	Country Position	Product Order	Country Position	Product Order	Country Position
Furniture	Last	Cars	First	Beer	Middle
Cars	Middle	Beer	Last	Furniture	First
Beer	First	Furniture	Middle	Cars	Last

NOTE: "Product Order" indicates the order in which each third of the subjects evaluated the three products. "Country Position" refers to the position that the attribute "Country-of-Origin" held on each group's set of ranking cards for each individual product.

TABLE 2

Error	30919.555	86	359.53			

NOTE: No significant differences exist at an alpha level of 0.01.

TABLE 4

Lilliefors' Test of Normality: Maximum Difference and Two Tail Probability Values for Sub-Groupings

Subjects	BEER		AUTOMOBILES		FURNITURE	
	Max. Diff.	P-Value	Max. Diff.	P-Value	Max. Diff.	P-Value
1 -30	0.266	0.000	0.217	0.001	0.229	0.000
31-60	0.231	0.000	0.273	0.000	0.236	0.000
61-89	0.139	0.156	0.166	0.039	0.271	0.000

NOTE: At N=30, the maximum difference values from Lilliefors' Table is (0.161). Thus all sub-groups (except for the group containing subjects 61-89 for beer) can be considered to assume a non-normal distribution at the various P-value levels.

TABLE 5

Bartlett's Homogeneity of Variance Test

	BEER	AUTOMOBILES	FURNITURE
Chi-Square	10.712	6.062	.593
D.F.	2	2	2
Probability	.005	.048	.744

NOTE: At alpha=.05, only the sub-groups for furniture exhibited homogeneity of variance.

for verification of the ANOVA assumptions of normality (Lilliefors, 1973). The results indicated that none of the subsets of data had a distribution that approximates a true normal distribution for the parent population. Table 4 provides each sub-sample's test statistic.

The ANOVA assumption of "equal variances" among the groups was tested using the Bartlett test (Bartlett, 1947). As can be seen in Table 5, although the furniture subsamples have equal variances, the test statistics for beer and automobiles suggest evidence of inequality of variance which represents another potential source of error accompanying any use of ANOVA on the data.

Thus, in order to utilize an ANOVA to accurately gauge the degree of order bias within the experiment, it is necessary to transform the standardized partworth values such that the new function fulfills the assumptions of the ANOVA model. At times, natural considerations of convenience may dictate that the ANOVA be conducted using "raw" data. In fact, even a brief review of published articles would seem to indicate that this is often the practice. However, the equality of variance and normality assumptions that have been violated in this case may be the least robust of ANOVA's assumptions. That is, violation of these assumptions is quite likely to affect the results. In an attempt to correct for these violations, a data transformation of the standardized individual country-of-origin partworths was conducted. The use of a square-root transformation on these partworth values resulted in the set of Bartlett tests, chi-

squares, p-values, and Lilliefors maximum distance values seen in Table 6.

As the results indicate, the group variances have been stabilized by the data transformation. The normality of the data is still partially in question but the transformation has now created a distribution that approximates the normal distribution a great deal more closely than did the raw, untransformed partworth values. This transformation makes the data amenable to ANOVA. Table 7 shows the results of an ANOVA using the transformed partworth values. As in the previous ANOVA no significant differences exist due to "country-of-origin" attribute positioning or product presentation order.

Another test of the hypothesis using the previously transformed partworth values compared each third of the respondents across all products. By looking at each group with regard to how they varied across all products, the effect of any bias that existed with regard to either attribute positioning or product presentation order is tested using an alternate method. Table 8 indicates that no significant differences exist. Since maximum normality was achieved via the previous transformation it was not necessary to test for it again, but a post-hoc Bartlett test for homogeneity of variance verified the equal variance assumption.

While these results might leave the impression that the use of a transformation is not worthwhile since the change in the F-ratios was found to be small, this is not true in many cases. The F-ratio may be strongly affected by transformation of the data (Kendall and Stuart, 1976). Similarly, the fact that the analyses of

variance was found to be robust with regard to its ability to account for the violation of homoscedasticity and normality depends strongly on the characteristics contained in the set of data under study (Keppel, 1982).

The violation of ANOVA assumptions may be a general finding when partworth values are used as input data for an ANOVA. It may be that because partworth values represent idiosyncratic usage preferences they will always have a tendency to assume non-normal distributions of unequal variances when grouped together.

SUMMARY AND CONCLUSIONS

The use of the statistical procedures outlined in the study to test the reliability of the conjoint measurement allows for the following conclusions.

The Hypothesis was not supported. There was no evidence of an attribute or product presentation order effect; no primacy, recency, or halo effect was found. Given the number of factors which have been found to influence these effects, it is not possible to state with certainty why they were not found. A potential explanation deals with the procedures used in a conjoint analysis. The subjects are not simply presented with a list of attributes, but rather they must physically manipulate cards with the attributes printed on them. In processing information about the product, the respondent may initially read the list of attributes from top to bottom, but thereafter is free to re-read the list in any order desired. Such a process would be likely to reduce the primacy-recency effects for attribute order.

Next consider the presentation order of the products. Typically, at this level of analysis, a halo effect would be expected to occur as the evaluation of one product influences or biases beliefs about the product or the overall rating of the next product. In this study, the concern was with the *weight* given to an individual attribute rather than either with the formation of a belief or with a global evaluation of the product. It is not clear whether the traditional halo effect would have an influence at this level.

The primary purpose of this article was to test for the effects of attribute positioning and product presentation order on partworth values. As the results did not find any order effects, randomization of attribute position and product presentation order may not be necessary. While this study contributes to the evidence that conjoint analysis is robust with regard to the order of attribute and product presentation, the prudent researcher may wish to utilize a design similar to the quasi-Latin square design presented here which will allow a determination of whether a bias exists. As noted, following this procedure a simple ANOVA can be used to test for the effects of order bias. Because of the time and expense associated with the process of doing two separate studies simply to assess the existence of attribute or product position ordering biases, it seems unlikely that researchers using conjoint analysis will choose that approach. If this is the case, then the researcher using a design and

measurements similar to the ones in the current study will at least be aware of whether ordering biases do exist.

Although the results of the study do not confirm the hypothesis, they are nevertheless positive in nature. Conjoint analysis was found to be robust with regard to order effects. This finding is another reaffirmation of the ability of conjoint analysis to serve as a useful tool in the measurement of consumer decision making.

The Power of Affective Reports in Predicting Satisfaction Judgments

Laurette Dubé - Rioux, University of Montréal

This paper reports a field study that empirically investigated the relative ability of affective reports and cognitive evaluations to predict consumer satisfaction judgments. The results of this research revealed that consumers' affective reports were highly predictive of the level of satisfaction. This effect was independent of, and more powerful than cognitive evaluations. The predictive value of affective reports and cognitive evaluations varied as a function of the emotional intensity of satisfaction judgments.

THE ROLE OF AFFECTIVE REPORTS IN PREDICTING SATISFACTION JUDGEMENTS

Research in consumer behavior has traditionally viewed satisfaction as an affective response to the comparison of actual consumption experiences with some internal cognitive standards. In most studies, consumers are asked to rate the performance of a product on a series of salient attributes and to express how this performance measures up to their expectations. Satisfaction reflects the outcome of a linear combination of discrepancies between actual performances and past expectations, and is directly related to the extent to which expectations are met (Oliver, 1980; Oliver and DeSarbo, 1988; Tse and Wilton, 1988; Woodruff, Cadotte and Jenkins, 1983). Typically, consumers' expectations reflect belief probabilities of attribute occurrence, corresponding to pre-purchase predictions of what the product performance will be (Bearden and Teel, 1983; Oliver, 1980; Westbrook, 1980).

The unique status of probabilistic expectations has recently been challenged by the inclusion of additional cognitive standards in models of consumer satisfaction. Best brand, ideal product performance, and equity-based comparison between costs and anticipated rewards have been empirically investigated (Cadotte, Woodruff and Jenkins, 1987; Tse and Wilton, 1988; Woodruff et al, 1983). Furthermore, the continuous and monotonic relationship between the magnitude of disconfirmation of expectations (or of any other standards), and the emotional intensity of satisfaction judgments has also been questioned. Woodruff and his collaborators (1983; 1987) have suggested that consumers' perceptual limitations create a "zone of indifference" surrounding cognitive expectations, so that positive or negative disconfirmation results only when a perceived performance falls outside this zone. The existence of these differentiated zones, i.e., zone of "indifference" and zones of "positive or negative emotional reactions" has yet to be demonstrated empirically. Nonetheless, recognizing a discontinuous function between expectancy disconfirmation and emotional intensity of satisfaction judgments suggests the possibility that

there may be no uniform type of affective responses or cognitive processes involved in post-purchase responses to consumer goods and services.

Although these recent conceptual developments have helped to improve the predictive ability of consumer satisfaction models, their scope is still exclusively cognitive. Affective responses to consumption have thus far been seen only as the outcome of extensive combinatorial processes. No research yet has investigated the feelings consumers experience as they consume products as a unique source of information on the resulting satisfaction. (For an exception, see Westbrook, 1987). Because affective reports often reflect motivation more directly than cognitive evaluations, they may surpass the latter in predicting satisfaction judgments and post-purchase behavior. Moreover, if satisfaction judgments fall in zones of differentiated emotional intensity, the relative predictive ability of affective reports and cognitive evaluations may vary as a function of the location of a specific consumption experience.

We addressed these research issues in a field study. The objectives were to compare the relative power of affective reports and cognitive evaluations in predicting satisfaction judgments, and to investigate the relative efficiency of these affective and cognitive predictors as a function of the emotional intensity of satisfaction judgments.

The role of affect in satisfaction judgments

Research findings from the areas of psychology and marketing have demonstrated that affective states influence many aspects of consumer behavior (for a review see Gardner, 1985). For instance, it has been shown that manipulating affective states influences the way consumers process information (for a review see Isen, 1987), and the level of satisfaction they express for products commonly used (Isen, Shalcker, Clark, and Karp, 1978). We therefore hypothesized that affective states experienced during the consumption of goods or services would also directly influence post-purchase responses such as satisfaction and the likelihood of repeat purchase. Indeed, affective reports differ qualitatively from cognitive evaluations and may be more directly related to behavioral predictions. The role of affective reports in determining consumer satisfaction may become essential for products in which the experiential aspect of consumption is important (e.g., services and highly symbolic goods) -- these products hardly being reducible to a list of discriminable characteristics on which adequate cognitive evaluations can easily be made.

Some empirical evidence in a related domain supports the prediction that consumers' reports of their affective states may be superior to cognitive evaluations of the same product in predicting

satisfaction. Drawing on the results of two national surveys, Abelson, Kinder, Peters, and Fiske (1982) demonstrated that affect patterns very powerfully predict political preferences. They found that the ability of affective reports to predict political preferences was independent of, and even surpassed, respondents' cognitive evaluations of a candidate. Thus, although feelings reflect one's cognitive appraisal to a certain extent, the information provided by affective and cognitive measures seems not to be redundant. In cognitive evaluations, respondents provide information about *others*, focusing on external stimuli, whereas they deliver information about the *self* in affective reports. Since affective reports concern the internal state of respondents, they may provide much more complex and realistic information than cognitive evaluations (Abelson et al, 1982). Furthermore, it seems that affective responses are less subject to consistency pressure than are cognitive evaluations. Cognitive evaluations seem to be "semantically filtered" to a greater extent than are affective responses (Abelson et al, 1982). That is, the overall conception respondents attempt to convey is weighted heavily in the ratings of individual items of cognitive evaluations. As a result, cognitive evaluations are more likely to be under the organizing influence of pre-existing expectations than are affective responses, which are a more "naive" and direct reflection of experiences. Therefore, we further hypothesized that the correlation between positive and negative components of cognitive evaluations would be higher than those of affective reports.

The relative role of affective reports and cognitive evaluations in satisfaction judgments

How different can satisfaction judgments be as a function of their emotional intensity? Are processes typically associated with neutral satisfaction judgments different from those associated with very positive or very negative affective responses to consumption experiences? Extending the cognitive categorization approach (for a review see Cohen and Basu, 1987), we suggest that with repeated exposures to a product, consumers learn to divide their experiences into neutral or emotional categories to form satisfaction judgments. The structure of these two affective categories -- neutral and emotional -- and the processes they involve differ. Fazio et al (1986) have shown that "affective" evaluation may indeed range in nature from a very "hot" affect (when the attitude object is associated with a strong emotional response), to a "colder" and more cognitively-based judgment of affect. We suggest that emotional categories include consumption experiences that have generated conscious positive (cases of satisfaction), or negative (cases of dissatisfaction) affective responses, with attentional capacity being devoted to satisfaction judgments. Consumption experiences included in the neutral category are these having generated a "scripted behavior", reflecting simply the absence of any significant purchase or usage

related problems. Such an affective response reflects the absence of dissatisfaction, and occurs when a consumption experience meets expectations. Gardner (1985) suggests that neutral affective responses rarely interrupt ongoing behaviors, simply coloring attentional processes and evaluations. Furthermore, Mandler (1982) suggests that a person may in fact be unable to report his or her true feelings for neutral affective responses further than a valuation of familiarity. Thus, we hypothesized that for neutral affective responses, cognitive evaluations would be superior to affective reports as predictors of satisfaction judgments. In addition, since both affective reports and cognitive evaluations result from a top-down processing of expectations, they should be more highly correlated in neutral than in emotional judgements. On the contrary, since the raise of emotional responses results from the bottom-up processing of affective reactions to some part of a consumption experience, we hypothesized that within this category, affective reports should be the best predictor of satisfaction.

METHOD

Subjects

Subjects were 52 customers (29 males and 23 females) recruited from three casual restaurants. The average age of subjects was 35. The three restaurants were mid-priced restaurants offering a diversified menu and a non-formal service style in a relaxed atmosphere.

Procedure

Subjects were intercepted at the end of their meal and were asked to fill out a questionnaire on consumer satisfaction. The questionnaire had to be completed before leaving the restaurant. Within three days of the actual dinner, subjects were asked to report the emotional intensity of their satisfaction with the dinner as a whole, and more specifically with the service. They were also asked about the frequency of neutral and emotional experiences they had with the service in casual restaurants at dinner time. These data were collected as part of a more extensive interview. Thirty six of the 52 original subjects completed the second part of the study.

Measures

The questionnaire included three multi-item scales. These scales measured satisfaction, affective reports and cognitive evaluations. Except for one item in the satisfaction scale, all measures specifically related to service.

Satisfaction measures: The ordinal scale of satisfaction judgment included five items. Subjects were asked to express how satisfied they were with the dining experience as a whole, and with the service in particular (1 = not at all satisfied, to 7 = completely satisfied). They were also asked the extent to which the service interaction met their needs and wants at this time (1 = extremely poor, to 7 = extremely well), the nature of their feelings

TABLE 1
Reliability of scales of satisfaction, affective reports, and cognitive evaluations

Positive items	.88
Negative items	.73

about the service (Westbrook's delighted-terrible scale, Westbrook 1980), and how happy they would be to be served by the same person on another visit (1 = very happy, to 7 = very unhappy).

Affective reports: The scale of affective reports included five positive ("warm feelings", "enthusiastic", "being valued", "surprised", "interested"), and five negative ("irritated", "annoyed", "unpleased", "bored", "indifferent") items. Subjects were asked how strongly these feelings described their reaction to the service they just had. The scale ranged from 1 to 7 points (1 = not at all, 7 = very strongly). The adjectives were selected from those most frequently mentioned in a pre-test in which comparable subjects were asked to freely elicit how they would describe their own feelings toward servers in casual restaurants, in dinners that either left them indifferent or with very strong feelings (good or bad). The adjectives were listed in random order on the questionnaire.

Cognitive evaluations: Subjects were asked to indicate the degree to which a list of adjectives described their perception of the server who just waited on them. The list of descriptors included six positive items ("friendly", "cooperative", "knows what to do", "knows what to say", "attentive", "in control"), and five negative ("hesitant", "looks stressed", "demanding", "unpleasant", "distant"). The scale ranged from 1 to 7 points, being anchored by "not at all" and "very strongly" respectively. These items were selected on the basis of the same pre-test used for affective reports. The items were listed in random order on the questionnaire.

Affective categorization of consumption experiences: Subjects were asked to categorize the service they receive on the target dinner in one of three categories: (1) "the service interaction was o.k., and did not leave me with any unusual or particular feelings" (Neutral); (2) "the service interaction was positive, and left me with very good feelings" (Emotional-positive); (3) "the service interaction was negative and left me with very bad feelings" (Emotional-negative). This retrospective

measure is a conservative assessment of consumers' actual emotional responses. Twelve interactions were categorized as neutral and 24 were emotional-positive. No service interactions left any respondent with very bad feelings. Subjects were also asked the following question: "If you could think of 100 dinners you had in casual restaurants, in how many of these would the service interaction have been...? The description of neutral and emotional categories presented above followed.

RESULTS

Reliability of the scales

Table 1 presents the reliability scores for the scales of satisfaction, affective reports, and cognitive evaluations as well as for their positive and negative subscales. All series of measures present a good reliability. The negative items were reversed and different summative scores were computed for further analysis: overall satisfaction, overall affective reports, overall cognitive evaluations, as well as positive and negative affective reports, and positive and negative cognitive evaluations.

Predictive ability of affect reports in satisfaction judgments

Recall that we hypothesized that affective reports would significantly account for satisfaction judgments, over and above their effect through cognitive evaluations. The critical dependent variable to test this hypothesis was the satisfaction judgment expressed by subjects at the end of the meal. A factor analysis with oblique rotation was conducted on the multi-item scale of satisfaction judgment. It revealed a unidimensional structure. Only one factor had an eigenvalue bigger than one (3.83) and accounted for 64% of the variance. The analysis of satisfaction judgments was conducted on the summative score of these five items.

Multiple regression analysis was conducted to test the predictive ability of affective reports and

* Standardized regression coefficients

cognitive evaluations. In conformity with our hypothesis, both affective and cognitive assessments significantly accounted for the variability in satisfaction judgments, affective reports being slightly superior to cognitive evaluations (Standardized b 's: affect = .48, $p < .001$; cognition = .39, $p < .005$). A regression model was also run to further investigate the specific contribution of positive and negative items within the affective and cognitive scales. Both positive and negative summative scores of affective reports accounted for a significant amount of the variance, whereas only positive items of the cognitive scale were significant (see table 2).

Relative predictive ability of affective reports and cognitive evaluations within affective categories

Neutral consumption experiences constituted the bulk of our subjects' past experiences with service in casual restaurants (mean frequency = 60%). On average, 30% of the visits generated strong positive feelings, and only 10% left very bad feelings. Turning to the relative ability of affective reports and cognitive evaluations to predict satisfaction judgments within each category, recall that we hypothesized that cognitive evaluations would be the best predictors of satisfaction within the neutral category, being outperformed by affective reports in emotional categories. The results confirmed this hypothesis. The overall cognitive evaluation was the unique significant predictor of satisfaction in neutral judgments (Standardized $b = .604$, $p < .060$), whereas affective reports played

the leading role in the case of satisfaction and dissatisfaction (Standardized $b = .504$, $p < .024$).

Correlational patterns

Interesting insights on possible differences in structures and processing strategies among affective categories are provided by the correlations presented in table 3. Because cognitive judgments are typically more "semantically filtered" than affective reactions, and are therefore more susceptible to the organizing influence of existing expectations, we predicted that positive and negative items of the cognitive evaluation scale would be more highly correlated than these of the affective reports. The expected pattern of correlations between positive and negative items (averaged across affective categories) was marginally significant (Cognitive evaluations: $r = .71$; affective reports: $r = .51$; $Z = 1.67$, $p < .10$).

We also observe that neutral and emotional categories do not present the same pattern of correlations between positive and negative items within the affective and the cognitive scales. For instance, as emotion arises in satisfaction judgments, positive and negative items of cognitive evaluations become more sharply correlated, whereas positive and negative items of the affective report scale become more independent (respectively $r = .75$ and $r = .42$; $Z = 1.70$, $p < .10$). Satisfaction judgments in the neutral category do not show such a pattern (respectively $r = .60$ and $r = .66$; $Z = .13$, $p < .40$). These findings parallel Abelson et al's (1982) observation that with strong emotional commitment, not only subjects show a significant halo effect that tints all cognitive evaluations, but

also, and somewhat paradoxically, they become more aware of both good and bad feelings they experience.

DISCUSSION

In summarizing the major results of this research, we have found firstly that consumers' affective responses were highly predictive of their level of satisfaction, adding significant variance explanation over and above the part due to cognitive evaluations. Secondly, we have provided some empirical evidence for the existence of affective categories that organize satisfaction judgments on the basis of their emotional intensity.

Perhaps the most psychologically provocative result of this research is the different behavior of affective responses and cognitive evaluations in neutral judgments, which we termed absence of dissatisfaction, compared to consumption experiences that generated emotional responses, which we suggested to be real satisfaction and dissatisfaction judgments. Recall that satisfaction is more directly related to affective reports in emotional categories, and to cognitive evaluations (the measure most often used in traditional studies of consumer satisfaction) only in the neutral category. In addition, when consumer satisfaction judgments resulted from very good or very bad feelings, positive and negative items of the cognitive evaluation scale became more highly correlated, whereas the magnitude of the relation between good and bad items of affective reports decreased. We take this as an indication of increased attentional capacity being devoted to emotional responses in these instances that are not assimilated into pre-existing expectations.

Can these results be explained on methodological grounds? This research presents limitations. First, it is a correlational study and observed differences may partly be due to subjects' self assignment to affective categories. Second, the

constraints imposed by the small sample size also have to be acknowledged. The very low sample size in the neutral category in particular resulted in low statistical power in testing some hypotheses. In addition, the study will have to be replicated to include consumption experiences that generated negative affective states.

Are these results bound to the specific domain of this research? We studied restaurants, and have focused on consumer satisfaction with the service. But we think that the two types of satisfaction judgments -- neutral, more top-down and theory-driven -- versus emotional -- more bottom-up and data-driven -- can be observed in all types of consumption experiences. The likelihood of activation of one or the other types of processes will vary with the nature of the product, its importance, and situational differences.

This research shows that affective reports differ qualitatively from cognitive evaluations and may be more directly related to behavioral predictions. Using consumers' affective reports should further our understanding of the processes involved in satisfaction judgments, and our ability to predict their outcome. Investigating the conditions and mechanisms mediating the effect of affective responses on satisfaction judgments should significantly contribute to a more accurate forecasting of consumer satisfaction and repeat purchase behavior.

Emotional States and Decision Making

Haim Mano, Washington University in St. Louis

ABSTRACT

This study investigates the influence of affect's two primary dimensions, Pleasantness and Arousal, on multiattribute choice processes. Subjects described their emotional state and performed two multiattribute choice tasks. The results indicate that subjects in more pleasant mood spent more time deliberating and used more decision-related information. The results are interpreted in terms of (1) a congruency between one's hedonic state and selected decision strategy, and (2) restriction in attentional capacity.

In recent years cognitive, social, and consumer psychology have shown an increased interest in the influence of emotional states on decision making (for reviews, see Gardner 1985; Isen 1987). Two common features of this line of research are that it (i) views affect as a unidimensional construct consisting of good, neutral, and bad mood, and (ii) examines affect's impact on behavior by experimentally inducing good or bad moods and contrasting between resulting behaviors (or with those resulting from neutral moods).

Until recently, both theory and evidence on the relationship between affect and decision making have suggested that people in positive affect will tend to reduce decision complexity by engaging in speedy and simplifying kinds of processing, e.g., shorter decision times, lesser acquisitions of decision related information (Isen and Means 1983). The suggested theoretical explanations were that either (i) positive affect increases the load on working memory, causing subjects to compensate for the increase by cutting elsewhere; or, (ii) if not increasing the load, positive affect somehow makes subjects more sensitive to and avoidant of the cognitive strain demanded when complex strategies are employed (Isen 1987). In particular, for a multiattribute choice task, Isen and Means (1983) found that--compared to subjects in a neutral mood--subjects in a positive mood made faster choices, revealed less information, were less likely to review information they had already looked at, used fewer attributes and ignored more attributes considered unimportant, and were more likely to eliminate from consideration alternatives that did not meet a threshold criterion on an important dimension.

Recently, Lewinsohn and Mano (1989) examined decision behavior of subjects whose moods were not experimentally manipulated. When performing a multiattribute choice task, subjects in naturally occurring pleasant mood spent more time deliberating, examined more decision related information, used more effort requiring interdimensional moves, and ignored fewer product attributes. Lewinsohn and Mano explained the contrasts with Isen and Means' (1983) in terms of the differential impact of affect's two primary

dimensions, Pleasantness and Arousal. Two mediating mechanisms were offered to explain affect's influence on decision making, one for Pleasantness and one for Arousal. Regarding Pleasantness, Lewinsohn and Mano suggested a congruency between one's current emotion and cognitive operations (Bower 1980; Isen 1987). Subjects experiencing higher Pleasantness would be in a more playful state of mind, which would lead them to enjoy the decision situation and satisfy their curiosity. Therefore a consequence of one's better mood would be a more thorough and deliberative decision process. This hypothesis, even though not consistent with Isen and Means's (1983) results, it is consistent with the notion that persons in a better mood state are more creative and perform better in problem solving tasks (Isen et al 1987).

The second mechanism, which was also examined and confirmed (Lewinsohn and Mano 1989) suggests that individuals experiencing higher levels of Arousal are more likely to have a narrower attention span (Kahneman 1973); in turn, this attention-triggered selectivity may lead subjects to spend less time deliberating, focus on fewer decision related information pieces, and ignore more of the products' attributes.

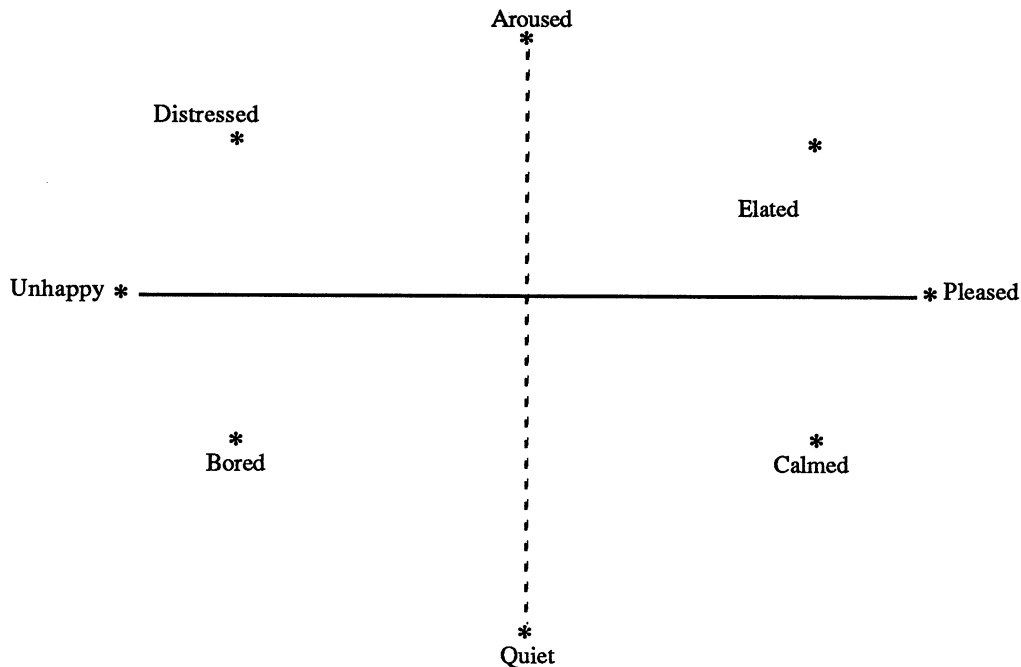

Given that Lewinsohn and Mano's (1989) results stand in contrast with those of Isen and Means, the present study will attempt to replicate and extend Lewinsohn and Mano's findings with subtle mood manipulations induced by exposure to television commercials, and to clarify further affect's influence on decision making, in general, and multiattribute choice, in particular.

AFFECT AS A MULTIDIMENSIONAL CONSTRUCT

The focus of much of past research on the relation between affect and cognitive and social behaviors has been on affect's hedonic tone (i.e., pleasantness-unpleasantness). However, a host of evidence has been offered suggesting that the affective experience is not unidimensional. Affect's multifaceted nature has been modeled in varying forms of structural complexity, generally categorized under two paradigms: Dimensional description and Classification.

The dimensional paradigm suggests two principal independent dimensions, Pleasantness and Arousal, as underlying the emotional experience whereby feelings are expressed as points on the perimeter of a circle--called a circumplex (Figure 1)--determined by the two dimensions (e.g., Holbrook and Batra 1987; Russell 1980). The parsimony and generality of two dimensions stands in contrast to the richer view of the Classification paradigm which suggests a number of independent clusters (e.g., Joy, Sadness, Anger) as the units for classification of emotions (Batra and Ray 1986; Batra and

FIGURE 1
THE MOOD CIRCUMPLEX

Holbrook 1988). Nonetheless, it is important not to consider the paradigms as opposing but rather as complementary (Havlena & Holbrook 1986; Russell 1980).

The present study views affect as a two-dimensional construct of Pleasantness and Arousal. By specifying in a more refined manner the decision maker's mood states, the two-dimensional view has important implications for the relationships between moods and decision making. Consider, for example, manipulations used to induce good mood (e.g., watching a comedy film, receiving a small free gift, or receiving success feedback in a motor-skills task). Even though these situations will induce positive affect, the evoked emotions may differ both in the intensity of their pleasantness as well as in the degree of their arousal (cf. Clark, Milberg and Erber 1984). It is important, therefore, to consider--both theoretically and empirically--whether the two central positive feelings, Elation and Pleasantness have the same effects on decision making and, if not, what their differential impacts are (Isen, Daubman and Nowicky 1987).

More generally, given affect's multifaceted nature we should delineate the effects of affect's specific facets on decision making. When examining whether an emotional state influences some behavior, one must examine whether the specific emotional state was active and what other emotional state(s) might have been active when the effect took place; and, what were the intensities of these activations. Otherwise, effects attributed to

one domain of affect may, in fact, be stemming from other or additional domains.

HYPOTHESES

- (1) It is expected that subjects experiencing a more positive mood will be engaged in more elaborate decision making activities.
- (2) Subjects experiencing higher degrees of arousal will have a narrower attention span and therefore will spend less time deliberating, focus on fewer decision related information pieces, and ignore more of the alternatives' attributes.

METHOD

The present study attempted to induce subtle emotional states by exposing subjects to TV ads prior to their performing two multiattribute choice tasks. Past research (Aaker et al 1987; Edell and Burke 1987; Gorn 1982) has suggested TV-advertising's ability to generate emotional reactions. In order to examine the ads' direct impact on emotions, the ads were not embedded as part of some ongoing TV program. Using a mood questionnaire, emotional states were assessed twice: immediately following exposure to the commercials and after the two choice tasks. The mood questionnaire measured the emotional intensity of each of the octants in affect's circumplex. Analyses concentrated on the impact and relationships among subjects' emotional

Unhappy	1	3	0	0
Distressed	2	0	0	1

states and decision processes involved in the choice tasks.

Subjects

Thirty-two subjects were recruited through ads placed in campus offering \$2.50 for participation in a decision making experiment that would last about 20 minutes.

Procedure

Subjects were randomly assigned to one of four different sets of ads and were run individually. On arrival, they read an overview of multiattribute choice followed by instructions for information acquisition and choice. Subjects were then trained by choosing from a 3X4 information board, similar to those used in the subsequent main choice tasks. After this practice task, subjects saw one of the four sets of TV ads and proceeded to answer the mood questionnaire. Next, they performed the two main choice tasks and, upon their completion, the mood questionnaire was readministered. Subjects then answered three cognitive-effort related questions. Finally, they were asked a few background questions, were debriefed, and paid.

TV ads

Each of the four groups of subjects was exposed to a set of ads intended to generate a somewhat different emotional impact. The ads were chosen from a previous study (Mano 1988) which assessed the emotional impact of 41 prime-time TV ads. In that study, following exposure to each ad, 18 subjects reported on a checklist format whether they felt emotions associated with each of the eight emotional states (for the list the emotions see "Mood Questionnaire"). Table 1 presents the total number of responses to the four ads on each affect scale.

All four sets started with Ad 1 which was expected to have a weak emotional impact. Set 1 consisted only of Ad 1. Sets 2, 3, and 4 started with Ad 1 followed by Ad 2, 3 or 4, respectively. Ad 2 was expected to have an impact on Pleasantness, Ad 3 on Elation and Pleasantness, and Ad 4 on Calmness and Pleasantness. It was anticipated that subjects exposed only to Ad 1

(Group 1) would retain their initial emotional state. On the other hand, subjects in Group 2, (exposed to Ad 2 after Ad 1), were expected to be induced into a more pleasant emotional state; similarly, Ad 3 (Group 3) was expected to have an impact on Elation and Pleasantness; and Ad 4 (Group 4) to evoke feelings of Pleasantness and Calmness. The rationale for using a mild ad first was based, in part, on recent evidence that preceding ads may become the background against which subsequent ads are evaluated; in particular, some contrast between two subsequent ads may enhance the emotional appeal of the second ad (Aaker et al. 1983).

Mood questionnaire

The questionnaire (Mano 1988) contains twenty four emotion-describing adjectives designed to assess the intensity of each of the eight regions in the Pleasantness-Arousal circumplex (Figure 1). The items contributing to each scale are: 1) *Aroused*: Aroused, Astonished, Surprised; 2) *Elated*: Elated, Active, Excited; 3) *Pleased*: Pleased, Satisfied, Happy; 4) *Calm*: Calm, At rest, Relaxed; 5) *Quiet*: Quiet, Still, Quiescent; 6) *Bored*: Sleepy, Sluggish, Drowsy; 7) *Unpleasant*: Unhappy, Sad, Blue; and 8) *Distressed*: Anxious, Fearful, Nervous. The items are presented in random order on 11-point scales (1 "not at all" to 11 "very much"). In Mano (1988), the reliabilities of the scales ranged from .64 to .91 (average .76); in Lewinsohn and Mano (1989), test-retest reliabilities resulted in correlations ranging from .67 to .95 (average .80). The questionnaire's construct validity has been examined by multidimensional scaling and factor analyses which revealed that it adequately describes the mood circumplex (Lewinsohn and Mano 1989; Mano 1988).

Decision making task

Subjects made choices from two information display boards. The information board is a matrix with choice alternatives, e.g., product brands, as rows, and attributes as columns; each entry contains the value of an attribute for a particular brand. The entries are first covered and the subject is asked to choose a brand after revealing as many information entries as desired, one at a time. An entry remained

visible until the next one was revealed. The boards were 6X5, i.e., 6 alternatives described on 5 attributes. The product employed was soft-sided luggage described on the following attributes: Volume (A), Handle control (B), Workmanship (C), Impact resistance (D) and Weight (E). Attribute values ranged from 1 (lowest) to 5 (best). The different pieces of luggage were described as equally priced and had to be judged only with respect to the five attributes. The decision making tasks were performed on a personal computer (IBM-PC). All information was administered, monitored, and recorded by the PC and subjects directed their search and made choices with the PC keyboard.

Dependent Variables

The information board methodology allows for the assessment of a number decision related variables. These include: amount of information searched, i.e., total number of revealed entries; decision time; and processing speed, i.e. average time spent per entry. The decision process can be examined in terms of search pattern; each move to a new entry within the same alternative is classified as interdimensional; a move to a different alternative but in the same dimension is classified as intradimensional. The number of times entries were revealed more than once was classified as number of repetitions; the number of attributes that the subject did not reveal any entry for a particular attribute was defined as number of ignored attributes. Cognitive effort and information load play an important mediating role in Isen's (Isen et al. 1987) and Lewinsohn and Mano's (1989) explanations of the influence of affect on decision making. Thus, in addition to the above decision variables that can also be used to assess indirectly effort, a complementary view of subjects' cognitive exerted effort was elicited by self reports. Subjects rated cognitive effort on three eleven-point scales: the amount of effort exerted to perform the choice tasks (Effort 1); how hard they had to push themselves to keep going (Effort 2); and, how much mental energy was required while working on the tasks (Effort 3).

RESULTS

Affect Measurement

The four sets of advertisements had no differential impact on subjects' emotional states; ANOVAs conducted on the eight scales did not reveal any differences between the four groups. Although unexpected, this lack of change can be explained--albeit post hoc--by a number of reasons. First, exposure to one or two short (30 seconds) TV ads may not constitute a strong enough emotional stimulus capable of generating an impact that lasts more than a few additional seconds (cf. Nowlis 1965). Second, the contrast between exposure to the ads and the mood questionnaire--both embedded in the context of a choice task--may have removed any of the ads' emotional impact. Third, a primacy effect could have taken place and only the first ad (with scant emotional content) may have affected the

subjects' emotional state. To assess further the ads' emotional impact, the eight scales were compared with those in the study by Lewinsohn and Mano (1989) which examined naturally occurring moods in a similar experimental situation but did not involve mood induction. The comparisons revealed that the two populations differed on only one of the eight scales: subjects in the present study were less bored than subjects in Lewinsohn and Mano; $M = 3.13$ vs. $M = 4.63$, $t(62)=3.0$, $p < .01$.

Given the lack of major differences between the four groups in their initial emotional states, the homogeneity of the emotions observed here and in Lewinsohn and Mano's (1989) noninduced moods, and the structural convergence of the eight scales (see next section), the four groups were pooled. This aggregation does not affect subsequent analyses that will examine the impact of emotions on decision making. In fact, the reasons that led to the pooling of the four groups are based on one of the notions presented in the introduction; namely, when it is assumed that some manipulation induced an emotional state, a careful and detailed examination must be carried out to find out whether that particular mood was indeed induced.

Changes in Affect and the Structure of Emotions

The intercorrelations of the eight affective scales between the pre- and post-decision task elicitation were: Arousal .79, Elation .86, Pleasantness 0.71, Calmness .60, Quiet .83, Boredom .72, Sadness .91, Distress .66 (all p 's $< .01$). Moreover, comparisons between the pre and post-decision affect scales revealed one significant difference (the degree of Elation decreased following the decision task; $t(31)=2.36$, $p=.02$). Thus the experimental task had only a minor effect on subjects' emotional state.

The joint structure of the pre-and post-decision emotional scales was examined by multidimensional scaling (MDS). Before presenting the results, an overview of the method is offered. In MDS of a correlation matrix, each variable is represented as a point in a geometric space whereby a higher correlation between two variables results in the points being closer in the space. To decide on the appropriate number of dimensions, two criteria are employed in conjunction: (1) an "elbow" in stress, i.e., a diminishing decrease in the levels of stress (or diminishing increase in explained variance), and (2) solution interpretability. The stress coefficients and percent of explained variance for the one to three-dimensional solutions were, respectively, .435 (43%), .11 (92%), .08 (96%). The two dimensional solution met both the stress reduction and interpretability criteria and appears in Figure 2. Visual inspection suggests a high degree of resemblance between the hypothesized circumplex of emotions (Figure 1) and the obtained map.

Decision Making: Effects of Good Mood and Arousal

As a first step in examining the influence of emotions on decision making, subjects were classified according to their intensities in Good Mood and Activation. To that goal, first, the scales that conceptually contribute to these two states were added; i.e.,

$$\text{Good Mood} = \text{Elation} + \text{Pleasantness} + \text{Calmness},$$

$$\text{Activation} = \text{Distress} + \text{Arousal} + \text{Elation}$$

In order to enhance the reliability of the two scales, one of the nine items was removed from each scale, resulting in alphas of .73 and .76 respectively. Then, using median splits, the population was divided into four groups for a 2X2 ANOVA with the two tasks serving as a replication (Table 2).

The results indicate that, despite the loss of power caused by the median split, subjects who were in a better mood worked longer ($p < .05$) and revealed more entries ($p < .05$). In terms of within-trials shifts, subjects processed information faster during the second task ($p < .01$); for processing speed there was also a significant interaction between Good Mood and Activation. Activation also had a significant impact on the three reports of cognitive effort. No other effects were statistically significant.

Overall, the above data replicate Lewinsohn and Mano (1989) and stand in contrast with those of Isen and Means (1983). Even though many effects failed to reach statistical significance, it is nonetheless clear that subjects in better mood made more deliberate considerations of the examined alternatives.

Correlational Analysis

While the preceding analyses indicate the joint effects of Good Mood and Activation on decision variables, they do not fully capture the multifaceted nature of affect or the intervality of the affect scales. A more detailed description of these relationships is suggested by their intercorrelations and MDS description. For these analyses, the means of the decision variables across the first and second choice tasks were used (the intercorrelations of the decision variables between the two choice tasks were: Decision Time .55, Revealed Entries .57, Seconds per Entry .54, Inter-Moves .76, Intra-Moves 0.71, Ignored Attributes .68, and Repetitions .76; all p 's $< .001$). The pre and post-decision measures were also added. The correlations between the decision variables and the 8 affect scales are reported in Table 3.

The joint MDS of affect and decision variables revealed the following stress coefficients for the one to four-dimensional solutions: .474 (31%), 0.259 (58%), .157 (77%) and .120 (86%). The three dimensional solution met both the elbow and interpretability criteria (Figure 3). Visual inspection reveals that the Good-Mood related states

(Elation, Pleasantness, and Calmness) were relatively close to one another, and, as a whole, they were close to decision time, number of revealed entries, interdimensional moves and repetitions. Projections on space 2-3 capture the circumplex of affect which is vertical to the two-dimensional space of the decision variables. This spatial analysis provides an alternative and complementary view on the previous ANOVAs. More importantly, however, it offers an interesting perspective for examining affect's construct validity, and the relationships between affect and decision making.

DISCUSSION

One of the original hypotheses was that subjects in a better mood would use more elaborate and time consuming decision strategies (Lewinsohn and Mano 1989). The results obtained here support that hypothesis and stand in contrast with Isen and Means' (1983) results concerning the influence of pleasant mood on decision making. The explanation offered here was that the decision maker chooses a strategy that is congruent with one's current emotion and is associated in memory with a similar to the currently experienced emotional tone (Bower 1981; Isen 1987). In the context of decision strategy selection, it is speculated that pleased subjects tended to employ a more elaborate and time consuming decision strategy because they framed the decision task as "cognitive play". Less pleased subjects, on the other hand, framed the same decision situation as a necessity that they had to get rid of. Given the subjects' playful state of mind, their goal was to enjoy the situation and satisfy their curiosity. As a consequence, they adopted a more "creative" approach and exposed themselves to more information.

The results presented here provide only partial support for the hypothesis that level of arousal would influence the attention allocation mechanism which, in turn, would effect decision strategy selection. Nonetheless, the direction of the results does not contradict that hypothesis. An explanation for the lack of strong results for arousal could be related to the possible confusion generated by the experimental manipulation, i.e., the presence of advertisements without a program context and within a decision situation.

These results suggest that Pleasantness and Arousal do not have an equally strong influence on the decision making process and that Pleasantness may have a more stable and longer term effect than Arousal (Lewinsohn and Mano 1989). Furthermore, Pleasantness may set the quality, direction, and to some extent, the intensity of the chosen cognitive strategy while Arousal allows slack cognitive effort to be allocated to the selected strategy.

Lewinsohn and Mano (1989) and the present study suggested a number of explanations for the seemingly contradictory findings with Isen and Means (1983). One aspect that seems to underlie these contrasting results may be the nature of the employed mood constructs. For example, there could be differences in the intensity of the hedonic

TABLE 2
MEANS FOR DECISION VARIABLES BY GOOD MOOD, AROUSAL AND WITHIN TASKS.

THE THREE DIMENSIONAL SPACE OF AFFECT AND DECISION VARIABLES

tone and level of activation; i.e., due to the manipulation (informing subjects that they performed at the 97th percentile on a perceptual-motor task) subjects in Isen and Means (1983) positive affect group may have experienced higher levels of pleasantness and elation than subjects in the present study. These higher intensities could draw more attention to the experienced emotions and thus decrease the slack of attentional resources required for elaborate information processing.

Similarly, Isen and Means' experimental induction could have incorporated a motivational

component which may have generated a "competition" framing leading to the use of more "efficient" decision strategies. Furthermore, procedural differences between the choice tasks (e.g., information-board sizes, computerized versus card-based information boards) might have also contributed to some of the contrasting results. Finally, because the mood manipulation was not successful, an alternative interpretation is that the present study examined the impact of some enduring personality variable rather than a temporary mood manipulation (cf. Diener and Larsen 1984). Note,

however, that whether affective responses are due to transient states or persistent individual traits, the suggested mechanisms mediating affect and decision making are still plausible.

The effect of emotions on decision making is powerful. The evidence that has been accumulated over the course of the last few years suggests that these interrelationships cannot be ignored. The present paper started from the premise that affect is not unidimensional; by examining in greater detail the decision maker's emotional state we might be able to understand better how and why affect influences decision making. Clearly, additional research is needed to clarify and further elaborate these issues.

Product Type: A Neglected Moderator of the Effects of Mood

Meryl P. Gardner, University of Delaware
John Scott, Pennsylvania State University

ABSTRACT

The role of product type as a moderator of the effects of mood on product salience, evaluation and use is examined from two conceptual perspectives: accessibility and mood management. The implications of these perspectives are discussed for a typology of product types based on the relationship of products in each classification to consumers' feeling states. Postulates regarding the effects of mood on product salience, evaluation and use are developed for four product types. The paper concludes with a discussion of conceptual and methodological issues associated with the proposed research agenda.

INTRODUCTION

Although the effects of mood states on consumer behavior have received much attention (e.g. Gardner 1985, Goldberg and Gorn, 1987), the role of product type as a moderator of these effects has been neglected. The general purpose of this manuscript is to explore the moderating role of product type on the effects of mood, and develop a set of postulates for future research in this area. By encouraging a richer understanding of the impact of product type on mood effects, we hope to provide useful insights for researchers trying to understand how mood works and practitioners trying to determine how mood affects consumers' evaluations of their products.

The manuscript has three major sections. First, the role of product type as a moderator of the effects of mood on product salience, evaluation and use is examined from two conceptual perspectives: accessibility and mood management. Then, the implications of these perspectives are discussed for a typology of product types based on the relationship of products in each classification to consumers' feeling states. Postulates are developed for four product types. The paper concludes with a discussion of conceptual and methodological issues associated with the proposed research agenda.

CONCEPTUAL UNDERPINNINGS

The moderating role of product type is viewed from two perspectives, accessibility and mood management, to provide depth and breadth of discussion. Accessibility focuses on largely automatic, memory-based, micro-level processes. Mood management emphasizes motivationally-based, learned behavior. The approaches are complementary: Accessibility involves the information which comes to mind; mood management involves the use of this information to manage one's moods.

Accessibility Perspective

Research in psychology indicates that mood states exert an important influence on behavior,

judgement and recall (Isen 1984). For example, when a memory associated with positive feelings is activated, others of the same affective tone may become more accessible (Isen et al. 1978). Such information may affect decision making and may make associated behaviors more likely (Isen et al., 1982).

This suggests that the affective tone associated with product experiences may moderate the impact of mood state on product salience. The memory trace for an affect-laden product experience may include both product-specific information and the accompanying mood state. Upon future experiences of that mood, product memories may become more readily accessible. This suggests that product types associated with affect-laden experiences will be more salient upon future experiences of the accompanying mood state.¹

Mood Management Perspective

Just as an accessibility perspective provides insights into the effects of mood on product salience, a mood management approach can be used to enhance our understanding of the effects of mood on the evaluation and use of products of different types. Studies have shown that most adults have learned to maintain positive moods and avoid the persistence of negative ones (Mischel, Ebbesen and Zeiss, 1973). Mischel (1973) suggests that individuals develop expectations for the outcomes of various behaviors which, in turn, direct their own behavior. If an outcome is seen as positive, then the behaviors that elicit this outcome are likely to be initiated; if an outcome is negative, then behaviors which lead to this outcome are likely to be held in check. For example, in a motivational analysis, elation was believed to increase the likelihood of leisure behaviors such as enjoying one's records (Cunningham, 1988).

Products may be used to bring about positive outcomes or to alleviate negative outcomes. For example, Rook and Gardner (1989) found that adult subjects in a study designed to examine impulse buying behavior, reported that they often used the purchase of material goods to perpetuate a desired mood or to alleviate a negative one. Axelrod (1963) suggests that current mood state may affect one's assessment of the desirability of future mood states. Desired mood states may, in turn, function as "mood goals" and enhance evaluations of products leading to such moods.

¹Note, however, that there is some controversy regarding this point: Bower and Mayer (1988) failed to replicate earlier findings of mood dependent recall (Bower 1981)

DEVELOPMENT OF POSTULATES

Taken together, the accessibility and mood management approaches suggest that a product's relationship to consumers' feeling states will affect the impact of mood on the product's salience, evaluation and use. This suggests that it might be useful to develop a product typology based on the relationship of products in each classification to consumers' feeling states. In this section, four product types are discussed and postulates are developed for each. Two product types involve consumers' feelings associated with product experiences -- i.e., past experiences (feel-good products) and expected experiences (feel-bad products). Two product types involve products associated with decreased levels of feelings -- i.e., feelings consumers try to control or ignore (try-not-to-feel products) and feelings which have worn away or never existed (no-feel products). This typology is obviously idiosyncratic and highly dependent upon the phenomenological experiences of each individual consumer. Equally obviously, it is not exhaustive -- i.e., for any given consumer some products may not fit into any of the four categories.

Feel-Good Products

We will use the term "feel-good" to refer to those products which are consumed for self satisfaction or as life's little pleasures. They may be used to alleviate negative moods or to accentuate positive ones. Informal observation suggests that we learn from childhood that some products can make us feel better when we are down or help us enjoy the good times in life. For example, parents sometimes use cookies to cheer up sad children and cake to celebrate the happiness of children's birthdays. The ability of some products to improve moods is given inductive support by research involving mood and helping: Subjects in positive mood states are more willing to help (Isen and Levin 1972; Aderman and Berkowitz 1970) and subjects who received a cookie in an experiment were more willing to help. Taken together, this is consistent with the notion that some products (e.g. cookies) are feel-good products, i.e., they make some consumers feel better.

If product memories are affectively encoded and become more accessible during congruent moods (Isen et al. 1982), then mood is likely to affect the salience, evaluation and use of feel-good products. Consumers may associate such products with previously experienced situations in which the feel-good product alleviated negative moods or enhanced positive ones. Rosenhan et. al. (1974) found that children in happy or sad mood conditions self-gratified by taking more candy relative to children in a control group. This is explained by Masters et al. (1979) who suggest that children elicit different treatments (i.e. receive or do not receive feel-good products) from parents, teachers or other agents of socialization depending on their mood. These treatments are likely then to influence future behavior.

Additional insights into the role of mood on the evaluation and use of feel-good products is provided by the mood management perspective. Self gratification can be viewed as a mood management technique: A study in which altruism was assumed to be a self-gratifying act, showed that helping can function to maintain a positive mood and to terminate a negative one (Cialdini and Kenrick, 1976). Self-gratifying with products as simple as cookies or candy may be used by consumers to produce or maintain positive moods. A more complex product experience, television viewing, has also been shown to affect mood states. Hirschman and Holbrook (1982) suggest that people use products such as television in what they refer to as "hedonic consumption." They cite two different types of mental images which affect consumers' perceptions of products. The first involves products that bring to mind past events such as smelling the perfume of an old romantic partner. The second deals with fantasy and what the consumer wishes to be true.

Zillman (1982) found that people use television to reduce unpleasant states of arousal or to generate or increase pleasant states of arousal. Zillman, Hezel and Medoff (1980) found that subjects selectively chose programs which held the greatest promise of relief of negative states or accentuation of positive mood states. In their experiment, subjects in a positive affective state elected to watch more comedy programs than those in a control group. In addition, subjects in a negative affective state (annoyance) watched fewer comedy programs and more game shows than those in a neutral state. The authors suggested that annoyed subjects avoided merriment from comedy but sought it from game shows because "prime time comedy is laden with so called put down humor" (Zillman, Hezel and Medoff 1980). People may not be able to distract themselves from their negative experiences if they are exposed to such humor.

The preceding discussion is consistent with both the accessibility and mood management perspectives. Products may be associated with affect-laden experiences and encoded in memory with these feelings. Future moods may cue product information, making it accessible and making the product a more salient candidate for use in mood management techniques. If successful, a product's use in mood management may serve to reinforce its use in future instances of the same mood. This is best illustrated by paraphrasing Mischel's (1973) article to include product use. If product use is seen as rewarding (reducing negative affect or enhancing a positive mood) then it is likely that the product will be favorably regarded; if the use of the product is seen as negative, the product will probably be unfavorably regarded.

Empirical evidence supports the mood-related use of some feel-good products by at least some consumer segments. Some products (e.g. liquor and cigarettes) have been shown to be used by consumers in both positive and negative affective states (Harris and Fennel, 1988, and Wills and

Shiffman, 1985). Although physiological factors may account for some habitual use, evidence suggests that at least some smoking is motivated by negative affect to reduce or eliminate tension, anxiety, and stress and by positive affect to produce stimulation (Wills and Shiffman 1985). The authors suggest that people smoke for both reasons depending on the time and place.

Alcohol use follows a similar pattern. Wills and Shiffman (1985) suggest that alcohol is consumed for two major reasons: 1.) to reduce tension, produce relaxation and divert attention away from problems, and 2) to induce pleasurable physical effects, increase enjoyment of social situations and enhance perceptions of oneself and one's future. Harris and Fennel (1988) have found that job stress is linked to alcohol consumption, but only for people who believe alcohol helps them deal with job stress.

Based upon the above discussion we postulate:

P1: For consumers in negative mood states, feel-good products will be more accessible, favorably evaluated, and likely to be consumed than for consumers in neutral mood states.

P2: For consumers in positive mood states, feel-good products will be more accessible, favorably evaluated, and likely to be consumed than for consumers in neutral mood states.

Feel-Bad Products

We will use the term "feel-bad products" to refer to those products associated with future needs with affectively negative tones. Need for these products depends on unpleasant predictions of the future. For example, the purchase of life insurance is based on the quite disquieting prediction of one's own death. A mood management perspective suggests that people in positive moods may choose to avoid thinking about such products in order to maintain their positive moods. This avoidance of negative stimuli has been shown in several studies. For example, Mischel, Ebbesen and Zeiss (1973) found success subjects focused their attention on their assets rather than their liabilities. Also, adults selectively attended to more positive and less negative self-referent information during positive (rather than neutral) mood states. Mischel (1976) found people tend to avoid any type of selective processing that would prolong the experience of an existing negative mood state. Forgas and Bower (1988) found happy subjects took more time reading and thinking about positive characteristics than negative ones while sad subjects took more time on negative material.

While consumers in positive moods may seek out products associated with positive experiences and avoid those associated with negative experiences, consumers in negative moods may view products associated with negative experiences as a

means for solving real life problems. This is consistent with Isen et.al.'s (1978) suggestion that those behaviors that endanger good mood or require thinking about material incompatible with a positive mood state should be less likely in a positive mood than when in a negative or neutral mood state.

Mood states also affect consumers' perceptions of risk. This, in turn, may lead them to evaluate some products -- e.g., insurance-- more favorably when in a negative mood. Dramatic differences in probability ratings of future events in different mood states were found by Bower (1983). In this study, subjects were placed in positive, neutral, and negative moods and asked to rate the probability of future events. Subjects in a good mood rated positive future events --e.g., vacations -- as more likely to occur; those in a negative mood rated negative future events --e.g., car accidents-- as more likely to occur. Further support is provided by Johnson and Tversky (1983), who found subjects in a positive induced mood showed a significant decrease in reported worry about potential risks than those in a control group.

Consumers' assessments of future risk probabilities may affect their product evaluations. For instance, people in negative moods may believe there is a greater chance of rain. If this is so, they will rate carrying their umbrellas more favorably. In contrast, people in a good mood may have a more positive outlook for the future and denigrate the importance of such products.

Therefore, perceptions of the importance and evaluation of feel-bad products may depend on mood. Their use however, is not affected by mood. For example, consumers who are standing in the rain don't wait until they are in certain moods to open their umbrellas.

Based on this discussion we postulate:

P3: For consumers in negative mood states, feel-bad products will be more accessible and favorably evaluated than for consumers in neutral mood states.

P4: For consumers in positive mood states, feel-bad products will be less accessible and less favorably evaluated than for consumers in neutral mood states.

Try-Not-To-Feel Products

We will use the term "try-not-to-feel products" to refer to products that are so important to consumers that they try to overcome the impact of mood states on salience, evaluation and use. Such products may be associated with high levels of risk and involvement (cf. Laurent and Kapferer 1985). When considering such products, consumers may be sufficiently motivated to use controlled processes to retrieve information that is not readily accessible, thus overcoming the effects of mood on accessibility.

In addition, a mood management perspective suggests that consumers may override biases

associated with mood states to make sure important purchases do not induce negative moods. This is consistent with Isen et al.'s (1982) suggestion that people in positive states will be as cautious on important tasks as people in neutral moods, because failure on such tasks would induce negative moods.

Thus, we postulate:

- P5: The salience, evaluation and use of try-not-to-feel products will be relatively unaffected by mood states.

No-Feel Products

We will use the term "no-feel products" to refer to products purchased by habit and used as part of one's routine. For such products, learning and attitude formation may occur after exploratory trial buying. Use of no-feel products is unlikely to be associated with mood-laden experiences or significantly affect one's mood state. Thus, neither an accessibility perspective nor a mood management approach predict that mood would affect the salience, evaluation or use of products that do not affect the consumer's mood state.

Thus we postulate:

- P6: The salience, evaluation and use of no-feel products will be relatively unaffected by mood states.

DISCUSSION

Conceptual Issues

Accessibility and mood management perspectives were used to examine the role of product type as a moderator of the effects of mood. Taken together, these conceptual approaches suggest that a product's relationship to consumers' feeling states will affect the impact of mood on that product's salience, evaluation and use. Accordingly, a product typology was developed in which classifications are based on the relationship of products to consumers' feeling states. The typology is uniquely suited to research involving product type as a moderator of affect-related effects, but is exploratory and preliminary.

Additional conceptual clarification may be achieved by addressing such questions as:

- 1.) Are product categories completely idiosyncratic or do consistent patterns of classification emerge across market segments or subculture groups?
- 2.) Are biologically-based product reactions inherently different from developmentally-learned reactions?
- 3.) How do product feelings based on personal usage experience differ from those based on indirectly acquired information?

- 4.) Under what circumstances are consumers unable to over-ride the biasing effects of mood states?

In addition, research is needed to explore how products may move from one category to another over time. For example, some products (e.g., liquor) may start out as feel-good products and later become no-feel products. Initially, such products serve as mood management tools. Later, the emotions associated with product use wear away and usage becomes merely habitual. Tomkins (1968) describes smoking as being used to augment affect or reduce negative affect initially and eventually becoming preaddictive or addictive for some smokers. Although the routinized use of cigarettes may be associated with a physical addiction to nicotine, use of other products can become routinized as well. Understanding this process may provide insight into overconsumption and addictive behavior.

Methodological Issues

As with any conceptually-based typology, the one presented here must be carefully operationalized. Traditional, qualitative, projective and physiological approaches can be used to triangulate on phenomenologically perceived feelings. Additional questions need to be addressed as researchers prepare to examine the postulates presented in this manuscript:

- 1.) At what level of specificity (i.e., negative mood vs. sadness) should feeling states be studied?
- 2.) How should individual differences be examined?
- 3.) How would one determine the set of products which comprise each category for a given individual?

The typology and postulates presented are intended as a preliminary stage toward developing our understanding of product type as a moderator of the effects of mood on product salience, evaluation and use. While further research is obviously necessary, we believe the ideas presented provide a critical first step in an important direction.

Feelings About Feeling-State Research: A Search for Harmony

Carl Obermiller, Seattle University
April Atwood, University of Washington

The '80's will be seen as the decade of feelings in consumer research. In the '70's, our focus was attitude, and the paradigm was a cognitive one, the multi-attribute model of structure. But the coldly cognitive framework, however useful, was clearly limited. Explained variance in global evaluation measures or behaviors rarely exceeded 20%, and was more often less than 10%. Moreover, like the more general *rational expectations* framework in decision making, multi-attribute attitude models assume a degree of elaboration that seems implausible for observed consumer behavior.

Early warnings were sounded by Krugman (1965) and Robertson (1971) who cautioned that much, if not most, consumer behavior is characterized by low involvement decision making and that low involvement results in subtler evaluation processes. Wright (1973) introduced the concept of *affect referral* to describe the role of feelings about brands in consumer evaluation. Wright proposed that uninvolved consumers would be insufficiently motivated to engage in an elaborate evaluation rule and would merely access a global feeling associated with each alternative. Wright, however, regarded those feelings to be the result of some prior cognitive processing, now stored separately in memory, rather than direct affective responses.

Not until Zajonc's (1980) landmark article on feelings as an independent, primary, and compelling evaluative force did consumer researchers begin to make dramatic changes in their conceptualizations. Throughout the decade, Zajonc has argued that affective responses are an independent processing system, which may respond to perceptual processes but may be as separate from cognitive evaluation as to originate in the muscular system. Gorn (1982) renewed interest in classically conditioned emotional responses. Mitchell and Olson (1981) helped to develop a stream of research on attitude-toward-the-ad, that has, in turn, acknowledged affective responses to ad experiences as important. Holbrook (c.f. Holbrook and Batra 1987) has lately done considerable work on the conceptual side of emotion in consumer responses. Isen (c.f. Isen, et al 1978) introduced new effects of feeling states on psychological processing, and Gardner (1985) followed by introducing consumer researchers to the effects of moods.

The preceding brief review is intended to emphasize the importance of feelings as a topic in consumer research for the past decade. A much longer paper would be required to describe how much progress we have yet to make before we can claim to understand feelings nearly so well as we have come to understand their cognitive counterparts, beliefs. We stand in a paradox; the ways we think and feel seem quite natural and simple; yet, the ways we think about the way we think and feel seem quite

artificial. Good science exhibits a variety of pleasing harmonies that our research into consumer feelings has yet to display: The harmony of mysteries revealed, when *theory* represents internally consistent concepts that generate surprising, yet compelling hypotheses. And the harmony of *methods* that are consistent with the goals implied in the theory or acknowledged by the scientist. And, finally, the harmony of *analyses*, appropriate to the methodology, and yielding interpretations appropriate to the theoretical or applied goals of the researcher. Such harmony within and among the aspects of scientific research has been elusive in our attempts to understand affective processes, and the three papers of this session are not exceptions. Notwithstanding their valuable contributions, mostly at the conceptual level, all of the papers exhibit disharmonies: Theoretical reasoning is internally inconsistent; conclusions are discordant with existing theory; methods are out of rhythm with research purpose; analyses are out of sync with the designs that generated them.

"Product Type: A Neglected Moderator of the Effects of Mood" by Gardner and Scott is admirable for its attempt to develop theory. The paper takes the logical step of refining known relationships between mood and outcome states--product information availability, product evaluation, and product use. Product type is proposed as a mediator of the mood-outcome relationships, which are premised upon structural and motivational effects of mood. The structural effect, termed by Gardner and Scott *accessibility*, is most associated with Isen's work showing a bias in information availability in memory, consistent with current mood. The motivational effect, which Gardner and Scott refer to as *mood management*, is associated with Mischel's work showing that behavior is consciously guided by desire to attain or sustain good moods and avoid or terminate bad moods. Gardner and Scott propose four product types as mediating conditions--"feel-good" and "feel-bad" products that, respectively, result in or cause good moods and bad moods, "try-not-to-feel" products, which imply consequences sufficiently important that consumers attempt to suppress mood when considering them, and "no-feel" products, which neither imply nor evoke an emotional response.

Two quite general concerns strike us at the outset. First, if we are to borrow the principle of mood management, we ought to examine it further. The authors paraphrase Mischel (1973), "individuals develop expectations for the outcomes of various behaviors, which, in turn, direct their own behavior." This may be the core of the mood management perspective, but it is little different from a cognitive instrumental learning perspective. Our behaviors are guided by the constant motivation

to seek instrumental outcomes. It is unclear why we need to invent a new theoretical perspective specifically for moods when an old standby will do as well. Moreover, the major flaw in instrumental learning "theory" is still evident in the mood management perspective--it can explain behavior *post hoc* but cannot predict. We have little confidence in our knowledge of the mood expectations consumers attach to product use.

Second, and related to the first issue, any attempt to construct theory based on product typology is limited by the idiosyncratic nature of responses to products. One consumer feels good about mortgage insurance, focusing on the security it brings; another feels bad, focusing on possible disaster; another tries not to feel, suppressing emotions because of the importance of the decision; still another is completely uninvolved and feels nothing. Gardner and Scott acknowledge this problem but should discuss it further. It is unclear that product type can be identified with enough accuracy to make it useful for predictions.

Aside from the general concerns, we find several internal inconsistencies in the logic of the propositions. While we fault the theoretical structure here, we suggest that these problems might be fruitful research questions. The first is a minor inconsistency in definitions. For P3, Gardner and Scott exclude effects on product use with an explanation in the form of an instance--consumers cannot let mood dictate when their cars will be repaired. The example is irrelevant, however, since, according to the definition, car repair is not a feel-bad product. Car repair implies immediate, not future, needs. Preventative car maintenance would qualify as a feel-bad product, and it should show the same biases in patterns of product use as in information availability and product evaluation. The exclusion of use from P3 is not consistent with the logic and definitions that are developed.

Two other incongruities suggest contradictory effects of the structural and motivational aspects of mood. The logic of P1 flows from mood management, but it contradicts the accessibility perspective. Information availability has been shown to be consistent with current mood, so when consumers are in a negative mood, they should exhibit a negative bias toward feel-good products. The logic of P5, on the other hand, appears to flow from the accessibility perspective--the availability of try-not-to-feel product information, because such products are defined as feeling-suppressed, is unaffected by mood. Yet, mood management logic suggests that, because the outcomes of such product decisions are important and mood relevant, we should expect to see positive biases associated with both positive and negative mood states. Whether motivational or structural effects of mood predominate for feel-bad and try-not-to-feel products may be an area for investigation.

Gardner and Scott attempt to refine theory by proposing mediating variables; Mano, in "Emotional States and Decision Making," attempts to refine the essential construct--feelings.

Borrowing from the work of Mehrabian and Russell, Mano questions the finding that positive mood state results in faster, less complete decision making (Isen and Means, 1983). His argument is cogent; positive mood state is multidimensional, including, at least, both pleasantness and some degree of arousal. The combination of pleasantness and high arousal (elation) should reduce attention relative to pleasantness and low arousal (calm). His aim was to manipulate degree of arousal within a narrow range of pleasantness to demonstrate that changes in decision making may result from both dimensions of mood.

Our objections to Mano's work are in the methodology, not in the conceptualization, which we find persuasive and fruitful. First, when one proposes a rival explanation of a prior finding, a claim against the construct validity of the original manipulation (as Mano does with respect to Isen and Means 1983), one should begin with the procedure not the result. Mano is correct when he claims that his "theory" can account for the Isen and Means data and for his own hypothesized outcomes, but the reader would be more persuaded by a careful contrast of the procedures. We are asked to assume that Isen and Means naively confounded pleasantness and arousal; we should be shown how their manipulation did so.

Second, and more fundamental, Mano's experiment falls into the crack between applied and theory testing research. The objective appears to be a theory test; yet, the manipulation procedure (exposure to "real world" commercials) is inadequate to the requirements of construct validity for theory testing. It is not mere hindsight that supports this criticism. There is no reason to expect exposure to commercials to be a strong pure manipulation of mood and no reason to trade off a weak manipulation for any external validity concerns. After all, there is no external validity in forced exposure to ads in a lab setting anyway. When we want to manipulate moods, we should design manipulations that do so, reliably and forcefully. Whether and how commercials affect moods in mundane conditions is a separate, very different question, to be answered with separate, very different methodology.

Because of the inadequate manipulations, Mano's research was reduced to a correlational analysis. Our final criticism is a minor one, referring to the nature of the analysis. Mano presents the results of an overall correlation in Table 3. He also divides the sample into low and high levels on the mood dimension (Table 2) and conducts analysis of variance. What is the justification for the anova, which has substantially lower power? Moreover, the data in the two tables show contradictory effects of activation (arousal). In Table 2, decision time, revealed entries, intra- and inter-moves, repetitions, and effort all increase from low to high activation; yet, the correlations in Table 3 are negative for decision time, revealed entries, and repetitions. Given that this is the central research question, this discrepancy should be discussed. If it is an artifact of the split sample

anova, it is further reason for not conducting that analysis.

Dube-Rioux, in "The Power of Affective Reports in Predicting Satisfaction Judgments," tackles feelings simultaneously as independent and dependent variable. Her contribution is to the conceptualization of satisfaction. It is typically characterized as a cognitive appraisal of attribute performance versus attribute expectations. Dube-Rioux argues for a significant independent contribution of affective response, in particular when satisfaction is, in her terms, "emotionally intense."

We are receptive to the claim that satisfaction should be reconceptualized and that feelings should be acknowledged as part of that construct. We were puzzled somewhat by Dube-Rioux's mediating condition--the emotional intensity of satisfaction. It is unclear what is gained by the claim that for "emotional" satisfaction, measures of emotional response play a larger part than they do for "unemotional" satisfaction. Perhaps some further work can be done to characterize the conditions under which emotion plays a greater or lesser role in satisfaction. One suggestion is to consider the product typology of Gardner and Scott. Affective response measures may be better predictors of satisfaction with feel-good or feel-bad products; worse for the other types.

The use of regression analysis of the contributions of affective and cognitive components raises several questions. First, the two measures are highly correlated, so evidence that only one component is statistically significant in an equation is not compelling evidence that the other has no explanatory power, especially with a small sample size. Second, a comparison of beta weights within an equation assumes that subjects interpreted the affective and cognitive metrics in the same way. In general, a comparison of affective versus cognitive contributions is a comparison of apples and oranges. It begs questions of measurement validity that cannot be answered satisfactorily. A better approach that is available in Dube-Rioux's framework is a comparison of the contribution of either component under different conditions. The appropriate test is whether the beta weights for affect or cognition change between emotional and neutral satisfaction conditions. Such a comparison, however, requires assumptions of certain equalities across samples that might not be met.

Beyond the use of theory, method, and analysis that are in harmony within a study, researchers in this area would do well to strive to conduct research that is clearly tied to the growing body of literature on the effects of feelings and moods. One important step is to define with care the constructs under study. Previous work has attempted to differentiate among affect, emotion, mood, and feelings on conceptual grounds (c.f., Gardner, 1985; Holbrook and Batra, 1987); current and future research should make clear which constructs are of interest and should indicate the operational definitions that are being used. Beyond

a clear definitional statement, the research should describe the underlying process of interest and should specify the role that moods or emotions assume. This trio of papers examines affective responses or moods in a variety of roles: Gardner and Scott treat mood as an independent variable whose effects on consumer behaviors are moderated by the type of product under consideration, while Mano examines emotional state as a moderator of consumer decision making, and Dube-Rioux, in her conceptualization of satisfaction as an emotion-based construct, considers feelings as dependent variables in the process under consideration. Some cataloging of which conceptual role the affective responses or moods are filling may help to organize the broad existing literature on moods and would help clarify the handling of the construct in each prospective study.

A second step toward better integration of new studies with existing work in the field can be taken in careful choice of measures. Researchers should consider consolidating, refining, and standardizing past measures of feelings before creating new ones. Ambiguity among constructs is exacerbated by a never-ending series of new operational measures.

A third and final general comment is to repeat a criticism of Mano's paper and issue a general call for more appropriate mood induction manipulations. If the aims of a study are to examine moods or the effects of moods in mundane consumer settings, then effects-testing procedures are appropriate and mood manipulations high in mundane realism would be called for. If, however, the aims of the research are theory-testing, then strong experimental manipulations or inductions of mood are appropriate. James Russell, a psychologist who has done considerable work in the area of conceptualizing mood states and examining their effects (c.f. Russell, 1980), reports that a relatively long (twenty minutes) audio tape using musical selections has been effective in inducing mood states (positive or negative); such an approach, while not resembling most real world situations, might be especially useful for theory-testing oriented studies of feeling states. We need to separate the research that aims to answer theoretical questions that are proposed as relevant to consumer behavior from the research that aims to describe the effects that occur in everyday consumer behavior.

An Empirical Assessment of Multiple Operationalizations of Involvement

Kapil Jain, University of Rhode Island
Narasimhan Srinivasan, University of Connecticut

ABSTRACT

Involvement is an important and much debated topic in consumer research. Rigorous measurements of the construct by Laurent and Kapferer and Zaichkowsky have led to scales which are finding increasing acceptance by several researchers. Building on recent studies, this paper makes an empirical comparison of the various scales in the literature: Involvement Profile (Laurent and Kapferer); Foote, Cone & Belding Planning Grid's involvement sub-scale (Vaughn); Personal Involvement Inventory (Zaichkowsky); and modifications of Zaichkowsky's scale. In so doing, the study brings further clarification and refinement to the involvement construct. A New Involvement Profile is distilled and offered for future research.

INTRODUCTION

Involvement has been the focus of a large number of studies in the consumer research area in the past decade (Houston and Rothschild 1977, 1978; Kapferer and Laurent 1985, 1985/86; Laurent and Kapferer 1985; Richins and Bloch 1986; Vaughn 1980, 1986; Zaichkowsky 1985). A multitude of conceptualizations are available in the literature: product/brand involvement, enduring / situational involvement, cognitive / affective involvement, instrument / response involvement and so on and so forth. This diversity of views provides a very rich perspective of the construct. However, the development in conceptualization has far outpaced the developments in operationalizations, leading to a call for better measuring instruments and empirical testing (Rothschild 1984) and simpler middle-range theories that are parsimonious (Kassarjian 1978).

Toward this end, Zaichkowsky (1985) and Laurent and Kapferer (1985; Kapferer and Laurent 1985) have concentrated their efforts on rigorous scale development. This study seeks to build on their work and others' in the direction of further refinement of measures in capturing the complexity of the involvement construct.

BACKGROUND

Much of the diversity in definitions adopted by researchers in the involvement area begins at the conceptual level. Starting from Sherif and Cantril's (1947) ego-involvement to Beatty and Smith's (1987) consideration of the interactive nature of involvement, the complexity of the involvement domain has increased. In this study, we focus on just two parallel streams of theory development: Zaichkowsky's Personal Involvement Inventory (PII) and its modifications/extensions on one hand, and Laurent and Kapferer's Involvement Profile (IP) on the other - the remarkable similarity of the conceptual domains tested in these studies cries out for empirical validation.

Zaichkowsky (1985) defined involvement as "a person's perceived relevance of the object based on inherent needs, values and interests." Ratchford (1987) adopts a comparable perspective: involvement implies attention to something because it is somehow relevant or important.

However, a unidimensional approach to involvement is not sufficient to capture its complexity. Rothschild (1984) provided a broader conceptualization: "Involvement is an unobservable state of motivation, arousal or interest. It is evoked by a particular stimulus or situation and has drive properties. Its consequences are types of searching, information processing and decision making." The above definition has gained wide acceptance (Laurent and Kapferer 1985; McQuarrie and Munson 1987).

Laurent and Kapferer (1985) strongly urge that involvement should be thought of as a profile of several facets. They offered a 19-item profile of five dimensions: Importance, Pleasure, Sign-value, Risk Probability and Risk Importance. However, the five dimensions collapsed into four factors during empirical testing, with Importance and Risk Importance loading on the same dimension. In a revised 16-item profile, Kapferer and Laurent (1985, 1985/86) tapped five dimensions again, but replaced Importance with Interest. The five factor structure was confirmed, although only two scale items were available for assessing risk probability. In the latest update of the scale (Laurent and Kapferer 1989), the same five factor structure is retained, but with a change in the number of items in each sub-scale (Interest - 3 items; Sign - 3 items; Pleasure - 3 items; RiskImp - 3 items and RiskPro - 4 items). It is important to note that the five distinct dimensions of involvement are non-orthogonal. Strong correlational relationships were found for the following pairs of factors: Interest-Pleasure (0.55), Interest-RiskImp (0.50), and Pleasure-Sign (0.47). The empirical evidence supporting this multi-faceted conceptualization comes from large numbers of non-student subjects in France, over a number of years and spanning numerous products. However, since the scale was developed using French items and has not been published in its entirety, the potential for its usage in the U.S. has been limited (Mittal and Lee 1988).

Coming to the other research stream of interest for this study, Zaichkowsky's empirical validation of the 20-item PII also covered numerous products. The PII appeared to capture one major factor - Relevance - across all product categories, and some minor factors, which were not considered further. The major factor accounted for approximately 70% of the variance. The PII is appealing in its simple structure (20 pairs of adjectives) and the single score used to represent the degree of involvement is useful for easy comparison of products along a continuum. In this fashion, it

has been used by other researchers (Celsi and Olson 1988).

The scope of the PII was expanded by McQuarrie and Munson (1987), who concurred with Laurent and Kapferer's emphasis on a multi-dimensional involvement profile. McQuarrie and Munson felt that the PII reflected two dimensions of the Involvement Profile, thought to be Importance and Pleasure. So, in their revision of the PII (RPII hereafter), they sought to incorporate Sign and Risk components and dropped certain items that were considered causes of attitudinal contamination and redundancy. Their revised version did not distinguish between Risk Importance and Risk Probability as two separate dimensions but had only a single dimension to capture the Risk aspect. However, their attempt to capture the Sign sub-scale was not successful. They too found significant correlations among the sub-scales: Importance-Pleasure (0.60), Pleasure-Risk (0.49) and Importance-Risk (0.41).

Higie and Feick (1989) in measuring enduring involvement, borrowed items from Zaichkowsky's PII and McQuarrie and Munson's RPII for their Hedonic (Pleasure) sub-scale and developed a reliable sub-scale for their Self-Expression (Sign) dimension. Therefore, the pool of items from these three studies (Zaichkowsky, McQuarrie and Munson, and Higie and Feick) collectively taps the same facets of involvement as does the involvement profile (IP) proposed by Laurent and Kapferer.

In summary, we have two streams of measure development that appear to share the same conceptual framework of a multi-faceted involvement construct. Or, are we really comparing apples with oranges? Speculations have been made about the overlap/congruency of the dimensions of involvement as used by earlier researchers (Ratchford 1987). However, empirical support for such inferences is not presently available. Hence, we decided to test the comparability of the two sets of items for domain congruency, potential differences in sub-scale reliabilities and relationship with the consequences of involvement.

STUDY DESIGN

The objectives of the present study included the following:

- i) translate Laurent and Kapferer's Involvement Profile (French items into English),
- ii) replicate scale structures (IP, PII and modifications),
- iii) compare the factor structures of the two sets of items, which conceptually can be expected to be similar,
- iv) assess correspondence/domain overlap between the various pooled items,

- v) abstract a subset of items (three in each sub-scale) that best captures the various aspects of involvement as a potential refinement of either set, and
- vi) test the performance of the abstracted scale.

Sources of scale items

We are grateful to Laurent and Kapferer for providing us with the original French items for the latest revision of their Involvement Profile, along with a tentative English translation. We used four other translators (two Americans and two Europeans) for independent translations and arrived at items 1-16 shown in Table 2. The other major sources were the published items of Zaichkowsky's PII, and McQuarrie and Munson's RPII, and Higie and Feick's study (items 20-49 in Table 2). Lastly, the published involvement items (items 17-19 in Table 2) used in the FCB grid were added to the pool (Ratchford 1987). The measure of involvement in the FCB grid had only three items. Its parsimony and the advertising industry's acceptance made it attractive for inclusion. Besides, there was a need for some "better" risk measures. Thus, there were 49 items in total, half of which were reverse coded.

It is significant to note two possible sources of bias: one involving translation and the other methodological. Responses to the English items may not necessarily yield a pattern similar to that of the original French items, not only because of the translation (differing usage of idioms and expressive aspects of the language), but also because of the differences in the marketplace settings -- product offerings, consumer tastes, and culture. The methodological issue concerns the reformulation from the original likert-type format to a semantic-differential format. The change in format was necessitated by the requirements for conformity with the rest of the items used in the study. In this respect, Jaccard, Weber, and Lundmark (1975) have shown that the two types of scales yield similar results, and hence this may not be a serious limitation.

Data Collection

Ten products were selected after a review of previous studies. Multiple products were chosen to retain the generalizability across product classes, similar to other researchers. The ten products were: alarm clock, batteries, calculator, chocolate, cologne/perfume, detergents, haircut/styled, music tapes/records, newspaper and radio. These products were chosen to reflect a spectrum of involvement profiles and in light of students' familiarity with the products. To reduce tediousness of the task and respondent fatigue and boredom, five pairs of products were established at the outset and each respondent completed the scales for only one pair of products.

A convenience sample of 375 student respondents, almost all of whom were undergraduates, was drawn from two major north-

TABLE 1
Cronbach Alphas of the Various Involvement Scales

Scales	Alpha	
	Previously Reported	Present Study
Laurent and Kapferer's Involvement Profile:		
- Interest	0.76	0.76
- Risk Probability	0.54	0.57
- Pleasure	0.83	0.72
- Sign	0.81	0.82
- Risk Importance	0.72	0.78
Zaichkowsky's PII:	0.95-0.97	0.94
McQuarrie and Munson's RPII:		
- Importance	0.95	0.87
- Risk	0.77	0.67
- Pleasure	0.92	0.88
- Sign Value	--	0.58
Higie and Feick's EI:		
- Hedonic	0.93	0.90
- Self-Expression	0.92	0.90
FCB Grid Scale:	0.77	0.81

eastern universities. Each respondent received two random orders of the pool of 49 semantic-differential items, one for each product in the pair. The product order in the pair was also randomized. A total of 735 usable responses, pooled across all products, were available for analysis.

ANALYSIS AND RESULTS

Replication of Previous Scale Structures

Responses were pooled across all the ten products for the analysis, and oblique factor analysis was used. The replication analysis of the various scales yielded consistent and encouraging results, both in the factor structures and Cronbach alpha values of the sub-scales.

The IP items yielded four factors: Interest and Pleasure loading on the same dimension, Sign, Risk Probability and Risk Importance. Together, the extracted factors explained 61% of the variance (Replication of the IP is discussed later). The PII items yielded two factors, accounting for 61% of the variance (major factor = 48%; minor factor = 13%). The first factor reflected Relevance/Importance and the second factor reflected Pleasure, as was expected. The inter-factor correlation was 0.46. Three factors were recovered for McQuarrie and Munson's RPII, that together explained 66% of the variance (46%, 11% and 9% for the three factors respectively). The three factors were Pleasure, Importance and Risk. The inter factor correlations were as follows:

Pleasure-Importance = 0.59, Pleasure-Risk = 0.35, and Importance-Risk = 0.29. The structure of the factor analysis reported by Higie and Feick was also recovered (77% of the variance was explained). The correlation between the two dimensions, Pleasure and Sign, was 0.56. The three FCB items yielded a single factor, recovering 72% of the variance.

Table 1 shows the Cronbach alpha values obtained in the present study as well as those reported in the literature. It can be seen that there is a great deal of consistency. Similar to the finding by Kapferer and Laurent (1985), the internal consistency of the Risk Probability sub-scale was not high (0.54 vs 0.57). McQuarrie and Munson's Risk items yielded a slightly higher alpha value of 0.67. The inclusion of the FCB scale to bolster the assessment of Risk is, therefore, seen to be justified, and its alpha value was 0.81. All the other sub-scales had alpha values in the range of 0.67 to 0.94.

Comparison of The Two Sets of Involvement Profile Items

The two sets of items were (1) the English translation of Laurent and Kapferer's (1989) latest revision of the IP (study 1: items 1-16 in Table 2), and (2) the combination of items from the PII and its modifications (studies 3, 4 and 5: items 20 - 49 in Table 2). Each set of items was factor analyzed separately with data pooled across all the products.

^a Study 1: Laurent and Kapferer (1989) (English translation)
Study 2: Ratchford (1987)
Study 3: Higie and Feick (1988)
Study 4: Zaichkowsky (1985)
Study 5: McQuarrie and Munson (1987)

Items 1-16, which formed the first set (taken from the Involvement Profile), yielded four factors (using the scree test and the eigenvalue criteria) that together explained 61% of the total variance (the varimax version showed the variance explained by Interest/Pleasure, RiskImp, Sign and RiskPro factors to be 36%, 12%, 7% and 6% respectively). Oblique rotation of the factors was used for interpretation. The Sign, RiskPro and RiskImp sub-scales were recovered as distinct dimensions. However, the sub-scales for Interest and Pleasure loaded on the same factor. One may recall that factors corresponding to these two sub-scales had the highest correlation amongst all the factors in the Kapferer and Laurent (1985) study. The inter-factor correlations of Interest/Pleasure with the Sign, RiskPro and RiskImp dimensions were 0.47, -0.08 and 0.46 respectively. Sign was correlated 0.02 and 0.45 with RiskPro and RiskImp respectively. The two dimensions of risk were correlated 0.11.

Items 20-49, which formed the second set were also factor analyzed. Again, using the scree test and eigenvalue criteria, four oblique factors were recovered, accounting for 64% of the variance. The dimensions which emerged were: Relevance, Pleasure, Sign and Risk (these accounted for 40%, 14%, 6% and 4% respectively in the varimax version). Relevance had a correlation of 0.44, 0.32 and 0.15 with Pleasure, Sign and Risk respectively. Pleasure was correlated 0.56 and 0.33 with Sign and Risk respectively. Sign and Risk had a correlation of 0.47.

It may be observed that the two sets, which were thought to be parallel versions, *did not yield similar factor dimensions*. Only Pleasure and Sign were common facets. Relevance emerged as a dominant dimension in the second set, but was absent from the first. The first set showed the two facets of risk, RiskImp and RiskPro, to be distinct, while all items related to risk loaded on the same factor in the second set. Hence, it may be expected,

that were both sets to be combined and factor analyzed, five dimensions would result (Relevance, Interest/Pleasure, RiskImp, Sign and RiskPro).

Testing Domain Overlap

Stewart (1981) recommends that a useful application of factor analysis is for testing the domain of various items which relate to the same construct. The present setting provides such an opportunity. Items 1-49 (Set 1, Set 2 and the FCB items) were subjected to an oblique factor analysis. As observed earlier, there is no theoretical justification for orthogonal dimensions. The scree test and eigenvalue criteria revealed five dimensions, as hypothesized. The emergence of the five dimensions from the increased set of variables indicates that the factors are robust.

Table 2 shows the factor loadings of the complete set of 49 items. The five factors are Relevance/Importance, Pleasure/Interest, Sign/Symbolic, Risk Importance and Risk Probability, explaining 59% of the total variance (in the varimax version, the factors accounted for 36%, 10%, 6%, 4% and 3% resp.). The pattern of the item loadings revealed that there were overlapping dimensions from the various scales. The first factor was the unique Relevance aspect of the PII. The second factor, Pleasure showed high loadings of items from the Pleasure/Interest sub-scale of the IP, and the Pleasure sub-scale of the RPII. The Sign factor had high loadings of items belonging to the Sign sub-scale of the IP, and the Self-Expression component of Higie and Feick's Enduring Involvement scale. The RiskImp factor had high loadings from items in the RiskImp sub-scale of the IP, the Risk sub-scale of the RPII, and all the three items from the FCB scale. Finally, the RiskPro factor reflected the RiskPro sub-scale items from the IP and the Risk items from the RPII.

Two salient findings emerge from Table 2. First, the Relevance component of involvement is totally untapped in the current battery of IP items. Interestingly, in Laurent and Kapferer's study reported in JMR (1985), the Importance items had loaded with Risk Importance and were replaced with Interest items in their later ACR and JAR studies (Kapferer and Laurent 1985, 1985/86). Perhaps, a different set of Importance items in the JMR study might have led to a distinct dimension, since Zaichkowsky's Relevance factor does have Importance related adjective pairs, such as "important/unimportant," "needed/not needed," and "essential/non-essential." Also noteworthy is that the RiskImp sub-scale remained as a distinct factor and did not load on the Relevance factor in the domain analysis.

The second salient finding relates to the mapping of Risk in the RPII on the Risk-related dimensions of IP. The three items of Risk load about equally on RiskImp and RiskPro factors. Hence, an argument can be made for retaining the two components of risk as distinct facets of IP, if more information is considered desirable. A counter argument, using a parsimony criterion, could be that

the Risk sub-scale of the RPII may be substituted for the two facets of risk in the IP, since the significance of RiskImp may have been boosted by the inclusion of the FCB items in this analysis. However, dropping the three FCB items still yielded the same five factors as in Table 2, with RiskImp and RiskPro remaining distinct.

Table 3 shows the inter-factor correlations of the five dimensions. The correlations of Sign with Pleasure and RiskImp were both 0.58, which is the highest value in the table. Relevance correlated moderately with Pleasure (0.42), Sign (0.33) and RiskImp (0.35). Pleasure correlated strongly with RiskImp (0.49), but not with RiskPro (0.05). The remaining correlations for RiskPro were also low - 0.21 with Sign and 0.23 with RiskImp. While Relevance, Pleasure, Sign and RiskImp appear to be related among themselves, RiskPro stands apart as a unique dimension by itself.

Abstracted Items for Sub-Scales and Performance Testing

Capitalizing on the strengths of different sub-scales offered by earlier researchers, we would now like to offer for further testing a concise set of items, reflecting a multi-faceted operationalization of involvement. The objectives of the pruning phase were the same as those of Laurent and Kapferer (1985/86): short scales (for convenience), multiproduct applicability (for generalizability) and single factored, reliable sub-scales (for psychometric purposes). The three items loading highest on each factor in Table 2 were chosen to yield a smaller set of 15 items for the New Involvement Profile (capitalized in Table 2). Particulars are shown below:

Dimension	Items (From Table 2)	Cronbach Alpha
1. Relevance	Items 24, 26, 34	0.80
2. Pleasure	Items 9, 42, 46	0.84
3. Sign	Items 20, 21, 22	0.84
4. Risk Importance	Items 15, 16, 18	0.80
5. Risk Probability	Items 5, 6, 7	0.56

The performance of the New Involvement Profile was compared to the other available scales in terms of ability to predict some of the consequences of involvement used in previous studies: greater information search, perception of differences among brands, and preference for a particular brand (Zaichkowsky 1985, McQuarrie and Munson 1987). Three items were used to capture the first proposition: "I would be interested in reading about this product," "I would pay attention to an ad for this product," and "I would compare product characteristics among brands for this product." The last two consequences were assessed using one item for each: "I think there are great differences among brands of this product" and "I have a most preferred brand of this product" respectively. All five statements were rated on a five-point scale from strongly disagree (1) to strongly agree (5). The

TABLE 3
Inter-Factor Correlations

	Factor 1 Relevance	Factor 2 Pleasure	Factor 3 Sign	Factor 4 RiskImp	Factor 5 Riskpro
Factor 2: Pleasure	0.42	1.00			
Factor 3: Sign	0.33	0.58	1.00		
Factor 4: Riskimp	0.35	0.49	0.58	1.00	
Factor 5: Riskpro	-0.02	0.05	0.21	0.23	1.00

TABLE 4
Regression Analysis: Various Scales Regressed on Consequences of Involvement

Consequence	Standardized Coefficients					Adjusted R-Sq.			
	Relv.	Hed.	Sign	R-Imp	R-Pro	New IP	IP	PII	FCB
1. Information search	0.17***	0.36***	0.06	0.23***	-0.03	0.35	0.35	0.28	0.25
2. Perception of brand differences	0.07	0.17***	0.12**	0.20***	-0.02	0.16	0.16	0.09	0.13
3. Preference for a brand	0.08*	0.20***	0.11***	0.07	-0.12***	0.13	0.13	0.09	0.06

* p < 0.05
 ** p < 0.01
 *** p < 0.001

three statements for greater information search were highly inter-correlated (alpha = 0.78) and were therefore combined into a single scale.

The results are summarized in Table 4. The predictive ability (adjusted R-squared) of the New Involvement Profile is seen to match the best of the earlier scales. The individual standardized regression coefficients for the five dimensions vary in significance across the five consequences of involvement used as the criterion variables. Every dimension of the New Involvement Profile has a significant impact on at least one consequence, thereby justifying retention of the five dimensions.

SUMMARY AND CONCLUSIONS

A multidimensional approach to measuring involvement was followed in this study. An English translation of Laurent and Kapferer's Involvement Profile and an alternative measure, derived from Zaichkowsky's Personal Involvement Inventory and its modifications, were tested empirically using multiple products. As shown in Table 5, the range of products studied captured a spectrum of involvement scores as measured by Zaichkowsky's PII (1985) and Laurent and Kapferer's latest Involvement Profile (1989).

TABLE 5
Involvement Scores of Products on PII and IP
 (Mean has been standardized to 100 for each column)

Newspaper	108	100	91	104	68	86
Radio	115	123	121	111	129	109

Empirical domain testing shows that Zaichkowsky's PII and Laurent and Kapferer's IP have *unique components*. A concise 15 item New Involvement Profile is abstracted from the sub-scales tested in this study, drawing on Zaichkowsky's PII measurement of the Relevance/Importance dimension, and the latest IP's contribution to the other four dimensions: Pleasure, Sign, Risk Importance, and Risk Probability. Obviously, this refinement process needs to be carried still further for understanding the intricacies of the Involvement construct. Specifically, the RiskPro subscale needs to be strengthened and the New Involvement Profile needs further validation on a fresh sample.

When Do The Measures Of Knowledge Measure What We Think They Are Measuring?

Rajesh Kanwar, San Diego State University
Lorna Grund, San Diego State University
Jerry C. Olson, Pennsylvania State University¹

In order to investigate the effects of knowledge on behavior, researchers have used a variety of methods to measure knowledge. But, research results on the convergent validity of these measures of knowledge are equivocal. Some researchers have found significant correlations between measurement methods such as self-reports, free elicitation, and paper-and-pencil tests, while others have not. This study attempts to explain the inconsistent results. The results suggest that the convergent validity of the different measures may depend on what, and how much, consumers already know about a knowledge domain.

INTRODUCTION

Because of the common assumption that what people know affects their behaviors, researchers have spent considerable effort on exploring the effects of knowledge on consumer behavior (see Alba and Hutchinson 1987). For instance, researchers have investigated the effect of knowledge on information search (e.g., Brucks 1985), assimilation of new knowledge (e.g., Graesser and Nakamura 1982; Johnson and Russo 1984), choice processes (e.g., Bettman and Park 1980), information processing strategies (e.g., Fiske, Kinder and Larter 1983), problem solving processes (e.g., Sweller 1988) and perceptual processes (e.g., Obermiller and Wheatley 1984).

In this research, knowledge has been measured through a variety of methods such as subjective self-perceptions, paper-and-pencil tests (conventionally called objective tests), product ownership, usage experience with a product, and free response techniques such as free elicitation (see Mitchell 1982; Cole, Gaeth, and Singh 1986). These methods of measuring knowledge generally fall into two broad categories, direct and indirect measures of knowledge. Paper-and-pencil tests, or free-association methods such as free elicitation, are direct methods of measuring knowledge. They attempt to measure knowledge stored in memory. On the other hand, measures such as self-reports, or usage experience with a product, are indirect methods. They do not directly measure knowledge stored in memory. Rather, they measure individual characteristics that are thought to be related to people's knowledge in the domain of interest.

In this research on knowledge and behavior, researchers have often used just one of these methods to classify people as being either high or

low in knowledge about a domain. This assumes that one method of measuring knowledge is as good as another. That is, the methods are equivalent in that they all operationalize the same underlying construct--knowledge. But, research results on the convergent validity of these measures of knowledge (across and within the direct and indirect methods) are equivocal. Some researchers have found significant correlations between measurement methods such as self-reports, free elicitation, and paper-and-pencil tests or questionnaires (e.g., Heneman 1974; Klimoski and London 1974; Cole, Gaeth, and Singh 1986; Dacin and Mitchell 1986; Marks and Olson 1980; Marzano and Costa 1988). But, other researchers report little or no correlation between such measures (e.g., Seigel and Pfeiffer 1965; Kanwar, Olson, and Sims 1981; Marzano and Costa 1988).

Moreover, in some studies the different measures of knowledge have produced opposing predictions about behavior, thereby suggesting that the different methods are not measuring the same construct. For example, Brucks (1985) found that consumers' self-perceived knowledge was unrelated to the number of attributes about which they acquired information when making choices. However, when questionnaires were used to measure consumer knowledge she found that more knowledgeable consumers acquired information on more attributes than did the less knowledgeable consumers. Other researchers have reported similar results (Lichtenstein and Fischhoff 1977; also see Park, Gardner, and Thukral 1988). Indeed, some researchers have gone so far as to suggest that some of these methods may be measuring concepts or constructs other than knowledge. For instance, Park and Lessig (1981) suggest that subjective measures such as self-reports may be measuring consumers' self-confidence rather than their knowledge in a domain. Other researchers have made similar suggestions (see Lichtenstein and Fischhoff 1977).

Since researchers often use just one of the various methods to measure knowledge, it is important for us to understand why past research on the convergent validity of these measures has produced conflicting results. In order to choose among these alternative methods with any confidence, we need to know when these methods are, or are not, valid measures of knowledge. Otherwise, we may never be certain of the validity of our research.

In this study we make an attempt to develop such understanding. We first review some of the methods that have been used to measure knowledge. Next, we develop and test hypotheses about the conditions under which these alternative measures of

¹This research was supported by the Science and Education Administration of the U.S. Department of Agriculture under Grant No. 5901-0401-8-0151-0 from the Competitive Grants Office to the third author.

knowledge are likely, or are not likely, to show convergent validity. We then test these hypotheses.

THE MEASURES: A REVIEW AND ANALYSIS

Of the direct and indirect methods, first consider two indirect methods of measuring knowledge--usage experience and self-reports (or self-assessment)². When researchers use the amount of product experience to operationalize consumers' knowledge they assume that past usage and experience is directly related to consumers learning and knowledge. Unfortunately this assumption is often invalid (Brucks 1985; Mitchell 1982). Because of differential product involvement, consumers with similar amounts of usage experience may have learned different amounts about a product domain. In fact, some consumers who neither own, or use a product, but hope to do so in the future, may actively seek information about it, and accumulate large amounts of knowledge about it. For example a teenager who does not currently own a car may be highly knowledgeable about cars (Mitchell 1982). Thus, operationalizations such as ownership, or past usage experience, may erroneously classify knowledgeable individuals as being relatively less knowledgeable, or vice versa.

Moreover, there is considerable evidence that a person's self-assessed knowledge is often an inaccurate representation of actual knowledge (see Gentner and Collins 1981; Fox and Dinur 1988). As conventional in knowledge research, by actual knowledge we mean knowledge as measured by performance on conventional tests of knowledge such as objective multiple-choice tests (Abelson 1979; Saegert and Young 1982). Gentner and Collins (1981) suggest several reasons for the discrepancies between self-perceived and actual knowledge. One reason, which is particularly relevant to this study, is how much people already know in that domain (see Park, Gardner, and Thukral 1988). This literature suggests that, relatively more knowledgeable people provide more accurate self-reports than relatively less knowledgeable people. Gentner and Collins (1981) argue that because people usually learn about domain related concepts and terminology first (Brucks and Mitchell 1981; Brucks 1986), relatively less knowledgeable people are likely to judge their expertise in a domain by how many domain related concepts they know or think they understand, rather than what needs to be learned. That is, they are likely to judge their expertise by the number of domain related concepts they can recall from memory. This is particularly true for people who have not undergone formal training in a domain. For instance, research in

educational counselling and assessment indicates that self-assessment of knowledge or learning is likely to be more accurate for students who have received feedback on their relative learning, than for students who have not received such feedback (see Laing 1988; Park, Gardner, and Thukral 1988). Consequently, errors of judgment regarding self-assessed knowledge are most likely for people who are not only relatively less knowledgeable in a domain, but have also learned the little they know through informal means, e.g., experience, rather than formal training (by formal training we mean situations where learning is accompanied by objective feedback on how much has been learned, or not learned).

In summary, two major testable propositions emerge from the above discussion. First, self-report measures of knowledge are likely to be highly correlated to objective measures of knowledge for relatively knowledgeable people who have undergone formal training (e.g., college courses) in a domain. But, the correlation between these two measures of knowledge is likely to be insignificant for people who are relatively less knowledgeable. This is particularly true for people who have learned the little they know through less formal means (e.g., experience), without objective feedback on how much they actually know. Second, as earlier discussion indicated, people who have acquired their knowledge about a domain through informal means are more likely, than people who have received formal training, to judge their knowledge in a domain by the number of concepts that they can recall from memory.

The number of salient concepts in memory (that is the number of concepts a person can recall) is precisely what free response measures of knowledge such as the free elicitation method³ attempt to operationalize. In the free elicitation method the experimenter says a word (a cue or probe) and asks the subject to verbalize all the thoughts that occur in response to that word. The concepts that subjects mention in response to the initial probe are recorded and then are used as probes themselves to further explore consumers' cognitive structures for a particular knowledge domain (down to some "level"). By using several domain related initial probes the researcher attempts to elicit as many concepts as possible. Obviously the elicitation procedure can continue indefinitely. Typically, the researcher uses empirical procedures to pre-select the combination of initial probes and levels that produce the largest number of unique domain related concepts, within the constraints of the subject time available (see Kanwar 1987). The total number of unique domain-related concepts

²Usage experience may be measured by a question such as "how long have been using microwave ovens _____?" And, self-assessed measures may be obtained through questions such as "on this 7 point scale could you please tell us how much you think you know about _____?"

³See Mitchell (1982), Kanwar, Olson, and Sims (1981), for a discussion of the theoretical basis of the free elicitation method.

elicited by each subject then serves as an index of the number of salient concepts in memory⁴.

Thus, because the free elicitation procedure measures the number of salient concepts in memory, the index it produces is likely to be highly correlated with self-report measures of knowledge for people who have acquired their knowledge, about a domain, through informal means. But, for people who have received formal education in the knowledge domain, this correlation is likely to be insignificant.

HYPOTHESES

In summary, we can generate two hypotheses regarding the conditions under which the different measures are likely to exhibit, or not exhibit, convergent validity.

- H1: Self-assessed and objective measures of knowledge are likely to be highly correlated for relatively knowledgeable people who have undergone formal training in a knowledge domain, but not for people who have learned what they know through less formal means (e.g., experience).
- H2: The free elicitation and self-assessed measures of knowledge are likely to be highly correlated for people who have acquired knowledge about a domain through informal means, but not for people with formal training in the domain.

METHODS

The study was carried out over two separate 1 to 2 hour sessions. During the first session, the free elicitation method was used to measure consumers' knowledge about nutrition and food. The second session occurred about a month later. During this session subjects filled out a questionnaire designed to obtain objective and subjective measures of subjects' knowledge about food and nutrition, and subjects' demographic characteristics. Subjects also conducted some other tasks during both sessions, but these are not relevant here.

Knowledge Domain

We selected nutrition and food as the knowledge domain of interest because it met two major criteria. First, we needed a knowledge domain in which formal training is usually available. The food and nutrition knowledge domain fulfilled this criteria because formal training programs on nutrition are available in most colleges and universities. Second, we needed a knowledge domain in which people can acquire knowledge through experience, rather than formal training. Again, the

food and nutrition knowledge domain met this criteria. People not only make food decisions daily, but are being constantly exposed to nutritional information and concepts through the general media and processed food labels. Thus, they have ample opportunity to learn about food and nutrition without undergoing formal training. In addition, because food is important to health and well being, people are likely to be motivated to acquire such knowledge.

Subject Characteristics

In order to generate evidence on the issues raised above we needed two heterogeneous groups of subjects. We needed subjects who differed in the extent of their knowledge, formal training, and experience, about food and nutrition. One group of subjects had to have learned about food and nutrition through formal programs, such as college courses, that provide objective feedback on the learning that has occurred. A second group of subjects had to be not only relatively less knowledgeable than the first group, but to have learned about food and nutrition more through experience, rather than formal training. Consequently, we used two very different groups of subjects in this study--housewives and undergraduate students in nutrition.

Altogether 62 women participated in this study. Thirty one were female undergraduate students majoring in nutrition at a large eastern university. The remaining 31 subjects were adult women, mostly housewives, who resided in the same town as the university. However, data for four subjects had to be dropped because they either did not complete the procedures or were adult women who had had college level courses in nutrition. Since these latter subjects had learned about food and nutrition through both experience and formal training they did not meet our needs for subjects who had learned mostly through experience or formal training, but not both. Hence, they were dropped. Subjects were paid \$5 per hour for their participation.

The average adult woman in the sample was 36 years old, married, had 2 children, and a family income between \$15,000 and \$20,000. She had 15 years of formal education, cooked about 83% of the family meals and bought 82% of the food for the household. None of them had college level courses in nutrition.

The average student was a 22 year old single woman, lived in a household of 2.4 people, and had about 15.6 years of formal education. She prepared about 69% of the meals in her household and bought about 75% of the food. Since all these students were nutrition majors they had had formal college level courses in nutrition.

As this description indicates, the housewives had greater responsibilities and broader experience in choosing foods, whereas the students had more formal education in nutrition. Thus, the undergraduate nutrition students were likely to have acquired their knowledge about food and nutrition through college level course. The housewives, on the other hand, were likely to have acquired their

⁴Kanwar, Olson and Sims (1981) define this property of knowledge structures as dimensionality.

knowledge through their greater experience in making food choices.

Procedures

As mentioned earlier, the free elicitation procedure was administered during the first of the two sessions. Briefly, for this procedure, subjects were told to verbalize all the thoughts they had in response to a word the researcher would say (e.g., nutrition). Subjects were also told that the same procedure would be repeated with several words.

The procedure was first carried out with a practice probe to make sure that the subject understood the procedure. The researcher said the word "cars" and recorded the subjects responses (first level responses) to this probe on a pre-developed form. Whenever the subject stopped talking, the researcher asked her if she had any more thoughts. If she did, they were recorded as described. If she did not, the researcher picked the initial response to the "car" probe and used it as a probe, again recording her responses. After the subject had finished articulating her (second level) thoughts to this probe, the researcher used the next first level response as a probe. The researcher conducted this procedure until all first level responses had been used as probes. Once the subject had understood the procedure the researcher conducted the free elicitation procedure, as described above, for each of six pre-selected probes. The six probes were presented in a random order for each subject. The entire session was unobtrusively tape recorded with the subject's permission.

The six probes used in this study were selected because pre-tests and previous work had demonstrated that these concepts were effective in tapping different portions of consumers' knowledge structures for food and nutrition.

Two judges later used transcripts of the tape recorded elicitations to code it for the number of unique nutritional concepts elicited. To aid them in the coding, the judges used a pre-developed list of food and nutritional concepts. The inter-judge reliability was above .8. Disagreements between the two judges were resolved by a third judge.

The questionnaire used to measure subjects knowledge in this study was developed on the basis of the questionnaire used by Kanwar, Olson, and Sims (1981). Since Cronbach's Alpha for the 23 item questionnaire developed by these authors was only .68, the questionnaire was expanded to 85 factual multiple-choice questions on food and nutrition. These items were selected from a larger set of questions used in nutritional research. The questionnaire was tested with 150 undergraduate business students at a major south eastern university. Cronbach's Alpha for this expanded questionnaire was .84. As is common, the total number of correct responses to this questionnaire was used as an indicator of subjects knowledge about nutrition. The questionnaire also contained questions on subjects' demographic characteristics and nutritional education levels, in addition to a single

item 10 point scale designed to measure subjects' self-perceptions about their nutritional knowledge.

RESULTS

Table 1 presents the results of this study. As this table shows, the self-report measure of knowledge was significantly correlated with the scores on the knowledge test, for subjects who had had formal training in nutrition. However, for subjects who had not had such training, the correlation was not significant. Thus, the results support the first hypothesis. Consumers who have had formal training are able to assess their knowledge more accurately than subjects who have acquired their knowledge about a domain through informal means.

As Table 1 shows, the results also supported the second hypothesis. For consumers who did not have formal training in nutrition, the free elicitation measure of knowledge was significantly correlated with subjects "self-assessment" of their knowledge about nutrition. However, the correlation was not statistically significant for subjects who had had formal training. Thus, it seems that when people are in doubt about their level of expertise in a knowledge domain, they use the number of concepts that they can recall from memory to make judgments about their expertise in the domain. But, people who have undergone formal training in a domain, receiving formal feedback during this process (as in college courses), are likely to rely on the more accurate formal feedback (e.g., performance on examinations) to judge their knowledge.

DISCUSSION

As we mentioned earlier, researchers have commonly used a variety of direct and indirect methods to measure knowledge. Recent research on the validity of these measures has been equivocal, with some studies reporting high convergent validity, and others reporting low or no convergent validity, between the different methods. This study provides an explanation for these inconsistent results. For example the results of this study explain why Kanwar, Olson and Sims (1981) found insignificant correlations between objective measures of knowledge and the free elicitation and repertory grid measures of knowledge. These authors used secretaries and housewives as subjects. This study's results suggest that the insignificant correlations occurred because such subjects are unlikely to have had formal training in nutrition. If these authors had used people who had had formal training in nutrition, the results may have been quite different.

In sum, this study's results suggest that alternative measures of knowledge may be equally valid under some circumstances, but not others. For instance, indirect and direct measures such as self-reports and objective tests are equally valid for measuring the knowledge levels of people who have had formal training in the domain of interest, but not for people who have not had such training. This difference arises because people who have had formal

2. Free Elicitation	-.08	.49*

Note: Correlations greater than .4 are significant at $p < .05$.

training in the domain seem to use different criteria to evaluate their knowledge about a domain than people who lack formal training. The latter, in the absence of formal evaluation of their knowledge about a domain, appear to use criteria such as how much information they can recall from memory to evaluate their knowledge about a domain. However, those with formal training are able to evaluate their knowledge about a subject more objectively because of the feedback they have received during their training or education.

However, the results of a single study can not be used to make major generalizations without further research. First, similar research must be conducted with knowledge domains other than food and nutrition. Second, this study was based on just three methods of measuring knowledge-- self-reports, free elicitation, and objective tests. However, several other methods such as product ownership, usage experience, the repertory grid, and response times (see Mitchell 1982), have also been used to measure knowledge. Research is needed to determine if the results of this study are also true for these methods. Third, some caution must be used in interpreting the results of this study because undergraduate students, unlike housewives, are constantly exposed to multiple choice tests. Thus, students may outperform housewives on such tests not because they have greater knowledge in the domain of interest, but because they are more proficient in taking multiple choice tests. Consequently, this study's results may reflect such differences in the test taking abilities of housewives and students. Finally, the relatively small sample size, although acceptable in an exploratory study, may have limited the power of the study. Future studies can address the latter two problems by using larger samples of subjects who have similar backgrounds except for the source of their learning-- experience or formal training.

In conclusion, this study's results suggest that researchers investigating the effects of knowledge on behavior must be careful in their

selection of the methods they use to measure knowledge in a domain. Not all measures are equally valid for all subjects. The methods used to measure knowledge must be suited to the characteristics of the subjects used in the study. Otherwise, the research is likely to result in misleading conclusions.

Individual Differences in Value Stability: Are We Really Tapping True Values?

L. J. Shrum, University of Illinois at Urbana-Champaign
John A. McCarty, University of Illinois at Urbana-Champaign
Tamara L. Loeffler, University of Illinois at Urbana-Champaign

ABSTRACT

A study was conducted which examined individual differences in the stability of a target value in the Rokeach Value Survey (RVS). Participants in the experimental conditions received a persuasive communication arguing for social recognition (a Rokeach terminal value) or one arguing against social recognition. Participants in the control condition received no communication. All participants ranked and rated the values of the RVS and completed a scale measuring private self-consciousness. As predicted, a significant persuasion by private self-consciousness interaction was observed for the evaluation of the value social recognition, indicating that those low in self-consciousness were more persuaded by the manipulations than participants high in self-consciousness. Discussion considers the theoretical implications for uses of value scales in marketing and consumer behavior.

INTRODUCTION

The last fifteen years have seen an increasing interest in research on values and their relationship to consumer behavior. Since Rokeach (1973) first developed the Rokeach Value Survey (RVS), consumer researchers have had a relatively easy instrument with which to attempt to assess personal values. With this in hand they have suggested that relationships exist between values and purchase of a particular product class (Howard 1977), choice criteria for a variety of products and services (Pitts and Woodside 1983, 1984; Vinson, Scott and Lamont 1977) and measures of advertising effectiveness (Sherrell, Hair and Bush 1984). Some have critiqued the RVS (Munson 1984), while others have offered other instruments for value assessment (Holman 1984; Kahle, Beatty and Homer 1986). Finally, the use of values as a market segmentation tool has been suggested (Kahle and Kennedy 1988).

While some have evaluated the validity of the RVS, the results have been decidedly mixed (Coyne 1988; Thompson, Levitov and Miederhoff 1982). Little research has investigated the ability of self-report surveys to accurately ascertain an individual's true value structure. This paper addresses these concerns, presents a study which indicates that individual differences may moderate such self-report tasks, and suggests weaknesses in a priori assumptions of links between values and behavior.

Values as a Construct

Values are considered to be relatively enduring beliefs that individuals possess and these beliefs are prescriptions for behavior (Rokeach 1973). As both Kluckhohn (1951) and Rokeach

(1973) indicate, values are statements of the ideal. That is, our values tend to suggest positive modes of behavior and positive ends. As Kluckhohn says, values are a statement of the desirable, not what the person may actually desire. In other words, they are often the conceptualization of how one *ought* to act in a situation, rather than how one *wants* to act.

Values have been defined in a variety of ways, although their abstract nature and endurance tend to be central to most definitions. Rokeach defines a value as "an enduring belief that a specific mode of conduct or end-state of existence is personally or socially preferable to an opposite or converse mode of conduct or end-state of existence (Rokeach 1973, p. 5)." Kahle calls values "social cognitions and adaptation abstractions" which involve preferences or evaluations (Kahle 1984, p. 7). Posner and Munson (1979) state that values consist of beliefs about what the individual considers just, fair, or desirable.

Values have generally been distinguished from attitudes, which are considered to be less abstract than values. Rokeach (1973), for example, states that an attitude refers to an organization of beliefs around a specific object or situation, while a value refers to a specific belief. Rokeach sees values as occupying a central position in the individual's cognitive makeup. Values serve to guide actions, attitudes and judgments, and therefore are determinants of attitudes as well as behavior. As Rokeach points out, others (Allport 1961; Watson 1966; Woodruff 1942) have also noted this relationship of attitudes depending on or reflecting values.

It has generally been assumed that values guide behavior, although evidence of strong relationships between values and behavior is virtually nonexistent. While it is not essential that values be related to behavior to hold that values exist as mental entities, the usefulness of values as an explanatory construct is weakened to the extent that they show little relationship to behavior.

Value Surveys

Virtually all contemporary methods for assessing personal values involve a self-report survey instrument. These procedures require subjects to either rank a set of values (the RVS, Rokeach 1973) or rate values on a Likert-type scale (the LOV Scale, Kahle, Beatty and Homer 1986). The assumption is that subjects are able to access their value structures and accurately detail this structure in the ranking or rating procedures.

Alternative explanations are also reasonable. It could be that when confronted with a value instrument, some individuals merely indicate their *attitudes* towards these words rather than accessing

inner feelings regarding *enduring beliefs*. The effectiveness of the scale then relies on the extent to which these attitudes accurately reflect the more abstract value structure. It is also reasonable to assume that there are individual differences in the ability to accurately report value structures. Some individuals may be better able to report their abstract values than others, depending on the extent to which they have considered their values in the past.

Should this be the case, a variety of implications exist. First, if the individual is not adept at accessing true values, the choice of values may indeed more closely approximate an attitude judgment. The reported value structure then may be dependent upon the myriad of situational demands which affect such attitude judgments. Secondly, the causal chain is called into question. If indeed, as Bem (1972) asserts, attitudes can be inferred from behavior, then it is reasonable to assume that the reported values might also be inferred from behavior. Finally, if the reported values more closely resemble attitude judgments, then the stability or consistency of the stated values should be low. This would call into question the legitimacy of the reported value as an "enduring belief."

Individual Differences

One individual difference variable which may differentiate responses to a value survey is private self-consciousness, as defined by Fenigstein, Scheier and Buss (1975). They define the construct as "the consistent tendency of persons to direct attention inward (p. 522)." Thus, private self-consciousness is the tendency to be aware of inner aspects of the self, and people high in private self-consciousness should be "particularly conscious of their own thoughts, feelings, attitudes, motives and behavioral tendencies (Carver and Scheier 1981, p. 46)." By such definitions, it is reasonable to expect that those high in private self-consciousness would be more aware of their values and value structure, and the part it plays in their psychological makeup. Given this, it would also be reasonable to think that this heightened awareness of personal values should lead to increased "sureness" with regard to the importance of particular values, and should therefore prove to be more impervious to manipulation. Others have found results supporting this line of reasoning. Scheier, Carver and Gibbons (1979) found subjects high in private self-consciousness to be more resistant to external suggestibility; Froming and Carver (1981) found private self-consciousness to be inversely correlated with compliance.

With this in mind, a study was designed to test the following hypotheses:

H1: Individuals scoring low in private self-consciousness will show a significant difference in value assessment as a function of a persuasive communication aimed at altering their evaluation of one of the values.

H2: Individuals scoring high in private self-consciousness will be unaffected by persuasive communications intended to change their assessments of particular values.

It was hypothesized that there would be a difference in the effectiveness of the persuasive communication depending on the degree of private self-consciousness. People high in private self-consciousness presumably have better and easier access to their inner motives and attitudes, and hence their values as well. They also presumably access this information, or self-schema more frequently, and this leads to enhanced availability of the schema (Carver and Scheier 1978) and a greater likelihood that the schema will be reaccessed and used (Srull and Wyer 1979, 1980). Consequently, they should be more confident of their value structures and hence less prone to a persuasive manipulation than individuals who are low in self-consciousness. On the other hand, individuals who are low in private self-consciousness, because they are less aware of their values, would be expected to be persuaded by the manipulation. Low self-conscious individuals receiving a communication arguing for a particular value should evaluate that value more positively than individuals receiving a communication arguing against the value.

METHOD

Participants

The participants in the study were a convenience sample of 130 undergraduate students in an introductory course at a large midwestern university. Participation in the study satisfied a course requirement.

Design and Overview

The study was a 3 (persuasive communication manipulation) X 2 (order of value surveys) X 2 (high private self-conscious vs. low private self-conscious participants) factorial design. Participants either received a written persuasive communication arguing in favor of social recognition (a Rokeach terminal value), a persuasive communication arguing against social recognition, or received no communication (the control). To avoid experimental demand neither of the communications explicitly used the term social recognition, rather they talked in terms that were deemed to be related to the value social recognition. It was anticipated that these communications would make salient either positive or negative aspects of one's concern with the recognition of others. Participants then completed the Rokeach Value Survey in one of two orders. Half of the participants received the terminal values to evaluate first, then the instrumental values while the other half received these in the opposite order. The third factor was the level of private self-consciousness of the participants as determined by their score on a private self-consciousness scale.

Procedure

Participants were told that they would be completing several studies during the course of the experimental hour. Participants in the two persuasive communication conditions received written instructions which explained that the first study was part of a project designed to assess message content. The communication was said to have been excerpted from an article written by a syndicated columnist and had appeared in a national news magazine. After reading the excerpt, the next page of the booklet asked questions related to their recall as well as the content, clarity, appropriateness, etc. of the message. A manipulation check asking if they agreed or disagreed with the writer's position was included in this page of questions.

All participants were next administered a Rokeach Value Survey of instrumental and terminal values and asked to rank these as suggested by Rokeach. For participants who had experienced a persuasive communication (the experimental conditions), the value survey was introduced by a new experimenter and they were told that the questionnaire to follow was a different study. Half of the participants received the instrumental value set first while the other half received the terminal set first. After rank ordering the two sets of values, the next page of the booklet asked the participants to go back and assign a number from 0 through 10 to each value to indicate its importance to them from "no importance" to "extreme importance."¹

After completing the value survey, the participants proceeded to the next part of the booklet which contained the ten-item private self-consciousness questionnaire. The instructions indicated that the participants should evaluate each of the items on the 6-point scales with end points of "certainly, always true" to "certainly, always false."

RESULTS

The manipulation check of the effectiveness of the persuasive communications was the question of whether the participants agreed, disagreed, or had no opinion regarding the position advocated in the written communication. Across both persuasive communication conditions, 78.8% of the participants agreed with the position advocated by the communication that they read, 12.5% indicated that they had no opinion, while only 8.8% disagreed. There were differences across the two conditions, with a greater likelihood for participants

in the pro condition to agree with the communication (89.7%) compared to participants in the against social recognition condition (68.3%).

Because some concern has been expressed regarding the factor purity of the Fenigstein, Scheier and Buss self-consciousness scale (Burnkrant and Page 1984; Mittal and Balasubramanian 1987), a factor analysis was performed on the ten-item scale (principal axis factoring with varimax rotation). As was found in the aforementioned studies, the private self-consciousness scale yielded two dimensions (rather than one as postulated by Fenigstein, Scheier and Buss): self-reflectiveness and internal state awareness. Table 1 presents the results of this factor analysis. The first factor, *self-reflectiveness*, relates to the extent to which individuals examine their motives while the second, *internal state awareness*, deals primarily with awareness of feeling states. Two of the ten items did not reliably load on either dimension. The self-reflectiveness dimension was deemed to be the most appropriate as an indication of the extent to which a person would be aware of their values and thus more appropriate for the current analysis.

Therefore, the five item self-reflectiveness subscale was used to divide the participants into low and high private self-consciousness conditions. (Even though the scale more accurately assesses self-reflectiveness, we will continue to use the term private self-consciousness for the sake of continuity in this paper.) The Cronbach's Alpha for the scale was .78, indicating high internal consistency. Participants were then classified as being high or low in private self-consciousness based on a median split of their total score on the five items of the self-reflectiveness subscale.

In the present study, the dependent measures of interest were the participants' ranking and rating of the value *social recognition*. An analysis of variance was performed on each of these measures with the independent variables being manipulation condition, order of values measured, and level of private self-consciousness of each participant. (The rankings of the values were transformed following the approach recommended by Hays (1967) and used by Pitts and Woodside (1984) such that they could be analyzed using parametric techniques.)

A similar pattern of results were obtained for the ranking and rating of the value *social recognition*, therefore, for the sake of brevity only the results relating to the rating of the value will be presented here. As predicted, there was a significant persuasion by private self-consciousness interaction effect ($F(2,118) = 7.92, p < .001$). Figure 1 shows this interaction effect for the *ratings* of the value *social recognition*.

As is clear from Figure 1, the persuasive communication had the expected effect in the case of participants low in private self-consciousness. That is, participants low in private self-consciousness who read a communication advocating social recognition rated it more positively than participants reading a communication against social recognition and more positively than the control

¹Both a ranking and rating of the Rokeach Values were included in this study. The ranking was included as this is what was originally recommended by Rokeach and is commonly used. A paper currently in preparation by the authors suggests, however, that a rating of each value may be preferable to the typical ranking. Therefore, both ranking and rating measures were collected in this study.

TABLE 1
Factors and Factor Loadings of the Self-Consciousness Scale

Scale Item	Factor 1	Factor 2
<u>Self-Reflectiveness</u>		
I'm always trying to figure myself out.	.74	-.26
I reflect about myself a lot.	.77	.03
I'm often the subject of my own fantasies.	.52	-.02
I'm constantly examining my motives.	.67	.27
I sometimes have the feeling that I'm off somewhere watching myself.	.58	.13
<u>Internal State Awareness</u>		
I'm generally attentive to my inner feelings.	.16	.82
I'm alert to changes in my mood.	.26	.41
I'm aware of the way my mind works when I work through a problem.	-.05	.47
<u>Neither Dimension</u>		
Generally, I'm not very aware of myself.	.16	-.35
I never scrutinize myself.	-.36	.20

Note - Items with loadings at least half the highest loading are considered as part of a factor.

group. An analysis of the simple main effect of persuasion among participants low in self-consciousness indicated that this pattern of mean differences was significantly different ($F(2,118) = 6.61, p < .002$).

It was anticipated that there would be little or no effect of the manipulation on participants high in private self-consciousness. Figure 1 suggests a slight shift in the opposite direction among these participants. An analysis of the simple main effect of persuasion among participants high in self-consciousness indicates, however, that these means did not differ significantly ($F(2,118) = 2.38, p > .09$). Therefore, the interaction effect was due primarily to the differences in means among participants low in private self-consciousness, as predicted.

Although not predicted, an order by private self-consciousness interaction was observed ($F(1,118) = 7.45, p < .01$). Figure 2 presents this interaction for the rating of social recognition. As the figure indicates, the order in which the values were rated had an effect on the evaluation of the specific value social recognition. An analysis of the simple main effects of order at each level of self-consciousness indicates that the differences in the rating of social recognition for individuals low in self-consciousness was significant ($F(1,118) = 10.01, p < .005$), while the slight difference in the means for the two orders of evaluation for the high self-conscious participants was not ($F(2,118) = .53, p > .40$). Therefore, there was less stability in the evaluation of the value social recognition as a function of order among participants low in private self-consciousness than among high private self-conscious participants. Participants low in private

self-consciousness rated social recognition (a terminal value) higher when it was evaluated before the instrumental set of values than when it and the other terminal values were rated after the instrumental set. The rating of social recognition among high private self-conscious individuals was resistant to the effects of the order of the evaluations.

DISCUSSION

The results of this study provide considerable support for our reasoning that degrees of private self-consciousness are related to value stability. This was shown by the differences in the evaluation of the value social recognition as a function of the nature of the persuasion and the level of private self-consciousness of the participants. It was found that the reported values of the participants low in private self-consciousness were more affected by the communications arguing for or against social recognition than were the reported values of participants who were high in private self-consciousness. The stability among those high in private self-consciousness was anticipated because it was assumed that they were more "in touch" with their values and hence their beliefs about the value were more resistant to the effects of the mild persuasion effort presented in the experiment. Therefore, the hypotheses of this study were strongly supported by the results.

A potential alternative explanation of the results of this study is experimental demand. To the extent that participants low in self-consciousness are more compliant (Froming and Carver 1981), they may be more likely to indicate a shift in their beliefs about social recognition because they

FIGURE 1
Mean Ratings of Social Recognition By Persuasion Condition and Level of Self-Consciousness

FIGURE 2
Mean Ratings of Social Recognition By Order of Value Surveys and Level of Self-Consciousness

believed that is what they were supposed to do. While this demand explanation can not be entirely ruled out, pilot testing of the research instruments and procedure showed no indication that experimental demand would be a problem. Furthermore, during the experiment, participants were lead to believe that reading of the communications and the completing of the value surveys were parts of entirely different tasks for different experimenters.

A relationship between order of instrumental and terminal values and degree of private self-consciousness was found in this study. Although this effect was not specifically predicted, it is consistent with the reasoning of the current authors regarding the extent to which different participants are aware of their value structure. Differences in the evaluation of the value social recognition were found for participants low in private self-consciousness as a function of order of the evaluation of the values; this order effect was not apparent for those scoring

high in private self-consciousness. Since those low in private self-consciousness were presumably less aware of their self-schema and values than persons high in private self-consciousness, the order in which they evaluated the various values appears to have affected their evaluation of the value social recognition. Individuals who were high in self-consciousness were more aware of their values and hence their evaluations of any particular value were not affected by the order in which the evaluations were made.

The study raises some interesting questions regarding value surveys, their generalizability, and their use in consumer behavior and market segmentation. The results seem to indicate that true values are not so easy to capture, especially via self-reported value scales. Such self-report tasks may indeed capture the value structure for *some people*, but it may be highly dependent on the extent to which the individuals typically engage in self-reflection. On the one hand, individuals who typically engage in self-reflection may be able to report their values fairly accurately. On the other hand, individuals who are not self-reflective may have difficulty assessing their true values when confronted with a value instrument and may therefore default to the easier task of inferring their beliefs about their values from recent behaviors. If this is the case, then clearly any behavioral predictions or segmentation conclusions based on this type of data is somewhat risky, particularly for individuals who are not self-reflective and who do not consider their values routinely. Perhaps a more in-depth or comprehensive questionnaire which assesses a wider scope of values, attitudes and behaviors might be more useful and provide a more reliable measure of the predispositions that affect some individuals' consumption behavior. Clearly, the relation of values to consumption behavior is an important area of concern; this study simply indicates that more work is necessary in the assessment and measurement of consumer values.

Issues in Measuring Abstract Constructs

Judith Lynne Zaichkowsky, Simon Fraser University

INTRODUCTION

The three papers presented in this competitive session attempt to clarify different constructs of involvement, knowledge and values. The paper by Jain and Srinivasan deals with trying to reduce a large number of possible indicators of involvement to a small number and then interpreting the resulting grouping of items as types of involvement. The paper by Kanwar, Grund and Olson attempts to demonstrate that self-report measures of knowledge may be representative of objective knowledge structures when elicited from people formally trained in that area. The paper by Shrum, McCarty and Loeffler looks at the interaction between private self-consciousness and value stability. The link among the papers lies only in their attempt to clarify the abstract constructs, therefore each paper will be discussed separately.

"AN EMPIRICAL ASSESSMENT OF MULTIPLE OPERATIONALIZATIONS OF INVOLVEMENT"

In the last five years I have read more than a dozen papers on improving measures of involvement. This fact leads me to believe that when a researcher disagrees with how others have offered to measure involvement, that researcher feels it is easy to construct their own "better" or more suitable measure of involvement. This is truly a noble cause, however, I believe it is difficult to improve on a measure in a purely empirical fashion as attempted in this paper.

First of all the present paper draws on items reported in several studies on involvement. However, the items in each of the previous studies were developed for several different purposes based on different conceptualizations of involvement. Laurent and Kapferer (1985) wanted to measure involvement with products and first conceptualized involvement as having five facets, namely importance, pleasure, sign-value, risk probability and risk importance. Therefore, they developed items to represent five dimensions. On factoring the items, they found importance and risk importance of the product to be indistinguishable in the minds of their respondents. Zaichkowsky (1985) developed a context-free measure of involvement applicable to products, advertisements and purchase decisions. Items were selected for the scale by "expert judges" to represent a single definition of involvement, namely personal relevance as reflected by needs, values and interest. Ratchford (1987) items related the decision of purchasing a product, not involvement with the product per se. The scales by Higie and Feick (1989) and McQuarrie and Munsen (1987) incorporate several items from Zaichkowsky (1985) along with items that these researchers subjectively felt captured a more hedonic enduring aspect of involvement with products.

I am unsure of the usefulness of combining measures developed for different purposes to see what emerges. Basically, you will get out what you put in. If you put five dimensions in, you should get five dimensions out. That aside, let me comment on the methodology. There is great variation due to the 10 products. Two products are more hedonic (chocolate, cologne) than the others and should elicit a different factor structure (Zaichkowsky, 1987). I would guess, based on my own experience, that if we factored each product separately, a different solution or structure would appear for each product. Some products are just very different in the type of involvement they elicit. This fact is demonstrated in Table 5 of the Jain and Srinivasan paper. What are the implications of irrelevant dimensions for some products?

What the Jain and Srinivasan paper contributes is another measure of five facets of involvement. If shorter is better, then maybe it is better, but there is no test of stability of the 15 item scale, criterion validity is not checked and the construct validity study provided is vague. Who were the respondents, what was the sample size, and what was the context of the study? Conceptually, what is the relevance of the five facets of involvement found in Tables 4 and 5? This part of the paper needs much more elaboration.

The bottom line is that this paper empirically offers the literature some variations on current measures of involvement. The success of the paper may be left to other researchers' use of the suggested measures. This is now a cold topic for consumer behavior researchers. I do not think there is much interest in one more paper that empirically attempts to suggest a better measure of involvement. However, let me leave the researchers with some ideas on what I think would be a more interesting study on the structure of involvement. Given that (1) there is a great variation among products on average level of involvement, (2) people vary widely on their level of product involvement, and (3) there seems to be different types of involvement, a three-mode factor analysis may shed light on the product/person/facet of involvement structure. This would allow us to investigate the different relationships between products, involvement and people. In other words, what kind of people view what kind of products in what view of involvement? Some products may be mainly pleasure products and some mainly risk products. What kind of people view haircuts as hedonic and what kind of people view haircuts as mainly risk? These types of questions are conceptually interesting to me as an involvement researcher. I hope the researchers continue to do work in this area, but implore them to move on from measuring involvement to discovering relationships between consumer behavior and levels of involvement.

"WHEN DO MEASURES OF KNOWLEDGE MEASURE WHAT WE THINK THEY ARE MEASURING?"

The clarification of the concept of knowledge, the process by which we acquire knowledge, and the implications of having knowledge are of fundamental concern to consumer behavior researchers. I would like to think that we all know that simple subjective self-report measures of knowledge are not representative of true objective knowledge structures. However, this paper tries to demonstrate that self-report measures may be correlated with more complex measures when dealing with experts -- experts being defined here as those with formal training. It also suggests that a free-elicitation method of abstracting knowledge is associated with self-reports of knowledge from non-experts. To me there are some complex issues here that have to do with knowledge obtained by experience versus knowledge obtained by training which may be germane to the argument at hand.

That aside, the first problem I had was understanding the free-elicitation method and its validity as a measure of knowledge. I would like to know what the six probes were for nutrition and the number of responses elicited for each group under each probe. The pre-developed list of food and nutrition concepts seems crucial for coding. Where did it come from? How valid is the list?

The decision to increase the objective knowledge test from 23 items to 85 items to increase reliability is misleading. A Cronbach Alpha of .68 for the 23 item test is actually more reliable than the .84 Alpha for the 85 item test. The formula (Nunnally, 1978) for deciding the number of items based on the reliability desired is:

$$k = \frac{r_{kk}(1-r_{11})}{r_{11}(1-r_{kk})}$$

where r_{kk} = desired reliability
 r_{11} = reliability of existing test
 k = number of times test would have to be lengthened (shortened) to obtain reliability of r_{kk} .

Given a reliability of .68 on a 23 item test and a desired reliability of .85, we can solve for

$$k = \frac{.85(1-.68)}{.68(1-.85)} = 2.67$$

Therefore, 2.67 x 23 items = 61 items should give a reliability of .85. The reliability of .84 on 85 items indicates less reliability than the original 23 item test. Clearly some of the 85 items should have been omitted due to low item-to-total correlations. There is no indication if the 85 items are a good measure of nutrition knowledge. We are not told what average scores were on the 85 items or what the variation in scores were among the groups.

Given that the two groups differed in age, marital status and probably with quantity of direct experience with food preparation, it is likely that the free elicitation method tapped into the subjects' knowledge based on prior use. In my research, I find experience or prior product use and subjective knowledge are usually correlated, while prior product use and objective knowledge are not necessarily correlated (Zaichkowsky, 1985b). Is that what we find in Table 1 where free elicitation and subject knowledge are correlated for housewives but not students?

In conclusion, I think the researchers are working in an important but difficult area. As a whole, I believe the topic area is tepid. The reason I say this is because special ACR sessions about knowledge and its relation to other constructs were rejected based on a low level of interest by other researchers. It may not be fashionable to work on this area, but I think many contributions are still to be made with respect to knowledge structures.

"INDIVIDUAL DIFFERENCES IN VALUE STABILITY"

The contribution of this paper is that it nicely demonstrates causes for instability in doing research on values. The usefulness of the construct "self-consciousness" as a covariate for all researchers who work on values is made explicit. This assumes, of course, normality of the data presented in this paper. I could not assess this point accurately, given the presentation of the data. Therefore, I would like to address the data analysis to raise some concerns I had about the paper and the methods used by the researchers.

First of all, the power of the experiment appears very low. If there were 12 treatments (3 communication x 2 order x 2 self-consciousness = 12 cells) and only 130 subjects, then only about 10 people appeared in each cell. Additionally, cell sizes were likely very unequal due to splitting on the self-consciousness measures. The authors were careful not to report on the exact number of people in each treatment. If the distribution among cells was very skewed with these small cell sizes, the reliability of the data analyses as a whole could be questionable.

The manipulation check suffers from a lack of significance testing. The categorical data seems to be open to a chi-square test. I would suggest future work using a scale similar to strongly disagree (1), disagree (2), neither agree nor disagree (3), agree (4), strongly disagree (5), and then do a t-test between groups to determine the strength of the manipulation. Also, one manipulation check question might not be enough. I would suggest two or three for reliability of the measure.

The authors' decision to cut up the self-consciousness scale baffles me. Conceptually an eloquent argument was made for self-consciousness, then some items were picked from the scale and called self-reflectiveness, but the authors continue to refer to self-consciousness. I take issue here with the usefulness of the information in Table 1. A

major question is what percent of the variance is accounted for by the first and second factor? If the first factor accounts for most of variance, then a unidimensional scale of self-consciousness exists. Conceptually, I do not see any difference between self-reflectiveness and internal state awareness. I see no content validity in saying that the item "I sometimes have the feeling that I'm off somewhere watching myself" represents the extent to which individuals examine their motivations and not awareness of feeling states, while the item "I'm aware of the way my mind works when I work through a problem" represents awareness of feeling states and not the extent to which individuals examine their motivations. The point I am trying to make here is that the authors have fiddled with the self-consciousness scale without proving they have done so in a valid and reliable manner. This raises the question in my mind "did the researchers use the full scale and find it didn't work, then scramble to data massaging to 'prove' their hypothesis?"

The authors do not tell us the median score that was used to divide the sample into high and low consciousness. Was it two or three on this five-point scale? Are people who scored two significantly different than people who scored three? Given this split and the likely unequal and small cell sizes, the authors report some strong effects on their dependent variable. Besides the significance of the independent variables, the authors need to report the amount of variance (omega squared) accounted for by each variable. This would give the reader a much better indication of the importance of order self-consciousness and message when measuring values.

Despite the methodological flaws, I really liked this paper as it had a strong conceptual argument. I feel the topic of 'values' will be hot for consumer researchers, mainly due to shifting values of consumers and how that shift reflects on their consumption patterns, for example, the success of green products in grocery stores. Some major issues to address in this line of research are the stability of manipulated values and interaction of overt behavior. If we can easily manipulate values of some people, what is the effect over time? Once a value is manipulated some way, can it be manipulated back to the original point with further communication? Does there have to be an overt commitment to the value via behavior to stabilize the value? We need more studies over long time periods to shed light on the above points. In conclusion, I would encourage the authors to continue research in this area.

Ad Affect, Brand Attitude, and Choice: The Moderating Roles of Delay and Involvement

Amitava Chattopadhyay, McGill University
Prakash Nedungadi, University of Toronto¹

INTRODUCTION

Marketers have long assumed that an individual's reactions toward an advertisement has an impact on their evaluation of an advertised brand and subsequent purchase decision. Based on this assumption, marketers have routinely measured audience reaction to ads (e.g., Schlinger 1979). Recently, Mitchell and Olson (1981) and Shimp (1981) have attempted to present a framework that tries to make explicit the relationship between an individual's responses to an ad and brand attitude judgements. They suggest that the effects of an individual's reactions to an advertisement on brand attitude are mediated by the construct attitude toward the ad. Mitchell and Olson (1981) also present empirical evidence in support of this proposition.

Following the pioneering work of Mitchell and Olson (1981) and Shimp (1981), a number of marketing researchers have theorized about and investigated the relationship between attitude toward the advertisement and consumer decisions under a variety of situations (e.g., Lutz, MacKenzie and Belch 1983; MacKenzie, Lutz and Belch 1986; Mitchell 1986; Moore and Hutchinson 1985; Park and Young 1986). A review of this research reveals that notwithstanding a growing body of research on the effects of attitude toward the ad on brand attitude, there are several limitations in our understanding of the relationship between attitude toward the ad and consumer decision making.

First, with the exception of the work of Moore and Hutchinson (1983, 1985), there is no research that has examined either the temporal stability of ad attitude or the relationship between ad attitude and brand attitude over time^{2,3}. Research

on this topic is important as the effect of ad attitude on brand attitude observed immediately following exposure may change over time.

Second, recent conceptual developments in psychology (e.g., Petty and Cacioppo 1981), their conceptual extension to the marketing context, and empirical tests of these ideas (e.g., Lutz 1985; Park and Young 1986) indicate that the effects of ad attitude on brand attitude judgement are moderated by the degree to which the message recipient is involved (Petty, Cacioppo and Schumann 1983) with processing the message. In situations characterized as low involvement, ad attitude has a bigger impact on brand attitude compared to situations characterized as high involvement. Given the differential impact of ad attitude on brand attitude as a function of message processing involvement, the relationship between ad attitude and brand attitude is likely to be influenced differentially with the passage of time. Since the effect of ad attitude on brand attitude is larger under low involvement, the relationship is likely to change more in cases where the initial attitude is formed under low involvement compared to when it is formed under high involvement.

Third, previous research has not examined the effects of ad attitude on choice behavior. It is not adequate to assume that the relationship between ad attitude and brand attitude will simply generalize to choice as there is evidence to suggest that the antecedents of attitude and choice may be different (e.g., Chattopadhyay and Alba 1988; Loken and Hoverstadt 1985).

This research seeks to examine (a) whether the effects of ad attitude on brand attitude are stable over time, (b) the effect of involvement at the time of processing the message on the ad attitude-brand attitude relationship over time, and (c) the role of ad attitude in influencing choice behavior.

EXPERIMENT

Using a 2x2x2 between subjects design the effects of ad attitude (neutral and positive) on brand attitude and choice as a function of delay (no delay and one week delay) and involvement (high and low) was examined. Subjects, run in small groups, were first presented with a typed sheet of instructions that informed them of the purpose of the study. To manipulate involvement, half the subjects were told

immediately following exposure. Since, in the research presented here, we compare the effects of a very favorable ad attitude with the effects of a relatively less favorable ad attitude on brand attitude, the effects observed by Moore and Hutchinson (1983, 1985) for extremely negatively evaluated ads is not directly relevant.

¹This research was supported by the Social Sciences and Humanities Research Council of Canada's Grant #410-88-1203 to the first author.

²Burke and Edell (1986, 1989) and Edell and Burke (1987) had subjects come to their lab for measurement of a variety of post-exposure responses at different time delays from the time of initial exposure to a set of target ads. However, prior to measuring subject's responses, subjects were all shown the target ads once. This last exposure, immediately prior to measurement, precluded the possibility of examining the effects of time delay on ad attitude and its effects on brand attitude.

³Moore and Hutchinson (1983, 1985) classified ads into five categories ranging from positive to negative. They found that for brands associated with the most negatively evaluated ads, brand attitudes became more favorable after a delay of seven days compared to brand attitudes measured

that we were interested in their evaluation of a new program being considered for airing in the local market (low involvement condition) and half the subjects were told that the purpose of the study was to examine their evaluation of advertisements. These latter subjects were also told that they should pay careful attention to the advertisements as they would be asked questions about the ads following exposure and they would receive up to five dollars depending on the accuracy of their responses to the set of questions that would follow (high involvement). Subjects then saw a fifteen minute segment of a TV program not aired in the area. The target ad was embedded in the program segment. Half the subjects saw the neutral version of the ad and half saw the positive version. Ad attitude was manipulated by altering the visual elements of the ad (see, e.g., Mitchell 1986).

Following exposure, all subjects completed a page containing five filler questions. At this juncture, half the subjects (no delay condition) completed the main questionnaire and the other half were dismissed with instructions to return a week later, ostensibly for another experiment (delay condition). Subjects in the delay condition were administered the main questionnaire during the second session a week later. Following completion of the main questionnaire, subjects were paid and debriefed.

In the main questionnaire, subjects' cognitive responses, ad attitude, brand attitude, and choice behavior were assessed. As well, questions designed to assess level of involvement and experimental demand were included.

RESULTS

Our results showed that subjects' attitude toward the ad had a strong effect on brand attitude. Further, neither delay nor involvement had any effect on either subjects' ad attitude or brand attitude. That is, the ad attitude-brand attitude relationship was not contingent on either delay between ad exposure and measurement or the level of involvement at the time of ad exposure. Our results also showed that ad attitude did not influence choice behavior.

The Vicissitudes of Product Experience: 'Songs of Our Consuming Selves' in Drama Ads

Gregory W. Boller, Memphis State University¹

ABSTRACT

This paper offers some tentative speculations and conjectures regarding the nature of drama ad processing. It is suggested that viewers of drama ads, in contrast to lecture ads, engage in a highly self-focused and self-participatory mode of processing. Data from an exploratory study are offered as initial evidence in support of this contention. It is suggested that future explorations of drama ad processing must give serious consideration to the role of vicarious participation (i.e., empathy).

INTRODUCTION

As several theorists have recently noted, advertisements are a virtual repository of meanings about consumption experience (e.g., Goldman 1984; McCracken 1987; Pollay 1986, 1987). In contrast to usual terse listings of information regarding product benefits, many advertisements instead provide intriguing images of the rich, social drama surrounding everyday products (McCracken 1987). Often filled with visions of ideal interpersonal relationships, these advertisements rarely provide information about a product's attributes or functional benefits. Instead, these ads simply tell a story about one or more characters' experiences with the product in question; their form is dramatic in nature (Wells 1988).

In his paper, Wells (1988) echoes an observation made by other theorists interested in communicative form (e.g., Applebee 1977; Bruner 1986; Fisher 1984, 1985)--viewers engage in a different sort of processing when exposed to dramas than when exposed to lectures. To date, however, the particular nature of drama ad processing still begs empirical description.

One of America's most celebrated poets, Walt Whitman, apparently understood the nature of this processing quite well. The poem entitled, *Song of Myself* (Whitman 1855/1940), is a magnificent template for those interested in celebrations of self-reflection. Whitman understood that poetic and dramatic forms of communication virtually demand a process of self-participation in and self-reflection on the depicted experiences. Or, as Coles (1987, p. 12) writes, dramas "...nudge us to connect our lives to the lives of various characters in their various stories--to immerse ourselves in a world with plenty of moral drama at work."

This research explores the notion that viewers exposed to dramas, and in particular drama ads, engage in a highly self-focused and self-participatory mode of processing. More

specifically, it is suggested that viewers come to understand the product experiences portrayed in drama ads by becoming vicarious participants in the experiences of drama ad characters.

Cognitive response data from four ads (two lecture and two drama) are offered to support the general contention of self-focused processing. Product evaluation data from the two drama ads are then examined in terms of their relationships to a measure of vicarious participation. Suggestions for the development of a theory of vicarious processing are offered as primary directions for future research.

A CONTINUUM OF ADVERTISEMENT FORM

Modern literary theorists assert that it is instructive to think about communicative form in terms of a continuum (Applebee 1977; Bruner 1986; Fisher 1984, 1985). At one end of this continuum, we find forms which are generally argumentative and lecture in nature. Narrative and drama forms of communication can be found at the other end of the continuum. Aside from serving as a relatively simple way to classify forms of communication, Bruner (1986) claims that this continuum serves to delineate two modes of thought--logico-scientific and imaginative thought. More specifically, Bruner argues the necessary relationship between communicative form and the mode of comprehension employed to make sense of the information contained in that form.

Lecture Ad Forms and Logico-Scientific Thinking

Lecture forms of advertising generally rely upon argumentative conventions of logic and validity for their import (cf. Wells 1988). An ad lectures to an audience by first asserting product claims, and then providing a carefully structured presentation of assertions in support of these claims. In general, lecture forms of advertising use arguments to establish the validity of asserted claims by providing a structured set of reasons (i.e., evidence) which logically defend those claims (see Boller, Swasy and Munch 1989).

Lecture advertisements, replete with argumentative thrusts and parries, are perhaps best thought of as purveyors of definitive product meanings. That is, lecture advertisements seek to convince an audience of the product's objective reality. Good lecture advertisements provide substantive information about the attributes and functional benefits of products to utility-maximizing viewers (cf. Resnik and Stern 1977; Shimp and Gresham 1983). After all, how can viewers make "informed" product choices unless they possess the facts regarding the features and benefits of competing product alternatives?

¹The author gratefully acknowledges support from GTE and the Avron B. and Robert F. Fogleman Academic Excellence Fund.

It is important to note that viewer acceptance of a product's "objective reality" is dependent upon their understanding and acceptance of the argumentative logic presented by the ad lecture. Viewers are not likely to accept the product claims until they discern, assess and accept the arguments offered in support of those claims (cf. Perloff and Brock 1980)

Wells (1988) writes that viewers process lecture advertisements "at a distance." Viewers assess the quality of the presented evidence, judge the authority and credibility of the source, and primarily counterargue the logical linkages between the product claims and their supporting evidence. Viewers process lecture ads "...at arm's length and use the outcome to help them think about how to behave" (Wells 1988, p. 15).

Stated differently, viewers tend to process lecture ads in argumentative fashion. That is, they qualify, challenge, and judge the arguments step by step (Applebee 1977; Bruner 1986). Viewers first identify which statements of evidence are used to support particular product claims. Next, they assess and counterargue these presented relationships with respect to their own understanding of what constitutes a logical relationship (Jaccard 1981; Reynolds and Burgoon 1984).

Drama Ad Forms and Imaginative Thought

In contrast to lecture ads, dramatic forms of advertising depend upon narrative conventions of plot and character for their import. Drama ads are foremost a story about one or more characters' experiences with a brand or service. Drama ads contain a plot--the correlative arrangement of story events and actions (Chatman 1978; White 1980). And drama ads also contain characters--protagonists given particular physiological and psychological traits, and through who's actions, brand-related experiences are conveyed to the viewing audience (cf. Martin 1986; Todorov 1977). However, unlike other forms of narrative (e.g., novels, tales and myths), pure dramas do not make use of a narrator.

In a pure drama, the actions of characters simply unfold--they are enacted or performed instead of told or recanted. Whereas narrated stories tend to provide overt interpretations of character actions with descriptions of their mental states and motives, dramatized stories require that their viewing audience provide these interpretations (Booth 1961; Iser 1976; Martin 1986). Overt narration tends to distance an audience from the characters. Specifically, narration prompts an audience to view the depicted experiences as "someone else's." In contrast, dramatized stories tend to prompt an audience to view the depicted experiences as "their own." Dramatic forms invite audience participation in the portrayed experiences. Through their imaginary apprehension of the characters' mental states and motives, audience members share in the enactment of the story actions (see Aristotle's *Poetics*).

Drama ads can be thought of as purveyors of meanings about the relationship between product and

self. That is, drama ads seek to convince viewing audiences of the subjective relevance of the advertised product. Wells (1988) writes that dramatic forms of advertising generally provide viewers with free samples of many of the emotional and psychosocial consequences associated with product use. And as viewers imaginatively project themselves into the perceptual and emotional perspectives of the ad characters, they learn not the objective reality of the advertised product, but the relevancy it holds to the management of their own lives (cf. Wells 1988).

SOME TENTATIVE CONJECTURES

As already implied, the major theoretical assumption underlying this research is: "There exists a necessary relationship between ad form and the processes employed by viewers to make sense of the information embedded within that form." In essence, the form of an ad provides viewers with a conceptual framework through which they can articulate product-related meanings. Lecture forms of advertising (with their reliance on principles of argument) provide viewers with a structured, and often sterile, system of attribute-benefit logic through which product meanings can be gleaned. The focus of viewers' processing will be directed toward the advertised product (object focused), and necessarily argumentative in nature.

In contrast, drama forms of advertising (with their reliance on principles of narrative) provide viewers with a story regarding the vicissitudes of product experience. Viewers are offered the opportunity to learn of the product's self-relevancy by imaginatively participating in the product-related experiences of a passionate, experience-seeking character. The focus of viewers' processing will be directed to the portrayed experiences (self focused), and necessarily imaginative or empathic in nature.

Based upon these ideas, and the preceding review, the following conjectures are offered.

Conjecture 1: Moving along a theoretical continuum of communicative form, advertisements which are increasingly lecture in form will invoke processing that is increasingly argumentative in nature.

Conjecture 2: Moving along a theoretical continuum of communicative form, advertisements which are increasingly dramatic in form will invoke a focus of processing that is increasingly self, as opposed to product-oriented.

The notion that drama forms of advertising invoke self-oriented thinking can be extended a bit further. Recall that drama ads provide viewers with a particular experiential perspective to articulate product meanings--the self-identity of an ad character. Provided that viewers imaginatively participate in the experiences of an ad character, their self-oriented thinking will be guided by the perceptual and emotional perspective of this

character. The greater a viewer's extent of imaginative participation in the experiences of an ad character, the more he or she will learn of the product's self-relevancy (cf. Wells 1988). But more importantly, the qualitative nature of what viewers learn is dependent upon the specific character they choose to imaginatively participate with. As such, a third conjecture can be offered.

Conjecture 3: Within dramatic forms of advertising, the nature of viewers' articulation of product-related meanings is dependent upon the specific character with whom they choose to imaginatively participate.

METHOD

In this study, a 1 X 4, between-subjects research design was employed. Two hundred student subjects were randomly assigned to one of four "ad-form" treatment conditions. Subjects assigned to treatment condition 1 were exposed to a television ad which was pure-form lecture; treatment condition 2--lecture voice-over with visual drama vignettes; treatment condition 3--drama with narrated voice-over; treatment condition 4--pure-form drama.

Subjects were recruited from a large liberal arts class, and received the sum of five dollars for their participation. The study was conducted in a laboratory setting, and consisted of exposing subjects, in groups of 15 or less, to the treatment advertisement, placed directly behind a segment of "soft news" from CNN. The programming context was designed to place subjects in a "television viewing mode," making them feel more comfortable with the task of viewing a television commercial. Immediately following exposure to the treatment ad, subjects completed a cognitive response task, as well as ad and product-related evaluations. For those subjects assigned to the drama conditions, measures of vicarious participation were also taken.

Ad Stimuli

As defined by the research design, four different television ads were employed. All treatment advertisements were Subaru automobile commercials. Two Subaru advertisements were lecture in form (one pure-form; one with visual drama vignettes), and two advertisements were drama in form (one with overt narration; one pure-form).

In the pure-form lecture ad, the primary line of argument was concerned with establishing the validity of a quality claim. In addition to other pieces of evidence, the spokesperson in this ad stated that, "In a recent consumer survey, consumers rated Subaru second only to Mercedes Benz in terms of customer satisfaction."

In the lecture ad with visual drama vignettes, the primary line of argument was concerned with establishing the validity of a road handling claim. Subjects exposed to this ad were offered dramatic visual evidence regarding the automobile's road handling ability under poor driving conditions.

The drama ad with overt narration featured a middle-aged, country veterinarian as the main

character. In terms of the storyline, the ad begins with a very concerned looking farmer placing a late-night call to a doctor (the audience does not yet know that the doctor is a veterinarian). The farmer tells the doctor that he thinks, "...she's ready." The doctor responds, "I'll be right over." Next, the doctor is shown driving through inclement weather in his Subaru wagon to the farmer's house. After the doctor's arrival, the farmer and his two daughters are featured anxiously awaiting word from the doctor regarding the condition of "the patient." The ad ends with a pronouncement from the doctor that mother and baby (a cow and her calf) are "...doing just fine." The narration primarily consists of statements regarding how dependent this veterinarian is upon his Subaru.

The pure drama ad featured an intelligent (although impish) college-aged individual as the main character. In terms of the storyline, this character was first featured asking his father for advice regarding the purchase of a new car. The father says, "Get another Subaru--it's been good to us." Immediately following the "advice scene," the son is shown speeding along back country roads in his new sports car. During the drive, the audience was treated to an examination of all the new features in this sports car. The main character arrives home to find his father, with a dismayed look upon his face, stating, "I thought we agreed you'd buy a Subaru." The son responds, astonished that his father would presume to doubt his car-buying ability, "But dad...I did!"

Procedure

Upon entering the laboratory, subjects were individually greeted by the researchers, and asked to take a seat in front of two television monitors. Subjects were seated at tables arranged in a U-shape around the monitors. A questionnaire packet and pencil were placed directly in front of each subject.

When all of the scheduled subjects had arrived and been seated, the researcher read a general description of the study. In short, subjects were told that that would be asked a number of questions about their reaction to a television commercial. After reading the general description, subjects were given the opportunity to ask questions regarding their role in the study. When all of the questions had been answered to their satisfaction, they were asked to read and sign two copies of an informed consent form. After all of the informed consent forms had been signed and collected, subjects were shown the news segment and the appropriate treatment ad. When the questionnaires had been completed, subjects were debriefed as a group, paid five dollars, and thanked for their participation. The total time for each session was less than one hour.

Measures

A total of five measures were used in this study. Cognitive response measures of (1) counterarguments and (2) ratio of self-to-product thoughts were employed to address the first two conjectures. Measures of (3) vicarious participation,

(4) attitude toward the product and (5) perceived self-relevance of the advertised product were employed to address the third conjecture.

Cognitive Response Measures. Immediately following exposure to the treatment ad, subjects were instructed to list all the thoughts that occurred to them during exposure. In accord with the conjectures of interest, subjects' thoughts were classified as (1) counterarguments, (2) self-related, (3) product-related, or (4) other by two trained judges. Interjudge agreement was 87 percent, and disagreements were resolved by a third judge.

Cognitive responses were classified as "counterarguments" if they consisted of statements of specific disagreement with what was shown or stated in the ad regarding the advertised product. The actual measure of counter-argumentative thinking (CA) consisted of the ratio of the number of counterarguments divided by the total number of thoughts in the response protocol. Cognitive responses were classified as "product-related" if they were (1) general statements (positive, negative or neutral) for the advertised product, or (2) specific statements about certain features or consequences of the advertised product. Cognitive responses were classified as "self-related" if they were (1) statements regarding some past experience the subject was reminded about, (2) statements which reflected an emotional feeling, or (3) statements regarding subjects' identification with the portrayed characters and/or events. The actual measure of self-predominant thinking (S/P) consisted of the ratio of the number of self-related thoughts divided by the number of product-related thoughts.

Vicarious participation measure. The extent to which subjects believed they vicariously participated in the experiences of ad characters was measured using a ten-item, six-point Likert scale known as the VEDA scale (Boller, Babakus and Olson 1989). The VEDA (Viewer Empathy in response to Drama Ads) scale consists of items such as, "I felt as though I were right there in the commercial experiencing the same thing," and "While watching the commercial, I felt as if the characters thoughts and feelings were my own." Scores on each of the individual items were summated to create the final measure (VP). Coefficient alpha was 0.96.

Attitude toward the product. This measure (Ab) consisted of a three-item, seven point Semantic Differential scale. Scale endpoints included Like/Dislike, Positive/Negative, and Good/Bad. Coefficient alpha was 0.97.

Perceived self-relevance of the product. This measure (PSR) consisted of a seven-item, six point Semantic Differential scale, derived from the Zaichkowsky (1985) Personal Relevance Inventory. Examples of scale endpoints include, Relevant/Irrelevant, Meaningful/Not Meaningful, and Beneficial/Not Beneficial. Coefficient alpha was 0.95.

RESULTS AND DISCUSSION

To address the first two conjectures, a MANOVA was performed, with ad form as the independent variable; CA and S/P as the dependent variables. The multivariate results indicate a significant effect due to ad form ($F=10.06$; $df=6$, 390 ; $p<.001$). Univariate ANOVAs indicate that ad form has a significant effect on both S/P ($F=15.54$; $df=3$, 196 ; $p<.001$), and CA ($F=7.44$; $df=3$, 196 ; $p<.001$). Mean values of CA, and standard deviations, across all four levels of ad form (pure lecture; lecture with drama vignettes; drama with overt narration; pure drama) are 0.32 (0.29); 0.20 (0.26); 0.13 (0.20); 0.12 (0.16), respectively. Subsequent contrasts indicate that cell means 2, 3 and 4 are not significantly different at the 0.05 level. Mean values of S/P, and standard deviations, across all four levels of ad form are 0.15 (0.40); 0.33 (0.82); 2.54 (3.13); 1.20 (2.15), respectively. Subsequent contrasts indicate that cell means 1 and 2 are not significantly different at the 0.05 level.

In sum these results provide initial evidence in support of the first two conjectures. Lecture forms of advertising tend to invoke argumentative thinking. In contrast, drama forms of advertising seem to invoke more self-oriented thinking, relative to the extent of product-oriented thinking. Within these results, however, an anomaly can be noted. Specifically, the ratio of self-to-product thinking in response to the pure drama ad was significantly less than that in response to the drama ad with overt narration.

One possible explanation for this finding is that subjects exposed to the pure drama ad vicariously participated in the experiences of the character who was actually feature driving the advertised automobile (i.e., the son). In contrast, subjects exposed to the drama with overt narration may have vicariously participated in the experiences of characters who were not featured using the product (i.e., the farmer and or his daughters). If this were indeed the case, we should expect more product-oriented thinking from subjects exposed to the pure drama ad because the character with whom they participated was featured actively thinking about the product.

As part of the VEDA scale, subjects were also instructed to indicate which of the featured characters they most strongly identified with. Nearly all of the subjects (98 percent) exposed to the pure-drama ad indicated that they most identified with the "son." However, only 32 percent of the subjects exposed to the drama ad with narration indicated that they most identified with the "doctor." This being the case, we should expect to find any relationships between the extent of vicarious participation and product-related evaluations to be stronger amongst subjects exposed to the pure drama than those exposed to the drama with narration ad. Simple Pearson correlations confirm this expectation. For those subjects exposed to the pure drama ad, the correlations between VP and Ab, as well as VP and PSR are 0.46 and 0.52, respectively. For those subjects exposed to the drama ad with narration, the correlations

between VP and Ab, as well as VP and PSR are 0.29 and 0.01, respectively. Apparently then, the types of meanings created during exposure to a drama ad depend upon the extent of vicarious participation, as well as the particular character with whom viewers choose to participate.

IMPLICATIONS AND CONCLUSIONS

The purpose of this paper was to explore the notion that viewers exposed to drama ads engage in a highly self-focused and self-participatory mode of processing. The results of the current study suggest that this particular notion is indeed viable. Viewers exposed to drama forms of advertising, in contrast to lecture forms, engaged in less argumentative thinking and more self-predominant thinking. And more importantly, the results suggest that viewers exposed to drama forms of advertising engage in self-oriented thinking from the perspective of another self-entity (i.e., an ad character).

I believe that it is instructive to think of ad forms as conceptual frameworks through which viewers are able to articulate product meanings. And the conceptual framework offered by drama ads consists of the complex perceptual, cognitive and emotional perspectives of an ad character. Future explorations into the nature of drama ad processing should start with careful consideration given to the vicarious relationships audience members establish with key characters.

Such research, however, presupposes an adequate conceptualization of empathy. At present, consumer researchers know precious little about empathy and its effects. Future research needs to ask some hard questions regarding, (1) Why do viewers empathize--what motivates them to engage in this form of processing, (2) How do viewers empathize--what sorts of cognitive subprocesses are employed to imaginatively project oneself into the thoughts and feelings of another, and (3) What sorts of meanings do viewers create during empathic episodes--are these meanings qualitatively different than meanings produced during episodes when they are not empathizing? Answers to these and other similar questions will likely enlighten our understanding of the ways in which drama ads provide "songs of our consuming selves."

A Citation Analysis of the ACR Proceedings: A Knowledge Development and Social Exchange Perspective

George M. Zinkhan, University of Houston

Mary J. Saxton, University of Houston

Martin Roth, Boston College

Gerald Zaltman, University of Pittsburgh

ABSTRACT

One way to assess the scientific status of a publication is to conduct a citation analysis. Such an analysis provides insights about the knowledge flows concerning ideas written in a publication. Here we study the conference proceedings which accompanies the annual Association for Consumer Research (ACR) Conference. We find that proceedings authors draw on a very diverse literature for inspiration. In turn, the proceedings has had an increasing impact on published work in related scientific disciplines.

INTRODUCTION

Scientific disciplines rely on both formal and informal mechanisms to foster the development, dissemination and application of knowledge. The scientific journal perhaps best embodies the formal system serving rigorous quality control and archival functions among many others. Colloquia and certain aspects of professional association meetings are examples of informal mechanisms where ideas are usually exchanged relatively early in their development and through direct face-to-face interactions.

The professional conference also has certain qualities that combine both formal and informal mechanisms. For example, a published conference proceedings, such as those of the Association for Consumer Research, involves peer review and thus some level of certification for the ideas they contain. Proceedings also provide archival functions and provide a basis for establishing intellectual ownership or recognition for contributions made. At the same time it is recognized that many of these ideas are in their early stages of development and are sometimes offered in a more informal or tentative (brainstorming) spirit than when the same basic idea may be later offered in a core scientific journal. In many disciplines, publication in a proceedings is considered sufficiently informal that it does not preclude later publication of the same idea (with suitable improvements, of course) in a formal journal. Thus the published conference proceedings represents an interesting vehicle to study if one is interested in the development of knowledge in a particular discipline.

The key objective of this paper is to make a partial assessment of the role of the ACR Proceedings in knowledge development in the field of consumer research. That is, what are the sources of the ideas which are presented in ACRP? And, perhaps more importantly, what sorts of future work does the ACRP influence and/or inspire? Do cognate

areas (such as psychology, sociology) "recognize" ACRP by citing it (thereby conferring status), and to what degree do ACR researchers recognize other disciplines by citing their works? A social exchange framework is used to identify and explore the nature of knowledge flows between ACR and other disciplines. The principal methodology is a citation analysis of the ACR proceedings (ACRP) to determine: a) what literature the ACRP cites; and b) conversely, what literature cites the ACRP. This effort is particularly appropriate as the ACR conference celebrates its twentieth anniversary (and the *Journal of Consumer Research* its fifteenth year of publication).

PUBLISHING AS A SOCIAL EXCHANGE PROCESS

It is possible to conceive of the citation process as a social exchange where, over an extended period of time, published authors exchange ideas (manuscripts, which include citations of others' work) for future recognition (partly in terms of reciprocal citations). In this context, we are viewing citations as frozen footprints which bear witness to the transfer of an idea (Cronin 1984). That is, the author who includes a citation to a previous work is acknowledging receipt of that idea and is conferring recognition of its importance upon the cited author.

Previous citation analyses which have been conducted in the consumer behavior literature have concentrated upon the sources of ideas (see, for example, Leong 1989). Our approach is different in that we also investigate the literature which has been influenced and/or inspired by the proceedings. This is of potentially greater interest from a knowledge development perspective. In fact, Price (1986) advocates thinking of the role of citations from a cumulative advantage perspective. He suggests viewing old papers as the citation base from which new literature grows, rather than conceptualizing new papers as simply referring back to the old. Such a view better accounts for the ways extant knowledge is used in subsequent knowledge developments.

Our identification of the literature which is eventually influenced by the ACRP provides one way to judge the efficacy and efficiency of the conference as an informal exchange network. Thus, by examining citing and cited patterns of proceedings articles, it is possible to gain some insight into the nature of the relationships between consumer research and other related areas, thereby tracking knowledge exchanges across the traditional

boundaries among the social sciences (Garfield 1979).

METHOD

Citing and cited data were collected from the *Social Science Citation Index (SSCI)* database for the four years 1984-1987. SSCI first began tracking ACRP in 1984. Citing in this case refers to journals which ACRP authors have referenced, and cited refers to the journals whose authors have referenced ACRP articles. The 1987 Citing Journal Listing includes entries for most of the more than 1,400 journals fully covered by the SSCI, provided that issues of the journal did appear during that year. While a few journal references contain citations to many kinds of items besides journals, for our analysis we included only citations to journal articles themselves and citations referring to the popular press (e.g., *The Wall Street Journal*, *Newsweek*). Throughout we are interested in making comparisons to Leong's findings for the *Journal of Consumer Research (JCR)*.

RESULTS

Each year SSCI calculates an impact factor for each journal, which is a measure of the frequency with which the "average" article in a journal has been cited in a particular year. It is a ratio between citations and published citable items corrected for frequency of publication, age of journals, and size of journals. In a sense, the impact factor is an indicator of the relative importance of a journal to researchers working in that field (Lutz 1989).

ACRP's status has been slightly growing over the years, as indicated by its increasing impact factor: 0.352 in 1984, 0.301 in 1985, 0.414 in 1986, and 0.449 in 1987. In comparison, JCR's ranking based on the impact factor has been relatively high and improving over the years (Leong 1989). For example, JCR's 1987 impact factor was 2.167, ranking it 39th among all social science journals.

Citing Patterns

Table 1 shows the cross-disciplinary references by ACRP researchers. As might be

expected, the most influential areas are: marketing (13.7%), psychology (13.3%), and consumer research (8.3%). There is a substantial drop in influence when moving to the next most important areas: communication and journalism (1.3%), business-general (1.2%) and sociology (1.1%). After sociology there is a sharp drop to the seventh area, popular press, which accounts for only .5 percent of the references over the four-year period. This order varies somewhat from what Leong (1989) found in his study of 5 volumes of JCR where the most cited area was psychology (26.8%), followed by marketing (20.4%), consumer research (18.0%), then economics (5.6%), mathematics and statistics (4.2%), sociology (4.1%), and communication and journalism (3.8%). JCR tended to cite psychology more frequently than marketing while ACRP cites marketing more frequently. For JCR the first three areas account for over 65 percent of the total references, while for ACRP they account for only a little over 35 percent. Also, while JCR draws from economics, mathematics and statistics, and sociology as secondary intellectual hinterlands of consumer research (4 to 6 percent of citations, Leong 1989), ACRP draws less strongly from these quantitative sources (.3% economics and 1.1% sociology, no mathematics and statistics).

Several trends are suggested by Table 1. We find that references to the marketing literature are decreasing over the four-year period, from 15.1 percent to 12.1 percent, while references to consumer research are slightly increasing, 7.6 percent to 9.3 percent. Leong (1989) also found a tendency toward greater reliance on consumer behavior sources for referencing, indicating an increasing self-sufficiency of consumer researchers. As an informal test of whether consumer researchers are more likely to cite their own core discipline and less likely to cite literature from related fields over the four-year period, we selected four core disciplines most often cited by ACRP authors (marketing, psychology, communication and journalism, and business-general) and compared the percent of references accounted for by these journals versus the percent of consumer behavior references over time. In 1984 this ratio was 0.22 while in 1987 it is 0.43, suggesting that ACRP authors are more likely to cite consumer behavior literature and less likely to cite literature from four related areas in 1987 than in 1984.

ACRP authors tend to rely more heavily on psychology and business journals than economic and quantitatively oriented academic journals, as evidenced by the small number of citations for these journals (see Table 2). *Psychometrika* is cited 42 times in four years, with .4% of total cites; *Econometrica* is cited 9 times (.1%), and *Management Science* 29 times (.2%). Also, ACRP tends to draw more heavily from the popular press (59 cites), especially such business-oriented media as *Newsweek* (12 cites), *The Wall Street Journal* (6 cites), and *US News & World Report* (6 cites).

We find that ACRP, JCR (as reported in Leong 1989, Table 3), and JMR and JM (Goldman

1979, Table 4) rely on very similar literatures. However, some differences in journal citations do exist. First, ACRP and JCR tend to cite JMR and JM less than the marketing journals tend to cite themselves (see Table 2). Second, in concurrence with Leong's JCR findings, the *Journal of Personality and Social Psychology* and *Psychological Bulletin* receive relatively greater attention in ACRP (3.4% and 1.0%, respectively) than they do in JMR and JM, combined (1.7% and 1.0%), but not as much as in JCR (5.9% and 2.2%). In contrast, the *Journal of Business, Psychometrika, Journal of Applied Psychology, Management Science*, and *Journal of the American Statistical Association* all receive higher proportions of references in the marketing journals than in JCR and ACRP.

Cited Patterns

Table 3 reveals a slightly different pattern for cited data than shown in the citing data of Table 1. As might be expected, consumer behavior is the literature most likely to cite ACRP (22.4%), while consumer research is only third in importance in the citing chart. The marketing literature is second most likely to cite ACRP (18.6%) during the four-year period; and consumer behavior and marketing together account for over 41% of all ACRP citations. Over time, the absolute number of ACRP self-citations has decreased (see Table 4, from 258 self-citations in 1984 to 200 in 1985, 205 in 1986, to 158 in 1987). This may be attributed to a general decline in the citing of books and proceedings (Leong 1989). Goldman (1979) found that in the marketing literature journals accounted for the bulk of reference sources, albeit marketing authors relied more on unpublished material than on conference proceedings. However, Leong (1989) found that in comparison to references cited from nonconsumer behavior sources, those from consumer research contain a much higher proportion of citations from conference proceedings than from books and academic journals. Thus, ACRP's incidence of self-citation is relatively small (7.0 percent) compared to authors of JMR (26.1 percent) and JM (28 percent) (Goldman 1979, p. 489).

As shown in Table 3 the psychology literature is the third most likely to cite ACRP (5.5%), while it ranked second in terms of being cited by ACRP. The fourth most likely is business-general (1.3%), which was the fifth most cited. Overall, in contrast to Leong's findings for JCR, the business literature is found to be moderately influenced by ACRP authors. There is a rather sharp fall off after this point, as no other discipline accounts for more than 1% of the cites to ACRP. It is interesting to note that while communication and journalism was the fourth area most cited, it slips to the sixth citing area with less than 1% total references.

While the proportion of citations to JCR has varied without a noticeable trend for the four years, it still remains ACRP's most cited journal (see Table 2). Furthermore, the proportion of citations in

economic journals (*Econometrica*, *Journal of Political Economy*, *American Economic Review*) is relatively small and concurs with Leong's (1989) finding that economic journals have paid less attention to consumer research over time.

Citing and Cited Patterns

When comparing citing and cited patterns for ACRP (see Table 5), it is obvious that ACRP draws more from the other disciplines (citings) than it repays (citeds). In only two areas, accounting and public relations, is ACRP cited more frequently than it cites.

More specifically, when comparing the ACRP citing and cited patterns by journals, it appears that there are some imbalances. While ACRP is heavily cited by *Journal of Economic Psychology*, it rarely cites JEP (ratio of ACRP citing/cited = 6.83, see Table 6). Also, the *Annual Review of Psychology* and the *Journal of Advertising* are more often citing ACRP than cited by ACRP (ratios of 1.58 and 1.54, respectively). However, it is interesting to note that 92% of the *Annual Review of Psychology* citations are due to the publication of one article written by a consumer behavior researcher (e.g., Bettman). This argues for an examination of

person-to-person communication flows rather than a focus on journal-to-journal exchanges.

The *Journal of Business Research* cites equally as often as it is cited (ratio of 1.0). With regard to European journals, ACRP is more often cited than citing. According to Table 4 the *European Journal of Marketing* is the tenth most likely journal to cite ACRP (27 cites, 1.4% of total cites) and the *Revue Francaise du Marketing* is the twenty-second most likely (4 cites, .2%), while ACRP does not cite them. This is consistent with Jobber and Simpson's (1988) finding that American marketing journals tend not to cite European journals. This trend continues in other international journals, too. For example, the *Journal of Economic Psychology* cites ACRP 41 times over a four-year period (2.5% of the total cites), but is only cited by ACRP 6 times, producing less than .1% of the total citations.

At the other extreme are some psychology journals heavily cited by ACRP but which rarely cite it in return (see Table 6): *Journal of Personality and Social Psychology*, *Journal of Applied Psychology*, *Journal of Social Psychology* (ratios of 0.01, 0.04, 0.14, respectively). JCR is more cited by ACRP than it cites (.42), as are most of the major

marketing journals, such as *Journal of Advertising Research* (.08), *Journal of Marketing Research* (.13), *Journal of Marketing* (.17), and the *Journal of Retailing* (.36). Finally, *Public Opinion Quarterly* is frequently cited by ACRP authors, but the reverse is very rare. Overall, ACRP continues to grow as an interdisciplinary publication. Currently, ACRP authors are more likely to draw their citations from related disciplines than they are to cite ACRP itself or the consumer behavior literature in general. Some observers (Price 1970) identify this as a sign of either an evolving or an applied discipline.

DISCUSSION

The ACR conference proceedings serves the role of an informal communication network as the turn around time between the submission of a paper and the presentation of that paper at the conference is relatively brief (six months or so). A subset of the conference papers appear in the proceedings, and we have briefly analyzed the impact of that proceedings on related areas of academic inquiry.

In terms of citing patterns, we find that ACRP authors are quite eclectic and draw from a large number of areas. In fact, ACRP authors are more interdisciplinary in their citing behavior than are JCR authors. Nonetheless, we find that ACRP authors are tied fairly closely to the marketing literature, which provides the main source of their

ideas (14%). There is also a surprisingly strong tendency to cite the business popular press (.5%).

There is some evidence that the consumer behavior field is maturing, as there is an increasing tendency for ACRP to rely on that literature (9.3% in 1987). Conversely, ACRP has had its biggest impact to date on the consumer behavior literature itself, as over 22% of all authors who cite ACRP do so from a consumer behavior journal. Nonetheless, ACRP has had a fairly strong impact on the marketing literature, as marketing authors made over 360 cites to ACRP in the four-year period which we studied. At the same time, ACRP is moderately influential for psychology (108 cites) and business (26 cites) authors. In addition, ACRP has had some impact on foreign marketing journals (31 total cites in the four-year period).

To date, ACRP has made a fairly strong impact on a wide variety of journals, especially in comparison to the impact other marketing-oriented journals typically have on related areas. And yet, ACRP requires a fairly idiosyncratic citation format as potential citers are required to include editors' names (and there are frequently multiple editors) as well as a place of publication. Under this format, a citation to an ACRP article can sometimes take up two times as much space (or more) than a citation to a traditional journal article. Perhaps ACR should

consider shortening its citation format, in the spirit of eliminating barriers to future citations.

In many academic institutions, proceedings publications count very little toward promotion and tenure. Here we uncover some evidence that the ACRP is at least as prestigious as some journals, in terms of contributing to new knowledge in a wide variety of fields. ACRP papers are noticed and do inspire additional, follow-up work. It would be interesting to track the influence which specific ACRP papers have had by utilizing SSCI data to conduct a network analysis.

In this brief study, we have examined a small portion of academic knowledge use. One way that an academic can make use of a published paper is by reading it and subsequently citing that paper in a future publication. There are, of course, other ways that academics may utilize the knowledge contained in a journal article and there are other ways that non-academics may also use such knowledge. For example, a manager may read something and then think about a strategic problem in a new way. It would be interesting to expand the scope of investigation and look into other ways that ACRP articles may make a difference. In a similar vein, it would also be enlightening to examine the impact that non-published ACR presentations have. Over time, there is a trend for authors to elect not to publish their ACR papers in the proceedings; but these papers also have the potential to contribute to knowledge through an informal exchange network. Explorations of such informal networks require something other than a citation analysis.

Metaphor In Promotional Communication: A Review of Research on Metaphor Comprehension and Quality

James Ward, Arizona State University
William Gaidis, Marquette University

ABSTRACT

Metaphorical comparisons are frequently used in advertising to generate beliefs or to enhance the image of a product or service. Yet, very little research has appeared in the marketing literature which has discussed the nature of metaphors, their cognitive processing, or their effects on inference and evaluation. Researchers have provided virtually no guidelines for the creation of more effective promotional metaphors. This paper discusses various models of metaphor comprehension and quality, and suggests guidelines for both marketing practice and future research.

INTRODUCTION

Metaphors abound in everyday conversation, in literature, and in advertising and other promotional efforts. A metaphor is usually described as an explicit or implicit statement that one concept is another concept. Marketers use metaphors in slogans ("Budweiser: The King of Beers," "Today's Chevrolet: The Heartbeat of America," "Nissan Trucks: The Hard Bodies," "Samsonite: The Survivor"), names ("Mustang" for a car, "Opium" for a perfume, "Trojans" for prophylactics), and other types of promotional devices. Marketers also employ metaphors to explain products and services to consumers by translating technical concepts into different and more understandable terms.

Despite marketers' frequent use of metaphors, the consumer behavior literature has had little to say about such issues as how consumers comprehend metaphors or how to create a metaphor that is apt, comprehensible, memorable, and encourages desired inferences and favorable affect about its subject (for exceptions to this neglect, see Kehert-Ward (1986) and the special session on metaphor noted in this volume of the Association for Consumer Research Proceedings).

This lack of recognition is unfortunate for several reasons. First, the study of metaphor has long been of interest to other disciplines. These include philosophy (for a review of historical and recent perspectives see Johnson 1981), psychology (for reviews see Billow 1977, Ortony 1979), linguistics (e.g., see Lakoff and Johnson 1980), literary criticism (e.g., see Johnson 1981, and Sacks 1978), and the aesthetic study of the visual arts (Arnheim 1969, 1974; Gombrich 1963, 1972a, 1972b). In the philosophy of science literature Black (1962), Kuhn (1979), Ward and Ruekert (1984), Arndt (1985), and Mick (1986) among others have suggested that metaphors can be powerful tools for the development of scientific theory (e.g., the cybernetic metaphor for cognitive activity).

Second, despite this long history of scholarship, theoretical issues about metaphor are far from being resolved. In fact, interest in the study of metaphor has increased in other disciplines enough to prompt Johnson (1981) to comment that, "We are in the midst of metaphormania. Only three decades ago the situation was just the opposite: poets created metaphors, everybody used them, and philosophers (linguists, psychologists, etc.) ignored them" (p. ix).

Third, scholars of consumer behavior might make interesting contributions to this interdisciplinary discussion. The mass of people may be more likely to be exposed to new metaphors through promotions than through poetry. Thus, the character of promotional metaphors and their relation to mass culture deserve study. Furthermore, promotional metaphors are usually intended to be apt, comprehensible, memorable, and to influence consumer beliefs and affect. These qualities of metaphor are the subject of controversy in other disciplines and further theoretical and empirical work seems necessary to help resolve these controversies.

To illustrate how promotional metaphors could be useful vehicles for the study of these issues, consider how the issues of comprehension, persuasion, and aptness are relevant to understanding the effectiveness of the metaphorical slogan "Nissan Trucks: The Hardbodies." To be effective, a promotional metaphor must minimally be comprehended by its intended audience. In other words, the audience must be able to see how trucks might be meaningfully related to people who have fit, hard-muscled bodies. An effective promotional metaphor should also help persuade consumers that a product or service has desirable characteristics. The "hardbody" metaphor seems intended to encourage consumers to infer that Nissan trucks have the characteristics of a fit body including strength, endurance, vigor, longevity, freedom from ills, and good looks. Young adults, an important market segment for compact pick-up trucks, are both likely to understand the term "hardbody" and to value such characteristics in themselves and trucks. If consumers make favorable inferences, their attitude to the product should improve. Furthermore, a promotional metaphor that is perceived as "apt" (that is, good, clever, and insightful) may create a more favorable attitude toward the promotion itself (Aad) which might also favorably influence attitude toward the product.

As this example suggests, marketing scholars have the opportunity to make significant advances in the study of metaphor that are both theoretically interesting and practically useful. From a theoretical perspective, issues such as how metaphors are perceived, processed, and remembered have fascinated scholars for decades, and fit with

marketing scholars developing interest in the study of symbol perception, processing, and meaning (e.g., Solomon 1983, Mick 1986, Sherry and Camargo 1987, Hirschman 1988). From an applied perspective, many promotional campaigns are based on a metaphor but metaphors vary widely in their success. People regard some metaphors as trite, inappropriate, or confusing, and others as apt, clever, illuminating, and memorable. The best promotional metaphors have become popular symbols of American culture, and have helped create legends around a few products. For example, the Ford Mustang's name suggests such associations as speed, freedom, independence, and even rebellion that probably helped increase the product's appeal to young people in the sixties (Iacocca 1984).

The purpose of this paper is to encourage students of consumer behavior to become more interested in the study of metaphor. All of the perspectives noted earlier cannot be adequately discussed in a short paper, so this review will focus on recent work in psychology which has attempted to explain how metaphors are comprehended and what makes one metaphor more apt, comprehensible, and memorable than another. Since the study of metaphor has become highly interdisciplinary, reference to work in philosophy and linguistics will also be made.

WHAT IS METAPHOR?

The question of what a metaphor is, and how a metaphor can be identified, is a complex issue. The simplest definition is that a metaphor is a statement that one concept is another. This is generally true, but is not sufficient to identify and distinguish metaphors from other statements. For example, by itself the statement that "Baking Soda is a rug deodorant" does not seem metaphorical. Many theorists have added the restriction that metaphors are literally untrue, or in the terms of linguistic theorists, "semantically deviant" (Matthews 1971). In this view, we recognize a metaphor by its violation of linguistic selection restrictions which govern what sense a lexical item can assume in relation to other lexical items in a sentence (Katz, 1964). For example, we recognize that the statement "Nissan Trucks (are) Hardbodies" is metaphorical by noting the incompatibility of, among other things, the marker [+ made of steel] attached to trucks and the marker [+ made of flesh] attached to hard bodies. However, Loewenberg (1975) and others have criticized this view by arguing that it focuses on literal falsity as a defining characteristic of metaphor when in fact falsity is a frequent but not a necessary characteristic of metaphorical statements. For example, a consumer might say that, "My stock broker is a gambler" and, if the broker plays cards, convey a literal and metaphorical truth. Loewenberg (1975) suggests that metaphors can only be identified by considering the context beyond the sentence in which the statement occurs. Johnson (1981) agrees with this view suggesting that "our identification of an utterance as metaphorical does seem to involve some

strain between the normal sense of the utterance and the total speech situation in which it occurs" (p. 23). In identifying metaphor, an important part of the speech situation may be the listener's inference about the speaker's intention. People assume that communication is purposeful (Grice 1975) and rely partly upon their perception of the communicator's intention to decide whether a statement should be interpreted as metaphorical or not. The consumer who encounters the statement "Nissan Trucks: The Hardbodies" could take the statement literally. After all, trucks do have hard (steel) bodies. But the consumer may note the statement is part of an ad and expect colorful metaphorical language that describes cars and trucks in human and animal terms that appeal to the truck's intended consumers. Such extra-linguistic contextual knowledge may facilitate the consumer's recognition of the statement as metaphorical and then guide the consumer's efforts to interpret the metaphor. For example, the consumer could think of many ways that a Nissan truck is like a well-muscled body (e.g., the more muscle mass a body has, the more calories are required to maintain the body) but, once again, the consumer realizes advertisers intend to convey favorable attributes about their products and this inference no doubt encourages focus on attributes like strength and durability.

The issue of what metaphors are and how they can be identified is far from resolved despite the long history of scholarship on this issue. But as the Nissan truck example illustrates, the study of promotional metaphors seems capable of furthering understanding of these issues.

THEORIES OF METAPHOR COMPREHENSION AND APPRECIATION

Theories of metaphor comprehension and appreciation are concerned with how people derive meaning from non-literal statements. Three major schools of thought or theories--the anomaly view, the comparison view, and the interactionist view--have dominated discussion of metaphor processing and evaluation. These theories are particularly interesting from a marketing perspective because they each suggest different guidelines for constructing effective promotional metaphors.

Prior to discussing these theories, a few terms need definition. Consider the metaphor, "Today's Chevrolet: The Heartbeat of America." The subject of a metaphor (e.g., "Today's Chevrolet") is called the tenor. The thing the tenor is compared to is called the vehicle (e.g., "The Heartbeat of America"). As noted, two important dependent variables in the study of metaphors are comprehensibility and aptness. Comprehensibility is merely whether people grasp the metaphor's intended meaning, and has often been measured in past studies as a simple rating of how understandable a metaphor seems (Katz, Paivio, and Marschark 1985). "Aptness" is a construct that seems to be unique to the metaphor literature. Apt metaphors are usually described as

good, pleasing, and appropriate metaphors (Katz, Paivio and Marschark 1985).

The Anomaly View

The anomaly view is perhaps the least developed account of metaphor comprehension and aptness of the three to be reviewed. Essentially, the emphasis in the anomaly view is on dissimilarity between subject and tenor. Anomaly theorists have focused on attempting to account for how people understand literally meaningless statements such as "Chevys are the heartbeat of our country." Scholars with this perspective tend to be linguistic theorists who see a metaphor occurring when the rules of a grammar are violated by a literally untrue assertion (e.g., Campbell 1975, Chomsky 1964, Katz 1964, Ziff 1964). Most of these scholars' theories focus on how linguistic rules are dropped, loosened, or changed to allow the tenor and vehicle of the metaphor to be compared, at least at a more abstract level. In their view, the motive for this process is to reduce the anomaly created by the comparison of unlike concepts.

Anomaly theorists tend to focus on dissimilarity as the source of aptness in metaphor (e.g., Campbell 1975). To these scholars, differences create tension, incongruity, and novelty. The perspective suggests that better metaphors will compare dissimilar concepts, at least to the point where the metaphor becomes incomprehensible.

At least two problems decrease the anomaly view's value as a theory of metaphor quality (Tourangeau and Sternberg 1981). First, as the concepts compared in a metaphor become more and more disparate, the metaphor may become incomprehensible. If comprehension is a necessary, but not sufficient, condition for aptness, the anomaly view fails for extreme examples. For example, "Nissan Trucks are Milkshakes" seems neither comprehensible nor apt. A second problem is that beyond suggesting that more dissimilar concepts are more apt, the anomaly view says little about why dissimilar comparisons are more apt or how they are understood. Usually, anomaly theorists rely on feature-matching to explain how people try to understand a metaphor like "Nissan Trucks are Milkshakes" In this case, the perceiver might search for similarities between Nissan Trucks and Milkshakes, perhaps noting that both cost money, are enjoyed by young people, etc. Although similarities can be found, their relation to the aptness of the comparison is not apparent. The analysis of feature matching seems to contribute little insight beyond the comparison view, to be discussed next.

The Comparison View

The comparison view has a long history in the literature on metaphor, and a number of different versions of this view have been advanced (Johnson 1981). In its simplest form this view asserts that we comprehend a metaphor of the form A is B merely by finding the set of similarities between A and B. In other words, the meaning of the metaphor

is the set of similarities between the concepts. Comparison theories also often suggest that a metaphor will be perceived as more apt to the extent the two things compared have more attributes in common.

Recent versions of the comparison view have been advanced by Johnson and Malgady (1979) and Ortony (1979). Johnson and Malgady (1979) advance a relatively simple model of metaphor comprehension that begins with the assumption that the meaning of a word can be represented by a set of features. When two words are combined in a metaphor, "the meaning of the word combination is determined by an additive summation of the feature sets or vectors for the words making up the compound." They suggest that the shared features of a metaphor are "raised in salience" in the resulting representation of the compound. They acknowledge that their model says nothing about how features are matched or whether some features are more likely to be matched than others. However, this shortcoming has long been a focus of criticism of the comparison view.

Black (1955) criticized the comparison view by noting that any two objects are to some extent similar, yet 1) not all comparisons are perceived as metaphors, and 2) even if a comparison is perceived as a metaphor (e.g., consider the metaphor "men are wolves"), we tend to ignore some similarities between men and wolves (e.g., both have backbones) and focus on others as the meaning of the metaphor. Black's criticism is essentially that a theory of metaphor comprehension and aptness needs to say more than merely "similar features are matched."

Tourangeau and Sternberg (1981) share this criticism but go farther by pointing out that the meaning of a metaphor often is more than the sum of the two term's shared characteristics, particularly if the focus is on literally shared characteristics. For example, the metaphor "Men are wolves" encourages us to see that both men and wolves are predatory, but men and wolves are predatory in different ways. The features are only similar, and therefore not exactly matched in similarity. In fact, the metaphor encourages us to apply attributes of the vehicle's predacity to the tenor's predacity that do not match. That is, the metaphor encourages us to "raise the probability" that attributes such as "voracious, ruthless, and insatiably murderous" apply to men. Of course, naturalists would likely disagree that the last mentioned attributes characterize wolves. Thus, a metaphor may create meaning beyond the usual meanings of matching attributes. According to Tourangeau and Sternberg, a metaphor may be more than the sum of its parts.

Ortony (1979) developed a version of the comparison view that attempts to deal with criticisms like Black's that "matching" is not a sufficiently specific account of metaphor comprehension. Ortony argues that people focus more on some matching features in interpreting a metaphor than others. More specifically, he suggests that people interpret a metaphor by

matching salient features of the vehicle to non-salient features of the tenor. He does not maintain that these matching features need be exact and literal matches, but only matches to "similar" features of tenor and vehicle. Ortony's work deals with some but not all the criticisms of the comparison view. Tourangeau and Sternberg (1981) point that Ortony's view does not focus on the way in which metaphors seem to reinterpret or create attributes. Furthermore, they note that his view acknowledges the presence of dissimilarity between the tenor and vehicle but does little to attempt to account for the possible contribution of dissimilarity to the perception of a metaphor as more creative, novel, and apt.

The Interaction View

Interactive theories of metaphor comprehension argue that the subject and vehicle of a metaphor interact to create a new meaning that is more than the intersection of the two concepts' feature sets. The interaction view emphasizes that a metaphoric comparison may encourage the perceiver to reinterpret both the tenor and the vehicle. The meaning of the metaphor results not just from a feature-by-feature matching of the literal features of tenor and vehicle but from a matching of characteristics in each concept that may be created by the metaphor itself. For example, the metaphor, "1988 Jaguar XJ6: A New Breed of Cat Prowls the Road," encourages the perceiver to reinterpret the literal meaning of "cat prowling for food," to include elements of status competition instead of competition for food, and to include elements of elegance, grace, and sophistication that might otherwise not be salient aspects of the image of a cat prowling.

Tourangeau and Sternberg (1981) have advanced the most recent and complete interactive model of metaphor comprehension. Their "domains-interaction" model argues that the best, most "apt" metaphors are those that show a close point-by-point correspondence between two widely separate domains or categories. This model considers two kinds of similarities. One is between-domain similarity, the similarity between the domains, or categories, of the tenor and vehicle. According to the model, a metaphor tends to be perceived as more apt, but less comprehensible, to the extent the tenor and vehicle are from disparate categories. However, the model acknowledges that the metaphor must at least be comprehensible to be perceived as apt. The other type of similarity, called within-domain similarity, is the degree to which the network of beliefs about the tenor is perceived as corresponding to the network of beliefs about the vehicle. For example, Proctor and Gamble's Dove soap has a metaphoric name. Obviously, soap and birds are widely separated domains. However, P&G has designed and promoted Dove soap to have attributes similar to a Dove. For example, the soap is white, gentle, and, like a Dove is thought to be pure and "innocent," i.e., lacking in harmful additives. According to the model, the comprehensibility of a metaphor should increase to the extent within-

domain similarity increases. However, if tenor and vehicle are from similar domains, the metaphor will seem less apt because it is an obvious, trite, "easy" comparison.

The domains-interaction model incorporates insights provided by the anomaly and comparison views but goes beyond either. From the anomaly view, the domains-interaction approach borrows the suggestion that a comparison of more disparate categories may be perceived as more "metaphorical" or clever than the comparison of similar categories. However, the comparison of extremely disparate categories often seems bizarre rather than apt. The question that arises is under what circumstances comparison of disparate categories seems apt. For the answer, the model borrows from the comparison view the insight that comparisons that are more complete are perceived as better. Tourangeau and Sternberg (1981) as well as Trick and Katz (1986) have tested this model and overall their results support the relationships the model hypothesizes between within and between category similarity and measures of metaphor comprehension and aptness. However, the interaction model still needs further development. Like the comparison view, the model is still somewhat vague about a variety of issues such as what is or is not a metaphor, the process of metaphor comprehension, and more specifically the process of within-domain attribute matching.

The interaction model provides suggestions for the creation of more effective promotional metaphors. Better metaphors will use tenors and vehicles chosen from disparate categories that occupy similar positions within their categories. In attempting to create such metaphors, marketers should consider how the vehicle (e.g., "Hardbodies") is similar to, and illuminates salient attributes of the tenor (Nissan trucks) that the advertiser wishes to emphasize. Ideally, the vehicle might suggest a novel, clever, attention getting but understandable comparison that causes consumers to think about salient competitive advantages of the advertised product, and perhaps encourages them to add favorable affect or beliefs about the vehicle to their associations about the product.

In further research using the domains-interaction perspective, Sternberg and Nigro (1983) have investigated how the presentation of a metaphor, specifically the order in which its terms are presented, influences perception of the metaphor's aptness. For example, they asked subjects to rate the aptness of different arrangements of a metaphor. Two of the forms are shown below:

- (1) Bees in a hive are a Roman mob.
- (2) Bees are a Roman mob in a hive.

They found that subjects rated the second arrangement as more apt than the first. Their explanation for this result is that the second form increases the perception of tenor-vehicle interaction relative to the first form. In the first form, the sentence is merely "Bees in a hive = Roman mob." In the second form, the terms of comparison are

mixed across the "are." This type of research might be relevant to advertisers interested in presenting their metaphors in the most effective way.

Stages of Processing

The views of metaphor processing discussed above focus on the characteristics of metaphors that influence their perceived aptness and comprehensibility. Another stream of research on metaphor processing has focused on the issue of whether the processing of non-literal statements requires more stages than the processing of literal statements. A three-stage model of non-literal and metaphoric language processing has been proposed and supported by Grice (1975), Clark and Lucy (1975), Searle (1979), and Janus and Bever (1985). These researchers begin with the assumption that people expect linguistic interactions to be governed by a "cooperativeness" principle in which communications are assumed to be truthful and informative. In the first stage of discourse processing, the model assumes people automatically construct a mental representation of the literal meaning of a phrase such as "Today's Chevrolet: The Heartbeat of America." Second, the perceiver tests this literal interpretation in context to determine if it is plausible and appropriate. Taken literally, the above phrase, which involves not one but two metaphors, makes no sense at all because Americans do not share a beating heart, and today's Chevies cannot be heartbeats. If the perceiver rejects the literal interpretation as the intended meaning, he or she then searches for the intended non-literal meaning. In this case, the perceiver might realize that "heartbeat" is an implicit metaphor for "collective values and folkways" and then begin to search for the relationship between Chevies and the national character.

The three-stage model implies that metaphors, unlike literal statements, are not understood automatically, and require more cognitive effort and time to understand than literal statements. In support of the three-stage model, Janus and Bever (1985) have found longer reading and processing times for metaphors as compared to literal statements.

For advertisers, the implications of this model include the possibility that consumers might take longer to comprehend metaphoric communications, but also might tend to process such communications more deeply than literal comparisons.

As an alternative to the three-stage model, Glucksberg, Gildea, and Bookin (1982) have argued that metaphors and literals are processed in the same way "using the same cognitive and inferencing machinery." In support of their contention, they cite Ortony et. al.'s (1978) finding that metaphors take no longer than literals to process, and that their own finding that metaphor meaning is accessed simultaneously with literal meaning (also see Glidea and Glucksberg 1983).

As with many controversies in the metaphor literature, the stages of processing debate has not

yet been resolved and therefore presents an opportunity to consumer researchers.

OTHER ISSUES

Memory

Very little research has focused on the factors that make one metaphor more memorable than another. The few studies available indicate that metaphors differ from one another in their memorability and that the vehicle may be more important than the tenor of a metaphor in organizing people's comprehension and memory of the metaphor. Marschark and Hunt (1985) asked subjects to rate metaphors on a set of measures of metaphor characteristics. Later they tested the subjects' unaided and aided recall for the metaphors. They found that only their measures of the number of interpretations subjects could give to the metaphor and the imageability of the metaphor's tenor were consistently related to recall. Verbugge and McCarrell (1977) performed a series of experiments involving cued recall and concluded that the vehicle of a metaphor is more important than the tenor for guiding comprehension of a metaphor, and organizing memory for its meaning. Further research on factors that influence the memorability of metaphors seems needed and could be a useful contribution by consumer researchers, especially considering the probable significance of the issue to advertisers.

Imagery

Marketers often present metaphors to consumers visually instead of verbally or in writing. Despite the prevalence of visual metaphor in the arts (paintings, photography, movies) as well as advertising, there have been few empirical studies of the role of imagery in the comprehension, appreciation and memory of metaphors, although the literature on interactive imagery seems highly related to this issue (e.g., Alesandrini 1983).

The few studies that have explored imagery and metaphor usually note Paivio's (1979) perspective on the role of imagery in metaphor. From his dual-coding theory, Paivio predicted that imagery should benefit comprehension and memory for metaphor. Several studies support these predictions (Marschark, Katz, and Pavio 1983; Katz, Paivio, and Marschark 1985; Marschark and Hunt 1985). Paivio also predicted that vehicle imagery is more important than topic imagery in the comprehension of metaphor. He suggests that, "metaphor processing begins with and is guided by the vehicle, especially if it has high image evoking properties. In metaphorical terms, a high-imagery vehicle functions as a particularly efficient 'conceptual peg' for retrieval of conceptual information" (Paivio and Clark 1986, p. 98). In a set of studies, Paivio and Clark found overall support for this hypothesis. Katz (1989), in a study of the vehicles that subjects chose to complete metaphors, found that his subjects preferred concrete over more abstract vehicles. This finding also

seems to provide some support for the importance of imagery, and particularly vehicle imagery, in metaphor appreciation although Katz studied concreteness and not imagery per se.

Context

Metaphors, like other types of communication, occur in contexts. Developing research shows that the context a metaphor occurs in can influence its interpretation and the ease with which it is comprehended (Shinju and Myers 1987, Inhoff et al. 1984, McCabe 1983). These laboratory studies suggest that the contexts in which promotional metaphors occur may influence their meaning. For example, if an ad using the "Nissan Truck: The Hardbodies" metaphor appears in a sports magazine, the comparison to an athletic body may be emphasized. Once again, further research on context effects seems warranted in consumer settings.

FUTURE RESEARCH

The opportunities for future research on metaphors in promotional communications are numerous and interesting. Only a few of the possibilities can be suggested. The models of metaphor comprehension and quality discussed earlier have not been thoroughly validated. In particular, the domains-interaction approach has only been tested in a handful of studies. So opportunities exist to further compare, develop, and refine these or new models of metaphor processing in the context of consumer behavior. As suggested earlier, issues concerning memory for metaphor, the role of imagery in metaphor processing, and the influence of context on metaphor perception seem ripe for study by consumer researchers.

An Introduction to Semantic Variables In Advertising Messages

Karen A. Berger, Pace University

Robert F. Gilmore, Baruch College, City University of New York

ABSTRACT

This article presents a new way to analyze the technical composition of language used in advertising messages. Three semantic variables, reports, inferences and judgments, known collectively as the "semantic trichotomy", are introduced with a review of the general semantics literature. A new conceptualization which adapts these notions for future experimental study is provided. Two preliminary studies provide the main focus of this paper to prove that this distinction is clearly discernible in consumers' minds, an essential step prior to further experimental study.

INTRODUCTION

A review of marketing and communication literature suggests a need for the study of elements of the English language which contribute to the creation of persuasive messages. A semantic dimension, hereafter referred to as the "semantic trichotomy", is proposed as one systematic way of analyzing the technical composition of language.

This topic has been selected in light of the need for systematic ways of analyzing and constructing messages. Numerous researchers have pointed out that relatively little work has been done in analyzing the technical composition of advertising messages (Fishbein and Ajzen, 1981; Petty and Cacioppo, 1986). Issues, such as strong vs. weak arguments, or argument length, and other factors which influence the effectiveness of the message as constructed, have been widely addressed by persuasion researchers (Petty and Cacioppo, 1984). However, little attention has been paid to confronting the language itself and asking the question, what elements of the language contribute to the creation of persuasive, or not so persuasive messages? (Petty and Cacioppo, 1986). For this reason, Fishbein and Ajzen (1981) have said that "the general neglect of the information contained in a message ... is probably the most serious problem in communication and persuasion research" (p.359).

At least three taxonomies superficially resemble the semantic trichotomy: the Fishbein and Ajzen (1981) distinction *descriptive, inferential and informational beliefs*, the Holbrook (1975, 1978) notion of *factual and evaluative messages* and the notion of *concrete vs. abstract sentences* (Begg and Paivio, 1969; Paivio 1971; and Yuille and Paivio, 1979). Each of these approaches can be shown to be quite different from the semantic trichotomy.

This paper presents the first, necessary step in the process of developing and exploring the effects of these three semantic variables. In the first section, the semantic trichotomy is introduced presenting definitions from the general semantics literature. A new conceptualization is then presented in order to 1) provide a way to clearly separate the semantic trichotomy for later experimental study and

2) explain *a priori* the process through which these variables operate. In sum, this conceptualization provides a way to incorporate the semantic trichotomy into a framework which will be used in later work to generate hypotheses for further study. The final sections present two preliminary studies which demonstrate that the semantic trichotomy is inherently discernible and differentiable.

THE SEMANTIC TRICHOTOMY

The notions of reports, inferences, and judgments are presented in a well-known, classic general semantics book, *Language in Thought and Action* by S. I. Hayakawa (1972). The definitions which are given for these terms in the aforementioned book provide a starting point for developing a semantically oriented approach to persuasion.

Report

Hayakawa (1972) defines a report as a statement about a stimulus based on sensory information, i.e. information which we or someone else has directly seen, heard, or felt. Furthermore, Hayakawa states that for a statement to be a report, it must be capable of verification, either directly or indirectly. Further, people often draw conclusions mistakenly when they confuse inferences and judgments for reports (Hayakawa, 1972; Korzybski, 1947).

Condon (1985) uses the term 'statement of description' to describe what Hayakawa calls a report. He argues that these types of statements are generally more believable. Condon also states that reports generally do not create debate. Rather, they are accepted easily (Condon, 1985).

Inference

Hayakawa (1972) defines an inference as a statement about matters which are not directly observed. Unlike a report which is based directly on the sensory information at hand, the observed sensory information is used as a starting point to draw conclusions. This process of drawing conclusions is called abstraction. There are numerous levels of abstraction. For example, one can reason that one's dentist bills will be lower if one uses a toothpaste which reduces plaque and retards tooth decay. Or one can reason that one will be more attractive to members of the opposite sex.

Condon (1985) emphasizes the lower verifiability of inferences as compared to reports. According to Condon, some inferences are immediately verifiable; others take longer to verify; still others are totally unverifiable. Rosenthal (1971) adds that if a message lacks verifiability, the pre-existing knowledge of the listener may be essential to interpret the message in terms of its "truth" or meaning.

This discourse concerning verifiability is very interesting, but an inference which cannot be verified is still an inference, eliminating this as a distinctive feature. Furthermore, if some inferences can be verified, then how does one tell the difference between a verifiable report and a verifiable inference?

Condon re-states the Korzybskian notion that an inference often has less truth value. This lower truth value is explained by Gorman (1962) in terms of the strength of the predictions about the future which can be made.

Judgment

Hayakawa (1972) defines a judgment as an expression of the writer's evaluation, often including approval or disapproval, of the event, persons or things being described. He provides this example: The report statement "The Senator was the only one who voted against the bill" can be turned into a judgment with the sentence "The Senator courageously stood by his principles and voted against the bill." The judgment has been made that the Senator has behaved in a morally superior fashion. In effect, the author is giving his stamp of approval. According to Condon (1985), a statement of judgment adds the values of the person making the judgment to the meaning of the statement.

Values do not provide the basis for a clear definition, since neither reports nor inferences include the person making the statement. Agreement does not distinguish a judgment from the others. Consensus can be extensive. For example, few would argue with the judgment "tall willowy blondes are beautiful".

NEW CONCEPTUALIZATION

The basic concepts of two theories, Kelley's attribution theory and Chaiken's heuristic model of persuasion, are used in developing the new conceptualization. While none of the attribution approaches works in its entirety to explain the semantic trichotomy, Kelley's explanation of causes of observable actions (Kelley, 1967, 1972a, 1972b) is the most useful approach for separating the semantic trichotomy so that operationalization can take place. Further, Kelley and Chaiken's work provide insight into the mechanisms which may be operative in the persuasion process. In the case of the semantic trichotomy, the "causes" of the statements are not actions, but rather underlying beliefs about the meaning of the information provided. These underlying beliefs communicated by the semantic trichotomy mediate the persuasion process. The cause for an event is seen as part of the individual or part of the environment. This basic notion can be applied to situations in which people are presented with messages and must interpret their meaning and assess their validity.

An important implication of the attribution framework is that persuasion involves message recipients engaged in logical, consistent cognitive processing. An alternative to the systematic approach to message learning has been proposed by

Chaiken (1980, 1982) and another similar version has been developed by Petty and Cacioppo (1981, 1984, 1986). Chaiken's heuristic model and Petty and Cacioppo's peripheral route to persuasion suggest that some message processing involves relatively little cognitive effort.

The concepts of report, inference and judgment can be viewed as message content terms which provide a set of information to consumers upon which various attributions are made. The persuasion process which occurs can be described in this way. (Figure A)

When message recipients hear or see a report, a high level of attribution to the stimulus occurs. When message recipients hear or see a judgment, a high level of attribution to the person occurs. In the case of inferences, the level of attributions lies somewhere in between reports and judgments.

The reading of a report, inference or judgment invokes a causal schema based on the stimulus x person x abstraction data revealed in the statement, suggesting heuristic information processing. This triggers the corresponding set of beliefs based on the data pattern. The naive psychology of human beings provides us with the ability to make this distinction. Based upon a person's experience with the external environment, one learns the underlying difference in these concepts.

A statement which is pure report, excluding all inferences and judgment, deals with properties of the stimulus in question. This characteristic provides the distinctive feature that separates the semantic trichotomy. The more a statement describes the stimulus exclusively in terms of those characteristics which can be perceived by the senses, the more the statement is a "pure" report excluding inferences and judgments. The perceived veridicality of the statement is derived from the attribution process in which, first, the statement is attributed to the stimulus and is perceived to be part of external reality. This is followed by the perception of the statement or message as more believable. Thus, the message is accepted more readily.

A judgment, on the other hand, is a statement which contains the affective response of the individual expressing the message. A pure judgment is one which only contains statements of how positive or negative the product is. Once again, the naive psychology of the listener/viewer provides the individual with the sense that the message is the property of the person as opposed to the stimulus. Last, a statement of inference contains different levels of abstraction from the stimulus or person.

Two issues which remain are (1) the effect of source on the perception of the product in the message and (2) the presence of systematic or heuristic processing. These questions have been left for consideration in another paper.

The conceptualization discussed here was then used to develop messages for preliminary testing. While it was recognized that the real issue was whether the semantic trichotomy can potentially add to our knowledge of persuasion, it was first

FIGURE A
Conceptual Model of the Persuasion Process

necessary to demonstrate that each member of the semantic trichotomy is perceived as different.

PRELIMINARY STUDIES OF THE NEW CONCEPTUALIZATION

Two preliminary studies were conducted. It was reasoned that if the semantic variables could be identified in an unguided sorting task, then this would be an indication that the report, inference, and judgment messages could persuade respondents differently.

Since it was hypothesized that there may be a source x semantic interaction, source and unmentioned source cells were included in the two studies which follow. However, it is not the scope of this paper to report on this dimension.

In each study, subjects were given 5 1/2" x 8 1/2" cards in random order. The following elements were kept constant:

- 1) For each category, each message was based on the same three attributes judged by the experimenter to be the three most important attributes in the category.
- 2) Each message contained three sentences.
- 3) The number of words on each card was the same plus or minus five words.

Respondents were deliberately given very little information in order to see if the three semantic variables could be identified. Specifically, they were instructed to sort the cards on the basis of the number of *types of statements* they perceived. Furthermore, they were told that the number and size of the piles was completely up to them. No other information was provided.

In each preliminary study, chi-square analysis of the data was performed to determine whether respondents were able to perceive the differences in the semantic trichotomy. Expected frequencies were developed based on perfect recognition of the distinction as will be explained below. Using the hypothesis that the observed frequencies are equal to the expected frequencies, it was expected that the chi-square values would *not* be significant if respondents were able to correctly place the statements into three or four piles.

Generally, scientific studies seek to reject the null hypothesis. However, chi-square analysis

provides a clear way to analyze this sorting study; consequently, the experimental hypothesis is that there will be little deviation from the expected pattern. Thus, if the semantic trichotomy is real in subjects' minds, then observed frequencies will be equal or close to equal to the expected frequencies resulting in *no* significance.

The observed frequencies used to compute the chi-squares were defined as 'the number of subjects placing a report message of that category into a report dominant pile'. The dominant semantic variable in each pile was defined as the 'variable with the majority of cards in the pile'. For example, if a pile contained five cards with three report messages, one inference message, and one judgment message, it was labelled a report pile.

First Preliminary Study

Thirty-one Mercy College students participated in this experiment: Fourteen received cards with the messages introduced by a high source and seventeen received cards with the messages introduced by no source at all. Two levels of inference, referred to as "high" and "low", were included in this preliminary study. Five consumer categories were used: toothpaste, bar soap, shampoo, disposable diapers, and floor cleaner. Two sets of expected frequencies were developed (See Tables 1 and 2).

Results. Subjects were unable to correctly place the cards into piles when the results were tallied using two levels of inference. The difficulty of sorting into four piles was due to the respondents' inability to perceive the difference between the low and high inference categories.

When the chi-square analysis was performed combining the low and high inference messages, respondents were generally able to perceive the differences in the semantic trichotomy. The differences between the observed and expected were not significant for all five categories for the non-source data and not significant for four out of five for the source data. Thus, the null hypothesis was not rejected (See Tables 1 and 2).

In light of this first preliminary study, a number of changes in the stimulus materials were made. First, the two inference levels were eliminated for the second preliminary study; second, the floor cleaner and disposable diaper categories were replaced by categories which, according to the

judgment of the experimenter, are more salient to the student population from which subjects were recruited.

The six categories chosen for the second preliminary study were toothpaste, bar soap, analgesic, shampoo, cake mix and dog food. Improvements were made in the operationalization and a low credibility source condition was added.

Second Preliminary Study

Sixty-six students from Mercy College and The King's College were used to conduct the sorting exercise. Subjects for each of the three source conditions received a stack of eighteen cards containing one report, one inference, and one judgment message for each of the six categories. The procedure used in the sorting exercise was the same as the first preliminary study. Messages for

one category are shown in Table 3. Expected frequencies appear in Table 4.

Results. Chi-square analysis revealed that almost all subjects were able to sort the cards into three categories. In all three source conditions, the observed frequencies were very close to the expected frequencies. The chi-square values were below one in the low and unmentioned source conditions, i.e. no statistically significant differences were found between the expected and the observed as predicted. The chi-square value in the high source condition was slightly higher ($\chi^2 = 1.71$), but still not statistically significant (See Table 4).

CONCLUSIONS

These two preliminary studies show that the distinction between report, inference and judgment is real in subjects' minds, although the terminology is

TABLE 3
Second Preliminary Study

Stimulus Materials
Pharmagesic Aspirin-Free Pain Reliever

REPORT

Pharmagesic aspirin-free pain reliever is a safe, effective medicine clinically formulated by health care scientists to work fast within ten minutes to relieve pain. Pharmagesic aspirin-free pain reliever has been shown in long-term clinical testing to get rid of severe, painful headaches and even dental pain in minutes after use. And the thin, smooth safety coating that surrounds each uniquely shaped caplet helps you easily and painlessly swallow Pharmagesic aspirin-free pain reliever.

INFERENCE

Pharmagesic is the aspirin-free pain reliever that works fast for today's modern person who is too busy to take time out from a hectic schedule. Pharmagesic aspirin-free pain reliever eliminates headaches and dental pain so you can concentrate on what you have to do and what you really want to do. You'll be ready to take the world on and you'll know you can win when you easily swallow Pharmagesic aspirin-free pain reliever.

JUDGMENT

Pharmagesic aspirin-free pain reliever is an excellent, fantastic medicine that receives extraordinary praise from all who use it whenever a pain reliever is necessary. Pharmagesic aspirin-free pain reliever will quickly show everyone who tries it that this remarkable formula is worth going out of one's way for. With the exceptional help of this incredible product when you need it, we know that you'll be satisfied and pleased with Pharmagesic aspirin-free pain reliever.

High Source Version (begins with this introduction)

The following statement about Pharmagesic aspirin-free pain reliever was made by Dr. Michael Stevenson, research physician from U.C.L.A.

Low Source Version (begins with this introduction)

The following statement about Pharmagesic aspirin-free pain reliever was made by Jeffrey Arnold, a movie usher from Brooklyn, N.Y.

not. Further study will be needed to deal with the larger issue of whether the notions of reports, inferences and judgments can potentially add to our knowledge of the persuasion process in advertising. It is hypothesized that the semantic trichotomy impacts on subjects' perception of goods and services and, hence, their intent to buy the products they have seen advertised. Since the preliminary studies suggest differences in the presence of source, this issue will also be incorporated into the model and will be further studied.

Temporal Variations In The Evaluation of Television Advertisements: The Role Of Key Nonverbal Cues

Siva K. Balasubramanian, University of Iowa

ABSTRACT

This study seeks to explain the variations over time in viewer evaluations (degree of liking) of television ads. A multiple regression analysis suggests that key nonverbal cues/dimensions explain a substantial proportion of these variations.

The large number of studies that directly or indirectly address individuals' evaluation of television ads are dominated by *post-exposure measures* involving multi-item scales (e.g., attitude-toward-the-ad), which carry some hidden drawbacks. First, post-exposure measures represent global evaluations of the *entire* ad, and may not provide insights on how individuals react to each of the several segments that span the time-duration of the TV ad. Such insights are potentially invaluable since they could establish a scientific basis to produce TV ads that generate high evaluative impact. Each of the several segments (in a TV ad) includes numerous audio and visual variables, and the analysis of the continuous, instant-by-instant, real-time evaluations of such segments could yield important new knowledge on which variables contribute most to positive viewer impact.

Second, post-exposure evaluations of the ad could be biased by primacy-recency effects: the attitude-toward-the-ad measure obtained may be more reflective of the individual's evaluation of the ad for segments he/she is more likely to remember, rather than a "true" global evaluation of the entire ad.

The above considerations underscore the need for obtaining "online" temporal evaluative measures of the ad; in simple terms, this involves measuring the individual's reactions to the ad over time, simultaneously while he/she is being exposed to the ad. However, only a few studies have focused on over-time measures of ad-related response: Alwitt (1985) and Rothschild et al. (1988) employed over-time electroencephalographic (EEG) measures of brain activity in response to ad exposure to assess whether they reflect variations in the content of the ad; in addition, Thorson & Reeves (1986) have investigated the effects of temporal variations in viewer liking for programs/ads on memory for ads.

Although this research follows the spirit of Alwitt (1985) in that it examines the importance of variations in ad content over time, there are key differences: (a) the dependent variable used in our analysis is different: the "degree of viewer liking" toward the ad over time, and (b) we focus attention on key nonverbal cue categories that account for the variations in the dependent variable. In sum, the study attempts to provide preliminary insights on the relative importance of several nonverbal variables in influencing advertising evaluations. The choice of the explanatory variables is primarily motivated by the heightened research attention paid

in recent years to the role of nonverbal variables in advertising (Hecker & Stewart 1988).

Selection of Nonverbal cue categories for analysis:

Three categories of nonverbal audio and nonverbal video cues (that characterize most TV ads) were chosen for this study: (a) music-related cues, (b) voice-related cues, and (c) camera-related cues. Prior advertising research supports the choice of these cue categories for analyses. For instance, the 18 nonverbal cue classes developed by Haley et al (1984) span all three cue categories above. Similarly, in assessing the role of ad-content on EEG activity in subjects, Alwitt (1985) has focused attention on music-variables (also see Stout & Leckenby 1988 for a discussion on the importance of music as a nonverbal element), while camera cues have been studied by both Alwitt (1985) and Rothschild et al (1988).

Selection of specific nonverbal dimensions within each cue category

Several nonverbal dimensions were selected as appropriate for analysis within each of the three nonverbal cue categories, and these are discussed next.

Music category: Past researchers have focused attention on the role of music in TV ads. Two studies (Hoyer, Srivastava & Jacoby 1984; Alwitt 1985), for instance, have attempted to analyze the impact of the presence or absence of music (music as a binary independent variable) in TV commercials. However, given the richness of nonverbal dimensions associated with music, this binary approach is unlikely to produce significant insights. Indeed, Hoyer, Srivastava & Jacoby (1984) note that dummy-coding of the music variable understates the variance in the variable, thus yielding low correlations with the dependent measure; they also suggest that "more refined measurements (e.g., the amount of music) could have resulted in higher R-squares" (p. 21) in their analysis.

While Haley et al (1984) avoided the problems inherent in the dummy-variable approach to coding music, these authors acknowledge that their coding scheme for the music related nonverbal variables may have been naive, because its focus was limited to a few broad aspects: whether the music was vocal or instrumental, the amount of music included, whether the music was in the foreground or background, and the type of music employed (classical, rock, country, jazz, etc). They suggest that future research needs to employ more sophisticated codes to capture the subtle nuances of the music such as rhythms, melodies, textures, and harmonies etc.

However, our review of the relevant literature suggested that more parsimonious approaches to coding music were possible. Asmus (1983), for instance, argues that affective responses to music can be measured by activity and evaluation dimensions (see also McMullen 1982 and Trolio 1976). Apart from these two dimensions, prior research also shows a relationship between the complexity of the music stimulus and subjects' affective responses (Conley 1981; Crozier 1974; McMullen 1974). In addition, Leblanc (1980, 1982) argues that another dimension (interest toward the musical stimulus) should also be related to affective response development.

Based on these research findings, it was decided to evaluate the musical component in TV ads using the following four scales: (a) Ugly/beautiful (evaluation), (b) passive/active (activity), (c) simple/complex (complexity dimension) and (d) uninteresting/interesting (interest dimension).

Voice-related category: Based on a survey of the paralanguage literature, the following two dimensions were used to score voice-related cues: (a) unpleasant tonal quality/pleasant tonal quality, and (b) slow speech rate/high speech rate.

Support for selecting the first scaling dimension above is derived from past research which suggests that subjects' inferences of a communication's affect depend substantially on the voice's tonal quality (Scherer 1972; also see DePaulo et al. 1980 for a review). Specifically, this line of research argues that atonal and tonal-minor stimuli evoke inferences of disgust (unpleasantness) while the tonal-major acoustic characteristic leads to judgments of pleasantness (or happiness).

Further, studies by Mehrabian and associates (see Mehrabian 1972 for a comprehensive review) and Miller et al (1976) strongly suggest that speech rate is correlated with positive inferences of message affect, thus justifying the choice of the second scale dimension above.

Camera-related category: Alwitt (1985) and Rothschild et al (1988) have focused attention on camera-related visual-nonverbal variables e.g., zooms and cuts. Further, these variables have been studied by several communication researchers interested in the complexity of cues associated with television; it was therefore decided to include zooms and cuts as nonverbal variables of interest for our analysis.

In addition to the several nonverbal variables/dimensions discussed above, we also decided to include another key dimension highlighted in the literature on nonverbal communication: the degree of consistency between the nonverbal and verbal variables. This dimension has been shown to be crucial while inferring the affect conveyed by a message (see Mehrabian & Weiner 1967; Mehrabian & Ferris 1967).

Method

Subjects

104 student subjects participated in this study; each experimental session accommodated only one subject and lasted approximately 15 minutes.

Stimulus Ads

To ensure that the data generated were free of biases due to subjects' prior brand-name/company/advertisement familiarity, we considered several English language TV ads from abroad, in addition to domestic TV ads (aired outside the immediate viewing region) representing products and companies unlikely to be familiar to our subjects. A total of 13 ads were chosen from this sample for the stimulus package, based on the following criteria: (a) each ad was different from other ads in the package (so that a broad range of ad themes could be represented in the study), and (b) the ads represented product categories of interest to student subjects (to enhance the validity of the study).

Procedure

A measurement device called the program analyzer was used to generate "online" evaluations of the TV ads in the stimulus package. These data represented the dependent variable, operationalized as the degree-of-liking for the ad segment the subject was being exposed to at a given instant. The analyzer used in this study consisted of a joystick linked to an IBM personal computer. The joystick served as an impromptu/surrogate Likert scale since it could be moved back and forth by the subject along a given plane, and was similar to the dial-turning equipment used by Thorson & Reeves (1986).

Before commencing the actual data collection, the subject was familiarized with the analyzer equipment with the help of a computer program that generated a visual display of a linear scale on the computer screen; this linear scale contained two anchors ("dislike" and "like" respectively). A feature of this program was that the magnitude and direction of any movement of the joystick would be correspondingly reflected in the movement of the cursor along the linear scale displayed on the computer screen. The subject was asked to practice using the joystick and its linear scale analog for 5 minutes, in order to gain "hands-on" familiarity with the sensitivity of the device. Further, since the valence of the Likert scale anchors were reinforced through pictures of a sad or a smiling face placed at either ends of the joystick plane, the subject was also familiarized with the location of the "dislike" and "like" scale anchors.

Following this familiarization procedure, the subject was exposed to 5 sample ads in an attempt to simulate the conditions characteristic of the actual study; the actual stimulus package was then shown to the subject.

The commencement of data collection via the analyzer was synchronized with the start of exposure to the stimulus package. For this study, the movement of the joystick along the vertical plane generated scale values in the range of 1 to 45 for

"dislike", and between 46 and 90 for the "like" evaluations. The computer sampled the joystick position 5 times every second during the data-gathering session. Any movement of the joystick (i.e., change in the scale values along the "dislike"/"like" scale) in these small time intervals was recorded by the computer along with a record of cumulative time elapsed since the beginning of the data-gathering session.

Thus, if one could separately code the exact (cumulative) time of occurrence of any nonverbal cue of interest in the stimulus package, the data-accumulation procedure described above provides a highly accurate basis for studying temporal variations in ad evaluations directly corresponding to these occurrences of the nonverbal cue. Details of such coding exercises by expert judges are described in the next section.

After the data-gathering session, the subject responded to two self-report items. The first item measured the degree to which the subject thought the joystick movements truly reflected his/her actual evaluations of the ad. This was measured on a 5 point scale (with 1=very unlikely and 5=very likely), and the mean and standard deviation across subjects on this measure (4.223 and .625 respectively) indicated a high level of confidence among subjects that the analyzer data accurately reflected their evaluations.

The second item measured the extent to which the subject was involved with the experimental procedure pertaining to the analyzer. This was also a 5 point scale (with 1=very uninvolved and 5=very involved), and the mean and standard deviation across subjects on this measure (4.485 and .778 respectively) reflected high respondent involvement with the experimental procedure.

The subjects' responses in debriefing sessions revealed that none of them had seen any of the foreign TV ads; however, most of them had seen 4 out of the 6 domestic ads included in the stimulus package. Despite the precaution of only including domestic ads (in the stimulus package) that were not previously aired in the immediate viewing region, several subjects indicated that they were exposed to these 4 ads when they had visited contiguous viewing regions. Since subjects' evaluations of these 4 ads could be contaminated by prior brand/company/ad familiarity biases, they were excluded from subsequent analyses.

Coding of commercials

Of the nine nonverbal dimensions discussed above (4 music-related, 2 voice-related, 2 camera-related and the nonverbal/verbal consistency dimension), we note that the camera-related dimensions (viz., zooms and cuts) are binary (present or absent) variables; the remaining variables had to be evaluated on a continuum (the research interest here was not merely on the impact of the presence of these variables, but on the magnitude of their presence). To use these dimensions as independent variables in a regression analysis, the stimulus package was coded for these

variables by a panel of several expert judges (at least 2 judges in this panel had specialist expertise vis-a-vis each of the three cue categories). All the judges were blind to the purpose of this study during the coding process, which is described next.

Coding Binary Independent Variables

The judges used a "binary-coding" version of the program analyzer to code the two binary variables (viz., zooms and cuts) for all the ads in the stimulus package. This version generated a binary coded time-series based on a button-pressing procedure; judges were instructed to depress the button for each instant of time when the cue under investigation was present in the stimulus package being viewed by them. Whenever the button was depressed, the computer recorded a "1" five times every second; otherwise, the computer recorded a "0" (a similar procedure was used by Alwitt 1985).

Coding Continuous Independent Variables

With respect to the six remaining continuous (i.e., interval-scaled) independent variables derived from the nonverbal cue categories, separate groups of expert judges coded each nonverbal dimension of interest one at a time using the same procedure as the subjects in the study; the only difference in this case was that the judges focused on evaluating the nonverbal dimension of interest. In contrast, the subjects in the study were required to evaluate the ad stimulus on the "dislike"/"like" Likert scale.

Note that these six variables pertained either to the voice-related or the music-related category; further, *neither category was present continuously for the entire duration of the stimulus package*. Since the continuous nature of the coded data generated by the analyzer did not recognize the time segments where voice or music were not present in the ad, it was necessary to avoid the inclusion of such spurious data. This could be accomplished by multiplying for each time period, the continuous time-series data generated by judges (corresponding to each continuous independent variable) with appropriate dummy time-series data on the presence (coded "1")/absence (coded "0") of voice or music in the stimulus package. Therefore, voice and music dummies were also obtained through the dummy coding procedure discussed.

Similarly, the degree of consistency between verbal and nonverbal variables in the ad was evaluated by two members of the judges panel.

Analysis

We used multiple regression analysis to assess the impact of the nonverbal independent variables (continuous as well as binary) on the dependent variable (interval-scaled "dislike/like" measure). We checked for two potential problems at this point: autocorrelation among the residuals, and the data-pooling issue.

Autocorrelation among the residuals

It must be noted that autocorrelation among the residuals might confound regression analysis of time-series data. Stated differently, if the evaluation of one segment of the TV ad affected how the segments following it were evaluated, the unique

TABLE 1
TEST-RETEST RELIABILITIES FOR THE NONVERBAL CUES/DIMENSIONS

Dimension coded	Test-retest reliability
<i>Voice-related:</i> Tonal quality (unpleasant/pleasant)	.75
Speech rate (low/high)	.87
<i>Music-related:</i> Evaluation (ugly/beautiful)	.76
Activity (passive/active)	.72
Complexity (simple/complex)	.70
Interest (uninteresting/interesting)	.78
<i>Verbal/Nonverbal consistency:</i> (inconsistency/consistency)	.92

impact of a given set of nonverbal variables at any given time cannot be assessed accurately. The program analyzer generated data at extremely short intervals for all the variables of interest; and to minimize the autocorrelation problem, we only used data drawn at 2-second intervals from this database. The choice of this data interval is consistent with prior research analyses of "online data" (see Alwitt 1985; Thorson & Reeves 1986), and yielded 15 observations for each of the 9 ads studied, for each of the 104 subjects.

To assess the presence of autocorrelation with this time-series data base, regression analyses were conducted on data from 10 randomly selected subjects. Durbin-Watson tests indicated that autoregression was not a problem, thus providing support for using program analyzer time-series data drawn at two-second intervals.

Pooling Data for Multiple Regression Analysis

The dependent measure ("dislike"/"like" scale) has both cross-sectional (across respondents) and time-series (across time within each ad) characteristics; to perform multiple regression analysis using this variable, a decision on pooling or aggregating the database was necessary.

The pooling approach used here involved: (1) standardizing the dependent measures *within* each subject to minimize individual differences in such responses, and (2) averaging this standardized data across subjects for each time period. Such data pooling will maximize relationships between the nonverbal dimensions of interest and the dependent measure, since it avoids the high variance that may characterize individual subject data.

Reliability for Coding Binary Independent Variables

Phi-coefficients assess the relationship between two discontinuous dichotomous variables

(Ghiselli, Campbell & Zedeck 1981), and are appropriate for estimating the inter-judge reliability of coding a binary variable. The phi-coefficients for the four binary-coded variables (at two-second intervals) given below are acceptably high:

<u>Variable coded</u>	<u>Phi-coefficient</u>
Zooms	.89
Cuts	.98
Music dummies (yes/no binary coding)	.90
Voice dummies (yes/no binary coding)	.95

Reliability for Coding Continuous Independent Variables

As already noted above, the six nonverbal dimensions (4 were music-related, 2 were voice-related) and the nonverbal/verbal consistency dimension were coded on a continuous scale. Test-retest reliabilities computed for these time-series data (coded by judges) are given in Table 1.

Results and Discussion

Table 2 summarizes the results of the multiple regression analysis with the averaged "dislike"/"like" data as the dependent measure; the independent variables were the various nonverbal dimensions described above along with the verbal-nonverbal consistency measure.

On the overall level, the predictors were able to account for a significant part of the variance in the dependent measure ($R^2 = .547$). Table 2 presents the regression results, which are discussed next.

Voice-related category: Although past research indicates that variables such as speech rate and tonal quality should be correlated significantly

Equation Summary:

$$R^2 = .547$$

$$\text{Adjusted } R^2 = .515$$

$$\text{Overall } F(9,125) = 16.779 \text{ (} p < .0000001 \text{)}$$

with the affective responses to communication, we note that the beta weights for these variables are not significant in the regression equation. A possible explanation for this may lie in the lack of variation in the data. The expert judges felt that there was little variability in these two variables over the ads in the stimulus package.

Music-related Category: Under the music-related dimensions, three of the four dimensions have significant regression estimates. The beta coefficients for the simple/complex and passive/active dimensions were negative, thus suggesting that as the music in the TV ad increases in complexity and/or activity dimensions, the affective evaluations tend to become more negative. This is consistent with the view of Krugman (1965) who suggests that TV is essentially a passive medium that disseminates messages in a "low-commitment" environment; therefore, the more simple or the more passive the music-related cues, the higher the affective evaluations.

On the other hand, the evaluation dimension characterized by the ugly/beautiful scale suggests that more positive evaluations of music in TV ads have a direct impact on the affective responses generated (note that the beta weight for this

dimension is both positive and higher than the other independent measures). This finding is important, and is consistent with prior research. For instance, there is some evidence that the music content in popular jingles and ads elicit positive evaluations; in other words, the more positive the evaluation of music in a commercial, the higher the likelihood of the ad also eliciting a positive evaluation. Gorn's (1982) research supports a similar inference with respect to the product advertised; in this study, a pen displayed with "liked" music elicited higher brand preference ratings relative to another pen that was paired with "disliked" music.

However, the uninteresting/interesting dimension was not significant, suggesting that affective responses to TV ads are not related to how the music-related cues perform on this dimension.

Camera-related Category: Table 2 also indicates that "zooms" (a camera-related visual nonverbal cue) have a significant beta coefficient (.197); further, the positive sign of this coefficient suggests that zooms in a TV ad directly generate positive affective responses to the ad. On the other hand, the beta coefficient associated with "cuts" was not significant. A possible explanation for this

could be that "zooms" typically promote greater focus on the visual stimulus, thereby increasing its informational content; however, "cuts" are synonymous with "breaks" in the visual stimulus which may disrupt continuity in the message and thereby distract the viewer. Zooms may be expected to have a positive impact on the affective responses to the ad since they enhance focus on the visual stimuli, while the distracting potential of "cuts" may not generate such impact at all.

Nonverbal/Verbal consistency dimension:

While prior literature would predict a significant and positive beta coefficient for this dimension (more consistency should lead to more positive affective responses), the analysis yielded a non-significant coefficient for this variable. This result stemmed from the characteristics of the stimulus package, in that variability across the verbal/nonverbal consistency dimension was minimal (the coefficient of variation for this variable was 0.06), and the impact of this dimension was not unequivocally assessed.

Limitations

Although the independent variables accounted for a good proportion of the variance in the affective responses generated by ads, it must be realized that the pooling technique employed could have inflated the R^2 estimate. The R^2 obtained for such pooled data (involving regression on means) are typically much greater than the corresponding R^2 values based on raw data. Future research could overcome this problem by estimating models (on raw cross-sectional time-series data) that satisfy rigorous statistical pooling tests (e.g., Bass & Wittink 1975).

Despite the above limitations, the study still provides useful, albeit preliminary, insights. The findings pertaining to the music-related nonverbal dimensions are interesting. They indicate that higher the level of perceived beauty, simplicity or passivity (in that order) associated with the music component in TV ads, the higher the likelihood of generating positive evaluations of the ad. Similarly, the analyses suggest that zooms in TV ads contribute to more positive evaluations, while cuts do not register any impact on the dependent measure. These findings were interpreted as conforming to prior findings in the advertising literature.

How Does an Advertisement Mean -- Cue, Claim, Metaphor, Resonance? Discussant's Comments

Edward F. McQuarrie, Santa Clara University

Each of the papers presented today looks at a different aspect of how meaning can be conveyed through advertising. The Balasubramanian paper uses the concept of a *cue* and examines affective meaning in an experimental context. The Berger and Gilmore paper draws on the discipline of semantics to describe several types of *claim* that can be made in an ad. The Ward and Gaidis paper reviews a number of literatures in order to profile various theories about *metaphor*. The concepts of cue, claim and metaphor encompass a great deal of contemporary discussion of meaning in advertising. My discussion begins with an examination of what these concepts do *not* cover; i.e., aspects of meaning in advertising which require other concepts for their explanation. I then offer some reflections about the kind of theory which consumer researchers need in order to take a comprehensive approach to meaning in ads. The discussion concludes with a review of the strengths and weaknesses of the individual papers.

CUE, CLAIM AND METAPHOR

"Cue" is an extremely flexible concept for describing aspects of a stimulus which may prove meaningful to a respondent. Any aspect of a stimulus which can be discriminated or recognized by a viewer can serve as a cue. This flexibility makes cue a useful notion in dealing with a variety of non-verbal aspects of advertising. Cue is also a useful notion in an experimental context: it suggests elemental or basic features of a stimulus which an investigator can add to or subtract from the stimulus in the course of devising manipulations. There are, however, two difficulties with the cue concept when the focus is on meaning. First, the very idea of a cue grows out of a tradition in psychology -- reinforcement and drive theory -- which has often been hostile to the notion of mental process. While the use of cue in a conceptualization does not presuppose or inevitably entail a behaviorist position, cue brings with it the idea of an involuntary or mindless response. The very flexibility of the cue concept can also be a drawback. Since virtually any and every aspect of an ad could potentially serve as a cue, we learn very little about the internal structure of an ad or about how different cues may have different effects. In this sense, to describe an element of an ad as a "cue" provides very little information about what the role of that element may be in the creation of meaning.

A claim is an assertion about truth value. As Berger and Gilmore show, several different types of claims can be distinguished. The idea of a claim is clearly relevant in two contexts: 1) issues of truth in advertising; and 2) issues of the persuasiveness of particular messages. Thus, a study of claims may tell us what meaning is conveyed, and whether a meaning will succeed in being conveyed at all.

"Claim," however, may be of more limited applicability than "cue" in the study of contemporary advertising. It seems to me that a study of claims limits one to a consideration of linguistic statements. The idea of claim seems to break down if we consider a television commercial: *Where* is the claim? Is it only present in words spoken or written on the screen? Or does the commercial as a whole constitute a kind of claim? The second problem with claim would appear to be its restriction to the explicit or the denotative. The idea of a tacit claim seems full of problems. If the claim has to be constructed by the recipient, is it fair to describe it as a claim made in the ad? If it is true that reports, inferences and judgments, as claims, are concepts that can be applied only with difficulty to non-verbal elements of ads, and to connotations of ads, then their utility may be quite limited in the assessment of meaning.

The idea of a metaphor is a rich one. It is clearly able to encompass both connotation and non-verbal elements in ads. Unlike cue, it also carries with it notions about internal structure. My problem with the discussion of metaphor in ads is simple: what about *metonym*? Metaphor is but one figure of speech; what about the others? I have to be suspicious of theories of metaphor that are not included within more general theories about figurative speech. In the absence of a more general framework, one fears that the specific phenomenon of metaphor will be so entangled with the general phenomenon -- figurative speech -- that one will be unable to tell whether the theory claims to explain the one, the other, or both.

RESONANCE: CUE, CLAIM, METAPHOR?

At this point I would like to describe a device for conveying or constructing meaning in advertisements that does not seem to be either a cue, a claim, or a metaphor. Consider the following ads:

1. A man's biceps are shown flexed as he works at an exercise machine. The headline reads, "Arm yourself."
2. A shapely woman is shown from the rear as she works out on a stair machine such as those found in health clubs. The headline reads: "People are starting to stair."
3. An ad to Trident gum has the headline, "Fight cavities with a stick."

Magazine ads of this type are not uncommon (McQuarrie 1989, 1990). I have coined the term *resonance* to describe the aspect that these ads share. Resonance may be defined as an echoing or a doubleness within the meaning structure of an ad, such that one element takes on multiple meanings,

or multiple elements are given a single meaning. A more common term, which describes some but not all instances of resonance, would be wordplay (Grinnell 1987). Two points can be made about the three ads described: 1) the picture and the headline work together to create meaning; 2) resonance requires both a particular structure in the stimulus, and constructive activity on the part of the reader, in order to occur. Thus, the Trident ad is not resonant until the reader supplies the phrase "a stick of gum."

Resonance could be described as an executional cue, but I do not see what is gained thereby. The stair ad contains any number of cues, and this categorization does not illuminate the action of resonance. There are probably claims made or implied by means of the resonant structure, but it is not clear that resonance itself is a type of claim. Similarly, resonance can be described as figurative speech, but it is not the same kind of figure as metaphor. However, this latter category takes us further than the first two (Polloy and Mainprize 1984; Stern 1988). Resonance definitely has a place within the matrix of figures of rhetoric developed by Durand (1987) and discussed in Chebat (1989) and Dyer (1982); it is a *false homology*.

Of course, cue, claim, metaphor and resonance are not the only devices for generating meaning in advertisement. The purpose of introducing the notion of resonance was to demonstrate how diverse these devices are, and to show that they cannot be reduced to one another. Having given some idea of this diversity, the question now becomes: What kind of theory do we need if the goal is to encompass the whole range of devices whereby meaning can be generated in advertisement? At a minimum, the desired theory or body of theory must be able to: 1) handle non-verbal as well as verbal elements; 2) encompass all the various rhetorical figures, and not just metaphor; and 3) include affective as well as cognitive meanings. Anything less condemns us to a piecemeal approach to the study of meaning in advertisement.

Perhaps the best candidate to fill this role is semiotics, as introduced to the consumer literature by Mick (1986), elaborated in Umiker-Sebeok (1987), and further developed in the works of Barthes (1985), Eco (1976), and others. We could also benefit from more works that offer extended interpretations of specific real advertisements, as done most notably by Williamson (1978; see also Dyer 1982; Leymore 1975; Liess, Kline and Jhally 1986; Vestergaard and Schroder 1985). After reading a book like Williamson's it becomes difficult to believe that atomistic ideas such as cue or claim can ever capture the sheer complexity of the meanings that an advertisement can create. As consumer researchers become more comfortable with interpretive techniques (Holbrook 1987; Hudson and Ozanne 1988), the need for theories that can bring order to interpretive activity, whether these be derived from semiotics or from some other tradition, will grow. Since marketers are among the most prolific producers of texts that cry out for interpretation, perhaps we can even hope that some

day consumer researchers will become the producers of, rather than just consumers for, theories of meaning in advertisement.

BALASUBRAMANIAN

Experimental investigations of meaning in advertisements are not easy to pull off, especially when one departs from a strictly cognitive paradigm. The difficulty is compounded when real rather than constructed advertisements are used. What creates the difficulty, of course, is the many threats to internal validity that have to be countered. I think the most important of these threats in this study involve the sampling of stimuli -- an intrinsically difficult problem, as noted by Nunnally (1978). In this case we have a judgement sample of stimuli: thirteen ads selected by the author to meet several criteria. In the case of such a judgement sample, it is impossible to rule out the rival hypothesis that the effects observed for certain properties are really due to some peculiarities of the ads that include those properties, and not the properties themselves. A different judgement sample might yield entirely different results.

A more vexed problem is that a small number of ads chosen unsystematically from the universe of advertisements is unlikely to contain a great deal of variation on some or all of the cues of interest. A solution would be to have judges rate a large number of ads for the presence of, say, beautiful or ugly music, and then sample from the extremes to construct, in effect, treatment cells for each cue of interest. While this would inflate the observed effects of the cue or property, it maximizes the probability that an effect will be found if in fact such an effect exists. The alternative, which is to randomly sample a sufficiently large number of ads to insure that there is enough natural variation on all properties, might lead to an extremely unwieldy array of stimuli.

Still another problem with the stimuli used is the large number of properties (9) in relation to the number of stimuli (13, later reduced to 9). Although sampling at two second intervals does create a greater number of observations, the fact remains that many of the properties are probably only present in a small number of the ads studied -- perhaps only one ad in some cases. This again makes it impossible to rule out rival explanations. If only one or two ads contain a certain cue, then any effects observed may be a function of the ad rather than the property. Hence, the table of significant and null effects must be read as preliminary and suggestive only. It offers no conclusive evidence about the affective consequences of any of the cues investigated. No amount of sophisticated data analysis can overcome these sampling problems.

I have a couple of minor points to make about aspects of the experimental procedure. It does not appear that the order of presentation of ads was varied over subjects. It is easy to imagine that subjects experienced more positive affect and perhaps more involvement with the rating task early in the procedure. If so, and if certain cues were only

present in ads shown at the beginning or the end of the sequence, then the effects uncovered in the analyses are biased to an unknown degree. On another point, inter-rater reliability for judges is just as important in the case of the continuous variables as the dichotomous variables. Test-retest reliability for a single judge is really no substitute. Again, this undermines our confidence as to whether an effect does or does not exist for any of the continuous variables studied.

In conclusion, the author is to be applauded for undertaking to measure temporal variation of cues within an advertisement. The use of the joystick rating method certainly has promise, and none of the difficulties mentioned above is insuperable. However, although continuous rating such as those provided by a joystick are rare in academic consumer research, they *have* been utilized for many years by several commercial providers of copy testing services, such as ASI. It would be interesting to know what sort of data archives exist that might reward study with respect to temporal variation. If a large archive exists, then this might provide a solution to many of the sampling problems discussed earlier. A model for such work would be the study of executional cues by Stewart and Furze (1986).

BERGER AND GILMORE

This paper attempts to integrate literature in the areas of linguistics and semantics with the more familiar (to consumer researchers) literatures on cognitive and social psychology, and also to validate some of the semantic distinctions identified. It is nice to see this effort to go outside of the customary and familiar psychological literature. But the absence of semiotic theory is keenly felt, and I would urge the authors to expand their horizon beyond general semantics. There is an enormous European literature on some of these issues (Eco 1976), and its omission is bothersome.

The fundamental difficulty I have with this work concerns the usefulness of the semantic trichotomy. Are these really three equally fundamental and tightly linked concepts that have to be analyzed as a unit? The connection between a report and an inference seems much more integral than that between a judgement and either one. I doubt that the three types of claim lie on a single continuum, nor do they seem to be related in any geometric or combinatory way, such as primary colors in a color wheel. I would ask the authors: What do we gain by treating all three together? Reports, inferences, and judgments are certainly of fundamental interest to advertisers, just as the authors argue; but to speak of a trichotomy is to suggest that these represent an exhaustive and mutually exclusive list of all the fundamental types of claims that can be made in an advertisement. I am not convinced that this is so.

The linguistic approach that underlies the semantic trichotomy also seems unduly limiting. Too much of the meaning generated in advertisements is both non-verbal and tacit. The

problem is particularly acute in the case of television advertisements, where the question becomes *what* is claimed, and *how*, and by *whom*? Should we focus on the sponsor, the presenter, or the text (broadly construed) of the ad itself? The inference category is particularly problematic. Whose inferences should we be studying: those offered about the product within the ad, or those made by the respondent in response to the ad? I would have appreciated the inclusion of real advertisements analyzed according to the author's scheme. The lack of concrete examples drawn from specific advertisements made the exposition difficult to follow at a number of points.

I would also point out what strikes me as an important flaw in the second experiment described. The whole point of manufacturing stimulus materials in advertising research is to exert the tightest possible control over what is being presented to subjects so that causal inferences are facilitated. The examples in Table 3 do not satisfy this standard; they seem to me fatally prolix. Too much is going on that is neither report, inference nor judgement, or that represents multiple occurrences of one or another of these. Hence, rival explanations for why subjects were able to successfully sort the statements can be offered. I suspect that the sort was done in terms of the extremity or the degree of exaggeration in the claims, and not because the three types of statements reflect some emic distinction made by respondents among types of advertising claims. I would also note in passing my skepticism that anyone in the study really believed that a research physician would use language such as that used in the Judgement text with respect to an over the counter drug.

In conclusion, I think the components of the semantic trichotomy are well worth investigation on their own, particularly in the context of research on misleading or deceptive advertising, or on the persuasive impact of each of these types of claims. In my opinion there would be more value in such pursuits than in attempting to establish the semantic trichotomy as a fundamental organizing principle for claims made about products.

WARD AND GAIDIS

I have less to say about this paper because personally I found it the most satisfying of the three. Again the authors have gone out and tapped into literatures not commonly discussed or cited at ACR. The value added is enhanced because they then go further and integrate some of this work into three distinct models of how metaphors work. The discussion of the models is balanced, illuminating, and rich in implications for future research. I congratulate the authors on a fine review paper.

I would like to second their comment about the role of the marketing function in producing a substantial percentage of the metaphors to which people are exposed. That says to me that consumer researchers potentially can make a significant contribution to the study of metaphors; it is home territory for us. Perhaps this is an area where the

positivistic tradition, with its understanding of experimental design, and the interpretivist tradition, with its firm grasp of the role of the reader in generating meaning, can usefully come together. Both will be necessary to understand what metaphor does or can do in advertisements.

I want to repeat my comment that investigations that do not clearly distinguish metaphor from other types of figurative speech are fraught with danger. We need both: general theories about how figurative speech works, and specific theories about how individual tropes or figures such as metaphor work. But if we do not keep the two levels of explanation separate we will have problems. Hence, a useful test to apply to each theoretical model of metaphor might be: Can this be made to work as an explanation for other rhetorical figures as well? If the answer is yes, then we are probably looking at an explanation of figurative speech rather than an explanation of metaphor per se. For such a general theory, the question would become: How many types of figures does this model illuminate? The problem here is that authors outside the literary tradition tend to be ignorant of the great variety of figures and tropes examined over the years. This is a natural but potentially dangerous blind spot.

One other point is relevant to consumer research on metaphor, and that is the changed meaning of "aptness" when we move from literature and everyday speech to paid messages devised by a corporation to further its goals of profitability, etc. In the traditions summarized by the authors, "aptness" represents an aesthetic judgement. In consumer research aptness will have a second meaning: effectiveness in advancing the sponsor's corporate goals. This raises several questions for research. Are aesthetically apt metaphors also more effective from a managerial standpoint? Does a metaphor have to be apt in an aesthetic sense to effectively serve the manager's pecuniary goals? We can imagine metaphors which are bad from any poetic standpoint but which still do the job asked of them by the person paying for the ad. These are questions about metaphor that may be unique to the consumer context. If we don't pursue them, no one else will.

The Animal 'Other': Self Definition, Social Identity and Companion Animals

Clinton R. Sanders, University of Connecticut

INTRODUCTION

In contrast to the other orienting perspectives employed by sociologists, symbolic interactionism emphasizes the subjectivity of human social actors. We operate within the context of "webs of meaning" (Geertz 1973) created and transmitted in the course of social interaction; the "reality" shaping and sustaining social life consists of *definitions* rather than objects possessing independent, external, intrinsic characteristics.

The "self" is the central component of the subjective world in which human beings operate. Like other features of social reality, the self is predominantly a *process* rather than a static object. As Charles Horton Cooley (1964 [1902]) emphasized, the self derives from the actor's interactions with others as he or she interprets the intentions and orientations of cointeractants and takes these interpretations into account in the ongoing process of self definition.

It is in the course of the myriad of interactional performances which constitute social life that the self is constructed, adjusted, displayed, and understood by the actor. Not only does one perform for others, performances are also directed at the self. The common experience of being "self consciousness" is the most obvious internal performance situation. The actor's "self concept" is composed of those role based features to which he or she has the most emotional commitment and which, consequently, is most resistant to change. Roles which are most "distant" from the actor's conceptualization of the "real self" are less intimately valued and typically performed in a more instrumentally purposive manner than are the components of self which are routinely performed for the self-audience (Goffman 1959:70@75. See also Blumer 1969; Lindesmith, et al 1977; Denzin 1989a; and Manis and Meltzer 1972).

Since performances directed at others (interactions) and the self (thought) most commonly make use of the (supposedly) unique ability of human beings to employ symbols to encapsulate and carry conventionalized information, words and objects which are socially defined as having meaning are central to the process of self definition and social identity (self presentation) briefly outlined above. Consumer researchers (eg., Solomon 1983; Sirgy 1982) and analysts of material culture (eg., Csikszentmihalyi and Rochberg-Halton 1981; Sanders 1989; McCracken 1988) have emphasized the importance of material objects as symbolic presentations of the self to others and as mechanisms whereby actors construct and bolster their self concepts. In a recent article, Belk (1988) has synthesized a general overview of the complex connections between what one *has* and who one *is*. In his view, things are meaningful principally as symbolic vehicles which human beings use to

"extend" (present, reinforce, exercise control over) the social self. Objects are acquired, consumed, displayed, manipulated, incorporated into rituals, connected to people and events, and otherwise imbued with meaning related to how one presents--both to self and others--what he or she was, is, will be, or wishes to be.

One category of possession/self extension which Belk discusses briefly (pp. 155-156) is pets. He presents pet choice as shaped by the owner's personality characteristics, pets as surrogate family members, pet death as loss of self, pets as transitional objects easing movement through the life cycle, pets as having therapeutic functions, and pets as objects of dominance.¹ In the remainder of this paper I will expand on Belk's analysis of companion animals and their relationship to the social self.² First, I will discuss companion animals as they symbolically represent the social identity of the owner and extend the interaction situations in which the owner acquires information about how he or she is defined by others. Next, I turn to the ways in which the relationship between the companion animal and its human counterpart affects the latter's self definition. Finally, I will present the human-companion animal pair as an acting unit ("with"). Of particular interest here are those social situations in which the animal behaves in such a way to significantly disrupt the more-or-less smooth flow of interaction between the

¹It is interesting, given the widespread popularity of pet ownership in the United States (some 60 per cent of American households contain pets [Cain 1985]) and the economic importance of the pet industry (each year pet owners spend approximately \$4 billion on pet food and \$3.5 billion on veterinary care [Serpell 1986:12; Bulcroft, et al 1986:2-3; Beck 1983:237@238]) that this topic is rarely discussed by consumer researchers. Even more surprising, given the social importance of pets and their impact on social interactions, is the relative failure of sociologists to focus on this significant phenomenon (see Bryant 1979; Bulcroft, et al 1986; Wieder 1980; Hickrod and Schmitt 1982 for exceptions).

²Because of my personal interests, research access, and the dominant focus of the literature on animal-human relationships, this discussion primarily deals with human interactions with domestic dogs. Dogs are the most sociable of the domestic animals commonly kept as companions within Western culture and, therefore, their interactions with people are most amenable to sociological analysis.

caretaker and the other human interactants in the situation.³

COMPANION ANIMALS AS POSSESSIONS: IDENTITY AND STATUS

Americans "possess" an astonishing number of pet animals. Currently, US households contain some 51 million dogs, 52 million cats, 14 million birds, 95 million fish, and 9 million other animals (*Anthrozoos* II #2 [Fall 1988]:133). Historically and cross-culturally the types of companion animals kept, the treatment they receive, and the ways in which they are symbolically defined has varied considerably (see Fogle 1983; Serpell 1986, 1988; Fisher 1983; Tuan 1984). While the dominant reason human beings fostered relationships with pet animals was, and continues to be, the desire for companionship, there has been a consistent linkage between companion animals and social status in western culture. Typically, the keeping of companion animals has been associated with upper-class position. Those with power and economic resources symbolized their advantage by owning non-functional and expensive animal property (Tuan 1984:110; Serpell 1986:38-47; ten Benschel 1984; Bustad and Hines 1984; Ritvo 1988). In turn, pet possession by members of the lower-classes commonly was condemned as inappropriate and wasteful.

To some degree, ownership of certain animals such as pedigreed dogs, cats, and horses continues to symbolize social privilege since they are relatively expensive to acquire and maintain. However, pets as they represent other aspects of self/social identity--rather than being demonstrations of elite status--is a more important factor in contemporary pet ownership.

The type and temperament of the companion animal one chooses and the instrumental purpose for which it is bred are other aspects of identity symbolization. Powerful and aggressive dogs such

as rottweilers and German shepherds, for example, not only have a protective function but also reflect their owners' desires to present social selves which are correspondingly aggressive (Fogle 1983:50, 84-86).

In general, it appears that possession of a companion animal does have a positive impact on the owner's social identity. Lockwood (1983), for example, found that people pictured with animals were judged by undergraduate respondents to be more sociable, content, and easygoing. The significance of the animal as a valued possession symbolizing the owner's material status is, at best, of minimal importance here. It is most likely that this apparent effect on social definition is related to the ability of companion animals to act as facilitators of interaction--an identity enhancing feature that will be discussed in a later section.

Although there is a positive correlation between income and likelihood of pet ownership (Covert, et al 1985), owners themselves rarely define their pet primarily as a publicly displayed symbol of their social and/or economic status. Harris (1983), for example, found only .4 percent of pet owners admitting to having chosen their companion animal primarily for its function as a status enhancer.

PETS AND EXTENDED SOCIAL INVOLVEMENTS

A variety of studies demonstrate that dogs and other companion animals act as effective "social facilitators." For example, 83 percent of those questioned in a Swedish study (Adell-Bath, et al 1979) agreed with the statement, "my dog gives me the opportunity of talking with other people." Similarly, 37 percent of the respondents in Cain's (1983) study of pets in the family said that their companion animals had aided them in making friends or had increased their social contacts.

Like a wide variety of the objects displayed in public--children, kites, unique articles of clothing, tattoos, and so on--dogs act as sources of "mutual openness" (Goffman 1963:131-139; cf., Sanders 1989: 57-61). Dogs and other items openly controlled by actors in public settings provide a shared focus of non-threatening interaction between strangers or casual acquaintances. Common affinity for and experience with dogs offer a relatively neutral and accessible conversational topic. Since, as Cooley (1964 [1902]) emphasized, interactions with others are the dominant sources of information one uses to construct a definition of self, the company of companion animals increases the quantity and enhances the quality of self-defining encounters. In this way, pets reinforce the possessor's positive self-regard and extend key aspects of his or her self into the public arena.

Companion animals facilitate social interaction and extend the situations in which caretakers receive self-definitional information in yet another way. Shared possessions, activities, and interests act as the organizational focus of what

³My research project directed at the general topic of animal/human interaction currently is in its preliminary stages. As a consequence, the observational and interview data upon which this discussion is based are, at this point, somewhat limited. Field data are drawn from participation in an eight week "puppy kindergarten" class and a novice dog obedience course (along with my two Newfoundland puppies and their co-owner) and participant observation in another puppy kindergarten class. In addition, I conducted 6 semi-structured, in-depth interviews with owners of young dogs contacted through these classes. I also collected fieldnotes in the course of my own early experience with the developing relationship between myself and the Newfoundland puppies. These "autoethnographic" data (Denzin 1989b; see also Cooley's [1964 (1902)] discussion of "sympathetic introspection") proved to be especially valuable in providing major insights.

Herbert Gans (1974) refers to as "taste publics". Like antique cars, comic books, polkas, or other items of taste culture, companion animals can act as central elements in extensive social rituals and organizations. Dog and cat shows, breed specific organizations, and animal activity competitions such as obedience work extend the social interactions of pet enthusiasts. Within these subcultural contexts, owners can achieve status and prestige. In this way, enthusiastic involvement surrounding and cooperative work with companion animals expands owners' social encounters and enhances their positive self definitions (see Veevers 1985:15-19).

RELATIONSHIPS WITH COMPANION ANIMALS AND THE LOOKING-GLASS SELF

The self is a social construction built on the information derived from a person's social relationships. As discussed above, companion animals act as facilitators of human-to-human interactions, thereby increasing (and enhancing) self-defining situations. However, the connection between companion animals and the caretaker's self concept is *direct* as well as mediated. Owners consistently define their pets as "persons" with whom they share lasting, intimate, and emotionally involving relationships (cf., Bogdan and Taylor 1989).

One of the most simple forms of personhood assigned to companion animals is seen when they act as surrogates for human others (Veevers 1984:19-26; Beck and Katcher 1983:39-58). Within this assigned role the animal acts as a "stand-in" for a human parent, child, friend, or other significant cointeractant. But companion animals act as much more than surrogates for real or imaginary persons; they are consistently defined as persons in their own right and are the direct focus of person-to-person interaction. From approximately half (Katcher, et al 1983) to three-quarters (Cain 1985) of pet owners define their companion animals as "persons" or as having "person status." In this role as person the animal is talked to (Beck and Katcher [1983:44] found that 80 percent of the veterinary clients they studied talked to their pets "in the same way they talked to people") and confided in. This communicative activity typically is defined as an authentic conversational exchange in that human caretakers believe that the animal understands what they say and responds appropriately (Cain 1985:7).

As a defined person, the companion animal is incorporated into the owner's extant network of relationships. The most common form of incorporation is for the human interactant to regard the animal as either a family member or close friend. Somewhere between 70 (Beck and Katcher 1983:59) and 99 percent (Voith 1983) of pet caretakers define their animals as members of the family and from 30 (Nieburg and Fischer 1982) to 83 percent (Bryant 1982) consider the pet to be a "special" or "close" friend.

Human-pet interactions proceed along the same lines as do human-to-human social exchanges. The social exchange entails mutual acknowledgement of coparticipation in the encounter, mutual definition of the perspective of the other, imaginative estimation of the other's intentional definition of the situation, and mutual adjustment of behavior based on the essential social process of "taking to role of the other."

Human participants in relationships with companion animals are engaged in the "social construction of humanness" in orienting their interactions vis-a-vis their pets. The human caretaker comes to construct the personhood of the animal--seeing him or her as an individual, communicative, feeling, reciprocating, and companionable being who is an integrated member of the group. From this socially defined position the companion animal acts as a "significant other" for the owner and their face-to-face interactions provide important, commonly rewarding, social experience containing direct information which the owner uses as part of the process of self definition.

Human interaction with the companion animal/person presents a variety of rewards. Like all primary relationships, that between people and pets predominantly affords intrinsic, rather than instrumental, social compensations. The research on companion animals persuasively establishes that companionship and affection are the primary advantages of this unique relationship as defined by the human participant. The animal is seen as non-judgmental, accepting, and genuine, requiring nothing from the relationship other than the affectionate reciprocation of attention.

Surveys of pet caretakers demonstrate the significance of the companionship and affection which are central to the animal-human relationship. For example, of the pet owners questioned by Bulcroft and his associates (1986), 94 percent agreed that "pets are an importance source of affection," 85 percent agreed that "my pet accepts me no matter what I do," and 83 percent agreed with the statement, "my pet makes me feel loved." This stable, emotionally rewarding, non@judgmental relationship with the animal is defined by caretakers as reflecting their self worth--heir self definition as deserving affection is reinforced by their experience of the presumed relational definition held by the animal cointeractant.

THE ANIMAL-HUMAN "WITH" AND EXCUSING TACTICS

The ongoing flow of interaction between human beings and the companion animals with whom they are associated is an eminent social exchange. Both members of the animal-human diad mutually construct definitions of the other and the situation and devise plans of action which require them to adjust their behavior relative to these situated understandings. The cointeractants are engaged in "collective action"--adapting their goals and activities within the context of their definition

of the situation so as to achieve some degree of cooperative interaction.

Mutual recognition of the other as cointeractant and imaginative estimation of the other's orientation toward and response to the situation entails the construction of a mutual understanding of the other's "personality." Research accounts (eg., Bulcroft, et al 1986:8; Hearne 1987) testify to the human actor's propensity to define his or her animal as having a distinctive personality and using this definition of the other to orient his or her behavior toward the pet.

The owner's ongoing interaction with the animal based on his or her knowledge of the animal's unique personal characteristics, has significant impact on the owner's definition of self. This intimate connection and the mutual behavioral orientation and control it implies is played out and expected (sometimes even legally required as in the case of "leash laws") when the owner and companion animal appear together in public settings. In this type of situation, the animal and the owner constitute what Goffman (1971:19) refers to as a "with." The mutual "togetherness" of the with is typically symbolized by "with markers" (Goffman 1971:65) or "tie signs" (Goffman 1971:188©237) which display the connection between the parties. Leashes, mutual gaze, physical contact (eg., petting, nuzzling), the owner's calling the animal by name, and a variety of other tie signs are used to publicly demonstrate that the animal and caretaker constitute a with. As a public acting unit, the animal-human with is bound by expectations of propriety and mutual responsibility. The weight of these expectations rests most heavily on the owner who is seen as being most capable of exercising "intelligent self-control" (Goffman 1971:121). Consequently, when the animal member of the with fails to perform in accordance with public expectations the owner typically is held to be responsible. Socially problematic behavior by the animal has the potential of degrading the social identity of the human partner. This judgmental social response by others typically generates the uncomfortable internal experience of guilt, shame, or embarrassment within the caretaker (Goffman 1982 [1956]).

The failure of the animal member of the animal-human with to abide by widely shared expectations of propriety disrupts the more-or-less cooperative, flow of public interaction. The experience of threatened identity and problematically impeded interaction presents an uncomfortable situation for the owner. As in other situations where problematic events occur which disrupt social interaction, the owner with a misbehaving animal is obliged to take steps to regain equilibrium and reestablish the smooth flow of interaction. In so doing, the owner also attempts to restore his or her positive social identity and regain those aspects of

positive self definition which have been degraded by the negative responses of human others.⁴

When encountering problematic situations generated by their animals' misbehavior, owners call up and present definitions of the immediate situation and/or offer accounts of their animals' motives so as to smooth out the disrupted interaction and repair their damaged self esteem. I will refer to the activities of owners in the face of the disruptive behavior of the animal member of the with as *excusing tactics*

It is possible to identify at least seven kinds of excusing tactics employed by owners. These various styles may be used separately or in combination and are typically chosen on the basis of what kind of violation is presented by the animal and the degree of apparent "harm" caused by the infraction.

Situating. Perhaps the most common excusing tactic is seen when the owner emphasizes the unfamiliarity or chaotic character of the immediate situation in which the animal is expected to perform appropriately. In the puppy kindergarten in which I collected field data, observations such as, "I don't know what's wrong with him tonight. He always does it at home. He just gets excited with all the other dogs around," were offered with considerable frequency.

Justifying. Owners also deflect responsibility for their animals' misbehavior by redirecting the blame on the human actor outside the with who is typically the aggrieved party. "You can't just walk up behind her like that" or "he gets really nervous when you touch him there" focus the blame for the infraction on the other person for having behaved stupidly or precipitously.

Redefining. It is common for owners to attempt to defuse the negative feelings generated by their animal by recasting the behavior as a positive rather than negative action. Often the human

⁴Goffman (1971:95-187) refers to these modes of interactional repair as "remedial interchanges." Alternatively, Stokes and Hewitt (1976) discuss "aligning actions" used by interactants to reestablish identities and relationships disrupted by problematic events. Discussions of "disclaimers" (prospective justifications presented to explain potential problems) (Hewitt and Stokes 1975), "accounts" (retrospective explanations) (Scott and Lyman 1968), "neutralization techniques" (explanations presented to self and others in order to ease feelings and ascription of guilt) (Sykes and Matza 1957), and other aligning actions are oriented around the symbolic interactionist perspective on motives. Rather than being seen as initiatory "motors" of human action, motives, from this standpoint, are regarded as *verbal* presentations offered to the self and others which are intended to situate the behavior in question in an *understandable* context (see Mills 1940; Blum and McHugh 1971).

companion labels the behavior as "cute" or "smart" in order to move it back into the realm of permissibility. In my experience, this tactic offers, at best, only limited success as a means of smoothing disrupted interaction.

Behavioral Quasi-Theorizing. Quasi-theories are commonplace cultural explanations employed in everyday interactions to "explain problematic situations and give them order and hope" (Hewitt and Hall 1973:367-368). When used as an excusing tactic, quasi-theories tend to emphasize that the behavior in question is "natural" (ie., justifiable) given the animal's phylogenetic position (eg., "That's the way dogs are") or stage in the developmental process (eg., "I'm sorry she chewed up your purse. She's just a puppy and she's teething").

Processual Emphasis. Related to quasi-theorizing is the excusing tactic which emphasizes that the companion animal acquires behavioral self control in the course of maturation and as part of a training process. Owners often acknowledge that the violation is indeed troublesome and present themselves as "working on" the animal's training in order to extinguish it from their behavioral repertoire. The lesson is in process but has not as yet taken hold to the owner's--or, presumably, to the affronted other's--satisfaction.

Demonstrative Disciplining. When owners confronted by problematic social encounters precipitated by their pet emphasize the animal's stage in the training process, they commonly link this excusing move with overt, commonly rather harsh, corrective actions directed at the animal. Through loudly shouting "NO!", jerking on the leash, striking the animal, and other disciplining gestures, the embarrassed owner symbolically acknowledges the violative character of the act while overtly demonstrating his or her desire to assert effective control.

Unlinking. This is the excusing tactic of last resort. It is a public confession that the animal-human relationship itself is in serious trouble. Frustrated and confused, the guilt-ridden owner publicly acknowledges that the animal other is "out of control" ("I just don't know what to do. I can't get him to stop barking. I've tried and tried but nothing seems to work") and, in essence, dissolves the animal-human with. The fault for the disruptive action is presented as being the animal's and, in turn, the human coactor is absolved of responsibility. Understandably, owners who come to employ this type of excusing tactic with any frequency usually soon end their relationship with the animal.⁵

CONCLUSION

The foregoing discussion has employed the symbolic interactionist perspective and its central conceptual element--the socially constructed self--to briefly explore the relationship between humans and their companion animals. To a major degree, this presentation was initiated by Belk's (1988) wide-ranging and insightful paper on the self as it is connected to and extended by consumer products. Despite scientific critiques (eg., Cohen 1989), Belk's article identifies central features of the relationship between human actors and material culture while constituting a major step in the movement of consumer behavior research out of the traditional confines of the natural science model into the realm of post-positivist social science (see Sass 1986).

I would argue that one of the most apparent, self extending, and emotionally involving relationships meaningfully discussed within the general phenomenon of consumer behavior is that between people and their companion animals. As a unique element in commercial culture, the companion animal provides comfort, protection, love, health, companionship, and an enlarged definition of self like no other thing which can be bought, sold, or traded. Hopefully, it is through the recognition of the special gifts we receive from our animal companions that we will come to remove them from the category of consumer product where they are defined as having commercial value and can be callously discarded when they are used up or otherwise lose their appeal as commodities.

The Role of Possessions In Constructing and Maintaining A Sense of Past

Russell W. Belk, University of Utah

In the little houses the tenant people sifted their belongings and the belongings of their fathers and of their grandfathers. Picked over their possessions for the journey to the west. The men were ruthless because the past had been spoiled, but the women knew how the past would cry to them in the coming days.

The women sat among the doomed things, turning them over and looking past them and back. This book. My father had it. He liked a book. *Pilgrim's Progress*. Used to read it. Got his name in it. And his pipe--still smells rank. And this picture--an angel. I looked at that before the fust three come-- didn't seem to do much good. Think we could get this china dog in? Aunt Sadie brought it from the St. Louis Fair. See? Wrote right on it. No I guess not. Here's a letter my brother wrote the day before he died.... No, there isn't room. How can we live without our lives? How will we know it's us without our past? (Steinbeck 1939, pp. 117, 120)

The notion of the extended self suggests that we transcend the immediate confines of our bodies by incorporating into our identities, objects from our physical environment (Belk 1988). This conception implies that the self is spatially enlarged by such extensions; that our possessions make us bigger people. However, there is another dimension in which self may be extended: the dimension of time. For besides being defined by our immediate circumstances, we are defined by our pasts and our futures. The self may be temporally enlarged when we announce that we once completed a marathon in under three hours or that we are studying to be a doctor. We also are temporally enlarged, in some circles, by having a lineage that can be traced to the Mayflower or having grandchildren named after us. And we are temporally enlarged by having visited the National Museum of American History or having heirloom silverware that we plan to bequeath to our children. Of the past and future directions in which self may be extended, the present focus is primarily on the past. Having an extensive or rich sense of past implies that we are able to clearly define ourselves and ground our identity in previous personal or group history.

Various forms of amnesia show what happens if instead we are able to think about ourselves only in the present. For instance, in a clinical case he labels "the lost mariner," Oliver Sacks (1985) reveals Jimmie G. who has no memory except for the past few minutes and his first 19 years up to 1945 when he was serving in the U.S. Navy. He thinks World War II has just ended and is baffled by the gray hair he sees in the mirror. He meets his doctor anew each day and has no memory of prior meetings. He is intelligent and can carry on a game

of checkers, but quickly gets lost in chess because the moves are too slow. When he meets his brother, Jimmie is baffled by his unaccountable aging. Without having any recent past, Jimmie has lost all sense of time, continuity with his past, and ability to envision his future. He has, in Sacks' view, lost *himself*.

Even those of us without amnesia lose or fail to recall parts of our past. For this reason our life history is often marked, commemorated, and announced by objects (e.g., Olson 1985). Photographs, souvenirs, trophies, and more humble everyday objects act, in part, as repositories for memories and meanings in our lives. The present paper theoretically explores how such objects aid in creating and perpetuating a sense of past in our lives. The theoretical structure presented has been developed with the aid of fieldwork from the Consumer Behavior Odyssey and several subsequent studies (see Belk, Sherry, and Wallendorf 1988, Belk, Wallendorf, and Sherry 1989, Kassarian 1987, Wallendorf and Belk 1987). Due to space constraints however, the present paper presents only the relevant background literature rather than the results of this fieldwork.

THE INDIVIDUAL REIFIED PAST

Security Objects

"Why," asks Tooley (1978, p. 176) "do we keep one earring, three foreign coins (total value 30¢), a jacket far too small that we will never wear again?" The immediate answer likely to suggest itself is that such objects are kept for sentimental value which has something to do with preserving memories of our past. But why should we want to preserve our past? Why use *possessions* to preserve our past? And do such objects allow us to accurately recall our pasts? Beyond the necessity of having a sense past in order to achieve the integral sense of identity that Jimmie G. lacks, there are other reasons that Western society deems a sense of past to be important. We tend to be especially concerned with having a past when our current identity has been challenged, as may be the case with a divorce (Csikszentmihalyi and Rochberg-Halton 1981, p. 212), a midlife identity crisis (Davis 1979, p. 40), feelings of inferiority (Stillinger 1980), states of excessive change and mobility (Klapp 1969), and lack of confidence in the future (Moriarty and McGann 1983). For as McCracken (1988) eloquently notes:

Surrounded by our things, we are constantly instructed in who we are and what we aspire to. Surrounded by our things, we are rooted in and visually continuous with our pasts. Surrounded by our things, we are sheltered from the many forces that would deflect us into new concepts, practices, and

experiences. These forces include our own acts of imagination, the constructions of others, the shock of personal tragedy, and simple forgetfulness. As Arendt has suggested, things are our ballast. They stabilize us by reminding us of our past, by making this past a virtual, substantial part of our present (p. 124).

The role of possessions in these cases is not only to act as ballast to keep us stable, but to serve as familiar transitional objects that, like the child's security blanket, provide us a sense of support as we confront an uncertain future. It is this apparent function that caused the boom in World War II photography as servicemen were provided and sought to carry with them snapshots as memorabilia of "the girl back home," their families, and their lives in prior times of peace (King 1984). These objects also served as hopeful reminders that war only temporarily ruptures the "flow" of time and that someday "normal" peacetime, loved ones, and familiar activities would be regained and the river of time returned to its proper channel.

Preserving Our Past

Objects of the past are often intentionally acquired and retained in order to remember pleasant or momentous times in one's past. Souvenirs and mementos are intentionally selected to act as tangible markers for retrospective memories in the future. Shopping suggestions are now a staple of travel guides and souvenirs commonly tangibilize the tourist experience. They not only allow us to confirm the experience to ourselves, but they may allow us the conversational cue for telling others about it (Gordon 1986, Cybart 1988). Similarly, family photographs taken especially during seasonal holidays, rites of passage such as graduations, weddings, and anniversaries, vacation trips, and (of children) during infancy, are meant to serve as edited markers and stimuli for future reflection, communication, and consolidation of sense of self. Chalfen (1987) calls the more than 11 billion amateur photos taken in the U.S. each year an investment in creating a memory bank. Hirsch (1981) notes that the development of amateur photography provided nineteenth century poor and middle class families with a visual way to preserve family heritage as could formerly be done only by those rich enough to bequeath heirlooms and estates to future generations of their families. With the mobility of twentieth century North American families, photographs now seem to serve rich and poor alike in this respect.

But as objects for retrospective reflection, photographs (along with home movies and videotapes) may act in a way that is in some respects opposite to that of other possessions. Whereas possessions like furniture, houses, and clothing may act as unchanging objects providing the security of the familiar in our lives, photographs remind us of who we once were in a way that invites comparison and highlights how we have changed.

We may not be wholly different people, since features, expressions, and mannerisms tend to be retained, but the change is undeniable. Other possessions may mark the passage of time by becoming stylistically outdated, physically worn, and sometimes altered by repainting, dying, or rearranging, but these changes do not as directly imply that *we* have changed. The objects we see everyday tend to change slowly and imperceptibly. Only when we see these objects in old photographs or through the eyes of an infrequent visitor do we see that they, like the people who are the normal focus of our photographic records, have changed. Another exception may be objects uniquely associated with a past event. Athletic trophies, awards, wedding gifts, clothing bought for a special occasion, and other such time-marked objects (often associated with rites of passage) are more likely to act as reminders of temporal discontinuity than continuity in our lives. But our favorite chair, our familiar dinner dishes, and our favorite sweater (as long as it is still serviceable and fits) all act as objects of stability in our lives. They provide an embracing feeling of warmth that McCracken (1989) calls *homeyness*.

Nostalgia and Memory

The objects that McCracken sees as participating in feelings of *homeyness* (e.g., crafts, knickknacks, books, seasonal decorations, gifts) are also likely to participate in feelings of nostalgia. Nostalgia has been described as a bittersweet emotion in which the past is viewed with both sadness and longing (Davis 1979, Starobinski 1966, Stewart 1984).

Cognitive Versus Emotional Memories. The first important characteristic of nostalgia is that it involves an emotional rather than a cognitive memory process. It is a wistful mood that may be prompted by an object, a scene, a smell, or a strain of music. As Ruml (1946) reflects:

The nostalgic sentiments are less well understood. Although abundantly represented in literature and in art, they have found no appropriate place in social theory. Nostalgic sentiments being incommensurable in the hedonistic calculus, are regarded as somewhat removed from the hard logic of nature and touched by a bit of moonlight and summer madness (p. 8).

Neisser (1982) suggests that another barrier to understanding emotional nostalgic memories is that the vast majority of research on memory has been in artificial contexts that may bear little relation to remembering in natural contexts.

Sacred Memories. A second important characteristic of nostalgia, as suggested by recent naturalistic studies, is that past times that are nostalgically recalled are sacred times (Belk, Wallendorf, and Sherry 1989). Especially when they are involuntarily remembered, these times are mysterious, powerful (*kratophanous*), unexpected

(hierophanous), mythical, and prompt feelings of ecstasy or flow. These are also the elements that seem to fascinate Proust (1981; originals 1913-1927) in his 3000+ page self reflective novel, *Remembrance of Things Past*. Rather than objects of nostalgia serving as simple cues to propositional memories involving knowledge *that* something occurred, these objects provoke rich textural memories involving knowledge *of* the experience recalled (Belk 1986, Langer 1963). For Proust, this mystery and rich textural detail are clearly evident in the three volumes of memories that well forth from the cup of tea and little *Madeleine* cakes which his mother served him (actually the mother of the novel's Marcel) one day during his ill health:

I feel that there is much to be said for the Celtic belief that the souls of those whom we have lost are held captive in some inferior being, in an animal, in a plant, in some inanimate object, and thus effectively lost to us until the day (which to many never comes) when we happen to pass by the tree or to obtain possession of the object which forms their prison...And as soon as I had recognized the taste of the piece of madeleine soaked in her decoction of lime-blossom which my aunt used to give me (although I did not yet know and must long postpone the discovery of why this memory made me so happy) immediately the old grey house upon the street, where her room was, rose up like a stage set to attach itself to the little pavilion opening on to the garden which had been built out behind it...and with the house the town, from morning to night and in all weathers, the Square where I used to be sent before lunch, the streets along which I used to run errands, the country roads we took when it was fine. And...so in that moment all the flowers in our garden and in M. Swann's park, and the water-lilies on the Vivone and the good folk of the village and their little dwellings and the parish church and the whole of Combray and its surroundings, taking shape and solidity, sprang into being, town and gardens alike, from my cup of tea (1981, 1, pp. 47, 51).

With sacred nostalgic memories evoked by sacred possessions, it is not so much that these objects "stand for" particular events evoked in documentary fashion, as that they are the stimuli for an evolving network of vivid memories; that is, they "lead to" other memories in an interwoven net that grows rich in associations, moods, and thoughts.

Imagining the Past. A third significant aspect of nostalgic memories is that, rich and evocative as they are, they are, like other memories of the past, imaginary rather than "real". As Mead observes, "...the past (or some meaningful structure of the past) is as hypothetical as the future" (1932, p. 12; see also Mead 1929, Lynch 1972, Maines, Sugrue, and Katovich 1983). Mementos, souvenirs,

photographs, and other possessions that may evoke the past for us, are all dumb objects that provide only mute and shapeless testimony that there was a past. Only when we *interpret* these objects do they have meaning. And like our selectivity in deciding which of these possessions we will save and treasure (Belk 1988), we also selectively interpret our hypothetical past in a way that is most pertinent to us, just as we unavoidably do when we read fiction (Larsen and Seilman 1988). As with most fiction reading and all of our approaches to the sacred, we dwell on the nostalgic past for its own sake rather than for some utilitarian purpose (Lowenthal and Prince 1976). Just as Proust comes to realize that it is not the magic potion of the tea that contains his memories, but rather is himself, we must realize that our things are the incarnation of our experiences only to the extent that we can bring them to life through the reflections and interpretations that they stimulate.

It is this imaginary character of our nostalgic memories that allows us to use the past as a safe haven to which we may displace our hopes and ideals (McCracken 1988). Our mythical images of a golden age of childhood, the good old days, or our carefree college years, when life was good and we were our ideal selves, help explain our fondness for adult collections of childhood objects such as dolls, toys, comic books, and Teddy bears (Schlereth 1985). It further accords with Kant's contention that the feeling of nostalgia is a longing for our childhood (1798, Starobinski 1966). And it also accounts for what Tooley (1978) sees as the ideal treasure trove of personal objects:

...souvenirs and bottle caps and trophies and photographs and baseball cards and sea shells and coin collections--things that have symbolic value in their own right (coins), things that have the capacity for stimulating pleasant memories, and things that reinforce a treasured mythology of the self, things that revivify a former version of a self overlooked in the press of the daily and present self; things that recall a time of happiness obliterated by the weight of current unhappiness; things to be touched fondly, turned over musingly, returned to the box, which is in turn shoved back into storage (p. 174).

Authenticity. One final significant aspect of nostalgic memories may seem to contradict the preceding one. Even though our nostalgic memories are essentially un-real and imaginary rather than objective and inherent in the objects that inspire them, we nevertheless insist upon the authenticity of these objects, and insist that unauthentic, faked, or forged objects cannot possibly contain the powerful memories of "the real thing." This apparent contradiction is best understood in terms of the nature of the sacred. As MacCannell (1972) argues, it is the very shallowness and artificiality of our lives that causes us to seek the authentic.

Restated, it is the ordinary profane nature of our lives that causes us to seek the sacred. This restatement is supported by the (sacred) characteristics thought by Baugh (1988) to define authenticity: it manifests itself to us and creates epiphany (hierophany), it is able to transform the world (kratophany), it is totally unique (singularity), and it causes us to suspend our perception of the everyday world (transcendence). However, the additional sacred element of contamination is the property most useful for understanding why we insist upon authentic objects from our past. Because the sacred experience is thought to contaminate only the objects that were present during its occurrence, inauthentic, faked, or forged objects lack sacred power to carry our memories. A similar wedding ring, a photograph of a similar family's Thanksgiving feast, or a car that is like the one we had in college, may provoke a brief nostalgic flashback, but they are clearly inferior to and would hardly be traded for "the real thing." To claim that we once met a person who looked just like Woody Allen is to say much less than saying we once met the real Woody Allen.

This desire for authenticity is time and culture specific. Only in the past several hundred years has Western culture come to revere the original and abhor the copy (Orvell 1989, Trilling 1971). The rise of interest in this sort of authenticity appears to be closely tied to the rise of individualism in Western culture (Belk 1984, Handler 1986). It is also within this temporal and cultural frame that singularity has come to be regarded as a property of the sacred.

Antiques and Old Things

The items considered to this point are those that are intimately connected to our personal past in some way. The role of such objects in creating and maintaining a sense of past is easier to appreciate than the role of other old objects and antiques that have not previously been a part of our personal past. If these objects are heirlooms from our family's past, they aid in aggregate identity as discussed in the next section. But if they are merely old things, even if others consider them sacred or valuable, how can they play a role in our own sense of past? To answer this question we must go beyond McCracken's (1988) concept of displaced meaning, since rather than keeping the past at a safe distance, the collector of old things ("owner" seems too dispassionate) seeks to bring it closer. A more useful perspective to keep in mind is the stipulation that the past, and especially the *nostalgic* past, is imaginary. Because of this hypothetical quality, we may seek to appropriate part of our identity from objects and time periods to which we have not previously been connected. By coming to know these objects and time periods we may come to feel we have knowledge of what it was like to have been a part of them. Their "otherness," presumably superior artistry, and survival in spite of fragility, make them more extraordinary and sacred than objects of the present. As we insinuate ourselves

upon the life of such objects we extend our identity to encompass what we imagine their original era to have been.

Hillier (1981) speaks of collecting antiques as an attempt at "conjuring up the past," based on the hope that "a particular antique has absorbed something of an earlier time, something which we may be able to distil from it" (pp. 71, 78). In this sense the antique acts as a fetish object or talisman. Some antique collectors, in an apparently projective attempt to establish an even closer connection to these objects, even suggest that an antique "speaks" to them because they have had some connection with it in a former life (Cherry 1989).

THE AGGREGATE REIFIED PAST

Self is comprised not only of our individual identities, but also of more aggregate levels such as family, work organization, city, and nation (Belk 1988). What applies at the individual level, also applies at these aggregate level. Americans who once prided themselves on being unencumbered by the past, have become as active as anyone in enshrining their material past in museums, archives, and monuments. These things offer a proof that the past was real and remains meaningful:

Americans must not dismiss the endless viewing of Lenin's refrigerated body and the preservation of the bones of saints as alien superstitions. These, like Dolly Madison's gown, Benjamin Franklin's printing press, and George Washington's uniform, are more than curiosities. They provide direct, three-dimensional evidence of individuals who otherwise exist only as abstractions (Hindle 1978, p. 6).

National, Regional, and Local Possessions

Just as individual antique collectors may appropriate senses of pasts in which they have not directly participated, nations may also try to appropriate pasts that are not their own. This may be done by imitation as with classical architecture in public buildings and classical poses and clothing on public statues, or it may be done more directly by acquiring the art and artifacts of another culture. The more direct appropriation may involve classical works like the Elgin Marbles in the British Museum or "primitive" works like the anthropological artifacts in the Smithsonian collection (Cole, 1985, Meyer 1973). Whereas the acquisition of the classical works attempts, like antique collection, to establish a lineage to the past and appropriate its imagined glories, the acquisition of "primitive" works is more an attempt to demonstrate the superiority of the acquiring nation (Chamberlin 1979). From the point of view of the nation whose heritage has been appropriated however, these transfers often amount to a theft of national selfhood. Repatriation attempts, such as Greece's claim on the Elgin Marbles and Nigeria's claim on the Ashanti regalia also held by the British Museum,

are not often successful however, despite arguments such as Nigeria's that:

'These antiquities are the only authentic objects which illustrate and illuminate the course of our development. This is vital to us as a people, as it enables us to establish our identity, and hence restores our dignity in the community of nations (Chamberlin 1979, p. 113).'

The same concern with magic, sacredness, and authenticity that we invoke in personal possessions is also an important part of aggregate national, regional, and local possessions. Walter (1988) depicts a cup that seems suitable for coffee or tea and notes that it appears boring and possessed of low energy, until its heritage is revealed and our perceptions change:

However, when we learn that the cup is made of amber and...may be as old as 1500 B. C., the energy changes. We marvel that the shape of the humble teacup claims such remote antiquity, but the fabric of the cup evokes even more wonder than the form. Amber, to prehistoric folk, was a sacred substance. It was valued as highly as gold (p. 73).

As Stewart (1984) explains, part of this new reverence is because we see the modern as cold and sterile while the antique is warm and exotic. But a part of the status of antiquities housed in museums is due to the authentication and sacralization that takes place in transferring these objects to the museum. Not only is the museum a sacred temple of modern society (Rheims 1961), but sacralization is aided by removing the object from ordinary use and transferring it to the context of other sacred objects (Belk, et al. 1988).

Over the "life" of a significant object, a number of sacred and profane transformations may take place before it reaches a museum, as Fisher (1975) illustrates with a hypothetical warrior's sword. As an object that the warrior views as both a sign of social status and a key instrument of survival, the sword may obtain personal sacred status for him. Upon his death if the sword does not become a profane spoil of war, the society's priests may obtain it as a sacred symbol of the spirit of the warrior. When the society falls and the sword becomes looted wealth, it enters the profane world. And when anthropologists finally obtain the object and transfer it to a museum, it is once again a sacred object in still another system of meaning. We might also note that in each step in this social biography of the sword it becomes increasingly alienated from its original context, being first appropriated by a more aggregate local society and ultimately by a totally foreign society.

While archaeological, anthropological, and historical museums are those that may seem most relevant to collecting objects that provide an

aggregate sense of past, natural history museums, art museums, and museums of science and industry perform similar functions. And museums are not the only repositories of sense of past at the local through national levels of self. Data collection in economics, meteorology, popular culture studies, and a variety of other disciplines also archive our past. So do libraries, historical societies, and cemeteries which now mark permanent graves rather than recycling the land for other burials. As Shapiro (1985) documents, the impetus for the development of each of these repositories occurred during the mid-nineteenth century in the U.S.. Prior to this time, the view of history seems to have been less linear and more cyclical. This difference is seen more clearly however in the contrast of present view of using the past to construct desired identities versus the medieval European view of a changeless social order and an irrevocable past (Mead 1929). Then, and in preceding civilizations, preserving the past in public institutions was not encountered (Lowenthal 1985, p. 365).

An aggregate sense of past implies a collective memory (Halbwachs 1950). There is some evidence that the salient past differs markedly by generation (Schuman and Scott 1989). The period of late adolescence and early adulthood when adult identity is crystallizing is an especially prominent source of generational memories. This seems to account for the different musical preferences of different generations (Holbrook and Schindler 1989) and the different eras of collectibles preferred by those who have reached midlife (Davis 1979). Collective memory is thus generation-specific.

Family Heirlooms

Unlike anonymous antiques, monuments, landmarks, and museum artifacts, family heirlooms have been directly experienced by individuals and families during their past. Such heirlooms are not universal in a society, but are restricted to higher social classes. These classes are more likely to have furnishings, jewelry, silver, collectibles, paintings, *objects d'art*, and even articles of clothing to pass along (Bossard and Boll 1950), although middle class families who have remained in one place over several generations may also have some heirlooms (McCracken 1988, chapter 3). U.S. blacks who are descended from former slave families may have oral traditions, but have been barred from multigeneration material cultures (Haley 1976). Although it is most common to think of traditional peoples as possessing only oral heritage (e.g., Bateson 1958), there is also a material heritage in groups like the Aranda of Australia (Strehlow 1947). In fact among the Northern Aranda, *tjurunga* objects are thought to be the embodiment of ancestors and are hoarded as most treasured possessions.

Having family heirlooms, collections, or other significant possessions that children or grandchildren are willing to take over can provide a sense of familial self continuity that extends beyond

death. Barthes (1984) reflects after his mother's death that he "finds" her in an ivory powder box, a cut-crystal flagon, a low chair, raffia panels, and the large bags she loved. Even when families do not pass heirlooms to succeeding generations, the continued existence of childhood home and other important objects may provide a sense of continuity or even immortality. When these objects are instead destroyed, we lose a part of our past, a part of our selves:

A picture of Barney's childhood home hung just inside the entrance of his own home. The childhood home had been deeded to his father when his father was a child. Though the house and the land had long since been sold outside the family, Barney expressed dismay when he told me of the experience of driving by some years before and finding it "wiped out." His voice quavered and tears came to his eyes as he told me this story.

The darn thing, last time I was up there, they even stripped the house out of there. The old home, well, I thought the thing would stand forever. That's what happens to everything; nothing comes of nothing anymore (Boschetti 1986, p. 42).

CONCLUSIONS

Previous studies of time in consumer research have ignored the role of possessions in creating and maintaining a sense of past. A sense of past is essential to a sense of self. The self extends not only into the present material environment, but extends forward and backward in time. Possessions can be a rich repository of our past and act as stimuli for intentional as well as unintentional recollections. While few of us undertake as comprehensive a life history review as Proust, our memories constitute our lives; they are us. We fervently believe that our past is accumulated somewhere among the material artifacts our lives have touched--in our homes, our museums, and our cities. And we hope that if these objects can only be made to reveal their secrets, they will reveal the meanings and mystery of ourselves and our lives.

To Me from Me: A Descriptive Phenomenology of Self-Gifts

David Glen Mick, University of Florida
Michelle DeMoss, University of Florida¹

ABSTRACT

Although the concept of gifts to oneself has been mentioned by researchers of gift-giving behavior, no empirical investigations have been conducted on the topic. This paper reports the findings of an exploratory study based on respondents' descriptions of recent self-gift experiences. Some distinguishing aspects of self-gifts are identified and directions for future research are suggested.

INTRODUCTION

Social scientists have noted for many years that gift-giving is a widely practiced and essential component of human relations. Probably the most common form and function of gift-giving is an interpersonal act of symbolic communication, with explicit and implicit meanings ranging from congratulations, love, and regret to obligation and dominance. Other functions include social exchange, economic exchange, and socializing. Since Belk's (1979) discussion of these functions, several additional papers in consumer research have addressed the conceptual side of gift-giving (e.g., Belk 1984, 1987, 1988; Belk, Wallendorf, and Sherry 1989; Sherry 1983) while a few empirical studies have also appeared (e.g., Macklin and Walker 1988; Scammon, Shaw, and Bamossy 1982; Sherry and McGrath 1989).

Across the span of social science and consumer research on gift-giving there is an underlying tendency to draw a dichotomy between goods acquired for giving to others and those acquired for personal use. Researchers like Gronhaug (1972), Ryans (1977), and Scammon, Shaw, and Bamossy (1982) have used this distinction overtly to examine differences in purchase behavior. For example, Ryans (1977) found that consumers buying for personal use were less likely to have a target price in mind than those buying a gift. Nonetheless, the phrase *personal use* is very broad and entails virtually every acquisition a consumer undertakes for him or herself. One outcome of this dichotomy has been a failure to recognize that some personal acquisitions may have dimensions that make them more like gifts than like other personal acquisitions. Such a distinction might lead researchers to a more refined understanding of consumer behaviors involving varied acquisitions for oneself, including situational and motivational determinants, acquisition strategies and processes, and experiential consumption meanings.

The idea of gifts to oneself is not novel, though to our knowledge it has received limited conceptual support and no direct empirical attention. Although focused on interpersonal (dyadic) gift-giving, Tournier's (1961/1966, p. 6) book actually begins with a short discussion of gifts to oneself:

Before giving myself the pleasure of undertaking a new work, I have wanted to finish up other works I have promised. This task is a kind of present which I've given myself and which I enjoy as a reward for finishing off other duties....There are gifts not only for others; there are also those we give ourselves, generous or parsimonious, according to the formation we have had.

Tournier (1961/1966) also maintains that gifts to other people can serve as gifts to oneself, insofar as personal pleasure is anticipated and derived from observing the gift receiver's happiness.

Schwartz (1967) has argued that the presentation of a gift imposes an identity on the giver and, especially, on the receiver (see also Belk 1979). After discussing issues of self-concept in gift-giving, Schwartz (1967, p. 3) goes on to say:

This leads us in to the interesting area of the giving of gifts to oneself. This is normally spoken of in terms of "self-indulgence," opposition to which, stripped to its essentials, represents an unwillingness on the part of the ego to strike a bargain with the id. This inflexibility is dangerous when other people (as sources of satisfaction) are not available, for it makes adjustment to hostile environments unlikely.... The "self-gratifier" is an interesting product of the non-intimate community who, despite his pervasiveness, has received little attention from the social sciences.

For Schwartz (1967), gifts to oneself are nutrients for emotional health when a person is devoid of satisfying interpersonal relations.

Tauber (1972) included *self-gratification* as a significant motive for people's shopping and purchasing behaviors, though he did not associate it with gift-giving to oneself. He proposed that the self-gratification motive leads people occasionally to buy "something nice" for themselves when they are feeling depressed.

Levy (1982, p. 542) appears to have been the first consumer researcher to suggest the possibility of gifts to oneself:

The complexities of gift giving and the meanings of [gifts] might both be further explicated by considering personal use as a

¹The authors are indebted to Lance Brouthers for his help in coding questionnaire responses. Thanks are also extended to Lance and Rich Lutz for helpful comments on an earlier draft of the paper.

form of gift giving to the self--"I owe it to myself." I as subject reward me as object.

Since Levy's comment, Sherry (1983) and Mick (1986) have briefly discussed gifts to oneself. Moreover, recent ethnographic work on gift shops has recorded some shoppers' remarks that reflect a potential richness to this phenomenon that calls for closer examination (Sherry and McGrath 1989).

In sum, self-gifts seem to be a viable concept, but remain a mystery within consumer research. Hence, we conducted an empirical study as a first, albeit exploratory step toward further substantiating and clarifying self-gifts. More specifically, like prior dyadic gift research, this study emphasized the *occasions* of self-gifts. Taking Lutz's (1979) suggestion, an added focus was consumer *motivations* for self-gifts. In general, this study constituted an emic research project aimed at the phenomenology of self-gifts. The study's insights are based considerably on the consumers' own words and actions as revealed through descriptions of self-gift experiences. This basic approach has been used recently in other consumer research, including studies on special possessions (Myers 1985) and impulse buying (Rook 1987).

METHOD

Respondents in this study were 54 undergraduate business students at a large American university who received course credit for their participation. The use of this convenience sample, other than being commonly acceptable for exploratory studies, was also justified based on prior focus group interviews which revealed that many students readily related to the term "self-gifts."

A questionnaire was used to collect information from the respondents. The introduction page noted that gift-giving takes place worldwide and that most of what is known about gifts is based on studies of gift-giving between two people, for example, a husband and wife or a boyfriend and girlfriend. It was then pointed out that we had heard people say that sometimes they give gifts to themselves. These so-called "self-gifts" were identified as the topic of the study. Respondents indicated their gender, age, and marital status at the bottom of the introduction page and then self-paced their way through the remaining four pages of the questionnaire. The term "self-gifts" was not defined for the respondents, mostly because so little is known about the concept and extra detail might have biased their responses rather than encouraging an array of self-gift information.

The next page adopted a "critical incident" technique by requesting respondents to recall the last time they had acquired a self-gift (see Rook, 1987, for another example of this technique). They were asked to "describe in detail the situation (where, when, who, how, why, etc.) that led you to acquire for yourself this particular self-gift." Respondents had a full page to provide their descriptions. The subsequent two pages asked respondents to list additional circumstances and motivations,

respectively, for self-gift behavior in which they had engaged. The final page asked them whether they had any final thoughts, opinions, or feelings about self-gifts.

RESULTS

The sample consisted of 23 males and 31 females, with ages ranging from 19-24. Only two respondents were married.

Traditional content analysis was performed by coding the reported circumstances and motivations, both in the self-gift story and in the subsequent mentions of further circumstances and motivations. Two short lists of potential circumstances and motivations were developed based on prior conceptual discussions of self-gifts and the focus group interviews we had previously conducted. The first author then reviewed the 54 questionnaires in order to check the completeness of the two lists, resulting in the addition of three more circumstances and three more motivations.

Generally speaking, there was an understandable one-to-one relation between certain circumstances and certain motivations for self-gifts, e.g., to reward oneself (motivation) for a personal accomplishment (circumstance). (However, this does not imply that all respondents reported matching circumstances and motivations, nor that we inferred one when only the other was reported.) After the coding lists were finalized, the second author and another doctoral student in marketing independently coded each respondent's entire questionnaire for *explicit* mentions of self-gift circumstances and motivations. The judges agreed on 83% of their codings; joint discussions resolved the disagreements.

Further analysis of the main self-gift stories was strictly interpretive. Both authors read the stories independently and made notes on perceived commonalities across the stories as well as other emergent revelations. The authors then compared their notes while reviewing the questionnaires again, seeking clear evidence and consensus for the interpretive insights discussed here.

Content Analysis and Crosstabulations

The frequencies and percentages of reported self-gift circumstances and motivations appear in Tables 1 and 2. On average, each respondent reported a total of three circumstances and three motivations. As Table 1 shows, the dominant circumstances related to self-gifts are times of accomplishment (e.g., high exam grades), when feeling down (e.g., from poor performance on an exam, from human relationship conflicts), when a holiday arrives (e.g., birthday, Christmas), when feeling stressed (e.g., from too many demands at school or on the job), when there is extra money to spend, and when the item may be especially needed. Table 2 indicates that the most frequent motivations are to reward, to be nice to oneself, to cheer up, to fulfill a need, to celebrate, and to relieve stress. Although there were some circumstances and motivations reported that were not included directly

TABLE 1
Reported Circumstances of Self-Gift Behavior

Circumstance	Frequency	As A Percentage of Total Circumstances Mentioned ¹	As A Percentage of Subjects Mentioning Circumstance
Personal Accomplishment	34	20%	63%
Feeling Down	28	16%	52%
Holiday	19	11%	35%
Feeling Stressed	18	10%	33%
Have Some Extra Money	18	10%	33%
Need	18	10%	33%
Had Not Bought For Self In A While	10	6%	19%
Feeling Good	7	4%	13%
Attainment Of A Goal Is Desired	6	3%	11%
Other	15	9%	28%
Total	173

TABLE 2
Reported Motivations for Self-Gift Behavior

Motivations	Frequency	As A Percentage of Total Motivations Mentioned ¹	As A Percentage of Subjects Mentioning the Motivation
To Reward Oneself	34	23%	63%
To Be Nice To Oneself	28	19%	52%
To Cheer Up Oneself	26	18%	48%
To Fulfill A Need	17	12%	31%
To Celebrate	14	10%	26%
To Relieve Stress	8	6%	15%
To Maintain A Good Feeling	7	5%	13%
To Provide An Incentive Toward A Goal	4	3%	7%
Other	7	5%	13%
Total	145		

n = 54

¹ -- These do not add to 100% due to rounding

in the coding lists (i.e., coded as "Other"), fully 92% of the circumstances and 95% of the motivations were classified according to prespecified categories. Given that these categories number nine and eight respectively, it appears that self-gifts are acquired within a relatively confined set of circumstances and motivations, several of which go hand-in-hand.

Bivariate analyses were performed, primarily crosstabulations between gender and the reported circumstances (or motivations). Most of these analyses produced non-significant results. Notable exceptions based on Fisher exact tests included a marginally significant higher frequency of the reward motivation reported by males ($p < .08$, 2-tail) and a significantly higher frequency of the celebration motivation mentioned by females ($p < .02$, 2-tail).

Interpretive Analysis

Levy's (1982) remark that people can perceive themselves as both subject and object in self-gift behavior was supported by several responses. One student wrote that, after some disappointing test grades, "*I took myself shopping*" (emphasis added). Another wrote that, when feeling down, "*I will treat myself to help make me feel better*" (emphasis added).

The stories also revealed a picture of self-gifts characterized by considerable variability and flexibility. Self-gifts ranged from clothing, compact discs, a computer, a stuffed animal, jewelry, and an aquarium (products), to hair styling, restaurant meals, and a spa membership (services), to socializing with friends (experiences). Certain types of self-gifts (e.g., clothing) were reported in multiple circumstances, as described in the self-gift stories.

The stories also illustrated that, like dyadic gifts, self-gifts inhere properties of sacredness that may serve to differentiate them from other personal acquisitions (cf. Belk, Wallendorf, and Sherry 1989). For instance, there can be ritualistic aspects to self-gifts involving patterns or rules of conduct. As one respondent revealed, "I usually reward myself either by going out for an expensive dinner or treating myself to something that I normally wouldn't--a play, perfume, etc." Self-gifts can also have a mysterious quality, not completely understood by the individual, and are capable of producing ecstatic experiences, as this verbatim shows:

The New York Rangers are my favorite hockey team and they have been in first place....For years I have always wanted to buy a Rangers t-shirt, but for some reason I never did. When I bought the shirt I was very excited and could not wait until I could wear it.

Self-gifts can also involve sacrifice, i.e., abstaining from personal acquisitions in preparation for self-gifts. As one respondent wrote, "I don't do it often because I like to save money and therefore when I do

buy myself something that I do not need but really want, it becomes that much more special." Similarly, self-gifts can be sacred by virtue of their opposition to other profane personal acquisitions--for instance, those that occur on a day-to-day basis. As another respondent wrote, "I try not to do it excessively because then it loses its specialness." In other words, excessiveness desacralizes self-gifts by making them more like regular, mundane personal acquisitions (cf. Belk, Wallendorf, and Sherry 1989). In sum, self-gifts appear to be a distinguishable form of personal acquisition based, in part, on their potentially sacred properties.

Another shared aspect of self-gifts and dyadic gifts concerns the role of self-concept. As noted earlier, Schwartz (1967) perceives interpersonal gifts as vehicles of identity imposition. Given that self-definition, self-consistency, and self-esteem are important dimensions of the global meaning of self-concept (cf. Sirgy 1982), it was evident in some respondents' stories that self-concept was crucial to self-gifts and vice versa:

Several weeks ago I ordered a set of champagne glasses and bucket for myself for an early Christmas present. I was leafing through a bunch of Christmas catalogues and saw the set. I will be moving to a new, beautiful apartment in January, and *I've always been a romantic, always loved champagne*, and finally am dating a guy who will drink champagne. So I ordered it. Forty bucks--*I figure I'm worth it.* (emphasis added)

Another story involved a student whose self-concept had developed partly from competitions in horse shows.

I had been studying extremely hard and I did not do well on two exams so I treated myself to compete in a horse show I could not really afford. My thinking was that *I had worked hard enough* over the summer to earn my spending money and worked hard as I could on my exams and that *it was time I did something for myself.* Something I wanted to do and it would relax me--get some fun and *sense of accomplishment out of my efforts.* (emphasis added)

This same respondent wrote that self-gifts "make me feel better about myself." And on a related point, another respondent wrote that "A self-gift tells that I'm a worthy person and I should be appreciated." These quotes suggest that the relationship between self and self-gift may be among the strongest of relationships involving the self and personal acquisitions. Hence, this characteristic may further serve to distinguish self-gifts from many other personal acquisitions.

DISCUSSION

Although a few respondents had difficulty in relating to the idea of self-gifts, most began writing their descriptions within moments after reading the instructions. This fact and the results from this study suggest that self-gift behavior may be fairly common among young American, college-educated adults. The self-gift stories also pointed to several key dimensions of self-gifts, including their variability and flexibility, sacred properties, and critical ties to self-concept. Extrapolating our findings to other populations is not possible. However, informal conversations we have had with other adults of varying ages and backgrounds have suggested that self-gift behavior may be widespread throughout American culture. Additional exploratory and descriptive research is needed across a broader sample.

This study determined that self-gifts can be products, services, or experiences and that they are partly differentiated from other personal acquisitions by their situational and motivational contexts. However, while some respondents mentioned "need" as a motivation for acquiring a self-gift, others openly stated that self-gifts are nonessential. At this point, our conjecture is that self-gifts may at times be needed (e.g., new shoes), but need motivation is probably not a sufficient condition (motivation) for a personal acquisition to be a self-gift.

A related issue concerns the term "self-gifts." One of our respondents commented that all purchases for oneself could be interpreted as self-gifts. From this it appears that future researchers should be careful in using the term "self-gifts" as the sole indicator to respondents about the topic under investigation, unless a wide range of responses is desired, e.g., if the researcher is attempting to uncover additional motivations, circumstances, or other general aspects of self-gifts not identified in the study reported here. Otherwise, at this stage our recommendation would be to use the circumstances and/or motivations of self-gifts that emerged in this study. For instance, respondents may identify more easily and more accurately with the idea of "rewarding" or "cheering up" than with the term "self-gifts."

Exploratory research typically raises more questions than it answers and, as a result, this study provides several directions for future research on self-gifts. The conceptual relation of self-gifts to interpersonal gifts should be investigated more thoroughly. This could lead to further distinctions of self-gifts from other personal acquisitions that could be significant for consumer behavior theory. The dyadic-gift literature might also suggest propositions for self-gifts that could be empirically tested. For example, Belk (1988) has speculated that the most gratifying form of gift-giving may occur when the recipient is a part of the giver's extended self. If so, then a comparative study might demonstrate that an even more satisfying form of gift-giving is self-gifts.

Research could address the socioeconomic correlates of self-gift behavior as well as the extent to which general and more specific types of self-gifts differ as a function of circumstance or motivation. In addition, given that qualities such as practicalness have been shown to vary across dyadic-gift circumstances (see Belk 1979), this same issue should be addressed with self-gifts.

The origins of self-gift behavior require research. For instance, the psychological impact of childhood dyadic-gift experiences on adult self-gift behavior is unknown; studies of parent-child relations and dyadic-gifts may serve as a good starting point (e.g., Belk 1987). On a macrolevel, the cultural influences on self-gift behavior might be considered according to the social history of possessions and consumption (Belk 1984; McCracken 1988).

The relationship between self-gifts and self-concept appears to be especially worthy of future research. For example, past research has shown that clothing often acts as symbolic self-enhancement (Holman 1981) and that improving self-esteem through weightloss has become a national preoccupation in America (Verba and Camden 1987). An investigation of clothing purchases by people who have recently lost weight may offer deeper insights on self-gifts and self-concept as well as the symbolic nature of clothing.

Another question concerns whether self-gifts are sometimes nothing more than *post hoc* rationalizations for dealing with cognitive dissonance, perhaps emanating from guilt or regret over certain personal acquisitions. One way that future research might address this issue is to have respondents indicate whether they determined the acquisition, for example, to be a reward either before or after acquisition. If self-gifts are truly similar to dyadic-gifts, then it would seem that self-gifts are rarely after-the-fact rationalizations.

The measurement of self-gifts needs to be addressed. One major challenge will come from the fact that self-gifts are highly subjective and may not be easily quantified for the purposes of nomothetic research (see Hudson and Ozanne 1987). One approach might be to assess the propensity of consumers to engage in self-gift behavior, perhaps drawing on the circumstances and motivations identified here and having respondents provide frequency estimates based on past behavior. This technique could then help to establish which consumers are most prone to self-gift behavior (e.g., males versus females, young versus old). However, it would not provide new insights about the fundamental role and meaningfulness of self-gifts in consumers' lives. This likely will require more qualitative, phenomenological research.

CONCLUSION

This paper reported an exploratory study of self-gifts involving responses to several open-ended survey questions by a convenience sample of undergraduate business students. Within this context the notion of self-gifts was found to be a

comprehensible concept and representative of behavior that most of the respondents reported having performed. For them, a self-gift was acquired primarily within a select set of circumstances and/or motivations. Descriptions of self-gift experiences pointed to additional distinguishing qualities of self-gifts and a number of directions for future research.

The Effect of Donor-Recipient Involvement on Consumer Gift Decisions

Janet Wagner, University of Maryland
Richard Ettenson, University of Maryland
Sherri Verrier, University of Maryland

The Sherry (1983) model suggests that gift-giving decisions vary by the level of involvement in the donor-recipient relationship. A conjoint task involving a gift purchase was administered to consumers in two conditions: 1) a gift for a new neighbor, and 2) a gift for a best friend. The results showed that the use of expressive and utilitarian attributes, as well as price, differed between the two gift-giving conditions. It was concluded that the results lend support to the Sherry model by demonstrating that level of involvement affects the gift purchase decision.

INTRODUCTION

Gift-giving is a phenomenon of economic and social importance, which has been the focus of a growing body of conceptual and empirical work in consumer behavior. In the economic realm, expenditures for gifts represent more than 3% of the annual budget of the average household (Garner and Wagner 1987). In the social sphere, gifts serve as important symbols in creating and maintaining relationships and in acknowledging important life cycle events (Belk 1979; Sherry 1983).

Conceptual Framework

Sherry (1983) proposed a multidisciplinary model of consumer gift-giving based on a typology with three major components -- the gift, the relationship between donor and recipient, and situational factors. According to this model, the gift-giving process has three stages -- gestation, pre-emption, and reformulation. Gestation resembles traditional consumer decision-making models (e.g. Engel, Blackwell and Miniard 1986), and may be of the most interest to marketers, because it culminates in a purchase.

Gestation begins with a precipitating condition, which is the donor's recognition of a gift-giving situation. During this stage, decision-making is affected both by the gift-giving motives of the donor and by hints from the recipient about his or her needs and wants. The donor evaluates alternative gifts in terms of their attributes and what those attributes communicate to the recipient. Finally, a purchase decision is reached.

According to Sherry (1983), the effect of product attributes on the choice of a gift may vary according to the level of involvement between the donor and the recipient. Expressive gifts are more likely to be given in close relationships, while utilitarian gifts are more likely to be given in distant relationships. Attributes such as price and quality may also be used to define level of involvement. More costly, higher quality gifts are usually given in closer relationships.

One major function of gift-giving is communication (Banks 1979; Belk 1979; Sherry

1983). Because gifts communicate information not only about the recipient, but also about the donor, consumers may engage in "impression management" (Sherry 1983). This suggests that gift-giving decisions are likely to be influenced by social norms.

Previous Research on Gift-Giving

Warshaw (1980) studied the relationship between social norms and perceived expense in the purchase of gifts by college students. The influence of social norms appeared to decrease as the perceived expense of a gift increased. Conversely, the influence of social norms appeared to increase as perceived expense decreased.

Belk (1982) studied the effect of involvement on the gift-giving strategies of adult women. Eighty-seven gift attributes were rated with respect to their importance. Price, quality, and convenience were hypothesized to differ by level of involvement. Subjects were assigned to three experimental conditions in which involvement was manipulated by intimacy of the relationship (close friend, casual friend, close relative) and gift-giving occasion (birthday or wedding). The results of analyses of variance (ANOVA's) showed that high involvement was associated with the importance of price and quality. The effect of the occasion on gift-giving was studied by Devere, Scott and Shulby (1983). Undergraduates rated the importance of 48 attributes of birthday and wedding gifts. In both situations, the most important gift attributes were those related to style, quality, usefulness, performance, and price. Style was more important in the birthday gift, and quality and performance were more important in the wedding gift.

Any resource -- a good, a service, or money -- may be used as a gift. Perhaps the most popular gift is clothing (Belk 1979; Caplow 1982; Jolibert and Fernandez-Moreno 1983). Because clothing conveys information about sex, age, status, and personality (Sproles 1979), a gift of clothing may be one of the most effective ways for a donor to communicate his or her perception of the recipient and the gift-giving relationship. Horne and Winakor (1988) studied gifts of clothing exchanged within families at Christmas, and found that subjects reported style, color, fiber content, and cost to be the most important attributes. Rucker, Boynton, and Park (1986) compared attributes used in gift and nongift purchases of children's clothing, and found that "embellishment" was more important in gifts. Andrus, Silver and Johnson (1986) studied the effect of brand on purchases of clothing gifts, and found that consumers were willing to pay 20% more for a gift in order to purchase a status brand.

Much of the research on gift-giving has been based on methods in which subjects are asked to

report or rate the importance of a set of product attributes (e.g. Andrus, Silver and Johnson 1986; Belk 1979; Devere, Scott and Shulby 1983; Horne and Winakor 1988). The results of such studies provide insight into consumer gift-giving behavior and are useful in generating list of attributes that may affect gift-giving decisions. The results must be interpreted with caution, however, for two reasons. First, self-reports are often poor surrogates for the decision-making process (Achenbaum 1966; Bettman 1979; Nisbett and Wilson 1977). Gift-giving involves social interaction, so subjects may have given socially desirable responses. Second, subjects have rated attributes one-at-a-time, in isolation from the bundle of attributes which typically define a product. Consequently, the results give little information about the psychological trade-offs which consumers are likely to make among product attributes in purchasing gifts.

In this research, conjoint analysis was used to compare gift-giving decisions in two situations, which were varied by level of involvement in the donor-recipient relationship: 1) a gift to a best friend, and 2) a gift to a new neighbor. Use of the conjoint approach was predicated on the assumption that the decision to purchase a gift, like the decision to purchase a product for personal use, involves evaluating and integrating information on multiple product attributes. Because the gift to a best friend was assumed to be more involving than the gift for a new neighbor, it was expected that price, quality, and expressive attributes would be more important in the best friend condition. It was also expected that utilitarian attributes would be more important in the new neighbor condition.

METHOD

Participants

One-hundred mothers were systematically sampled from the P.T.A. membership list (N=197) of a public elementary school in the suburbs of a major metropolitan area in the Mid-Atlantic region. Adult females were used as subjects for two reasons. First, most donors are female. As the "unpaid social directors" and "chief gift-givers" of American society (Schnudson 1986), women purchase 84% of all gifts (Caplow 1982). Second, the decision-making task upon which this study was based involved a gift for a baby shower. Consequently, the use of adult females ensured that the subjects were familiar with the gift-giving situation. Permission to recruit the mothers was obtained from the P.T.A.'s executive board at its meeting in the month prior to administration of the research. To encourage participation, the P.T.A. was promised a \$5 donation for every completed instrument returned to the researchers.

The Gift-Decision Task

Participants were given a set of instructions in which they were told that they had been invited to a baby shower and that the guest of honor had hinted that she wanted one-piece jumpsuits for her

new baby boy. An infant's jumpsuit was defined as a one-piece garment, with feet, to be worn while the baby was either awake or asleep. Half of the 100 mothers sampled were told to assume that the guest of honor was a best friend, and the other half were told to assume that the guest of honor was a new neighbor.

The research instrument consisted of a set of decision-making tasks, based on a 2 x 2⁸ mixed 1/16 fractional factorial design, with full replication (Hahn and Shapiro 1966; Plan 7b). The two main factors were: 1) the relationship between the donor and the recipient (a between-subject variable) at two levels: best friend or new neighbor; and 2) eight product attributes (within-subject variables) at two levels each. Attributes were borrowed from the Sproles (1979) model of fashion-oriented consumer behavior, and levels were selected through a focus group of mothers with demographic profiles similar to those of participants. The eight product attributes and their corresponding levels were: price (\$15.00 vs. \$8.00), color (mint green vs. blue), brand (Carter vs. LACOSTE), fiber (100% cotton vs. 100% polyester), size (6 months vs. newborn), fabric (t-shirt knit vs. terry cloth knit), quality (good vs. very good), and style (classic vs. fashion). In the instrument, all attributes except for style were presented in written descriptions of infant jumpsuits. Style was presented in accompanying sketches. The instrument was pretested with a group of 10 mothers of elementary school children. The results indicated that the two levels of price initially chosen, \$5 and \$20, were perceived to be unrealistically low and high. The levels were adjusted accordingly.

The experimental design involved 16 cases in which infant sleepers were described. This made it possible to analyze main effects for the eight product attributes as well as six two-way interactions. Each of the 16 cases was fully replicated. By replicating the cases, it was possible to estimate both experimental error in the individual-subject ANOVA's and within-subject consistency. Eight "filler" cases were also included, so each participant made a total of 40 decisions. For each case, participants were asked to evaluate the likelihood of purchase by placing a slash along a 100 millimeter continuum, with ends marked "Not Very Likely" and "Very Likely," which appeared at the bottom of the page. The decision-making task was followed by a post-experiment questionnaire, in which socioeconomic and demographic information was collected.

Procedure

A packet of research materials was mailed to participating mothers in November, 1988. Included were: a cover letter from the researchers, a letter of endorsement from the president of the P.T.A., the research instrument, and a stamped, pre-addressed envelope for return of the completed instrument. The participants were asked to return the instrument within 2 weeks. Reminder letters were sent to those who did not comply. Of the 100 instruments

No	20	.26

mailed, 69 were completed and returned by the first deadline. An additional eight were received after the reminder, yielding a response rate of 77%. Completed instruments were received for 35 mothers in the new neighbor condition and 42 mothers in the best friend condition.

RESULTS

Descriptive statistics for the 77 participating mothers are presented in Table 1. For the most part, the mothers were older, better educated, more likely to be working, and more likely to be married than one would expect of mothers of elementary school children. The majority reported having given a shower gift in the last year.

Use of Attributes

An individual-subject analysis of variance (ANOVA) of the fractional design was performed on the gift purchase decisions. This made it possible to identify which attributes affected the gift purchase decisions of each participant. The results are

summarized in Table 2. Table 2 shows that the attributes which most often affected the decisions of the 35 mothers in the new neighbor condition were size, fiber content, and price. Table 2 also shows that fiber content and size were the attributes which most often affected the decisions of the 42 mothers in the best friend condition. Compared to the mothers in the new neighbor condition, price seemed to affect the decisions of fewer mothers purchasing gifts for a best friend. Few significant two-way interactions were found between attributes in either the new neighbor or the best friend condition.

Relative Importance of the Attributes

Hays' (1973) omega-squared (w^2) was used to evaluate the relative importance of the attributes in the decision-making of individual subjects. The average w^2 values for the mothers in each experimental condition are presented graphically in the Figure. It appears that the gift purchase

TABLE 2
 PERCENTAGE OF SIGNIFICANT ($p < .05$) EFFECTS FOR GIFT ATTRIBUTES: NEW NEIGHBOR
 AND BEST FRIEND

Attribute	New Neighbor (n=35)	Best Friend (n=42)	Total Sample (N=77)
Price	40%	21%	30%
Color	17%	19%	18%
Brand	14%	12%	13%
Fiber	57%	64%	61%
Size	69%	40%	53%
Fabric	11%	7%	9%
Quality	29%	19%	23%
Style	20%	21%	21%

decisions of mothers in both conditions were dominated by fiber content, size, and price. Style and quality seem to represent a second-tier of effects, and fabric, color, and brand a third tier.

Differences in Decision Making by Level of Involvement

A two (level of involvement) x eight (attribute) ANOVA was performed on the w^2 values to determine whether or not the gift purchasing strategies differed by intimacy of the relationship. The result showed a significant effect for attributes ($F [7,525] = 16.45, p < .05$) and no effect for level of involvement ($F [1, 76] = 2.92, p > .05$). There was, however, a significant level of involvement x attribute interaction ($F [7,525] = 2.84, p < .05$). The results of a post-hoc Scheffe' test demonstrated that there were differences in the use of the three dominant attributes -- fiber, size, and price. While fiber had more of an effect on the decisions of mothers purchasing gifts for a best friend ($w^2 = .32$ vs. $.18, p < .05$), size had a stronger effect on the decisions of mothers purchasing gifts for a new neighbor ($.20$ vs. $.10, p < .05$). Price appears to have been more important to mothers purchasing a gift for a new neighbor ($.15$ vs. $.08$); that difference was, however, only marginally significant ($p < .10$).

DISCUSSION

The results of this research provide insight into the tradeoffs among product attributes that consumers may be willing to make in gift purchase decisions. More important, the results lend support

to the Sherry (1983) model of consumer gift-giving, by demonstrating that gift-giving strategies may differ by level of involvement in the donor-recipient relationship.

Tradeoffs Among Product Attributes in Gift Decisions

The gift purchase decisions of the mothers were dominated by fiber, size, and price. Fiber content was the most important attribute. This may reflect both expressive and utilitarian qualities. Fiber content may be expressive because it is subject to fashion change, which is, in turn, associated with status. Examination of the marginal utilities for fiber content showed that all but one of the mothers whose decisions were affected by that attribute favored the 100% cotton garment. Because cotton is more fashionable than polyester (Rowland 1987), consumers may believe that it communicates a desirable impression of the status of the donor as well as the recipient. This suggests that, in making their decisions, the mothers engaged in what Sherry (1983) termed "impression management." Cotton also has utilitarian properties, such as comfort and absorbency, which may have affected the gift purchase decisions.

The dominance of fiber content may reflect the relationship between social norms and perceived expense observed by Warshaw (1980). Fashion is a social norm, so preference for, cotton, the more fashionable fiber, may have been related to the perceived expense of the jumpsuit. Had a more expensive gift been involved, the effect of fiber content might have been weaker. The importance of

FIGURE
AVERAGE W^2 VALUES FOR EACH GIFT ATTRIBUTE: NEW NEIGHBOR AND BEST FRIEND

fiber is consistent with the results of Horne and Winakor's (1988) study on Christmas gift-giving.

Size, which might be interpreted as a utilitarian attribute, was the next most important influence on the gift-giving decisions. This finding lends credence to Sherry's (1983) contention that utilitarian considerations may affect gift-giving, and to the results of Devere, Scott and Shulby (1983), who reported that the usefulness of an item is likely to be an important consideration in purchasing a gift. The marginal utilities showed that, among the mothers with a significant effect for size, all but two favored the six-month over the newborn. Given that newborns usually grow quickly, the mothers may have perceived the larger size to be useful for a longer period of time than the smaller size. Mehrabian (1972) suggests an alternative explanation. If size is associated with status, then giving a larger size may be one way of conferring status upon the recipient.

The importance of price is consistent with the results of previous research in which price was reported to be an important attribute in purchasing a gift (e.g. Belk 1979; Devere, Scott and Shulby 1983; Heeler, Francis and Okechuku 1979; Horne and Winakor 1988). It appears, however, that consumers may be less concerned with price than with either the status communicated by an item or its usefulness.

Quality and style appeared to be attributes of secondary importance. Quality was reported by both Belk (1979) and Devere, Scott, and Shulby (1983) to be an attribute of importance in purchasing gifts. The results of this study support their finding, but with the qualification that, compared to other attributes, quality seems to have a smaller effect. Both Devere, Scott and Shulby (1983) and Horne and Winakor (1988) reported that style affects gift-giving decisions. The results of this research indicate that, relative to other attributes, the effect of style is not large. This may be related, however, to the situational context, in that participants were told that the shower was being held for the mother of a baby boy. Although one function of gift-giving is socialization, sex-role socialization may not begin in earnest until a child is older. Consequently, style may be of less importance than other attributes in gifts of clothing to infants. The marginal utilities showed that all but one of the mothers who had a significant effect for style preferred the classic jumpsuit. This may reflect the fact that fashion continues to have less effect on the clothing of males than the clothing of females (Hyde 1988).

Color, brand, and fabric appeared to be the least important of the gift-giving attributes. In Horne and Winakor's (1988) study, color was reported to be important in gifts of clothing. The results of the conjoint analysis suggest, however,

that compared to other attributes, the effect of color is small.

Andrus, Silver and Johnson (1986) reported that consumers are willing to pay a higher price in order to purchase a status brand as a gift. The results of this research indicate that, compared to other product attributes, brand may have little effect on gifts of clothing. The importance of fiber, relative to brand, suggests that physical attributes of a product may communicate more about status than does brand. The price x brand interaction was tested, and 16 (21%) significant interactions were observed across the two experimental conditions. In most cases, the mothers preferred to pay less for LaCoste, the higher status brand. The w^2 value for this interaction was, however, negligible. Although the Sproles (1979) model suggests that fabric is one of the "critical characteristics" in purchases of clothing, this attribute had little effect on the gift purchase decisions of the mothers in the sample.

Comparison of Gift Decisions by Intimacy of Relationship

Differences were observed in the relative importance of fiber, size, and price in the best friend and new neighbor conditions. Mothers giving a gift to a best friend were more likely to use fiber, and less likely to use either size or price, than were mothers giving a gift to a new neighbor. This lends support to the Sherry (1983) model, which suggests that gift-giving decisions differ by the closeness of the donor-recipient relationship.

According to Sherry (1983), gifts may be either expressive or utilitarian. Expressive gifts are more likely to be given in close relationships, and utilitarian gifts more likely to be given in distant relationships. The use of the gift attributes by the mothers in the two conditions appear to reflect this. Fiber might be considered the more expressive of the two attributes, because it may communicate information on the status of both donor and recipient. Since natural fibers (e.g. cotton) are perceived to be more fashionable than synthetic fibers (Rowland 1987), a gift of a natural fiber garment might be seen as one way of communicating the importance of a relationship. Size might be considered the more utilitarian of the two attributes. Consequently, the decisions of mothers in the new neighbor condition, in which the relationship was distant, were more strongly affected by size.

An alternative explanation for the importance of fiber in the best friend condition might be that consumers make purchases for close friends in much the same way that they make purchases for personal use. Ettenson, Wagner, and Gaeth (1988) found fiber content to be a dominant attribute in decisions involving purchases of clothing for personal use. Heeler, Francis and Okechuku (1979) reported that, in making purchases of gifts for close friends and purchases for personal use, consumers access similar types of information. This interpretation is consistent with the anchoring and adjustment model developed by Davis, Hoch and Ragsdale (1986), in

which both husbands and wives were found to anchor their predictions of spousal preferences on their own preferences.

Although the difference was marginal, price appeared to be less important to mothers purchasing gifts for best friends than to mothers purchasing for a new neighbor. Both Sherry (1983) and Caplow (1983) suggest that the value of a gift may reflect the importance of the relationship. This implies that a more expensive gift might be preferred in a closer relationship. However, the less expensive jumpsuit was favored by all of the mothers with a significant effect for price, regardless of level of intimacy. Low cost of the jumpsuit was, however, of more importance to the mothers purchasing a gift for a new neighbor than to mothers purchasing a gift for a best friend. In light of the importance of fiber content, it appears that for some gifts, there may be attributes more effective than price in communicating the importance of a relationship. The difference in the importance of price between the best friend and new neighbor conditions lends support to the work of Belk (1982), who reported that the amount of money spent on gifts is likely to vary by level of involvement.

CONCLUSIONS AND IMPLICATIONS FOR FUTURE RESEARCH

The results of this research contribute to development of the Sherry (1983) model and suggest directions for future decision-making research in a gift-giving context. Gift purchase decisions were studied in the context of a shower gift to be given to either a best friend or a new neighbor. The results demonstrated that the use of product attributes by the participants differed in the two situations. Thus, it appears that the gift-giving decisions of consumers differ by level of involvement in the donor-recipient relationship.

Four directions for future research are suggested. This study was limited in terms of sample size and range of products. Consequently, the most obvious extension of this research is to a larger, more representative sample of consumers and a wider range of products. A second extension of this research might involve using the conjoint method to compare gift-giving decisions to decisions involving purchases of goods for personal use. Given that gift-giving tends to be seasonal in nature, such information might be useful to the marketing establishment in planning seasonally-appropriate promotional strategies. A third avenue of research might be based on the anchoring and adjustment model of evaluative judgment (Tversky and Kahneman 1974). Davis, Hoch and Ragsdale (1986) used this approach to study spousal preferences. In that research, both husbands and wives were found to be not very accurate in their predictions of spousal preferences. It would be interesting to explore the accuracy of donor predictions of recipient gift preferences, by level of involvement. Finally, given the burgeoning of interest in family decision-making, the study of gift-giving decisions within the family, not only

between husbands and wives, but also between parents and children, presents intriguing possibilities.

Gift Giving: Consumer Motivation and the Gift Purchase Process

Cathy Goodwin, University of Alaska, Fairbanks

Kelly L. Smith, Georgia State University

Susan Spiggle, The University of Connecticut

This paper proposes that the extent to which gift givers are motivated by primarily voluntary or obligatory motives shapes the gift selection, acquisition, and post purchase process. A pilot study utilizing a naturalistic data collection technique provides some empirical support for hypotheses developed from the conceptual scheme based upon obligatory versus voluntary motives.

Gift giving has been studied by a number of consumer behavior researchers. Earlier research focused on the differences between purchasing for personal use and for gift giving (Belk, 1982; Heeler et al. 1980; Scammon et al. 1982). More recently, researchers have suggested that gift giving is a multi-dimensional phenomenon. In his analysis of gift giving, Sherry (1983) suggests that gift giving has social, economic, and personal dimensions and develops a typology employing the nature of the gift, the relationship between donor and recipient, and situational conditions, such as holidays. Belk (1979) identifies four functions of gift giving: to mark important life events, to establish and maintain interpersonal relationships, to create a medium of economic exchange and to socialize children into the customs of society.

A number of questions about gift giving have been raised that are relevant to the field of consumer research. Lutz (1979) and Tigert (1979) both suggest that product category selection and pricing issues should be addressed. Banks (1979) suggests the importance of the gift search process, and Belk (1979) suggests the need to look at givers' perceptions of the recipient's needs and tastes. Sherry (1983) emphasizes the giver's motivation.

This paper addresses a number of these questions. It links product category selection, making decisions about time and monetary constraints, the search and gift selection process with the giver's motivation. The motivational dichotomy employed here is the distinction between gifts that are given because the giver feels an obligation and those which are given freely, without a sense of obligation.

In contemporary American society, perceived obligations of gift giving may arise from a variety of sources. In a corporate office setting, a feeling of obligation to contribute to a coworker's wedding may be created by the need for acceptance as a "team player." Families and friends create mutual obligations at holidays and often birthdays, as well as one-sided obligations at weddings, house-warmings, and graduations. People in dating relationships may develop gift giving customs to honor certain occasions and events such as Valentine's Day. The threat of strained relations caused by one partner's failing to honor the gift giving custom may create strong feelings of

obligation for both partners. Through such gift giving acts, individuals may be communicating affirmation of the relationship. However, the motive for affirmation is externally defined. Thus, the giver's motivation is generated by social obligation. Under such circumstances, the obligation to purchase a gift may be perceived as a threat to freedom, eliciting psychological reactance (Clee and Wicklund 1980), creating a negative rather than positive purchase experience.

In contrast to these occasions, people give gifts from what appear more voluntary motives: to cheer up a depressed friend, share a unique object found in the shopping mall, express apology, concern or affection. Voluntary gift giving can be manipulative or threatening rather than benign or altruistic (Schwartz 1967). For example, giving a child a set of warm clothes may imply that the parents are careless (Poe 1977), and a small sub-literature addresses the topic of patients who use gifts to manipulate or create a lasting bond with the therapist (e.g., Stein 1965; Orgel and Shengold 1968; Silber 1969; Kritzberg 1980). Culturally mandated gift giving (holidays, birthdays, weddings etc.) may be characterized by voluntary motives. That is, the predominant feeling of the giver may not be "I'd better give X a gift". Rather, the giver *may* be using the occasion as an opportunity to express sentiments through gift giving. In this case the giver's predominant sentiments are of communicating solidarity or affection, although failure to give would have negative social consequences. Accordingly, in socially defined gift occasions the giver's motive may be predominantly voluntary, predominantly obligatory, or some combination of the two. Thus, whether the precipitating conditions are culturally mandated, centering around widely recognized celebrations, or generated by individual relational dynamics, the giver may be motivated by feelings of obligation, or feelings of autonomy and control (voluntary giving). The voluntary/obligatory nature of gift giving may be best seen as a polar continuum with analytically distinct end-points. Any empirical act of gift giving may fall somewhere in between, not exhibiting characteristics of the pure type.

The point at which a gift-giving act falls on the voluntary/obligatory continuum may affect a variety of consumer behaviors. Belk (1979) observed that virtually all gift objects convey symbolic meaning; therefore, the choice of gift may be affected, as well as the price to be paid and the effort involved in gift selection. The outcome of the process may vary depending on whether the giver perceives the event as obligatory or voluntary.

The distinction between voluntary and obligatory gift giving as the dominant motive differs from that suggested by Sherry (1983). In his

3-stage model of gift giving, he distinguishes between altruistic and agonistic motives which occur in the initial stage of the gift-giving process and which presumably affect activities at subsequent stages. The agonistic motive is self serving (the wife seeking to regain affection from an alienated husband). The altruistic motive is selfless (the father expressing esteem for his child). In the motivational scheme presented here, these are both encompassed under voluntary motives. Sherry's scheme explicitly incorporates a situational variable--"formal or emergent precipitating condition," that may include the extent to which the initiating condition is structured by custom (the father's holiday gift), or not (a particular instance of marital discord). This variable, however, is presented as external to motivation (although shaping it) and is exogenous to his gift-giving model.

The motivational dichotomy presented here uses a more fundamental motivational distinction in that it subsumes Sherry's altruistic and agonistic dichotomy under the voluntary pole and proposes an opposite motivational pole that: (1) suggests a greater motivational contrast and (2) we think more significantly shapes activities in subsequent stages of gift giving.

This paper represents a pilot study which explores the distinction between obligatory and voluntary gift giving. In this empirical study gift giving at the polar ends of the continuum is explored in order to demonstrate how the obligatory/voluntary distinction operates to shape the gift giving process along dimensions relevant to consumer research--information search, monetary and time resource allocation, criteria for decision making, and selection.

MOTIVES FOR GIFT-GIVING

Symbolic messages

Gifts may convey a wide range of symbolic messages such as "the status of a relationship, a promise of future interaction, or a statement of love, concern or domination" (Poe 1977). Clinical psychologists and psychotherapists have identified needs of patients communicated by gifts, e.g., "The patient who presents the doctor with a plant may wish to remain rooted in the office" (Stein 1965); and "The gift...permitted a fantasy of symbiotic involvement with the therapist to be acted out via the gift..." (Silber 1969).

Gifts may represent symbols of a relationship: "A gift is a ritual offering that is a sign of involvement in and connectedness to another" (Cheal 1987, p. 152). Specific gifts may further delineate the nature of the relationship. For example, money may communicate a variety of negative messages, such as thoughtlessness (Webley et al. 1983) and unequal status (Poe 1977; Caplow 1982), while a practical gift given to a business associate communicates that the relationship is not intended to be close or intimate.

Gifts may also symbolize identities of the giver or the receiver. Schwartz (1967) suggests that, "Gifts are one of the ways in which the pictures that others share of us in their minds are transmitted," as when a parent gives a male child a gift of toy soldiers. Similarly, gifts can communicate the giver's identity, as in the "display of masculinity through the giving of gift cigars following the birth of a child." Identity may be expressed more freely when in non-ritual gift situations, and in some societies may represent a means of self-expression allowed only between intimates (Betteridge 1985).

Obligation

Mauss (1954) was one of the first to note that gifts often appear to be generously offered, but the "accompanying behavior" derives from "obligation and economic self-interest." Gift-giving obligations have been well-documented in primitive and archaic societies (e.g., Mauss 1954; Levi-Strauss 1964). Muir and Weinstein (1962) found that the concept of social obligation was familiar to all of their 120 adult female respondents of varying social classes. While all respondents indicated that they "like to do favors for others," only 8.9 percent indicated that they "like being obligated to others."

Individual reactions to obligations can be potentially important to researchers investigating consumption experiences. Poe (1977) suggests a number of consequences of psychological reactance experienced by the recipient; for example, the person who receives a set of skis may feel constrained to spend time on the slopes. However, it is not hard to imagine reactance occurring as part of an obligation to purchase a wedding gift, particularly if everyone in an office is "asked" to make a contribution. A giver may attempt to restore freedom (Brehm 1966) by limiting expense and effort associated with the requisite gift. Support for this association comes from Warshaw's (1980) contrast of the influence of norms on expensive and inexpensive gifts--a necklace or sweater compared to a box of candy and card. In an experimental setting, he found that evaluative attitudes (e.g., "It is good for me to buy Product X for someone") rather than norms (e.g., "Others who are important to me think...") influenced intentions to purchase expensive gifts, while evaluative attitudes and norms were equally correlated with intentions to purchase inexpensive gifts. Thus, gifts purchased from obligation might be associated with lower cost and less effort.

Two specific forms of obligation can be identified: *reciprocity* and *ritual*. Reciprocity in this context represents giving a gift as part of a mutual exchange or in return for another gift, as when family members exchange gifts at Christmas or wedding gifts over the course of their lifetimes. In contrast, some gifts may be given when there is no custom that would lead to a return gift obligation; for example, a married person may feel obligated to give a wedding or housewarming gift to

a new neighbor or colleague. In these situations, the giver expects no reciprocal gift.

A number of social scientists have emphasized the special social significance of reciprocal gift giving. Levi-Strauss (1964) cites examples of the potlatch functions of the Indians of the Pacific Northwest. Strauss (1964) notes that the exchange can be intangible rather than tangible, and that "a mysterious advantage" seems to be related to commodities obtained by reciprocal gift giving rather than commercial exchange. In effect, he seems to suggest, gift giving represents another form of distribution.

Gouldner (1960, p. 176) suggests further that "the norm of reciprocity thus provides a second-order defense of the stability of social systems," offering a basis for moral sanctions of otherwise unregulated transactions. Moreover, he suggests, reciprocity may take the form of deference or gratitude rather than another tangible gift.

Reciprocity norms are influenced by need and ability to reciprocate and by closeness of the relationship. Muir and Weinstein (1962) suggest that middle class recipients of favors feel stronger norms of repayment as compared to lower class recipients, who "help when they can." Schwartz (1967) suggests that a high degree of "correspondence" between gifts exchanged will be more likely to occur in low-sentiment relationships; however, he goes on to say, some level of reciprocity will be necessary if a relationship is to avoid domination by the exchange partner whose gift is greater.

Ritual represents another aspect of obligation. Poe (1977) noted that ceremony and ritual are present today as well as in primitive societies. A number of researchers have focused on the Christmas gift ritual (e.g., Caplow 1982, 1984; Moschetti 1979; Cramer 1977).

Rituals often are associated with reciprocity; Davis (1973, p. 164) notes that at Christmas, "the obligation is to match benefits simultaneously, by ingenious pre-estimation." Caplow (1982, 1984) uncovers detailed norms surrounding the selection, presentation and reciprocity of Christmas gifts; Cramer (1977), on the other hand, views Christmas giving as a means of atonement for past neglect or obligations and a freedom from norms of economy and thrift.

A specific act of gift giving may have elements of ritual (Valentine's Day), reciprocity (I expect you to give me a Valentine's gift), and symbolic communication (I enjoy expressing my affection for you). The following hypotheses have been derived from the preceding discussion to suggest how these elements might shape gift selection and the gift purchase process.

HYPOTHESES

H1. Gift selection will be more likely shaped by a desire to express recipient or donor identities when the gift-giving motive is voluntary rather than obligatory.

H2. Gift selection will be more likely shaped by the desire to communicate feelings of caring and reinforcing the relationship between giver and receiver, when motives are voluntary than when motives are obligatory.

H3. Consumers will report greater expenditures of time and effort associated with gift selection in the voluntary than the obligation motive.

H4. Consumers in obligatory gift situations will be more likely to expect tangible or intangible expressions of gratitude or reciprocity than in the voluntary gift situations.

H5. Consumers who give from a sense of obligation are more likely to select practical or utilitarian gifts as compared to those who give from a voluntary motive.

METHOD

Subjects were 90 graduate and undergraduate students at a large southeastern university. Despite their student status, these subjects appeared to be genuine consumers. Average age was 24.7 years (ranging from 19 to 41 years), and mean work experience was 2.2 years of full-time experience and 4.0 years of part-time. Fifty-eight percent were males.

Subjects were asked to identify a recent gift-giving experience, followed by a series of open-ended questions regarding why the gift was given; what, if anything, the subject intended to communicate with this gift; considerations which influenced search time and effort as well as price; and what, if anything, was expected in return. A final question, intended to elicit norms of gift giving, asked subjects, "If you were to advise someone from another society who was unfamiliar with gift-giving customs in a similar situation, what would you say?"

Two versions of the questionnaire were prepared and distributed randomly to subjects. In one version, subjects were asked to identify a gift experience "in which you felt obligated;" in the other, to identify a gift experience "in which you felt no obligation to give a gift." Questionnaires were completed in classroom or office settings in the presence of one of the authors.

A content coding scheme was developed by one of the authors. The coding categories were developed through a combination of a priori deduction from the conceptual background and inductive abstraction from inspecting over one half of the data. The final coding scheme consisted of between four and six abstract categories for each question. A precise definition was attached to each category. (See Appendix). Following Kassarian's procedures (1977), responses for each question were content coded by the other two authors working independently. Disagreements were resolved through

discussion. by two of the authors. Interrater reliability coefficient was 90%. Because some subjects failed to answer an occasional question, and because some responses fell into the "other" category, numbers of responses will vary among the analyses reported here.

RESULTS OF PILOT STUDY

Chi-square tests were employed to analyze the relationships between the ordinally scaled variables. It is noted that in some instances, small cell size may affect interpretation. However, where results are highly significant, we would expect to reject the null even with more exact tests.

Subjects reported giving gifts in a variety of relationship situations. Thirty-two percent of the males, as compared to 8 percent of the females, chose to report gifts to dates or spouses. Otherwise, males and females made similar choices of relationships. However, differences in relationships reported were significantly different for obligatory and voluntary giving (Table 1).

When the variety of relationships was grouped into three relationship types--close friends and spouses, family and casual friends/business

associates--Table 1 shows that, not surprisingly, gifts to casual friends and business associates were reported only in the obligatory category.

Hypothesis 1 was partially supported (Table 2). Surprisingly, respondents suggested that both voluntary and obligatory gifts were made for reasons related to caring or sentiment, such as "to say I care," "to say I love you," or "you are important to me." Similarly, both obligatory and voluntary givers used gifts to express the importance of the relationship and their own feelings, such as, "I thought it would make me happy," "To say I missed them and loved them," or, "to let them know I was thinking of them." However, obligatory gifts were more likely to be given in celebration of an occasion, and voluntary givers reported a higher likelihood of giving a gift "just because he's a nice person" or "she needed cheering up."

Twenty-four respondents indicated that the reason they gave the gift was from a sense of obligation (defined by answering why they gave the gift, rather than which version they filled out). When these respondents were compared with those who reported reasons based on recipient needs or characteristics, the difference between versions appears even stronger (Table 3).

	Time & Cost Constraints	Recipient Need	External Infl	Reject Constraints	Cost-Benefit Calculation
Voluntary	21	10	0	6	1
Obligatory	20	5	5	12	8

Chi-square = 12.74, $p < .013$

Hypothesis 2 was also partially supported (Table 4). Surprisingly, a large number of respondents in each motivational category indicated that they wished to communicate feelings about the quality of the relationship or the recipient. However, desires to mark the event ("because it's Christmas") and wishes to communicate "nothing" (when the word "nothing" was written explicitly) were reported almost entirely by respondents who completed the obligatory version of the questionnaire.

While no hypothesis was developed, Table 5 suggests that the nature of the relationship between receiver and giver also affects the type of communication expressed by a gift. While gifts to casual friends and acquaintances may either communicate feelings or simply mark an event, gifts to family and close friends almost all tend to communicate relational qualities or emotional states. As the numbers are small, however, this finding should be interpreted cautiously.

Hypothesis 3 was also partially supported (Table 6). Although caution is required to interpret significance due to the number of cells with counts below 5, this pattern of responses suggests that financial and time constraints were salient to the majority of respondents in both categories, possibly (but not necessarily) due to their student status. However, 26% of voluntary givers mentioned recipient needs as compared to 10% of obligatory givers. Ten percent of voluntary givers mentioned external definitions of what was appropriate ("I didn't want to appear cheap" "spending less would have been tacky" "That amount was expected of me" "with her expensive tastes anything over \$50 would be a good gift"). Sixteen percent of obligatory givers explicitly mentioned some calculus having to do with the importance of the relationship and what was expected in return ("the dollar value depended on how well I knew and liked the person" or "they always gave me good stuff so I had to get them something decent" or even "she wasn't that great of

a friend") compared to only 3% (1 respondent) from the voluntary category. Voluntary givers were more concerned with the recipient in their calculations. One giver reported looking for an inexpensive gift for a spouse on an occasion which was not a major gift-giving occasion for them, stating, "I wasn't sure he was giving me anything and didn't want him to feel badly if he didn't."

Eighteen respondents explicitly rejected time and/or money constraints with such statements as, "Money was not an issue; whatever gift I saw was the one that I would get." Surprisingly, two-thirds of these responses came from obligatory givers and one-third from voluntary givers. Further research will be needed to explore whether strength of norms is sufficient to override financial and time constraints, or whether these respondents are experiencing some form of reactance: while they are obligated to give a gift, they retain their freedom to spend as much time and money as they please. Additionally, people reported giving obligatory gifts to less familiar recipients (casual friends, business associates) where it is more difficult to assess recipient needs; therefore more time and money may be required to select an appropriate gift. Further, wedding presents to casual friends or business acquaintances may be politically motivated and therefore involve greater risk, thus justifying greater expenditure of time and money.

Hypothesis 4 was also partially supported (Table 7). Voluntary givers were more likely to expect an emotional response, such as "expressions of affection," "a smile," or "just to see her happy." However, approximately 14% of each category of givers expected verbal expressions of gratitude, such as, "a thank you note," or explicitly stated "gratitude." On the other hand, 31% of the obligatory givers expected tangible gifts, compared with only 2% of the voluntary givers. This result

may be due to norms of the obligatory situation, such as Christmas. Surprisingly, 31% of the obligatory givers but only 20% of the voluntary givers explicitly resisted reciprocity, with such statements as, "I don't expect anything in return," or, "I don't give gifts to get something back." Again, the obligatory givers may be attempting to reclaim freedom from norms of the gift exchange process as an expression of psychological reactance.

Hypothesis 5 seems to be supported (Table 8), although the significance level of the results considering all types of gifts ($p < .113$) suggests caution. Gifts were classified into four categories: clothing; lasting gifts, such as jewelry or artwork; toys and board games; and "practical" gifts, such as kitchen appliances, linens, calendars and pen-and-pencil sets, as well as other gifts which did not readily fit this classification. As only half the responses fit these four categories, the numbers are extremely small. However, of eight respondents reporting "practical" gifts, seven were obligatory gifts. The small size of the sample suggests further investigation.

Norms Identified by Respondents

Respondents were asked as a final question, "If you were to advise someone from another society who was unfamiliar with gift-giving customs in a similar situation, what would you say?" Responses were coded into 8 categories, including recommendation to give a specific gift, recipient needs, benefit to the giver, such as a way to express feelings, a general moral imperative ("better to give than to receive" or "it's the thought that counts"), custom, specific shopping recommendations ("Go to the mall" "If unsure ask a middle-aged female"), explicit rejection of obligation ("don't give a gift just because you feel you should" and "Don't have expectations about what you'll receive in return or

TABLE 9
Norms Identified by Respondents

Advice to Others	Frequency	Percent

Moral imperative	21	27%
Custom	9	12%
Shopping recommendations	4	5%
Rejection of obligation	8	10%
Non-altruistic comments	2	3%

you'll be disappointed") and non-altruistic comments ("Make sure you'll be getting back at least as much as you've been given" or "Give less than what you expect to get back").

Table 8 summarizes the responses. Clearly, subjects expressed or strongly supported altruistic norms, focusing on benefits to both giver and receiver. Of the 8 subjects who explicitly rejected norms of obligation, 7 completed the "obligatory" version of the questionnaire, again suggesting the occurrence of reactance. Otherwise, differences between versions were minimal and non-significant ($\chi^2 = 7.9, p < .34$).

Males and females did not differ significantly with respect to categories of norms identified ($p < .17$). However, 43% of the males compared to 17% of the females suggested moral imperatives; in contrast, 30% of the females but only 15% of the males suggested norms involving attention to needs of recipients. ("Giving gifts makes others happy when they are not"). Differences in age were also not significant among categories of norms identified; however, the mean age of those identifying norms associated with "custom" was 23.22, while the mean age of those who explicitly rejected obligation was 23.5. On the other hand, the mean age of those who indicated attention to recipient needs was 27.4. It is possible that younger subjects experience both greater concern with customs as well as greater perceptions of threats to their freedom when complying with customs. However, due to the limited age range, interpretation must be speculative, suggesting guidance for future research.

SUGGESTIONS FOR FUTURE RESEARCH

This pilot study suggests that consumers tend to define gift giving as obligatory or voluntary, and this distinction affects their the gift selection process and post-purchase behaviors.

Several implications are proposed for future research. First, a variety of psychological reactions may follow an obligatory act of gift giving. Considerable research has demonstrated that reactance may occur when an individual's freedom is threatened (Clee and Wicklund 1980); in this case, anticipated freedom of purchase and gift giving is

curtailed by obligations of gift giving, which may involve norms associated with choice of gift object, price, and presentation--even selection of retail outlet, as in the case of bridal registries. While the potential for recipient reactance has been identified (Poe 1977), reactance may represent a useful framework to explore gift-giving behavior in obligatory situations. The occurrence of reactance seems to explain differences in search and price preferences identified in this and other studies (e.g., Warshaw 1980). Furthermore, reactance may influence satisfaction of both giver and recipient following completion of the process.

On the other hand, the act of gift giving, whether voluntary or obligatory, may represent an act of public commitment (Kiesler 1969). In this case, the giver will be likely to express more positive feelings for the recipient following purchase of a gift. Such reactions presumably are desired outcomes of ritual exchanges of names for gift giving in offices and fraternal organizations.

Second, consumer researchers may wish to explore non-altruistic motives of consumption, or the "poisonous" gifts colorfully described by Orgel and Shengold (1968). Such research might best be carried out from the recipient's perspective, as even the psychotherapists note that these motives are often unconscious. As Belk (1979) observes, few gifts are rejected, and gifts often seem to mark the status of the recipient. The possibility that a recipient may resent a gift, and even wish to dissociate his self-concept from a gift, suggests a category of experiential post-purchase consumption activity that warrants further study. A related question involves attribution of gift-giving motive: is an obligatory gift experienced the same way as a non-obligatory gift? Belk (1988) suggests that possessions take on meaning within a household; for example, items in a collection take on aspects of the sacred.

Third, this study represents a pilot conducted with student subjects. A study encompassing a wider range of ages would be useful to identify developmental responses to gift giving. In this sample, it was noted that subjects who associated gift-giving norms with custom or resistance to obligations tended to be younger than those who professed more altruistic norms, such as concern for

APPENDIX
Coding Scheme

Why did you give the gift?

1. Occasion -- gave because it was person's birthday, or wedding reference to occasion without reference to obligation
2. Obligation -- may refer also to occasion; felt obligated; they gave me a gift; receiver expected it
3. Receiver need or characteristic -- receiver depressed, receiver a nice person; No mention of relationship or expression
4. Giver sentiment -- thought it would be nice; would make me happy; this relation is important to me; BUT NO mention of desire or attempt to express this through the gift
5. Expression of giver sentiment/relationship -- giver wants to say I care about you; you are a nice person, you are important to me
6. Does not fit; no answer

What did you expect in return?

1. Emotion -- expression of delight, happiness, other emotional state which giver can enjoy: NOT gratitude
2. Gratitude -- expression of gratitude, thanks; emphasis more on recipient acknowledgement of giver generosity
3. Resistancy to reciprocity -- explicit rejection that giver expected anything from receiver
4. Reciprocity -- receiver expects gift, or some object of value in return
5. Does not fit; no answer

What advice would you give someone in a similar situation?

1. Gift object -- recommendation to give a particular type of gift
2. Recipient need or characteristic -- recommendation to give gift that receiver needs, wants; or find out what it is; or give gift receiver would not buy self; or will make recipient happy; focus on the right gift for the person
3. Benefit to giver -- focus upon positive feelings that giver gets from giving, making someone happy, etc.
4. Moral imperative -- focus on moral note: better to give than receive; it's the thought that counts; and similar though unfamiliarly phrased ideas
5. Custom -- focus upon norms and customs of gift giving
6. Does not fit; no answer

the recipient. A wider age range might produce even greater diversity.

Many researchers associate rituals with holiday and other society-wide events. However, groups of friends may develop informal gift-giving rituals which can be associated with strong obligations. For example, sororities often have rituals involving gifts of flowers or exchange of gifts between members. Families within a neighborhood may start their own "potlatch" in the form of a series of potluck dinners. Groups of friends may develop elaborate norms of gift giving within their own circles. The origin and development of these small-scale norms represents a fruitful area of research as a sizeable segment of people look to informal social associations for social rewards.

Finally, gift giving has been shown to be of great economic significance in both modern and premodern economies and of social significance in all societies. Given its importance, consumer researchers may profitably pay more attention to gift giving as it shapes variables of significance to consumer researchers--product selection, search behaviors, allocation of resources, and post purchase experiences. We suggest that the obligatory/voluntary dimension is especially fruitful

for understanding the dynamics of these consumer behavior variables.

Motivations and Symbolism in Gift-Giving Behavior

Mary Finley Wolfinbarger, University of California, Irvine¹

ABSTRACT

The premise of this paper is that gifts are more valuable to participants for the symbols involved than for the material benefits exchanged. Utilizing the perspective of symbolic interactionism, this paper focuses on the motivations of givers and the symbols they choose. Through the use of gift-giving literature as well as an exploratory study, three types of motivations for giving--altruism, norms, and self-interest--are investigated and related to the symbolism found in gifts.

INTRODUCTION

Studies of gift-giving have proliferated in anthropology, social psychology, and sociology and each of these disciplines has developed a particular framework for studying gift-giving. Anthropologists have focused on gift-giving as a "total social fact," in other words, as a medium for social as well as economic exchange (cf. Levi-Strauss 1965, Mauss 1954). Sociologists have been interested in gift-giving from the perspective of "norms" of giving, social responsibility, and reciprocity (cf. Caplow 1982, 1984). The most promising approach, however, has been that derived from social psychology; this approach focuses on gift giving as an opportunity to express the giver's perception of both him or herself and the receiver, or more broadly, as complex movements in the management of meaning (cf. Cheal 1988, Schwartz 1967, Schieffelin 1980). This viewpoint is consistent with a more general research paradigm known as symbolic interactionism.

Faced with the vast heritage afforded them by these other disciplines, marketers have taken diverse approaches to their study of gift-giving. Some studies have been mainly descriptive (Scammon, Shaw and Bamossy 1982, Jolibert and Fernandez-Moreno 1983, Heeler, Francis, Okechuku and Reid 1979, Devere, Scott and Shulby 1983), while others have been conceptual (Banks 1979, Belk 1976, 1979). Only Belk (1976, 1979) has been consistently conceptual and empirical. However, Sherry (1983) has called for more exploratory research to form a basis for conceptual and empirical work (1983), a call which has been at least partially heeded (Sherry and McGrath 1989).

The first subject of this article is the motivations receivers attribute to giving, a topic which has been virtually untouched by marketers, and a task which Lutz (1979) has referred to as "opening the black box." From a search of the gift-

giving literature, three general (not necessarily mutually exclusive) categories of motivations have been identified: (1) self-interested giving or "indebtedness engineering," (2) compliance with social norms and (3) altruistic giving, or "pro-social" behavior.

Admittedly, anthropologists have studied the motivations for giving in depth in primitive cultures. However, in primitive cultures, the gift was equally economic and symbolic. In societies with well-developed markets, it is hardly surprising that the gift has been at least partially stripped of its economic importance, leaving in a much more prominent position the symbolic value of gifts. As a result, the symbolic value in general, and more specifically, the symbolic statement that gifts make about the giver, the receiver, and the relationship between the giver and the receiver are important topics in gift-giving research. Therefore, a second focus of this article is the general symbolic functions of gifts (revealed in the interviews) and more particularly, the ability of gifts to symbolize the giver, the receiver and/or their relationship. The primary function of gifts in modern society is symbolic; this must be true because people are generally the best judge of their own wants and needs and would obtain more functional benefit through self-purchase (Tournier 1963). As a result of the symbolic nature of gifts, the perspective of symbolic interactionism (SI) is particularly well suited to studying gift-giving.

Symbolic interactionism is a viewpoint which hails from social psychology (cf. Charon 1985, Cooley 1902, Hewitt 1988, Mead 1934, Stryker 1980, Wicklund and Gollwitzer 1982, Wood 1982). This perspective was introduced into marketing by Solomon (1983), who has pointed out that SI stresses the importance of product symbolism as a mediator of self-definition and role performance. The central tenet of SI is that people communicate with symbols. Consistent with this notion, Belk (1979) has characterized gift giving as a process of symbolic communication where the gift is both message and medium, providing support for the use of symbolic interactionism in the study of gift-giving. Utilized in the realm of gift-giving, SI aids in explaining how gifts are symbolic of (1) the giver's self (2) the giver's concept of the receiver, (3) the role of the giver and the receiver in their relationship, and (4) how gift symbolism is used by givers.

This article will begin by discussing the exploratory study utilized to comprehend gift-giving in spousal dyads. Then, the motivations for giving will be reviewed. Finally, the symbolic aspects of gift-giving will be investigated.

THE EXPLORATORY STUDY

The salience of each of the motivations as well as the more general communication aspects of

¹The author would like to thank Mary C. Gilly and Cornelia (Connie) Pechmann, University of California, Irvine for their comments on earlier versions of this paper.

gift-giving were investigated through interviews with 18 subjects (9 couples), married over 25 years. Married couples were chosen so that both sides of a gift-giving relationship could be studied. Subjects were located utilizing contacts made through a major Southern California University's Executive MBA program, and one couple consisted of a Ph.D. student and his wife. Because the study was exploratory, no attempt was made to obtain a representative sample. Couples had been married anywhere from 25 to 46 years.

The interviews were semi-structured, and ranged from 30 minutes to an hour. The following topics were covered in the interview: (1) feelings about gift-giving in general (2) the success of self and spouse in choosing gifts (3) a detailed story about the respondent's favorite gift from their spouse and (4) a detailed story about the gift the respondent felt would be their spouse's favorite gift. It was hoped that favorite gifts would be more memorable, elicit more details, and unearth the most salient aspects of preferred gifts. The drawbacks of utilizing favorite gifts were the fact that three respondents did not have a favorite gift, and secondly, some details of the occasion (and even the occasion itself) had been forgotten over the years. An alternative would have been to ask them about the most recent gift; however, the symbolic aspects of a random gift were likely to be less rich than those of a favorite gift. Asking about favorite gift most likely biased the likelihood that respondents would choose an object based more on symbolic rather than functional attributes (Wallendorf and Arnould 1988). A second bias towards more symbolic gifts was introduced because as Americans age, they are less likely to choose functional objects as favorites (Wallendorf and Arnould 1988). Nevertheless, because symbols were of particular interest in this study, no attempt was made to overcome these difficulties.

Interviews were tape recorded and later transcribed. The interviews were analyzed by exploring the gift-giving stories for recurring themes. Although the questions did not explicitly explore historical aspects of the gift-giving relationships, historical trends were reported by respondents. For instance, the amount of gifts exchanged appeared to have declined significantly for people married over 40 years (2 couples), whereas for those married from 25-30 years, 3 wives reported that their spouse's choices of gifts had improved significantly in the last 10 years or so.

One major shortcoming of the exploratory study is that it did not focus on gifts that respondents did not like. It was felt that, in personal interviews, many respondents would be reluctant to dwell upon their least favorite gifts. An innovative curative for this drawback would be to cull anonymous letters about gift-giving situations from advice columns and content analyze them for recurring themes.

MOTIVATIONS FOR GIVING-- OPENING THE BLACK BOX

Altruism as a Motivation for Giving

Leeds (1963) defines an altruistic act as one which a) is an end in itself, not directed at gain, b) is emitted voluntarily, and c) does good. For many, "To bestow freely is the *sine qua non* of a gift" (Barnett, 1954). Moreover, one of the major differences between giving in primitive and modern society is the presence of self-sacrificial motives in giving (Lowes, Turner and Wills 1971, Shurmer 1971). Altruism especially arises when a receiver appreciates a gesture, but as with a first gift (Simmel 1950), cannot entirely return the favor. Heider (1958) hypothesized, and Tesser, Gatewood and Driver (1968) found evidence, that gratitude was stronger when recipients perceived that the giver sincerely expected little or nothing in return.

Spouses uniformly felt that their favorite gifts had been given out of the desire to show love (an altruistic motive). These gifts were quite often complete surprises, and were often described as something that the giver normally would not buy. Furthermore, most of the favorite gifts often had cost the giver much sacrifice, either in terms of the relative affordability of the gift, or the time, effort, and thought that the gift had taken. For instance, one woman had saved for months out of her small personal budget to buy her husband a very special silver bracelet which she had to put on layaway for 6 to 8 months in order to pay for it. One husband saved \$6000 in an account from outside consulting work, and used it to surprise his wife with a trip to San Francisco in order to choose a specially designed ring.

Besides the more general motive of expressing love for the receiver, more specific motives could be identified. The two motives revealed in the interviews included the reparation of loss experienced by the receiver (not caused by the giver), and the altruism of the receiver. The reparative motive is especially consistent with the theory of symbolic self-completion espoused by Wicklund and Gollwitzer (1982), except that in giving gifts, someone else (the receiver) is "completed" rather than one's self. One spouse reported giving a ring to her husband after he lost a valued ring received from his father. The same woman reported that her favorite gift was a wedding ring her husband purchased after she had lost her first ring. A different kind of loss is apparent in a story told by a colleague who reported that her favorite gift from her husband was a bracelet (inscribed with a "River of Life" pattern) she received to ameliorate her sorrow after her uncle died. Another woman reported that a six-week vacation for her and her husband in Puerto Rico was a reparation for his long absence on a worldwide speaking trip, and her grief over the death of her stepmother. As for the motive related to the altruism of the receiver, one spouse reported that she seldom bought for herself. Her spouse therefore bought her many gifts to compensate for the fact

she bought herself so little, and possibly also to show his appreciation for her selflessness.

Unfortunately, there are several difficulties with construing gifts as altruistic acts. Altruism can only be attributed to donors, not established (Krebs, 1970). Even blood donation (generally believed to be the exemplar of altruistic giving) was found to be encouraged more by messages emphasizing benefits to the blood donor than by messages emphasizing other-oriented benefits (Barnett, Klassen, McMinimy and Schwartz 1987). Furthermore, Belk (1988) maintains that altruism can be explained as "aggrandizing a broader level of self...the broader communities incorporated within the self (p. 154)." Perhaps it is more important in understanding gift-giving behavior that receivers attribute altruism to givers, than that such altruism can (or cannot be) definitively established.

Gift-Giving as A Norm

The strength of the norm of giving on occasions was displayed in a study wherein respondents were asked to contemplate the possibility of *not* giving gifts at Christmas. Only 6% would consider this, expressing their feeling that relatives, children, and friends would feel forgotten and unappreciated (Lowes et al. 1971). The guilty feelings which were expressed by respondents are due to the fact that the norms of gift-giving in part flow from the role they play in marking relationships within a family social network (Caplow 1982, Poe 1977, Sahlins 1972, Titmuss 1971).

In addition to marking relationships, gifts also mark life events as they accompany various rites of passage. The recipient of such gifts often receives items which will enable him/her to perform in a new role, and thus these items often symbolize the new role as well as social support for the new role occupant (Schwartz 1967). In that symbolic interactionism focuses on the concept of role (cf. Hewitt 1988), SI can be utilized to enhance the understanding of the link between gift-giving and roles. Roles of the giver vis a vis the receiver are highlighted in gift-giving in several ways. First, gifts are often given to support performance of newly acquired roles, such as the baby stroller given to the expectant parent. Consistent with the notion that gifts are sometimes given to support role performance, empirical research has found that household goods are the predominant wedding gift (Lowes et al. 1971).

Moreover, gifts are also ceremonial tokens which are given in recognition of role status (the watch given to a retiree) and recognition of achievement (medals given to Olympians, diplomas given to graduates). In this respect primitive and modern societies are similar. One gift in the exploratory study was ceremonial; it was a jewel, which had been funded in part by a volunteer organization in order to commemorate one respondent's term as head of that organization.

One cue that transmits information about appropriate gifts is the intimacy of the relationship

between giver and receiver. The closeness of the relationship defines the appropriate role of the giver with respect to the receiver as either a friend, a close friend, a parent or a spouse. A closer relationship makes more intimate (Belk 1979) and more expensive gifts appropriate. Consistent with this proposition is the fact that in the interviews conducted with spouses (generally the closest of relationships), the most frequently reported favorite gift item was a piece of jewelry, or a watch (11 of 18 respondents). These items are simultaneously expensive and intimate.

A final comment on norms is their probable attachment to specific gift-giving situations. Utilizing a 3-mode factor analysis in order to simultaneously classify types of givers, recipients/occasions and gift characteristics, Belk (1979) came up with 5 classifications of gift-giving situations which in all probability transmit messages to gift givers about appropriate behavior. However, it remains to be proposed what kinds of norms each of these situations transmits, and how they impact gift decisions. Chase (1984) hypothesizes that scale (the importance of the event) varies directly, and periodicity (how often the event occurs) varies inversely with the expense of gifts. For instance, weddings frequently garner the most expensive gifts as they are large scale, low periodicity occasions. Important, low periodicity occasions in the study were 60th birthdays (2), 15th, 25th, and 30th anniversaries (3), and recognition of a major achievement (1).

The norms attached to giving, however, are sometimes violated. This is most likely with expensive gifts (Warshaw 1980), and in close relationships, wherein the giver and receiver feel free to make their own rules. One woman reported that if she had cared about receiving gifts on birthdays and anniversaries, she and her husband would have been divorced long ago, because he only enjoyed spontaneous giving. Also, the general "norm of giving" was similarly violated between two of the couples who no longer felt compelled to buy each other gifts on occasions.

Self-Interested Giving

To many authors, the only motivation for giving is self-interest, or as Firth (1983) would have it, "indebtedness engineering." Bourdieu (1977) and Levi-Strauss (1965) agree that gift-giving is simply an exchange in which non-functional attributes are given relatively greater weight, with the "payoff" consisting mostly of social recognition. Scholars in the area of gift-giving have suggested several benefits self-interested givers may desire:

1. to establish wealth and status (or more generally, achieving goodwill by impressing receivers with gifts) (Belshaw 1965, Veblen 1926);
2. as a correlate of (1), the desire to advance one's consumption scale (Chase 1984, based on Douglas and Isherwood 1979);

3. to reinforce relationships that are highly valued, but insecure (Caplow 1982, 1984);
4. to garner the social recognition as a philanthropist one may achieve through giving (Kerton 1971);
5. to ingratiate one's self with the receiver, in part by extending one's self into the other's life through a gift (Sartre 1943, Belk 1988);
6. the lessening of guilt for not achieving the ideal of brotherhood to man (Barnett, 1954).

The most general utility obtained by the self-interested giver is the creation of receiver indebtedness. The creation of obligation was central to Mauss' (1954) analysis of gift-giving in primitive societies. Similarly, Barnett (1954), in his analysis of Christmas gift-giving from the 1800s to 1950s in the United States, comments on a similar phenomenon, calling it "psuedo-giving" and a "polite form of bribery." When a gift is perceived as being given to obligate the receiver, the giver "becomes a depriver about whom various degrees of ambivalence may emerge" (Schwartz 1967, p. 88).

The mechanism through which obligation is created is the norm of reciprocity (Gouldner 1960). Research by Belshaw (1965) and Ryans (1977) is supportive of the idea that reciprocity is an important element of gift-giving, and that gift-giving participants lean towards the ideal of fair exchange. However, reciprocity is not strictly maintained. Two factors determine reciprocation: the resources of the donor, which determine relative sacrifice, and the motives that receivers attribute to the giving (Heeler et al. 1979, Banks 1979).

Furthermore, the ideal of giving as disinterested sacrifice permits unbalanced accounts to be maintained "without rancor" (Pryor and Graburn 1980). In support of this idea, in his study of gift-giving in Middletown, Caplow (1982, 1984) found that reciprocated gifts do not have to be of equal value, and that in 4347 gifts (no number is given for those that were not reciprocated) at Christmas, there were no expressions of anger or disappointment when gifts were not reciprocated. Moreover, an unwillingness to be obligated on the part of the recipient can be shown by immediate reciprocation, thus transforming the gift into an economic, not a social transaction (Blau, 1964).

Taken together, this evidence indicates that gifts do not obligate recipients in the same fashion as market exchange. Finally, almost 80% of the gifts in Middletown at Christmas were given to relatives, and the 20% given to non-relatives were much more likely to be token gifts. In relationships with relatives, givers are unlikely to have as a primary motive the creation of obligation. Therefore, the importance of self-interest in giving has most likely been overestimated by researchers. Perhaps a study of "least favorite gifts" would be more enlightening in investigating the extent and prevalence of self-interested giving.

THE SYMBOLIC CONTENT IN GIFTS

Several consumer behavior researchers, along with social psychologists, have recognized that gift-giving is an intrinsically semiotic activity (Belk 1979, Mick 1988, Poe 1977, Schieffelin 1980, Schwartz 1967, Sherry 1983). The idea that people communicate with symbols is the central tenet of symbolic interactionism (Hewitt 1988); the process by which symbols are utilized is similarly central to understanding gift-giving. Gift-givers, like advertisers, are creative directors in the management of meaning, seeking, through the principle of contiguity, to shift meaning from what McCracken (1986) refers to as the "culturally constituted world" to the chosen gift. One example of symbolism can be noticed in the *faux pas* that results when price tags are not removed. Even in the case when a recipient knows the price of a gift, the tag will be carefully removed (Shurmer 1971), the removal of the tag symbolizing the non-market, non-economic ideal embodied by gift-giving.

One symbol commonly attached to gifts is uniqueness (Sherry and McGrath 1989). In the exploratory study, both the giver and the receiver of a cocktail ring described it as "one-of-a-kind." Similarly, the brooch a woman received for being head of a volunteer organization was unique because it was three-dimensional (unlike the jewels made for the past recipients).

Another symbol attached to many of the gifts was togetherness. Those to whom we give are symbolically included within group boundaries (Belk 1979, Schneider 1981). Although many of the favorite gifts were valued because they were surprises, others were valued because the gift had been jointly chosen by the couple. A diamond anniversary ring, a replacement for a lost wedding band, a Seiko dress watch, a videocamera, a 6-week trip to Puerto Rico, and a series of trips one couple made to San Francisco to choose the emeralds and design for a \$2500 ring, were all gifts the respondents felt were especially memorable, in part because they had been chosen together, and thus were emblematic of the relationship between the giver and the receiver. This theme is also apparent in Wallendorf and Arnould's (1988) study of favorite objects in which the authors found that respondents with strong ties to other people often represented those ties in favorite objects.

A third symbolic theme discovered through the interviews was the idea that the gift was representative of a turning point in the couple's life together. One woman reported that she had always wanted a diamond when they "were poor," and had imagined getting one at some point in the future when they could afford one. Her husband surprised her with a \$4000 diamond for Christmas, about 10 years ago. She values the ring not only because she always wanted it, but also because it was a symbol that they had "made it." A colleague related a similar story in which her husband had given her a grandfather clock she always wanted at a time when they were finally financially comfortable. The clock

was symbolic not only of her relationship with her husband, but also of a turning point in their lives.

A last theme apparent in the interviews was the richness of symbolism often attached to favorite gifts. Layers of symbolism were evident in the gift of an emerald brooch. The gift was a crown and scepter pin which the respondent had recently received for being "Queen of the Nile," a volunteer organization run by Shriner's wives. Her husband had designed the emerald and diamond brooch, and a cousin (a jeweler) had made the gift. A flower in the brooch contained a single diamond, received from her husband three months after their marriage (now over 40 years ago) during a short weekend they spent together between his service commitments. The husband had spent his last dime on a ticket for his wife to come visit, and a diamond ring. The young wife had been impatient to become pregnant, and the ring was a reparation of sorts for their seeming slowness to conceive. The couple's first daughter was conceived that weekend. Another woman had her favorite gift (a diamond) put in a setting similar to that of her mother's wedding ring. Recently, she had inherited her mother's ring, and added the stone to her own. This theme of collapsing meaning into symbols is also evident in Olson's (1985) investigation of artifacts in the home. Olson explains this phenomenon: "Human experiences are so complex, people are forced to summarize them. One way of producing summaries is by means of symbols, which often take the form of visual representation" (p. 388).

Gift-Giving as a Symbol of Self and Other

Humans are social by nature and crave interaction and feedback from others (Mead 1934, Wood 1982). Each new gift provides communication from others that confirms and often extends the views of self developed through previous interactions. As a result, of all the gift's symbolic functions, the presentation of self (the giver), and other (the receiver) is the most obvious (Belk 1979). Gifts convey both the giver's self, and the giver's perception of the receiver (Schwartz 1967, Shurmer 1971).

Utilizing Holbrook and Grayson's (1986) approach of analyzing the consumption symbolism in art to augment an understanding of consumer behavior, the ability of a gift to symbolize the giver and receiver is apparent in the recent movie, *Working Girl*. Tess, a secretary with dreams of upward mobility, receives a birthday gift of sleazy lingerie from her boyfriend. Tess asks him why he doesn't ever buy her something she can wear *outside* the apartment. Clearly, Tess's boyfriend, Mick, views her as nothing more than a sex object. In contrast, Tess's new love interest, Jack Trainer, buys her a beautiful leather briefcase, thus symbolizing his appreciation of her business acumen. Later in the movie, Mick also gives scanty lingerie as an engagement gift to a couple. From this, the audience learns that not only does Mick view Tess as a sex kitten, but in addition, he thinks of all women as sex objects.

In an empirical study, Belk (1979) discovered that the largest influence on the gift chosen was the giver's ideal self-concept, followed by the giver's present self concept, and only thirdly by the perceived characteristics of the recipient (although the later two factors were also significant). One wife expressed this idea in explaining her inability to choose gifts her husband really liked, saying that she bought items she wanted him to have, rather than gifts he really wanted. Based on their qualitative research, Sherry and McGrath (1989) support the idea that gifts are predominantly based on self concept of giver, noting that customers of gift shops often said they would like to receive as gifts the objects they were purchasing for others.

A second semiotic element of gifts is the messages that they send about the receiver. When asked why a particular item was chosen for their spouse, many respondents said quite simply "It was him (or her)." One husband described at length a beautiful black velvet dress and jacket he had purchased for his wife about 20 years earlier. He had found the gift serendipitously, and given it spontaneously, paying a great deal of money for it because the dress "was beautiful... and it wore like iron... was just the right size...it was Connie." One respondent had passed a corner jewelry store where a silver bracelet caught her eye because it "was him...strong and traditional."

On the other hand, *poor* choices are often the result of a poor fit between the gift and the receiver. Caplow (1982), in his research, specifically identified clothing that is too large as the standard disappointing gift. The oversized clothing is most likely decoded by the receiver as a message by the giver that s/he is overweight. Similarly, a colleague felt that a cappuccino maker received from her boyfriend meant that he no longer considered her to be sexy. Finally, one couple in the study each mentioned an incident where she had received a frilly blouse from her husband that she did not like at all. When asked why she did not like the blouse, her husband replied, "I think it represented to her a woman she felt she wasn't."

Motivations and Symbolism in Giving

The results of the exploratory study suggest that motivations for giving may be related to the symbolism chosen by givers. Four categories of symbols are suggested by the exploratory research: (1) gifts which are symbolic of the self of the giver (2) gifts which are symbolic of the giver's perception of the receiver (3) gifts which are symbolic of convention and (4) gifts which are expressive, and have many meanings attached to them. More altruistic gifts should be symbolic of the receiver, while more self-interested gifts should be congruent with the self of the giver. Gifts symbolic in a conventional fashion should predominate when motivations for giving are norm-dominated. Furthermore, more expressive gifts should result when motivations for giving are altruistic.

Gifts are more likely to be perceived as self-interested when they are congruent with the giver's ideal or real self-image and additionally are incongruent with the receiver's self image. As an example of this phenomenon, Tournier (1963) tells a story about a man who collects pipes giving his wife a pipe for Christmas (a gift *she* did not consider to be altruistic). It follows that a gift that is inconsistent with the giver's self-image, but consistent with the receiver's will be perceived by the receiver as a truly altruistic gift. In support of these propositions, many favorite gifts were described as being bought in places the giver never goes, and as being objects the giver never purchased before. These gifts may have been perceived as more altruistic because they were something the receiver wanted, rather than something the giver wanted to give. Most gifts (as opposed to favorite gifts), however, are probably compromises between what the receiver wants, and what the giver wants the receiver to have.

The next step in gift-giving research is to identify which antecedent variables are most likely to lead to perceptions of particular gift-giving motivations. Based on these antecedents, and the resulting motivations for giving, different types of symbols are likely to be chosen for gifts. For instance, Belk (1979) has discovered that ideal self-concept and self-concept of the giver are more important than giver's concept of the receiver in predicting characteristics of gifts. However, it remains to be determined in what situations the giver's self-concept may be less or more important in choosing gifts.

CONCLUSION

Consumers are their own "creative directors" in the management of meaning. As in primitive cultures, exchange (both gift and other) is a system of meanings involved in the shaping of both personal and cultural meaning. Sharing items brings others into a shared microcosm, and into our extended selves. There are 3 general motivations a receiver may attribute to a giver: self-interest, norms, and altruism. Depending on these attributions, and the statements the receiver perceives the gift makes about the donor, himself, and their relationship, the receiver will feel more or less satisfaction, obligation, and desire to reciprocate.

The symbolic value of gifts (in market settings at least) appears to dominate the economic value of gifts, except possibly for philanthropic giving. Furthermore, benefits to the giver and the congruence of the item with the giver's self tend to dominate gift purchase, although benefits to other and congruence with the receiver's self are somewhat important in gift decisions. However, the more selfless the gift is perceived to be by the receiver, the more the gift tended to be congruent with the receiver's self image, and additionally, such gifts were often incongruent with the giver's self image. Givers and receivers are thus participants in a process most generally described as "the

management of meaning," although most participants hardly conceptualize gift-giving in this fashion.

Symbolism, Obligation, and Fiber Choice: The Macro to Micro Continuum of Understanding Gift Giving

Scott D. Roberts, Old Dominion University

INTRODUCTION

The papers in this session stand out as examples of how distinct micro and macro perspectives on consumer behavior research really are. The two anchor points or extremes of that continuum are represented by Wagner, Ettenson and Verrier (1989) and Wolfenbarger (1989), respectively, along with a description of gift giving which falls somewhere in between, provided by Goodwin, Smith and Spiggle (1989). The purposes of this paper are threefold, namely: 1) To offer a constructive critique for each of the presenters, 2) To draw out similarities and distinctions among the presentations, and, 3) to integrate (if possible) the knowledge gained here, or at least offer some sense of where we might go from here.

SYMBOLISM

Wolfenbarger (1989) does a fairly thorough job in reviewing prior work in the area of gift giving. She chooses as her approach to focus on symbolic interactionism within the gift giving process, an approach derived in the field of social psychology. This is fine, but I do not agree, and I think others would perhaps wince at her statement that this is "the most promising approach..." one might use when seeking to understand gift giving. In fact, in Wolfenbarger's conclusions we find vague comparisons with primitive cultures on exchange as "a system of meanings involved in the shaping of both personal and cultural meaning," suggesting that anthropology remains important for understanding gift giving. This serves as a reminder that it is often very difficult to unravel where the insights from one disciplinary perspective end and the insights offered by others begin. And while most consumer researchers have allegiances to one or perhaps a few disciplinary viewpoints, it seems that gift giving is a phenomenon which cannot be fully understood without treating it in a multidisciplinary way. Firat (1988) suggests, in fact, that scholars could fruitfully approach *all* their work in a multi-philosophical way. Thankfully, ACR operates with just that in mind.

Part of the method of the exploratory part of this study involves eliciting stories from married informants about favorite gifts they have received and given to their spouse. This open-ended, projective technique can produce data which are difficult to interpret, but when done well, the rich and full-bodied nature of the findings are well worth the struggle. Wolfenbarger's stories about a unique ring or a "Queen of the Nile" brooch, for example, really begin to give us some meaningful "meat" to hang on our skeletal understanding of what gift giving means and is.

INVOLVEMENT

In Goodwin, Smith and Spiggle (1989), the question of how felt obligation affects the giving of gifts is explored. Using open-ended responses to several questions about a recent gift giving experience, Goodwin, et al. have discussed some important distinctions between gift givers who perceive their giving as either voluntary or obligatory. Within the construct of obligation, the authors identify two specific forms, reciprocity and ritual. What they are really describing is roughly one-half of Marshall Sahlins' tripartite reciprocity continuum (1972). Any discussion of gift giving is at least partly incomplete without mention of generalized and balanced reciprocity and the accompanying notions of kinship distances and social/other obligations involved in these exchange relationships. This is especially true when dealing with a study in which level of obligation is a key independent variable. The authors may or may not feel that Sahlins' work is relevant to their own, but they are certainly obligated to give Sahlins credit for conceptualizing a continuum of obligation nearly two decades ago.

On a more technical note, the abstract of Goodwin, et al. suggests a "naturalistic data collection technique" was employed. The description in the method section runs counter to that promise, however. Ninety students filled out "questionnaires [which] were completed in classroom or office settings..." What sets apart studies claiming to be naturalistic is related to the setting within which the research data are gathered (Belk, Sherry and Wallendorf 1988) and the degree to which "a priori units" are imposed on the outcome by the researcher (Lincoln and Guba 1985; Willems and Raush 1969). What Goodwin, et al. *have* done is gather qualitative data, but according to these definitional criteria at least, they *have not* conducted naturalistic research. One final note on the method - the authors are almost apologetic for their use of students in consumer research. In some instances student samples are not appropriate for measuring consumption, but it seems to me that anyone who has given a gift (this would exclude few people) is a likely informant to this type of study. It almost seems comical when the authors refer to their subjects as "genuine consumers." Is there any other kind?

FIBER CHOICE

The paper by Wagner, Ettenson and Verrier (1989) stands apart from the other papers in this session in several ways. It asks consumers to make hypothetical choices about what gifts they might choose when presented with several combinations (forty) of eight attributes which are apparently salient to givers of clothing gifts. The task is a measured by conjoint analysis, with the dependent

variable, slashes on a 100 mm continuum with "very likely" and "not very likely" to buy, as anchor points. As alluded to earlier, this study qualifies as a very micro approach. I do not wish to argue with their chosen tack, except to say that they should recognize that gift giving is very difficult to reduce to a few, clean independent and dependent variables. All sorts of context has been ignored by Wagner, et al..

The part of this paper that I find especially troubling is the main finding of the study related to fiber choice, which they translate into information that somehow "lend[s] support to the Sherry [(1983)] model by demonstrating that level of involvement affects the gift purchase decision." The fact that fiber choice emerges in their statistical analysis as the driving consideration when buying baby shower clothing ought to raise big, red flags to anyone evaluating this paper. A careful reading of the method and results can perhaps provide the reader with clues as to how this clothing attribute came to displace seven others, including price, quality, and brand name. The choices given to measure fiber preferences were 100% cotton versus 100% polyester. Only one of the 77 PTA mothers surveyed chose the polyester jumpsuits with any consistency. This finding obviously has nothing to do with whether the subject was in the "new neighbor" or "best friend" condition. A more likely interpretation would be that the highly educated and somewhat older sample are simply reacting to the major stigma attached to the word "polyester." I'm not saying that this fiber isn't wonderful and versatile, but no one can deny (especially textiles scholars, such as the authors) that ugly images of lime-green, double-knit-with-contrast-stitching ladies sportswear in the mid-to-late 1970s continue to plague and challenge polyester makers everywhere in getting consumers to take their product seriously.

The conjoint task is only as good as the choices given (Cattin and Weinberger 1980). The concern of researchers who use this method, then, should be to use the utmost care in choosing levels or alternatives within each treatment or attribute (Hair, Anderson and Tatham 1987) since otherwise the results will reflect a very strong "garbage in-garbage out" flavor. The levels chosen by Wagner, et al. on the treatments of fiber (all cotton/all polyester) and size (newborn/6 months) are subject to criticism, with the fiber issue already discussed. Being the father of two (three by the time these proceedings finally get mailed), it strikes me that no one really considers newborn sizes unless the baby is very small at birth. This is simply a utilitarian concern on the part of buyers, since children grow so rapidly. In fact, the authors report that very few subjects consistently chose the smaller size. Having said these things, and perhaps weakening the arguments made for fiber and size as the number one and two main reasons for choosing a garment to be given as a gift, the third major dimension seems to offer some true relevance to the questions at hand. This is no surprise since the treatment of "price" was pretested with a focus group before the conjoint

part of the study was carried out. Careful consideration beforehand yielded a meaningful (if already apparent) finding, that the amount spent on a gift will vary according to how well you know the receiver and how you feel they will interpret the perceived gift price. The real finding of this study is that hypothetical givers will be more concerned with the new neighbor's interpretation than that of a close friend, which is hardly a surprising piece of information.

IMPRESSIONS AND DIRECTIONS

These studies are all geared toward the communication that takes place within the gift giving process. Whether this communication process is studied from a macro or a micro level analysis is really not as important as recognizing that, separated from the context, gift giving loses the bulk of its meaning. While much literature, both from the social sciences generally and from within the field of consumer research is currently available, there is much still to be done if we are to truly understand gift giving.

Given the sheer amount of extant knowledge, perhaps it is time to begin the process of true integration. This is, I believe, what Wolfenbarger is trying to do with her work, although as mentioned, she seems to prefer a strongly unidisciplinary mindset. When I say true integration, I mean a model which requires multidisciplinary vision. A caveat about embarking on such a model is that it should not be approached as a giant boxology - a la Howard and Sheth. The process could surely be modeled in such a way, but not without diminishing the *gestalt* of the gift exchange phenomenon. It would also be difficult to include in such a model the constant role of communications in gift exchange, which has been conceptually so important in these papers.

Another relatively untapped area for scholarly exploration is the receiver's view of the process. This begs for a remedy if we want the full picture of the gift giving/gift exchange process. The Wolfenbarger study begins to scratch the surface by asking people about gifts they have received. Certainly such a perspective is imperative to a complete understanding of the phenomenon in question.

Choose Your Own Price: An Exploratory Study Requiring an Expanded View of Price's Functions

Michael Lynn, University of Missouri - Columbia

ABSTRACT

The existing consumer behavior literature generally presents prices as costs which consumers try to minimize and/or as cues which consumers use to judge quality. This limited perspective on price's functions assumes that, if allowed to choose their own price for a good or service of known quality, consumers would always choose the lowest price possible. This assumption is tested in a study examining the price choices of patrons at a restaurant that allowed its customers to choose the price they wanted to pay for entrees they had already consumed. Forty-four percent of the customers chose to pay more than was necessary for their entrees. This finding requires an expanded view of price and its functions. Additional price functions that might explain this finding are presented and discussed.

A perusal of the consumer behavior literature reveals two major perspectives on the functions of price (c.f., Erickson & Johanson, 1985; Lichtenstein, Block & Black, 1988; Monroe & Petroschius, 1981). First, prices are seen as costs which consumers try to minimize. This perspective is borrowed from economic theory which sees price as a constraint on what consumers with fixed incomes can buy. Rational consumers are supposed to maximize utility by paying as little as possible for each good purchased.

Second, prices are seen as sources of information about product quality. Researchers have found that consumers do use price as an indication of product quality, especially when other product information is unavailable (see Olson, 1974 for a review). Thus, lower priced products are not always preferred to more expensive ones. When price is used as an indicator of quality, then high priced goods can be perceived as better buys than low priced goods.

These two perspectives on price are so dominant that they have come to be seen as exhaustive by many consumer behavior researchers. The following quotation from Lichtenstein, Block and Black (1988) is illustrative. They write that:

"... to the degree buyers make price-quality inferences, they view price in a favorable light, believing that higher prices reflect better materials, finer workmanship, and so on. Because price plays a positive role for these consumers, they are more likely to find higher prices acceptable (John, Scott & Bettman, 1986). To the degree consumers do not make price-quality inferences, price is viewed as a negative element only, reflecting resources yielded" (p. 244).

This restricted view of price and its functions assumes that, given a choice of different prices for the exact same product, consumers would always choose the lowest price -- different prices for a single product could not reflect differential quality, so they should be perceived only as costs to be minimized. The present study tests this assumption. More specifically, it examines consumers' price choices at a restaurant that allowed its customers to choose the price they wanted to pay for entrees they had already consumed.

Of course, there is already some evidence that consumers will pay more than they have to for a given good or service. Many people give money to public television stations even though such contributions are not required to have access to the stations' programs, and even though individual contributions are not large enough to seriously impact the quality of the stations' programming. Similarly, people regularly leave tips to waiters and waitresses even though the services have already been received and even though a gratuity is not legally required. These behaviors challenge the restricted view of prices as only costs and/or cues-to-quality, but they differ from most economic purchases in several ways that may limit the need for an expanded view of price's functions.

First, public television stations are non-profit organizations while most businesses are not. It is possible that people will voluntarily contribute to non-profit organizations but that they will not make such voluntary contributions to the profits of businesses. Second, tips are given to individuals while prices are generally paid to business institutions. People may be willing to give what are essentially monetary gifts to other people but may not be willing to give similar gifts to businesses. Finally, both tips and donations to non-profit organizations are supported by social norms while paying more than necessary to businesses is not. It is possible that people are willing to pay more than they have to for goods and services only when such actions are called for by social norms.

By exploring people's willingness to pay a restaurant more than necessary for its entrees, this study provides a more general test of the restricted view of price's functions. If some of the customers at the restaurant studied chose to pay more than they had to for their entrees, then price must have served as more than a cost and a cue to quality for those customers. This would indicate that the restricted view of price as only a cost and/or a cue to quality is inadequate to fully understand price's functions even in transactions with profit oriented businesses.

METHOD

Data Source

El Matador was a Mexican restaurant in a large midwestern city that allowed its customers to choose the price they wanted to pay for a select group of entrees (hereafter referred to as "special entrees"). After finishing their meals, dining parties who ordered these entrees were given a sheet of paper with a set of four prices per type of entree (see Exhibit 1) and were asked to circle the price they thought appropriate. Usually, only one choice per table was permitted for each type of special entree regardless of how many people at the table ordered that item. [One apparent exception was omitted from this study.] However, dining parties that ordered two or more different types of special entrees could make two or more price choices. Customers' entrees, price choices, and other information were recorded on the restaurant's checks. The owner of this restaurant allowed me to borrow the checks written during the month of May 1986. The evening checks that contained at least one special entree were used as the source of data in this study.

Variables

Several variables were recorded from the checks. One set of observations was made per check except in cases where it was clear that two or more checks came from a single table. In such cases, the checks were ignored for being non-independent. Also ignored were several illegible, or otherwise unclear, checks. The variables recorded from those checks providing usable, independent observations for this study were:

- a) the identity of the server (the coding identified four individual servers and a group of several other servers who had only a few customers each),
- b) the number of people at the table,
- c) the number of alcoholic drinks ordered,
- d) the number of different types of special entrees ordered,
- e) the number of special entrees of each type ordered,
- f) the general expensiveness of each type of special entree (different special entrees had different price alternatives and the lowest price choice allowable was recorded), and
- g) the price customers chose to pay for each type of special entree they ordered (the rank order of the selected price was recorded with 1 representing the lowest price alternative and 4 representing the highest price alternative).

A random check on the recording reliability for these variables revealed no errors. A total of 175 sets of observations were obtained for this study. However, some of the restaurant's checks did not contain all the above information, so the number of observations for some variables is smaller than 175.

RESULTS

Description of Price Choices

A frequency distribution of price choices was tabulated for those dining parties with only one type of special entree (see Table 1). Eighty-two (or 56%) of these one hundred forty seven people chose to pay the first (or lowest) price for their special entrees. However, sixty-five (or 44%) of these people voluntarily chose to pay more than they had to -- forty-one people chose to pay the second price, twenty-one people chose to pay the third price, and three people chose to pay the fourth (or highest) price. The second, third and fourth prices respectively were 16%, 28% and 38% more than the first price, so these sixty five people chose to pay meaningfully higher prices than they were required to. Since these price choices were made after the entrees had already been consumed, the higher than necessary prices were not paid in the hope of getting higher quality food or larger portions. Apparently, price served some other functions for these customers.

Predicting Price Choice

Separate regression analyses were performed to explore the relationships of price choice (among those having only one type of special entree) with (a) the identity of each dining party's server -- server identity was dummy coded, (b) the number of people in each dining party, (c) the number of alcoholic drinks ordered by each dining party, (d) the number of entrees each dining party's price choice applied to, and (e) the general expensiveness of each party's special entree. For these analyses, people's price choices were converted to percentages of the lowest price -- prices 1 thru 4 were assigned values of 100, 116, 128 and 138 respectively.

Only the server's identity and the general expensiveness of the special entree significantly predicted price choice. People's price choices were related to their servers' identities [$F(4, 140) = 3.81, p < .006$] and this relationship remained at least marginally significant after partialling out the effects of the other independent variables [$F(4, 124) = 2.36, p < .06$]. People also chose higher prices the more expensive their special entrees were [$r = .17, F(1, 145) = 4.23, p < .05$] and this relationship remained significant after partialling out the effects of the other independent variables [$spr = .20, F(1, 124) = 5.67, p < .02$]. People's price choices were *not* related to the number of people at the table [$F(1, 132) = .13, n.s.$], the number of alcoholic drinks ordered [$F(1, 145) = 1.26, n.s.$], or the number of entrees each party's price choice applied to [$F(1, 145) = 1.09, n.s.$].

Multiple Price Choices

Twenty-eight dining parties in this study ordered two different types of special entrees and, thus, had two different price choices to make. Twenty two (or 39.3%) of their fifty six choices were for larger prices than necessary -- i.e., for prices 2, 3 or 4. A correlation between the two

Choose Your Own Price

There is nothing a vendor in Tijuana would rather do than bargain with a Yankee. Trying to be as authentic as possible, we decided to carry on this tradition--"North of the Border."

Now that you've experienced the taste of Mexico, it's time to enjoy the tradition. Choose your own price! Simply (1) Grasp your pencil, (2) Find your item, (3) Draw a circle around your chosen price, (4) Tell your friends that they too can choose their own price at EL MATADOR.

READY, SET, GO!!!

	<u>GREAT</u>	<u>FANTASTIC</u>	<u>AWARD WINNING</u>	<u>BEST I'VE EVER HAD</u>
10 Inch Mexican Pizza	\$4.70	\$5.45	\$6.00	\$6.50
Smothered Burrito	\$3.20	\$3.70	\$4.10	\$4.40
Plato De Sopapilla	\$4.10	\$4.75	\$5.25	\$5.65
El Bandito	\$3.95	\$4.60	\$5.05	\$5.45
Burrito Con Queso	\$3.20	\$3.70	\$4.10	\$4.40
El Puerco	\$8.25	\$9.55	\$10.50	\$11.40

TABLE 1
Frequency distribution of price choices among customers with only one type of special entree.

Price	Frequency	Percent
1 "Great"	82	55.8
2 "Fantastic"	41	27.9
3 "Award ..."	21	14.3
4 "Best..."	3	2.0

price choices made by these dining parties was highly significant [$r=.91$, $n=28$, $p<.0001$], suggesting that their decisions were fairly consistent. However, six (or 21%) of the dining parties chose different price alternatives for their different types of special entrees.

DISCUSSION

Many of the customers at this restaurant chose to pay more than they had to for entrees they had already consumed. This finding cannot be explained from the limited perspective of prices as only costs and/or cues-to-quality that predominates the consumer behavior literature. This finding requires an expanded view of price and its functions. Two other potential price functions might explain this finding -- prices may be used to display status and wealth and/or to equitably compensate the providers of goods and services.

Impression Management Function

The customers at this restaurant may have paid more than they had to for their entrees because of impression management concerns (ala Schlenker, 1980; Tedeschi, 1981). Veblen (1889/1965) noted that the wealthy often buy expensive goods whose costs cannot be justified by their functional characteristics. He concluded that the wealthy buy these over-priced goods as a way of displaying their wealth -- a phenomena he called conspicuous consumption. It is possible that price's impression management function is more general than this. People may also prefer moderate prices over lower ones in order to avoid appearing poor or cheap.

The impression management function of price may also help explain why people's price choices were related to their servers' identities and to the general expensiveness of their special entrees. First, the customers at the restaurant may have been more concerned about impressing some servers than others because some of the servers may have been more attractive, more judgemental, etc... than were the others. If customers did choose higher prices in order to make favorable impressions and if servers did differ in the extent to which they evoked impression management concerns, then it makes sense that customers' price choices were related to who their servers were.

Second, some customers may have been dispositionally more concerned about impressing their servers than were other customers. Those

customers who wanted to impress their servers may have tried to do so both by ordering more expensive special entrees and by choosing the higher price alternatives for those entrees. Thus, the relationship between price choice and the general expensiveness of the special entree may be due to their joint dependence on customers' concerns about impressing servers.

Very little research has examined the behavioral effects of prices' status and public-image implications. However, these aspects of price may prove important in understanding several types of consumer behavior. Donating to charities, tipping servers, redeeming coupons, comparative shopping, selecting stores, and choosing brands are all behaviors through which consumers determine/select the prices they pay for things. If people use price as an impression management tool, then all of these behaviors may be affected by the desire to appear wealthy and/or by the desire to avoid appearing poor or cheap.

Compensatory Function

The customers at this restaurant may have paid more than they had to for their entrees because they felt that the higher prices were fairer than the lower ones -- i.e., were more equitable compensations for the entrees. Equity theorists (e.g., Adams, 1965; Walster, Berscheid & Walster, 1976) argue that society socializes people to feel anxiety or distress when in inequitable exchange relationships. Exchange relationships are said to be inequitable when the various participants' outcomes relative to inputs are unequal. According to the theory, people attempt to minimize their own psychological distress by maintaining (or restoring) equity in their relationships with others.

The restaurant in this study labeled price alternatives 1 thru 4 "great", "fantastic", "award winning", and "best I've ever had" respectively. These labels may have suggested to customers that they were expected to choose the prices for their entrees on the basis of how much they enjoyed those entrees. Such a decision rule would be consistent with equity theory and could explain why some customers chose to pay more than they had to. Equity theory may also explain why six out of twenty-eight dining parties selected different price alternatives for the different types of special entrees they ordered -- those six dining parties may have considered their different entrees to be of unequal

value and may have chosen to pay different prices in order to equitably compensate for the different values received.

Equity theory has received a great deal of empirical support in the areas of business relationships, exploitative relationships, helping relationships, and intimate relationships (see Walster, Walster & Berscheid, 1978, for a review), but has been applied to consumer behavior and to the pricing of consumer goods and services only rarely. One domain of consumer behavior to which equity theory has been applied is restaurant tipping. Although several early studies failed to find a relationship between service quality and tip amount (c.f., Crusco & Wetzel, 1984; Lynn, 1988; Lynn & Latane, 1984; May, 1978), the measures of service quality in many of these studies were of questionable sensitivity and/or validity. A more recent study in which customers rated specific aspects of their own service did find that people tip more the more favorably they perceived their service (Lynn & Grassman, 1989). This result is consistent with the hypothesis that consumers will pay more than they have to for goods and services in order to equitably compensate the providers of those goods and services, but more research is needed to rule out alternative explanations for this result and to assess its generalizability. If people do want prices to equitably compensate sellers, then this compensatory function of price may prove important in understanding and manipulating price acceptance.

Assessing the Relationship Between Perceived and Objective Price-Quality: A Replication

Scot Burton, Louisiana State University
Donald R. Lichtenstein, University of Colorado¹

ABSTRACT

A study is reported that attempts to replicate results of recent research concerning the level of correspondence between consumers' price-quality perceptions and objective price-quality relationships present in the marketplace. The study employs a dissimilar, alternative measure of price-quality perceptions from the one used in previous research examining this relationship. Results support previous findings by indicating that the relationship between price-quality perceptions and objective price-quality is positive, but not large. Findings also are consistent with previous results that indicate that this relationship is moderated by product type (durable and nondurables).

Two research streams of significant interest in pricing research concern (1) the relationship between price and quality perceptions and (2) the relationship between price and "objective" quality. Both of these research streams have been of interest to pricing researchers for many years (Leavitt 1954; Morris and Bronson 1969). Research pertaining to the price-perceived quality relationship suggests that the use of price as an indicator of product quality is considered to be widespread (Etgar and Malhotra 1981; Gerstner 1985), but that its effect varies significantly across individuals and products being judged (Peterson and Wilson 1985; Zeithaml 1987).

Objective quality previously has been defined as the "unbiased measurement of quality based on characteristics such as design, durability, performance, and safety" (Riesz 1978, p.19). Research pertaining to the relationship between price and "objective" quality suggests that while the association between price and objective quality for some product categories is high, across product categories the overall relationship is low, and in some cases, negative (cf. Geistfeld 1982; Gerstner 1985; Morris and Bronson 1969; Oxenfeldt 1950; Riesz 1978, 1979). For example, Oxenfeldt (1950) reported an average correlation between price and objective quality of .25, with correlations ranging from 0.82 to -0.81, for a sample of 35 product categories that included durable goods, clothing, and food. Riesz examined 685 durable and nondurable product categories and found an average correlation of .26. In a follow-up study, Riesz (1979) found an

average correlation of .09, with a objective-price quality correlations ranging from .88 to -.65 for 679 packaged food product categories. Gerstner (1985) reported an average correlation for 59 nondurable products of only .01 with a range of .73 to -1.00, and an average correlation for durable products of .19, with a range of .66 to -.73.

Such findings have led price-objective quality researchers to conclude that "results indicate that price and [objective] quality do correlate, but at a level so low as to lack practical significance" (Morris and Bronson 1969, p.33). Similarly, Riesz (1979, p.246) states that "consumer reliance on price as an indicator of product quality is an unwise purchasing strategy."

In a recent study, an attempt was made to integrate the price-objective quality research stream with research on consumers' subjective price-quality perceptions (Lichtenstein and Burton 1989). Because this integration permits an assessment of the consistency between the price-quality perceptions of consumers and price-objective quality relationships present in the marketplace, it potentially has some important implications for both consumer researchers and policy-makers.

In this recent study, single-item measures were used to assess price-quality perceptions for different product classes. There is some concern about using a single-item measure for such a complex relationship because of failure to capture the full domain of this construct and the questionable reliability of such a single-item measure. The objective of the present research is to attempt to replicate results obtained in the Lichtenstein and Burton (1989) study using a measure of perceived price-quality that is very different from the one employed in this previous study. Specifically, this dissimilar measure is used in an attempt to replicate results concerning (1) the overall relationship between consumers' price-quality perceptions and price-objective quality relationships, and (2) whether the relationship between price-perceived quality and price-objective quality varies across the type of products being judged (i.e., durable or nondurable).

HYPOTHESES

In the research conducted by Lichtenstein and Burton (1989), a principal question concerned the "accuracy" of consumers price-quality perceptions. This question of how accurately consumers perceive price-objective quality relationships pertains to (1) whether consumers perceive a price-quality relationship when there actually is a positive relationship, and (2) whether they perceive *no* price-quality relationship when the actual relationship is zero or negative. Weighing evidence both pro and con, Lichtenstein and Burton (1989) hypothesized

¹The authors express their gratitude to an anonymous reviewer for his/her suggestion concerning an alternative measure of perceived price-quality used in this paper. For purposes of comparison, this paper includes a portion of the results from Study 3 reported in Lichtenstein and Burton (1989).

that, overall, there would be a positive correlation between perceived and objective price-quality relationships. They noted that consumers often lack the effort required to obtain information about quality (Alpert 1971; Gerstner 1985; Zeithaml 1987), and consumers sometimes may only be able to assess quality in a very cursory manner. Also, the mere survival of brands in the marketplace that offer poor quality in relation to their price suggests that consumers are less than perfect in their evaluations of relationships between price and quality. On the other hand, quality variations are often recognizable, and, in general, consumers are viewed as rational processors of information who should not be regarded as totally uninformed about issues pertaining to price and quality. Lichtenstein and Burton argued that, taken in sum, these points suggested that there is likely to be a positive, but not strong relationship, between perceived and objective price-quality relationships. In their first hypothesis they postulated that "there is a positive relationship between perceived and objective price-quality relationships." Results in which single-item measures of price-quality perceptions were used supported their hypothesis. A principal objective of this study pertains to how results using an alternative price-quality perceptions measure will compare to those reported by Lichtenstein and Burton (1989).

A second hypothesis of interest in the Lichtenstein and Burton (1989) study pertained to differences in the accuracy of price-quality perceptions across product types. It was hypothesized that consumers' price-quality perceptions for nondurables are more accurate than their perceptions for durables. The rationale for such a hypothesis was drawn from integrating the results from price-perceived quality studies and price-objective quality studies. Findings across price-objective quality studies have consistently indicated that price is *not* a good predictor of product quality for durables *or* nondurables (Gerstner 1985; Riesz 1978, 1979); however, price-perceived quality studies have demonstrated that consumers *expect* much stronger price-quality relationships for durable than for nondurable goods (Gardner 1970; Leavitt 1954; Monroe and Krishnan 1985). Lichtenstein and Burton suggested that this greater reliance on price for durables than for nondurables should lead to more erroneous perceptions. Specifically, it was hypothesized that "the correlation between price-perceived quality and price-objective quality will be higher for nondurable goods than for durable goods." Results reported by Lichtenstein and Burton (1989) that employed single-item measures of consumer price-quality perceptions supported this hypothesis.

METHOD

Product Classes

The criteria for selection of the 18 product categories used in this study included: (1) an equal split between product types (i.e., 9 durable and 9 nondurable product categories), and (2) for both

durable and nondurable product categories, three products have a positive price-objective quality correlation shown to be stable over time (i.e. consistent across the two most recent ratings by Consumer Reports), three have a (near) zero price-objective quality correlation shown to be stable over time, and three have a negative price-objective quality relationship shown to be stable over time. Correlations between price and quality ratings for over 100 product categories rated at least twice by *Consumer Reports* within the last 10 years were computed to find product categories that met these criteria. Based on these analyses, 18 product categories meeting the above criteria were selected.

Measures

Measure of Perceived-Price Quality. The measure of perceived price-quality for the eighteen product classes examined in this study was operationalized in the following manner. Respondents were asked to assume that there were 10 brand alternatives in each product class, five of which were high priced and five of which were low priced. For the five *high-priced* alternatives, respondents were asked how many were of high quality and how many were of low quality. Then, the respondents were asked for the five *low-priced* alternatives how many were of high quality and how many were of low quality. A small pretest indicated that this procedure could be easily understood by respondents. These responses were used as cells in a 2 X 2 contingency table (i.e., high and low levels of price and quality), and individual-level phi correlations were then calculated for *each* of the 18 product classes (Nunnally 1978). The formula used to calculate the phi correlations was: $(A * D) - (B * C) / \text{SQRT}((A + B) * (C + D) * (A + C) * (B + D))$, where A, B, C, and D are the cell frequencies in the 2 X 2 contingency table.

Although this measure has some limitations (which are addressed in the Limitations section of this paper), it was quite different from the one used to assess price-quality perceptions in the four studies reported by Lichtenstein and Burton. In those studies perceived price-quality was operationalized by respondents' level of agreement with the following statement: "The higher the price of the product, the higher the quality of the product" (7=strongly agree, 1=strongly disagree) for each product category. This measure, which was also used in a previous study on price-quality perceptions (Peterson and Wilson 1985), has the advantage of being quite direct. However, it may underrepresent this complex construct as well as introduce random measurement error for any single response (Churchill 1979).

Measure of Objective Price-Quality. Measures of the relationships between price and objective quality were calculated from *Consumer Reports* data. Arguments have been stated both for and against the use of *Consumer Reports'* ratings as a basis for measures of objective price-quality relationships. An overview of these arguments concerning

objective price-quality measures is offered in the Limitations section of this manuscript.

Spearman rank-order correlations were used to test hypotheses. Given the use of rank-order correlations, positive (objective) price-quality correlations were recoded to a 3, correlations near zero were recoded to a 2, and negative correlations were recoded to a 1. This recoding scheme was used because many of the product categories have very similar objective price-quality correlations, and small correlational differences would be accentuated given the use of rank-order correlations. Thus, tests using these recoded values were considered the more conservative and appropriate approach.

Description of the Sample

Respondents in the study were junior and senior undergraduate business majors at a major state university. Sample size for this study was 128. All data were collected in a classroom setting. (This sample and data collection method are consistent with that used by Lichtenstein and Burton (1989) in Study 3 where respondents were also junior and senior undergraduate students and questionnaires were completed in a classroom environment.)

RESULTS

Table 1 shows the mean phi correlations calculated from responses to the questions concerning perceived price-quality in this study. As shown in Table 1, the mean phi correlation for the durable products (.354) was larger than the correlation for the nondurable products (.281). This difference is consistent with results reported in previous perceived price-quality research which has shown that consumers expect stronger price-quality relationships for durable products (Leavitt 1954; Monroe and Krishnan 1985; Peterson and Wilson 1985). Results are also consistent with those offered by Lichtenstein and Burton, where across all studies respondents perceived stronger relationships for durables than for nondurables.

One advantage of this measure demonstrated in Table 1 is that it permits a direct assessment of the specific price-quality correlations as perceived by respondents. For example, relatively few respondents expected negative price-quality relationships for any of the product classes examined. (The highest percentage of respondents perceiving a negative correlation was 10% for the product class of tea bags.) However, for some product classes there were rather large differences concerning positive correlations ranging from .31 to 1.0. For instance, for the product classes of stereo speakers and ten speed bicycles, two-thirds of the respondents thought that price-quality correlations exceeded .30; for laundry bleach and fabric softeners fewer than one-third anticipated correlations above .30. For the set of (nine) durables examined in this study, on average, 58% of the respondents expected correlations to be greater than .30, while 45% perceived correlations to be above .30, on average, for the set of nine nondurables.

Results showing how findings using this measure compare to those using the single-item measures of perceived price-quality employed by Lichtenstein and Burton (1989) are presented in Table 2. The last three columns in Table 2 are of principal interest. The third column shows the average objective price-quality correlations calculated from the two most recent ratings for these product classes in *Consumer Reports*, and the coding of these correlations as positive (3), near zero (2), or negative (1); the fourth column shows the mean price-quality ratings using the single item price-quality measure (as reported in Study 3 of Lichtenstein and Burton (1989); and the fifth column shows the mean phi correlations for the perceived price-quality measures employed in this study.

A quick comparison between the mean phi correlations (column 5) and the mean ratings for the single item measure of perceived price-quality (column 4) reveals a positive relationship between the two measures. In fact, the Pearson correlation between the mean perceived price-quality ratings and the mean phi correlations is .83. Thus, across these two samples, the price-quality ratings and correlational measures appear to tap into the same underlying construct.

This high correlation between these two measures bodes well for assessing the consistency of results of hypotheses involving this phi correlational measure and the price-objective correlations (column 3) and previous findings of Lichtenstein and Burton (1989) using the single-item perceived price-quality measures. A comparison of results pertaining to these tests of hypotheses are shown at the bottom of Table 2.

The first hypothesis offered by Lichtenstein and Burton (1989) postulated a positive correlation between perceived and objective price quality relationships. As predicted, these correlations, although not large, were positive for both the phi correlation measure (Spearman $r = .29$, $p < .15$) and the single item measure (Spearman $r = .18$, $p < .25$). Thus, results across the two measures of perceived price-quality are relatively consistent and provide general support for H1.

A second hypothesis of Lichtenstein and Burton (1989) concerned the moderating role of product type on the accuracy of price-quality perceptions; it was hypothesized that the correlation between perceived and objective price-quality would be greater for nondurable than for durable products. Results across both the single-item and phi correlation measures of perceived price-quality support H2; the rank-order correlation between objective price-quality and the single-item perceived price-quality measure was .58 for nondurable products and .05 and for durable products. For the phi correlation measure, these respective relationships were .47 and -.05. Thus, results across the two alternative measures of perceived price-quality were consistent and increase confidence in results pertaining to both hypotheses.

DISCUSSION

The purpose of the research was to attempt to replicate some of the results reported by Lichtenstein and Burton (1989) using a dissimilar alternative measure of perceived price-quality. It has been argued that greater value should be placed on replication studies in marketing research (Sawyer and Peter 1983). Given the newness of the attempt to integrate the objective and perceived price-quality research streams, the potential importance of this integration, and the use of single-item measures of price-quality perceptions in the previous research effort, a replication using this alternative measure was viewed as worthwhile.

Specifically, this study used a phi correlation measure to (1) assess the accuracy of consumers' price-quality perceptions and (2) determine if the

accuracy of these perceptions is moderated by the type of products being judged. Results using the alternative phi correlation were consistent with those reported by Lichtenstein and Burton (1989), where single-item perceived price quality measures were used. As suggested by the previous findings, there appears to be a positive, but not strong, correlation between the perceived and objective price-quality relationships (Spearman $r = .29$ using the phi correlation measure). Also, given that these perceived and objective price quality relationships were greater for nondurables than durables (.47 and -.05, respectively), results suggest that consumers may hold more accurate price-quality perceptions for nondurable products than for durable products. Some limitations of the study, implications of the results, and directions for future research are addressed in the remainder of this section.

Limitations

In this study, we wanted to assess the comparability of results using a very different measure from the single-item measures of perceived price-quality previously employed (cf., Peterson and Wilson 1985; Lichtenstein and Burton 1989). While the individual-level phi correlation measure is viewed as being quite different, this measure has some limitations. First, use of this measure may result in the violation of some statistical assumptions. For example, the within-cell responses are not independent and the fixed row marginals and marginal totals (i.e., row marginals equal 5 and marginal totals for each product class equal 10) affect the number of possible correlations and thus the shape of the underlying distribution. Such problems lead to questions concerning the normality of this underlying distribution. Also, any column marginal equal to zero results in an inadmissible algebraic operation, leading to a greater number of missing values than would be obtained from most other measures. These problems may limit the usefulness of this measure in most contexts, but given the goal of this research (i.e., to see if these results were comparable to those using the single-item measures), these problems were not considered devastating.

Other measures of price-perceived quality relationships could have been employed. For example, Lichtenstein, Bloch, and Black (1988) asked respondents to evaluate a \$75 pair of running shoes in relation to a \$35 pair of running shoes across four individual product attributes. However, employing such a measure here would have been problematic for a couple of reasons. First, requiring respondents to rate 18 product categories across multiple attributes would have represented a demanding task. Second, questions about how to combine individual attributes to be comparable to a single price-quality measure would have also presented problems. Future research may examine the equivalency of such measures on a reduced set of product categories.

To assess the accuracy of price-quality perceptions, some measure of the "true" relationship between price and quality must be used. Objective quality ratings from *Consumer Reports* were used to evaluate the accuracy of price-quality perceptions. The validity of the concept of "objective quality ratings" rests on the premise that attributes and attribute weightings used by expert raters (e.g., *Consumer Reports*) to judge quality reflect tastes and preferences across consumers. The validity of any general quality rating scheme may be questioned because individual tastes and preferences vary across consumers (Hjorth-Anderson 1984).

In response to the position of Hjorth-Anderson, Curry and Faulds (1986) contend that as long as the attribute weights used between different possible rating schemes are *ranked* similarly, and attributes within a brand are positively correlated, rating scales are not affected substantially by the absolute values of the weights. There is also much support among other researchers for use of *Consumer*

Reports ratings as appropriate measures of objective quality (Gerstner 1985; Oxenfeldt 1950; Riesz 1978). While further discussion of this issue is beyond the scope of this paper, interested readers are encouraged to refer to the arguments of Hjorth-Anderson (1984, 1986), Curry and Faulds (1986), and Sproles (1986).

In testing hypotheses in this replication, a traditional statistical significance criterion (i.e., $p < .05$) was not used. Because sample size is equal to the number of product classes ($n=18$), the power associated with statistical tests of hypotheses is low. Sawyer and Peter (1983) have argued that there is often an overreliance on statistical significance to the exclusion of descriptive statistics of effects size and the use of study replications. In this replication study using an alternative measure of price-perceived quality, similar results were found to those reported by Lichtenstein and Burton (1989) where four different samples of respondents were used. Given these generally consistent results across five studies, in our opinion strict reliance on a .05 level of significance would fall into this category of "overreliance on statistical significance." Also, similar procedures are generally followed in price objective quality research where small sample sizes lead to levels of significance below conventional standards (cf., Curry and Riesz 1988.) However, other researchers may wish to test these postulated relationships across a larger set of product categories where there would be greater statistical power.

Implications for Marketers and Consumer Advocates

Taking all other market factors as constant, the findings from this study suggest that production of a low cost, low quality durable product which is sold at a high price may be the basis of a successful marketing strategy. Considering evidence that suggests that consumers do not generally engage in much search, even for expensive items (Gerstner 1985), and assuming that segments that routinely use price as an indicator of durable good quality are of sufficient size, the large profit margins per unit sold may make the high price - low quality option an especially attractive strategy for certain consumer segments. Furthermore, it may be argued that as long as the product is not below some minimum quality threshold (i.e., the product performs its basic function for some reasonable period of time), consumer purchasers may interpret the product's performance as "confirming" prior beliefs (cf. John et al. 1986).

While the above scenario ignores the complexities of the competitive marketplace, it nevertheless presents a grim picture of marketers operating in a "let the buyer beware" environment. Results indicate that consumer advocates may wish to play a more active role in disseminating information concerning studies on the relationship between price and objective quality. Similar suggestions have been made previously. For example, Beales et al. (1981) have suggested that

more research is warranted on how information from unbiased, third-party sources can be formatted and disseminated to consumers at low cost (including nonmonetary as well as monetary costs). This, itself, may likely require additional research on supplying information in a format consistent with consumer decision-making, and/or research on modes of disseminating the information (e.g., advertising, retail stores, newspaper articles, computer "bulletin boards"). The recommendations of Beales et al., considered in conjunction with findings from this research, suggest that because of the variance in the relationship between price and quality across product categories (for both durables and nondurables), consumers should be made aware that using a stored rule (i.e., high price is always associated with high quality) to assess price-quality relationships will not result in consistently accurate perceptions. Consumer advocates and policy-makers may encourage consumers to evaluate price and quality on an individual product category basis, and inform consumers that if quality received for the price paid is important, information from test report magazines should be obtained.

Areas for Future Research

The impact of product knowledge on the propensity to make price-quality inferences is an area worthy of empirical investigation. Rao and Monroe (1988) recently provided evidence that highly knowledgeable consumers used price as an indicator of quality to a greater extent than did moderately knowledgeable consumers for a product that had a positive price-objective quality relationship. However, no product classes possessing negative price-objective quality relationships were employed. Although logic would dictate that the use of price as an indicator of quality by more knowledgeable consumers was based on knowledge rather than on an inference, it has yet to be empirically demonstrated that consumers with product knowledge hold more accurate price-quality perceptions than consumers without such knowledge. In fact, although hypothesized in the context of their specific experimental design, consumers with low knowledge actually held the most accurate price-quality perceptions for the product category. Presumably, this was because they were operating on a price-quality *inference* and the product used in the study happened to have a positive objective price-quality relationship. Future research may use similar designs but include products possessing negative price-objective quality relationships to aid in the interpretation of results.

Research may examine other potential moderators of price-quality perceptions and price-objective quality relationships. Measures of the number of brands researched and tried, social relevance of the purchase, product and purchase involvement, perceptions of product similarity, and perceived risk, may impact the propensity to use price as an indicator of quality (Alpert 1971), and further, the accuracy of price-quality perceptions. Also, the ability of consumers to assess price-

quality relationships accurately under controlled conditions where they are provided with detailed information about prices and objective quality of various brands in specific product classes would be of interest. Such future research appears warranted because of the potential implications of results for both marketers and policy-makers interested in consumer welfare.

Tipping as a Consumer Behavior: A Qualitative Investigation

John A. McCarty, University of Illinois at Urbana-Champaign

L. J. Shrum, University of Illinois at Urbana-Champaign

Tracey E. Conrad-Katz, University of Illinois at Urbana-Champaign

ABSTRACT

The present study investigated the consumer behavior of tipping in the restaurant context. The methodology involved depth interviews with waitpersons in a representative sample of restaurant categories (diners, four star restaurants, etc.). Tipping was perceived to be a function of individual factors of the consumer, quality of service provided, and situational factors. Knowledge of the tipping custom was perceived as the primary individual factor that affected tipping behavior. Quality of service was discussed in terms of actual service provided and rapport with the customers that enhanced the dining experience. Situational factors included size of party and perceived social pressure to tip well in front of others.

These exploratory findings will lead to future qualitative and quantitative research on this neglected consumer behavior.

INTRODUCTION

The custom of tipping is very prevalent in American culture, as it is in many other cultures. In spite of this, there has been little academic work on the custom; virtually none has appeared in the consumer behavior literature. The custom of tipping is of potential interest, however, for a variety of reasons. First, tipping represents a direct exchange between the consumer and the service provider. The act of tipping does, therefore, represent a consumer behavior and one in which almost everyone engages at some time. Secondly, tipping represents the major source of income for individuals in many service industries, therefore, it is a consumer behavior of enormous importance in the economy.

The third and perhaps most important reason why tipping should be an area of research activity relates to the inherent uniqueness of the behavior. Tipping is one of the few areas of the economy where the exchange is dictated by informal rules of custom rather than explicitly stated procedures. While there are certainly other instances where informal rules dictate the exchange (e.g., the interchange at a swap meet (Belk, Sherry and Wallendorf 1988; Sherry 1988) or the purchase of a used car), these tend to be less prevalent than tipping. For most goods and services, the rules of exchange between buyer and seller are clearly known by the participants. Prices are ordinarily stated explicitly and the time and method of payment are known. In contrast, the custom of tipping is guided by informal rules and norms. While suggested amounts of tips and who should be tipped are indicated in books on etiquette (Post 1975) and on tipping (Star 1988), these are particular individuals' perceptions of the custom and many people are unaware of these sources.

Tipping is also unique as a consumer behavior because the payment for a service is set by the consumer rather than the service provider. While the informal rules suggest an amount or percentage to tip, how much to tip is still the choice of the consumer. Therefore, price, which is often used as a cue to quality for most services (Zeithaml 1981), cannot be used for tipped services since the consumer determines the price of the service.

For these reasons, tipping represents a viable and interesting area of study for consumer behavior. The current study will present some of the literature on this custom as well as an analysis of interviews conducted with waitpersons in the restaurant industry. These interviews represent preliminary findings of the current authors' research program in progress. While the analysis of these interviews leads to tentative conclusions, they are also considered by the authors to be a first step towards more qualitative and quantitative work.

The Origins and Prevalence of Tipping

The origins of the custom of tipping are not entirely known, although the custom dates back to at least 18th century England where boxes were placed in inns and coffee houses in which people could place coins (Lynn and Latane 1984). Signs affixed to the boxes stated "To Insure Promptness," thus the supposed origin to the term "tip." Star (1988) indicates that the custom may date back to early Rome. If one equates tipping to a type of a bribe for special attention (in some countries, the same word is used for tipping as for bribing, Shamir 1984), it is indeed likely that some form of the custom has been around for as long as people have used money as a method of gaining special attention.

Tipping likely evolved as a bonus to wages, provided in an effort to garner better service. In this sense, it was a small bribe that was accepted by servants who were otherwise poorly paid. Over the years the custom has become more formal, although far from having the explicit rules of other areas of the economy. As etiquette books developed, such rules were recorded and presented in a manner to suggest that tipping is a proper behavior for cultured individuals. Furthermore, as services have become more prevalent, tipping has become recognized as a method of payment for many service employees and therefore not considered the "bonus" that it once may have been.

Tipping is relatively prevalent in the United States and books on etiquette have, through the years, indicated the degree to which someone should tip in various situations. The earliest book on etiquette by Emily Post (1922) mentions that a

waiter should be tipped about ten percent. Later books by Post indicate levels of tipping for different situations (e.g., how much is tipped in a smorgasbord restaurant) and that 15 percent is the appropriate amount in a typical restaurant situation. Indeed, an examination of the books on etiquette since Post's first book indicates a degree of formalization of the custom in our culture with the rules having become more explicit in recent years (Post 1922; 1931; 1945; 1975; Towne 1939). The 1975 edition of Emily Post's book includes a separate chapter devoted to tipping in a variety of situations.

Literature Review

There is a paucity of research on tipping considering the prevalence of the custom and the research that does exist is spread rather thinly across several disciplines, primarily sociology, organizational behavior, and psychology. In general, the focus of sociological and organizational research has been on the employee in the exchange relationship and his or her perceptions of the job (satisfaction, autonomy) as a function of this form of payment. William Foote Whyte's (1948) extensive study of the restaurant industry indicated that tipped employees tended to believe that the custom was responsible for their feelings of inferiority relative to the customer. Analysis of the sociological literature by Shamir (1984) confirms this perception of status difference by tipped employees. Research by Butler and Skipper (1980, 1981) showed that waitpersons were more satisfied with the tipping arrangement when they were provided with autonomy by the organization for which they work. The less control employees had over their work situation and the more surveillance exerted by management, the less they were satisfied with tipping as a method of payment.

A study by Shamir (1983) investigated job satisfaction, perceptions of the relationship between performance and pay, attitudes toward customers, and role conflict among tipped employees and those not receiving tips. It was found that tipped employees perceived a greater relationship between pay and their performance compared to the perceptions of non-tipped employees. Shamir also discovered a greater tendency among tipped employees to take the perspective of the customer and to perceive more conflict between the demands of customers and the demands of management. He speculated that this relates to the direct reliance of the tipped employee on the customer for their pay.

Psychological investigations of tipping have tended to use tipping as a dependent measure in field experiments with the intent of lending ecological validity to phenomena previously investigated in laboratory settings. Seligman, et al. (1985), for example, investigated the link between attributions and subsequent behavior, finding that persons believing that a late delivery of a pizza was the responsibility of the delivery person tipped the delivery person less than those who were led to

believe that the late delivery was caused by factors beyond the control of the delivery person.

Several have investigated group size and tipping behavior (Lynn and Latane 1984; Snyder 1976), finding that the larger the party, the smaller the tip on a per person basis. This phenomena was explained as diffusion of responsibility (the more people present, the less responsible each feels for the tip, Lynn and Latane 1984) and equity theory (the larger the party, the less energy a waitperson has to expend on each person at the table, Snyder 1976).

Lynn and Latane's (1984) study related tipping to numerous other factors in addition to group size. These authors found that tipping was related to customer's gender (men tipped higher than women), method of payment (credit card customers tipped higher than those paying cash), and per person bill size in some cases (the larger the per person bill size the smaller the percentage tipped on the total bill, although this differed as a function of type of restaurant). Tipping was not found to be related to the atmosphere or food of the restaurant, the waitperson's gender, or the waitperson's efforts, nor was it related to customers' perceptions of service quality. However, other research (May 1978, cited in Lynn and Latane 1984) indicated that tip size was related to the number of non-task visits by the waitperson, although not related to observers' independent ratings of service. In a different line of research, investigators have found that merely touching the customer had an effect on the size of tip received by the waitperson (Crusco and Wetzel 1984; Stephen and Zweigenhaft 1986). These latter studies seem to indicate that tip size may be related to the rapport (visits to the table, touching) between waitperson and customer.

Purpose of the Study

The present study represents an initial exploration of the custom of tipping from a consumer behavior perspective. The academic literature on tipping raises some interesting questions, although this literature does not exist as a coherent body of work on the behavior of consumers. The present authors felt that the subtle aspects of the custom could best be investigated initially through a qualitative study involving individuals who interact most directly with consumers, namely restaurant waitpersons.

The academic literature on tipping and anecdotal information guided the authors in outlining general areas to be investigated. The most general area addressed was the waitpersons' overall feelings about the custom and their receptivity to alternative methods of payment for their services. The interest here was in their satisfaction with the exchange as a consequence of the behavior of the consumers.

Much of the academic literature has dealt with the factors that affect tip size and this was the second area of concern. The literature seems to indicate that characteristics of the customer as well as situational factors (size of party, etc.) affect tip

size and these were addressed in the current study. In general, tip size has not been found to have a strong relationship to service quality. This counterintuitive finding was thought by the authors to need further scrutiny, particularly in light of the findings that suggest that attention by waitpersons (trips to the table, touching) do relate to tip size.

Shamir's (1983) research showed that waitpersons experience a certain amount of role conflict due to their direct reliance on the customer for their pay. Other work has indicated servers are placed in a subservient position relative to the customer which may lead to feelings of inferiority. These findings prompted an interest in waitpersons' relationships with the consumers and this was yet another broad area of concern.

Finally, the authors felt it would be useful to investigate the behavior of waitpersons when they are in the role of customer. Therefore, an additional area of interest related to the tipping behavior of waitpersons when they dine out.

METHOD

Informants

A non-random sample of informants was selected for this project. Restaurant waitpersons were selected such that the following criteria were met: 1) a broad range of work experience (from less than one year of experience to over twenty years), 2) a broad range of age (early twenties to mid forties), 3) a broad sampling of restaurant class (diner, four-star, continental, etc.) and 4) a varied geographic representation (small, medium, and large cities predominantly in the Midwest). A total of thirteen interviews were conducted.

Data Collection and Analysis

Data were collected through personal interviews. The venues for the interviews varied, some occurring in the homes of the informants, others occurring at the restaurant. Audio recorders were used to document the interviews, along with supplemental journal notes made by the authors. The data were then transcribed for subsequent analysis.

Although the interviews were purposeful and positivistic, every attempt was made to keep them as unstructured as possible. Consequently, no set script or series of questions were followed; rather, general topics of interest were pursued. The interviewers did not go into the interview process with specific a priori assumptions or propositions to be tested, but certain areas of inquiry (previously described) were discussed by the interviewers prior to data collection. In order to allow for non-preconceived themes to emerge as well, care was taken to allow the informants the utmost freedom to take the conversation or interview in whichever directions they desired.

General standards for the analysis of qualitative data were followed. It should be noted that the analysis of this type of data is not a distinct process completely separable from data

collection, but occurs continually throughout the collection process. The primary analysis involved thematic interpretations based on the collected interviews. These interpretations resulted initially from individual analysis of the transcribed data, followed by a discussion among the interviewers of emerging patterns and themes. Once patterns and themes were identified, they were assembled and a search for contradictions to these findings was conducted. Judgments were then made as to whether the themes were strong enough to stand alone; if they weren't, they were rejected.

RESULTS AND DISCUSSION

The interviews with restaurant employees yielded a rich body of data. The current discussion will deal primarily with themes that relate to the behavior of the consumer and the attitudes and behavior of the waitpersons that have a direct bearing on their relationship with the consumer. These themes are classified by the general headings that follow. (Some themes dealt with the waitpersons' relationships with management and these will not be presented here).

Waitpersons' Shared Culture

It was apparent from the interviews that tipping is something that virtually every tipped employee in the restaurant business thinks about a lot and discusses with fellow employees. As many said, it will often be the topic of conversation during breaks or after work. Consequently, there was a great deal of consistency across interviews in terms of what was discussed. It is unclear therefore, to what extent any individual informant's comments reflect his or her own observations versus a report of these shared beliefs. Most informants admitted that conversation often centered on the tipping behavior of various customers, and also admitted to making certain value judgments about the customer based on the size of the tip. It is important to note, however, that many of the respondents would tell the interviewers of a shared belief, then explain how their own experiences have deviated from this folk wisdom. This was particularly true of their beliefs about what kind of customers tip well.

It is ironic that tipping is constantly on the mind of restaurant employees and is discussed among them frequently, yet it is rarely discussed with customers. To a great extent, the custom seems to dictate that one cannot directly confront a customer about a bad tip. Also, it was evident from the interviews that most restaurants have a stated or unstated policy concerning this. Even if not restaurant policy, the employee culture dictates that they not talk about tips with customers. Therefore, one side of the exchange, the service provider, thinks about tipping a lot, yet is powerless to "educate" the other party in the exchange, the customer.

Factors Affecting Tipping

The informants indicated that they believe several factors affect the amount tipped. The

waitpersons interviewed tended to perceive the amount of their tip to be a function of the customer (some people simply tip more than others) as well as a function of their own performance. Therefore, contrary to previous findings, waitpersons believed the quality of service does affect tip size. Further, situational factors were seen as playing a significant role in the size of the tip. Informants indicated that the same person may tip differently in various situations. For example, a person may not tip well when alone, yet tip a greater percentage when with others.

Beliefs About Customers

According to the informants, there are stereotypes about kinds of restaurant patrons in terms of who are good tippers and who are not. This seems to be a part of the folk wisdom among the people in the industry. For example, it is generally held that a table of older women are the worst tippers. What is interesting, however, is that in spite of these shared stereotypes, most waitpersons indicated that one never knows who is going to tip well. They indicated that they may size a customer up when he or she sits in their station, thinking about the kind of tip they will get from the individual or party. Many mentioned that they were often surprised. For example:

Interviewer: "Are there any rules of thumb that you can use to determine if someone is going to be a good tipper?"

Informant: "No, you'd be surprised. It's something that we talk about at the restaurant occasionally. That you can't ever peg a customer. And you really shouldn't try to because you'd be surprised in the end who's going to tip and who isn't. And sometimes by stereotyping or pegging, you end up getting the kind of tip you expected because subconsciously or consciously you end up giving worse service because you expected it."

The respondents tended to attribute poor tipping on the part of someone to a lack of knowledge. Therefore, even if they believe one of the stereotypical beliefs, such as gender and tipping, they attribute it to people not knowing any better. Several informants, for example, mentioned that older women do not tip well because they are used to their husbands paying, however, younger working women tend to be good tippers.

This lack of knowledge on the part of many customers is obviously a point of frustration for tipped employees. Many indicated that customers simply do not understand that waitpersons are paid less than minimum wage and must rely on the tip as income. They are often frustrated because they have little recourse if they are not tipped well. This indicates that tipping has evolved from being a "bonus" for extra service to the main source of income for these employees.

Relationships With Customers

Contrary to earlier findings, informants did not seem to view tipping as reflecting any status difference between them and the consumer. While they may at times feel inferior to the customer, it does not appear to be the case that tipping *per se* causes this feeling. This finding is inconsistent with previous research. This inconsistency may be related to the increase in services in our culture. To serve or wait on someone in a business establishment is more prevalent than in previous years. Furthermore, it is likely that individuals who are tip recipients have higher status now than forty years ago when Whyte was engaged in his project. There are fewer class distinctions with the burgeoning middle class. Restaurant employees include students on their way towards another profession, as well as aspiring actors and actresses, etc. Moreover, our interviews tend to show that waitpersons perceive the tip as their pay rather than an act of a superior to an inferior.

Another aspect of waitpersons' relationships with customers that was apparent from the interviews is that tipping places them in a liaison position between customer and management. This seems to be true since their pay is directly dependent on their relationship with the customer. This is consistent with the findings of Shamir (1983) who found role conflict among tipped employees. It is clear that waitpersons act as advocates for customers on occasions such as returning food or getting something taken off the check if the customer did not like it. This liaison or "middleperson" relationship is evident from the following:

"It's like now you're a sub-contractor, you know, you go in and work for this guy but you really have your own little business in there and how well you do is a reflection of your ability at your job . . ."

"The service person is the link between that customer and the cook and management and it's their job to make sure that person's satisfied. So if something happens in the kitchen to screw things up then people should be compensated in some way, you know, they shouldn't be expected to pay for inferior food, and if they fail in that responsibility, if they fail to make amends for shortages elsewhere then they haven't been doing their job and consequently, if the tip suffers, it's understandable."

Quality of Service and Tipping

Informants indicated that quality of service would decline if tipping was replaced by another method of payment (e.g., a flat service charge, higher wages). That is, they believe that the amount of effort and enthusiasm that is put in the job by waitpersons is, to some degree, related to the incentive of the tip. Furthermore, they seemed to believe that customers have a right to this control

and customers should be able to pay as a function of the service that they receive.

Respondents also believed that the size of a tip is related to quality of service provided. It is interesting to note, however, that service was defined by respondents in a couple of different ways. On the one hand, service quality was discussed in terms of anticipating customers needs, keeping the water glasses filled, etc. On the other hand, good service was often equated with rapport with the customers. Service was frequently discussed in terms of smiling, being pleasant, and friendly. For example:

"Probably the biggest thing is being friendly overall. Because even if I'm really busy and I don't spend as much time as I should, as long as you're really friendly then they are more willing to forgive you."

". . . because their perception of service and the personal interaction that is going on between you and the table, how much you can entertain them and make them feel comfortable, different customers have different ideas of what they want from the waiter. Some waiters are very good at entertaining a table . . ."

This is interesting, in light of the findings of May (1978, cited in Lynn and Latane 1984) mentioned earlier. May found that tips were related to non-task trips to the table but not to quality as rated by independent observers. It appears that waitpersons seem to know that enhancement of the total dining experience is related to tip size and they seem to define general attention and rapport as an aspects of service.

Although not mentioned by all respondents, there seemed to be a sense that customers would not necessarily tip less in cases when the restaurant got busy and the waitperson could not be as attentive. Some mentioned that customers would sometimes tip better in these instances because they felt a certain empathy for the waitperson.

The Waitperson as Customer

The individuals who were interviewed were asked about their own tipping behavior when they are a customer in a restaurant. A clear finding is that people who are waitpersons are good tipppers. This is probably the case for several reasons. Since they are in the industry, they may empathize with similar others. Also, there is a good chance that they may know their waitperson personally since people in the industry socialize a lot with others in the business. Further, informants generally admitted to making value judgments about customers based on how much the customer tipped. It is likely that the waitperson is acutely aware of this when they are a customer and want to be looked upon favorably by their server. Most informants said they would tip 20 percent or more in the general case. Most also said that they would never go below 15 percent even

if the service they received was extremely poor. In spite of this floor of 15 percent, most felt that they usually tipped as a function of the quality of service that they received.

SUMMARY AND CONCLUSIONS

Tipping is an exchange between consumer and service provider that is guided by informal rules and custom. It appears that those who occupy one side of this exchange relationship, the waitpersons, feel that many who occupy the other role, the customers, do not understand the rules, since these rules are not explicit. The waitpersons, on the other hand, are part of a culture that considers and discusses the custom at length and these discussions pass on the shared beliefs and folk wisdom about the custom and about customers.

Consistent with previous findings, the custom of tipping helps place the service provider in a liaison position between restaurant management and the customer. While the service provider represents the restaurant to the customer, he or she also acts as advocate for the customer if something is not correct with the meal. Most waitpersons believe that the customer and service will suffer if the system of payment is changed to higher wages or a service charge.

People in the restaurant business believe that the amount they receive for their service is a function of aspects of the consumer, perceptions of service quality provided, and situational factors. In general, while stereotypes exist about different customer groups, waitpersons seem to believe that the causal variable related to individual differences is *degree of knowledge of the tipping custom*. Quality of service is perceived to be a matter of actual service as well as rapport with the consumer. Situational factors include who is present with the paying customer (e.g., whether the tip is a method of impressing someone) and the number of people present at a table.

Future research will investigate the consumer behavior of tipping in more detail and will include surveys of consumers and service providers. Particular areas of interest are how consumers define service quality, the extent to which consumers are knowledgeable of tipping protocol and what factors consumers identify as most important in determining tip size. The authors are also interested in individual difference variables that may mediate tipping behavior. A cross-cultural investigation of tipping as custom is also planned.

Consumer Market Beliefs: A Review of the Literature and an Agenda for Future Research

Calvin P. Duncan, University of Colorado-Boulder

ABSTRACT

Consumer market beliefs are an important and under-researched construct in consumer research. It is argued that strongly held market beliefs serve to simplify consumer decision making by directing search and evaluation activities. The paper explicates the construct of market beliefs and reports findings from an empirical study which illustrate popular market beliefs. Future research directions are then outlined.

INTRODUCTION

Consumer researchers have adopted various theories of cognition and information processing to describe consumer decision making behavior. In most of these theories, consumers are portrayed as information gatherers and integrators whose judgments result from movement through a series of cognitive stages (e.g., attention, encoding, memory retrieval, etc.). A frequently reported finding is that decision minded consumers process information sparingly (e.g. Hogarth 1980; Bettman 1979); memory retrieval is selective and external search and evaluation efforts are influenced by considerations of efficiency and past effectiveness. One construct which helps explain how consumers simplify their processing activities is prior beliefs.

Prior beliefs, as used here, are general opinions that are formed from experience and used to reduce complex judgments to simpler cognitive operations. One characteristic of prior beliefs is that they vary in their specificity and the manner in which they are employed. Thus Tversky and Kahneman (1973, 1974) have identified a relatively small number of broad-based prior beliefs, in the form of judgmental principles or heuristics, which are applicable across a wide range of decision settings. Decision makers, for example, may reveal a belief in local representativeness: they rely on results from small samples to be valid indicators of entire populations (Tversky and Kahneman 1971). Adherence to this "law of small numbers" belief may influence information processing behavior, especially in discouraging elaborate pre-decision search.

Other prior beliefs operate at a more detailed level. In contrast to the general purpose heuristics identified by Tversky and Kahneman, more context-specific beliefs are applied in particular decision environments. Thus, a baseball manager relies on the strategy, "When behind in the ninth inning, it's best to go for the tie at home and the win on the road." Similarly, a business employer may believe that a job applicant's professionalism is indicated by the neatness of her attire. Even the student, when confronted with a multiple choice exam question resorts to the rule that "Statements containing extreme words such as 'always' or 'never' should be marked false" (Sherman and Corty 1984).

This paper addresses the role that context-specific prior beliefs play in still another decision environment, the consumer marketplace.

The purpose of this paper is to stimulate additional interest in prior market beliefs as a potentially valuable construct for explaining consumer decision behavior. The paper begins with a definition of prior market beliefs (hereafter referred to as "market beliefs") and a discussion of some of their basic characteristics. Theoretical and empirical contributions from previous research in the area are reviewed. Some preliminary empirical findings are then reported and an agenda for future research is proposed.

CONSUMER MARKET BELIEFS

In the marketing literature, beliefs typically have been conceptualized in narrow, object-attribute terms: beliefs are linkages between a particular brand and specific brand attributes, i.e., "consumer k's belief as to the extent to which attribute i is offered by brand j" (Wilkie and Pessemier 1973, p. 429). However, as Duncan and Olshavsky (1982) point out, not all consumer beliefs are of this kind. Beliefs may also express more generalized associations--between classes of objects (e.g., buyers, products, vendors), between product attributes (e.g., price, quality), and as notions about how the marketplace operates over time (e.g., competition, change).

Market beliefs, then, are defined as intermediate level beliefs which convey information about the association between independent market concepts (adapted from Kendler 1968, p. 579). They are more specific in context than judgmental principles; yet, more general in their application than brand-attribute beliefs. They assume more than one type or function. Many market beliefs appear as simple decision rules, incorporating product or store cues as surrogate indicators of more complex information. Other beliefs are expressions of opinion about the shopper's own abilities as a judge, variances in market offerings, or keys to success in the marketplace (Duncan and Olshavsky 1982). Examples of specific market beliefs include: "Smaller stores charge more for the same brands than larger stores," "More heavily advertised products are more expensive to buy," "Products in end-of-aisle displays are usually on sale," "Sales people always push their most profitable items," "I am a poor judge when it comes to evaluating technical products," and "In general, warranties are worthless."

Consumers use market beliefs because they provide focus. They encourage the individual to selectively attend to specific aspects of the information environment. In doing so, they reduce decision complexity and enable the decision maker to make judgments more quickly and with less

cognitive effort than if a more thorough analysis were undertaken (Sherman and Corty 1984).

Consider an individual searching for a new compact disk player. Assume that this shopper holds the following market beliefs: "In most product categories, the top brands are all about the same," "Price is rarely a reliable indicator of product quality," "Advertising costs are passed on to buyers in the form of higher prices," "The longer a product's warranty, the more dependable it is," and "It's always a good idea to stick with brands you know." In combination, these beliefs can be expected to shape and simplify the buyer's information processing task. As he begins his decision making process, he will probably scan memory for information on brand familiarity and brand advertising. He is likely to search for and selectively attend to specific external cues: top brand names, relative prices, and product warranties. Finally, he will evaluate alternatives by considering the top brands, shying away from those perceived to be most heavily advertised or highest priced, and identifying ones offering longer warranty periods. Additional strongly held beliefs such as "Foreign manufacturers are superior to American firms in electronics and high technology product categories" and "High volume stores offer the best deals" may serve to constrain his problem space still further.

This illustration is simplistic, of course. Market beliefs are typically not the only influence or even the most important influence on consumer information processing behavior. Nevertheless, such beliefs appear to play a key role in explaining how buyers cope with information complexity by relying on experience-based opinions and biases to collapse the choice process. The illustration suggests some other general characteristics of consumer market beliefs:

1. Each consumer subscribes to a large number of market beliefs, although only a few may be salient for a given decision.
2. Individual market beliefs vary in their universality. Some beliefs are widely shared ("Price is a reliable indicator of quality") while others are idiosyncratic ("Large corporations are politically corrupt and their products should be avoided").
3. The salience of market beliefs and the confidence with which they are employed are situationally dependent.
4. Market beliefs can be employed individually and in combinations. Combinations of beliefs are often hierarchical in nature, where one belief is built on another ("Firms with the best products sell the most"... "Firms that sell the most, make the greatest profit"... "Profitable firms do more advertising"... Therefore, "Firms which do

the most advertising, sell the best products.")

5. Market beliefs, once formed, are resistant to change.

PAST RESEARCH

A growing number of studies in consumer behavior have found empirical support for the notion that prior knowledge influences information processing behavior (Bettman and Park 1980; Kardes 1986; Park 1976; Park and Lessig 1981; Rao and Monroe 1988; Srull 1983). Although prior knowledge can take different forms in memory (Hastie 1981; Hayes-Roth 1977; Rummelhart 1981), much of the previous research has looked at the effects of knowledge level, where amount of knowledge is measured in terms of either perceived or objective product knowledge. Thus, Alba (1983) reported that subjects high on self-reported knowledge could recall from memory significantly more product information than less expert subjects. Johnson and Russo (1984) found support for an "inverted U" relationship between degree of subjective product familiarity and total amount of new product information recalled. Finally, Brucks (1985) reported level of product class knowledge to be positively related to a third dimension of information processing activity, variability of repurchase search.

Market beliefs represent another aspect of a buyer's knowledge structure. Although level of knowledge has been linked to the formation of market beliefs (Park and Lessig 1981; Rao and Monroe 1988), relatively few studies in consumer behavior have focused on the impact of market beliefs on buyer decision making. The present review of this literature identifies three distinguishable research approaches.

The first approach includes studies which have investigated specific market beliefs relating to the evaluation of hidden product benefits. Economists have long observed that, in imperfect information markets, buyers will use prices to signal level of quality among unfamiliar alternatives (Sciotvsky 1945; Wolinsky 1983). In marketing, a number of researchers have confirmed that consumers frequently do subscribe to a "price is a reliable indicator of product quality" belief (e.g., Enis and Stafford 1969; Gardner 1970; Monroe 1976; Olson 1977). Inferences of product quality have also been linked to level of seller's advertising expenditures (Salop 1978), market share (FTC Publication 1979), product warranty (Kelley 1988; Priest 1981; Wiener 1985), brand image (Allison and Uhl 1964; Gardner 1971; Jacoby, Szybillo, and Busato-Schach 1977), length of time in business (Beales et al. 1981), and country of manufacture (Lillis and Narayana 1974). Olshavsky (1984) has tied the use of such surrogate-based beliefs to decision making, identifying them as one of five consumer preference formation behaviors which can ultimately affect brand (or store) choice. He contends that adoption of a surrogate-based preference formation strategy may

reduce search by causing the buyer to focus on cues in lieu of other available information. One correlate of this argument is that the more reliable the surrogate is perceived to be, the less search and evaluation effort the decision maker will expend.

A second, related research stream has also dealt with surrogate-based market beliefs but is narrower in its emphasis. Here, researchers have focused on a single market belief, "price is positively related to quality," to investigate how beliefs may be formed and, once formed, how they may impact on patterns of information search and evaluation. Borrowing from work on the judgment of covariation by social perceivers (Crocker 1981), Bettman, John, and Scott (1984, 1986) identified covariation beliefs as one type of prior market belief. Covariation beliefs "refer to those beliefs regarding the degree of relationship or association between two events or concepts" (1986: p. 316). They are learned through the processes of hypothesis-testing and assessment of covariation (Crocker 1981). The hypothesis-testing model suggests that consumers develop notions about market relationships, prototypical products, effective buying strategies, and so forth. For example, after observing friendlier service in stores which are smaller in size, an individual may hypothesize a relationship (recognize a covariation) between service and store size. According to the model, the consumer will assess the adequacy of the hypothesis by sampling and interpreting additional information. He will revise the hypothesis if necessary and use it to guide behavior only as it becomes validated.

In a study that investigated the price-quality relationship as a covariation belief, John, Scott, and Bettman (1986) reported that subjects who believed that price was positively correlated with product quality tended to sample higher priced products than subjects who did not subscribe to the belief. These findings, and subsequent work by Grimm and Agrawal (1988), indicate that the hypothesis testing process is biased; the content of prior surrogate-based market beliefs has a systematic effect on subsequent information search patterns.

A third approach to the investigation of market beliefs was taken by Duncan and Olshavsky (1982). These authors conducted a survey of 164 recent color TV purchasers in an attempt to (1) identify a diverse set of commonly held market beliefs and (2) find empirical support for hypothesized associations between specific belief endorsements and types of information seeking behavior. Twenty-seven market beliefs were isolated. They varied in content from "benefits of search" and "attribute surrogate" items to beliefs pertaining to perceived "variance of offerings" in the market. Eleven of the 27 beliefs were classified as "alternative limiting" in function. The authors hypothesized that all 27 beliefs would affect *amount* of information search for a new color TV set. Alternative limiting beliefs were those beliefs which were expected, a priori, to have a significant impact on the *type* of brands or stores considered during the

decision process. It was through their influence on size and composition of the buyer's consideration set that alternative limiting beliefs were expected to reduce total amount of information seeking.

Bivariate correlations between market belief endorsements scores and extent of search were found to be statistically significant (in the predicted direction) for 15 of the 27 belief items. Although regression analysis revealed only five of the 27 beliefs to be significantly related to extent of search, the model explained 50% of the variance in prepurchase information seeking among the color TV buyers. Finally, five of the 11 alternative limiting beliefs influenced type of brand and store actually patronized.

Duncan and Olshavsky described their findings as "encouraging" and called for additional research in a number of areas. Perhaps most pressing in their view is the need to generate a more comprehensive inventory of market beliefs of all types.

MARKET BELIEF ITEMS: ADDITIONAL EMPIRICAL FINDINGS

A research program is currently underway to broaden and extend previous findings on market beliefs. An initial phase of this program involves the generation of a more comprehensive list of consumers' market beliefs. Selected preliminary findings from this research are presented here.

Data were collected from a convenience sample of nine individuals living in a medium sized city in the western United States. Participants were either personal acquaintances of the project team or individuals solicited through an advertisement for study volunteers. Respondents included five men and four women, all between the ages of 21 and 55 and from different households. All participants were aware that they would receive \$20.00 for their involvement in the study. At a prearranged time, an interviewer met with each of the participants in his (her) home to explain the purpose of the study, define terms (e.g., "market beliefs"), discuss study procedures, and answer questions. Participants were given written instructions and a response form to guide their activities.

Participants were given one week to complete their tasks. Instructions to individual respondents varied, although each included both a "shopping experience" and a "scenario response" component. One purpose of the study was to test different data collection approaches to identify methods which are most effective in encouraging individuals to reveal their market beliefs. The shopping experience task required respondents to engage in an actual shopping visit to spur their thinking about beliefs. During the week, each person was asked to (1) visit and examine merchandise in either a shopping center or two different types of stores, and (2) record as many market beliefs as possible (while on site and later at home).

After a reminder phone call at mid week, a second meeting was arranged. At this time, the interviewer reviewed each participant's recorded

entries, requested clarifications, and obtained feedback on the procedure. The interviewer then asked the respondent to listen to and then react to one of three decision scenarios. The purpose of this part of the interview was to probe for additional market beliefs not elicited from actual store visits. Each scenario involved a different hypothetical decision task (e.g., a stranger, who for some reason specified in the scenario, knows nothing about shopping, products, or stores, and seeks advice and useful guidelines on how to understand the marketplace and make effective buying decisions). Upon completion of the scenario response task, respondents answered questions on demographic variables and received payment. Interview sessions lasted between 60 and 90 minutes.

Analysis of findings produced over 150 items which were interpreted to be market beliefs. A subset of these items, grouped into descriptive categories, is shown in the Table. Many of the beliefs take the form of surrogate-based opinions expressing a relationship between an external product (store) cue and some benefit or quality (e.g., "The more sales people there are in a store, the more expensive are its products"). Other beliefs communicate buyer convictions about his (her) own ability as a shopper, the benefits and advisability of search activity, and preferred shopping strategies. In some cases, items are shown in combinations to accurately record the respondent's stream of logic (e.g., "When you are not sure what you need in a product, it's a good idea to invest in the extra features. You'll probably wish you had them later." and "It's advisable to stay away from products when they are new to the market. It usually takes the manufacturer a little time to work the bugs out.").

This research also provided useful insights on the strengths and weaknesses of the belief elicitation techniques used in the study. In general, the hypothetical scenarios performed well although specific areas in need of refinement were identified.

DIRECTIONS FOR FUTURE RESEARCH

Thus far, research on market beliefs has been largely exploratory in its approach and more piecemeal than programmatic in its content. This is not surprising. One obvious reason is that the study of market beliefs has not been viewed as a separate, integrated research area. Instead, investigators have focused more narrowly on the examination of screening devices, information signals, and covariation beliefs or more broadly on consumer inferential beliefs and decision heuristics--all of which are related to market beliefs.

The argument for integrating separate research streams under the umbrella of "market beliefs" is more semantic than substantive. The important point is that our understanding in these areas can be improved if common elements of each research area are identified, overlapping terminology and conceptualizations are reconciled and simplified, and a more integrative, systematic approach is taken in future research.

With these thoughts in mind, an agenda for future research on market beliefs is proposed. Six issue areas are identified and briefly described.

Composition of Beliefs and Belief Structures. Results from the empirical study described earlier in this paper suggest that it is possible to identify a large number of market beliefs. However, our interest is confined in those beliefs which are widely endorsed (positively or negatively) and frequently applied in decision making. Future studies should use structured and unstructured response formats to uncover as many additional popular beliefs as possible. Moreover, further work is needed to determine the underlying dimensionality of known market beliefs. A factor analysis performed by Duncan and Olshavsky (1982) on subject endorsements of 27 beliefs produced mixed results. Although belief dimensions emerged (including "ability to judge"), patterns of factor loadings made their interpretation difficult. A priori, we might expect future researchers to find separate and relatively well defined market belief dimensions.

Belief Endorsements--By Whom? Once a collection of popular beliefs is identified, we should determine who holds them and to what degree. Are there distinguishable patterns in the belief structures of different consumer groups? For example, do belief endorsements (and the confidence in those endorsements) correlate with gender, age, education, or other variables?

Effect of Market Beliefs on Behavior. Past findings suggest market beliefs, as part of the consumer's knowledge structure, do exert an influence on information processing and final choice behavior. Future research should attempt to clarify and extend these results. For example, Furse, Punj and Stewart (1984) reported evidence in support of a beliefs-search relationship but were quick to note that "no simple relationship was found between the amount and type of search and such (belief) variables..." (p.424). Similarly, while common sense and limited empirical work suggests that beliefs such as "the best brands are usually the ones that sell the most" and "heavily advertised brands are overpriced" will influence the composition of a decision maker's evoked set and, thus, his evaluation process, additional research is needed to confirm the strength and frequency of these effects.

Conditions Under Which Market Beliefs Are Employed. Consumers appear to apply their market beliefs selectively. What are the circumstances under which market beliefs are more (or less) likely to be used as part of the consumer's decision process? When beliefs are incorporated into a decision, which factors determine the *specific* beliefs that will become salient? Past research has failed to clearly resolve these issues.

Variables posited to influence the use of market beliefs include: level of consumer knowledge (Beattie 1981; Park and Lessig 1981; Rao and Monroe 1988), consumer involvement (Furse, Punj, and Stewart 1984), task complexity and ambiguity (Henry 1980), and stage in the decision process (Bettman 1979). Yet, the manner in which these

TABLE
Selected Market Beliefs

Brand

All brands are basically the same.
Generic products are just name brands sold under a different label at a lower price.
A brand's quality is the most important determinant of its success. Bad brands just don't survive.
The best brands are the ones that are purchased the most.
When in doubt, a national brand is always a safe bet.
In established product categories, brands which have been around the longest are the most dependable.

Store

Specialty stores are a great place to familiarize yourself with the best brands. But once you figure out what you want, it's cheaper to buy it at a discount outlet.
A store's character is reflected in its window displays.
Sales people in specialty stores are more knowledgeable than other sales personnel.
Larger stores offer better prices than small stores.
Stores that sell on a volume basis can afford to charge less for their merchandise.
Locally owned stores give the best service.
A store that offers a good value on one of its products probably offers good values on all of its items.
Credit and return policies are most lenient at large department stores.
Stores that have just opened usually charge attractive prices.

Sales Personnel

In my experience, sales people who work during the day are more knowledgeable than those who work in the evenings.
Customers should always listen to sales personnel with real skepticism.
A good way to judge brands is if sales people in different stores have the same opinion.
Older sales people know more about the products they sell.
The more sales people there are in a store, the more expensive are its products.
Sales people are instructed to push brands that make the store the most profit.

Prices/Discounts/Sales

Better products cost more to make. That's why higher prices usually indicate better quality.
Sales are typically run to get rid of slow moving merchandise.
Stores that are constantly having sales don't really save you any money.
Within a given store, higher prices generally indicate higher quality.
Sales that do not specify pre-sale price levels do not offer any real savings.

Advertising and Sales Promotion

I associate "hard sell" advertising with low quality products.
The most heavily advertised brands are normally among the best brands.
Stores that advertise a lot have overpriced merchandise.
Items tied to "giveaways" are not a good value (even with the freebee).
Coupons represent real savings for customers because they are not offered by the store.
When you buy heavily advertised products, you are paying for the label, not higher quality.

Alternate Distribution Channels

The quality of products that are sold door-to-door is usually quite good.
Buying through catalog is cheaper because you eliminate the retailer's profit.

Ability as a Shopper

I can make pretty good decisions without a lot of running around (search).
One of the best ways to know which brand to select is to look at what everybody else is buying.
Electronic products are changing so fast that I usually have to start all over again in figuring out which brand to buy.
I have a very good idea of what is a fair price for most products.

Product/Packaging

Larger sized containers are almost always cheaper per unit than smaller sizes.
New products are more expensive when they're first introduced. Prices tend to settle down as time goes by.
When you are not sure what you need in a product, it's a good idea to invest in the extra features. You'll probably wish you had them later.
Items that come in fancy packages are not a good value.

how market beliefs can be changed with special attention given to the problems involved in reversing inaccurate or false beliefs.

CONCLUSION

In the past decade, consumer researchers have begun to look at the effects of consumer knowledge structure on information processing and choice behavior. In only a few cases, however, has this interest focused on the role of consumers' prior beliefs as a dimension of knowledge content. This paper has attempted to consolidate past research related to market beliefs. It contends that additional conceptual and empirical development is needed to explore the nature of market beliefs and their impact on consumer search and evaluation processes.

TABLE (CONT.)
Selected Market Beliefs

In general, synthetic goods are lower in quality than goods made of natural materials. It's advisable to stay away from products when they are new to the market. It usually takes the manufacturer a little time to work the bugs out.

Manufacturer

Consumers shouldn't feel obligated to buy American made products.
I am loyal to smaller companies because I believe their intentions are good.
Well known companies can't afford to jeopardize their reputations by introducing inferior products.

Product or Service Warranties

In general, warranties are worthless!
Companies and stores that offer strong warranties and no hassle returns have better products.
Extended product warranties cost more than they're worth.
If a manufacturer won't back his product with a warranty, it probably means it won't last.

Required Search

The more information you have, the better.
Once you find a good brand, it pays to stick with it.
It takes time to make a smart purchase.

Store Location

Stores in enclosed shopping malls charge higher prices because they pay such high rents.

factors may affect the employment of market beliefs is unclear. For example, consumers with little product knowledge (novices) may resort to simplifying beliefs ("the highest priced brand is the best") as a means of coping with market uncertainty. Experts, however, may also employ market beliefs, but for a different reason. Possessing well developed knowledge structures, they use beliefs as a tested, reliable way to make decisions easily. Future studies need to clarify the role that product knowledge and other factors play in influencing consumer dependence on market beliefs.

At the same time, additional research on how market beliefs are organized in memory may provide clues as to how specific beliefs are retrieved and utilized. Deighton (1983) and others have suggested that individual beliefs may be stored in memory as components of schemata. It can be hypothesized that, as a particular schema is activated, the market beliefs associated with the schema become available to the individual for use in decision making.

Accuracy of Consumer Market Beliefs.

Clearly, beliefs do not always correspond to reality; they are not always applied in an accurate way. In many cases, this is true because specific conditions create exceptions to generally observed relationships. Heavy advertising may indeed cause prices to be higher. But higher costs are not always passed on to the consumer. Moreover, advertising's demand stimulation effect may actually cause price per unit to decline in certain situations. The misapplication of "wrong" beliefs represents an intriguing opportunity for empirical research. Are there commonly held market beliefs that are inaccurate much of the time? What are the effects of

inaccurate beliefs on consumers' information processing and choice behaviors?

Belief Formation, Durability, and Resistance to Change. To the extent that market beliefs affect decision behavior, an understanding of how they are originally formed appears useful. Like all beliefs, market beliefs may be formed directly--though observation of a relation between two concepts or receipt of information about such a relation--or indirectly through an inferencing process (Fishbein and Ajzen 1975). Beliefs formed from inferencing are derived from other beliefs already held by the consumer. This process suggests that these beliefs (developed through inferencing) may be organized in hierarchical fashion in memory. If so, they may be retrieved and applied as part of the same information chunk.

Finally, as Duncan and Olshavsky (1982) observed in their earlier research, it is important for product manufacturers and store owners to understand the difficulty involved in effecting belief change. For example, consider the problem that a manufacturer of prestige brands may encounter when it decides to distribute in mass merchandise outlets. If potential buyers of prestige brands share the belief that mass merchandise stores carry less expensive or lower quality merchandise, they may (1) eliminate mass merchandise stores from their store set, or (2) lower their quality perceptions of these brands when they are encountered in the mass merchandise environment. The work of John et al. (1986) suggests that market beliefs may be difficult to change because consumers tend to gather information that is consistent with their prior beliefs. Additional research is needed to determine

A New Perspective On Choice

Kathleen M. Rassuli, Indiana-Purdue University at Fort Wayne
Gilbert D. Harrell, Michigan State University

ABSTRACT

A variety of consumer researchers have suggested changes in the way we approach the study of consumer behavior. Part of the discontent with the present approach may lie in the limitations of modeling brand choice -- the definition of attributes, the approach to dynamics and in the directionality of the models. This paper proposes a new conceptual base; choice is depicted as the beginning of a consumption process. Consumption sets and consuming style are introduced. The broader treatment of consumption phenomena should provide a mechanism to tie together several divergent research streams and result in new insights into consumer behavior.

INTRODUCTION

While some authors may disagree, the consumer behavior discipline seems to be in a state of flux (Holbrook, 1987). Several prominent scholars have expressed the need for additional research avenues in consumer behavior, particularly more encompassing yet theoretically sound (Kassarjian 1978, 1987; Hirschman 1985, 1986; Belk 1985; Holbrook 1987). The search for new approaches appears to be as intense as at any other time in the history of the discipline. Kernan (1987, p. 133) says: "[Holbrook's] plea is not the ranting of a lunatic fringe, but rather a position that represents a growing number of consumer researchers who, for whatever reason, have been unable or unwilling to express it." In response, this paper utilizes a new conceptual base. The intent is to show that the process of consumer behavior encompasses a great deal more than brand choice alone. The broader treatment of consumption, represented in the new conceptual model, provides a mechanism to tie together several divergent theoretical avenues.

THE CURRENT STATE OF AFFAIRS

In the minds of many leaders of the discipline, it appears that conventional theories and techniques have taken consumer researchers to a certain point in understanding the consumer but may have reached their limit. Mittelstaedt (1971) and Sheth (1979) criticize what the former refers to as the "eclectic borrowing" on the part of consumer behaviorists. The latter calls for consumer behaviorists to develop their own constructs rather than rely on psychology or sociology.

According to Sheth (1979), three main difficulties plague research in consumer behavior. The first is the implicit assumption of a rational problem-solving process, as exemplified by multiattribute information processing and brand choice models (ibid., p. 573; also see Olashavsky and Granbois 1979). As a remedy, Sheth suggests that researchers turn their attention to habit and

conditioning, situationalism, novelty-curiosity, deviant, and obsessive consumer behavior. Along the same lines, Zajonc (1980) and Zajonc and Marcus (1982) suggest a shift from cognitions to affect. Gardner (1985) focuses on research to date concerning affective dimensions of mood states. Foxall (1983) suggests a shift to behaviorism implicit in such notions as habit and conditioning.

Sheth points to the overemphasis on the individual and the lack of focus on groups as the second and third problems in consumer research (1979, p. 573). Even such groups as market segments, social classes, and ethnic groups are studied as "aggregates of individual consumers rather than distinct group entities" (ibid.). Sheth suggests research should examine dyads, small groups, families, and organizations. Research is needed into nonproblem-solving group behavior (ibid.). Moreover, "research should be directed at the *macro* (group) rather than at the *micro* (individual) level" (1979, p. 514). Hirschman (1985), Belk (1985), and Uusitalo and Uusitalo (1981) have similarly called for more macro research. Alderson (1957) developed the rudiments of a consumer theory with the household as the unit of analysis. Glock and Nicosia (1964), Nicosia and Mayer (1976), Foxall (1976), and Zielinski and Robertson (1981) all have called for the interjection of sociology into the study of consumer behavior.

The literature has tended to treat consumer behavior as a static rather than a dynamic process. Calls for recognition and incorporation of a process orientation have been made (Jacoby 1976; Sheth 1979). Jacoby points out that the discipline uses static methods to understand dynamic processes (1976, p. 3) and suggests that the discipline should focus on consumption behavior as opposed to just buyer behavior (1976, p. 10). Alderson (1957) was among the first to call for such a shift, noting that there is a difference between buying behavior and consumption behavior.

In concluding this section, the call has gone out for new theories and new methods. A variety of alternatives have been proposed, some are radical. Solutions range from theoretical focus within brain function to changes in metatheory. Often a change in emphasis is accompanied by a change in method, or preceded by a change in metatheory. Included are the following: (1) change in focus from cognitions to affect; (2) change in school from cognitive learning to behaviorism; (3) shift from psychological theories to other related disciplines, such as sociology, and anthropology; (4) change in methodology, for example, from questionnaires to projective techniques, and/or from respondent answers to observation, and/or from correlation to causal modeling; (5) change in metatheory and ways of generating theories, for example, from logical positivism to humanism.

EXPLAINING AND PREDICTING CHOICE

Part of consumer researcher's dissatisfaction might be explained by briefly looking at the major research streams that have attempted to discover variables that relate to, or predict, choice. Many seemingly disparate research streams have been dominated by attempts to explain choice. Models that deal directly with choice include the decision-making process, the communication hierarchy, and stochastic choice models, to name a few. Preference and attitude models often address choice; that is, while their main purpose is to explain preference, correlations with brand choice are often used to validate the models. Also, in the literature on information overload (Jacoby, Speller, and Kohn 1974) choice is touched on tangentially; correct product choice is used to determine overload. In fact, one taxonomy of consumer behavior models shows that all models (with the exception of pure evaluation models) touch on choice (see Lilien and Kotler 1983, p. 205).

The variables linked to choice can be classified into three categories. Individual difference variables are used to divide people into homogeneous groups (demographics, personality, and life-style). Process variables describe how choice occurs (preference and attitude formation). Broad environmental exogenous variables (culture and social class) help describe the influence of norms and societal variables.

Individual Difference Variables

Personality and Demographics. Early research linking personality and demographic variables to product and brand choice found very low R^2 's (Evans 1959; Fry 1971; Alpert 1972). Saranson et al. (1975) analyzing 102 personality studies found an average R^2 of .045 for situational variables, .03 for personality variables and .01 for demographic variables. (Also see Peterson et al. 1985). According to Wells (1975, p. 196), "work with personality inventories has been judged 'equivocal'... The correlations have almost invariably been low, and the relationships uncovered have been so abstract that they could not be used with confidence in making real-world marketing decisions." (Also see Kassarian and Sheffet 1975).

Psychographics. Later, emphasis shifted to life-style research (see, for example, Levy 1963). Wells (1975, p. 196) called the area of psychographics a blending of personality inventories and motivation research. Darden and Perrault (1975), in a typical study, found that life-style accounted for about 15 percent of the variance in behavior (vacation choice). Andreason (1984) found a correlation coefficient of 0.14 looking at changes in life-style and in preferences. Some recent work on life-styles assumes that certain groups constitute "a life-style" and begins analysis at that point (for example, "housewives" and "working wives;" see Jackson et al. 1985; also see Andreason 1984). Wind and Green (1974, p. 106) listed five different ways life-style was measured and

attribute the practice of using different measures to a lack of theory in the life-style research stream. Fenwick et al. (1983) draw a similar conclusion. "The components of this 'life-style' are both unspecified and by design unexpected" (1983, p. 71). Roscoe, LeClaire, and Shiffman (1977) point out that the purpose of psychographics is not to predict behavior, but to help explain and describe consumers.

The strength of relationships documented in the literature are summarized in Figure 1. Demographics probably predict life-style better than brand choice. Life-style (psychographics) predicts choice somewhat better than does personality or demographics.

Process Variables: Multiattribute Models

Consumer research has been dominated by the multiattribute attitude models (Sheth 1979). The multiattribute approach suggests that once attitude is known, it can help predict and understand preference (that is, affect), purchase intention, and choice.

Again, in this literature, the strength of the relationship between attitudes and behavior is varied (Harrell and Bennett 1974). In the psychology literature, Ajzen and Fishbein (1977) report correlations of between 0.02 and 0.49. The relationships reported in marketing have usually been between 0.20 and 0.30.

Disappointing results have been attributed to several factors. Ajzen and Fishbein (1977) felt that incongruence between the content of attitude questions (which focused on general attitudes) and the type of behaviors or actions studied (specific) could account for weak relationships. Studies that measured the attitude-behavior relationship in the context of specific situations did, in fact, attain higher correlations. Bagozzi et al. (1979) noted that lack of consideration for the "tripartite" nature of attitudes, (cognitive, affective, and behavioral intention components) may account for the results.

Multiattribute models have been useful in deciphering various aspects of information processing, the components of attitudes, and relationships of attitude formation to other variables. However, it should be noted that these models are founded upon the assumption that attributes are important. Researchers then ask "which" attributes are important, "how" people use attributes in decision making (the evaluations component), and "how" people attach significance to attributes. However, none of these models ask *why* attributes are important. Therefore, research in this area has not addressed opportunities that explain and predict behavior as opposed to information processing.

Exogenous Variables

Attempts have been made sporadically to show that variables such as culture and social class are related to consumer decision making and choice. Social class provides a case in point. Social class came to prominence in marketing in the 1950s, but Bettman, Kassarian and Lutz (1978) conclude there

FIGURE 1
Overview of Variables Related to Choice

was little improvement in research beyond 1960. Coleman (1983) believes that social class, as a legitimate area of study in consumer behavior, was hampered by measurement problems and expense, as well as questions about when and how to apply social class, and because of sociologists' disagreement about the "value and validity" of the concept. Coleman (1983) believes that the controversy over income versus social class led researchers to shift focus to other variables.

Nevertheless, both Fisher (1986) and Coleman (1983) emphasize that social class is still relevant to the study of consumer behavior. New research question should not focus on whether income or class is a better predictor of choice, but on the how class affects the use of income (Coleman 1983). Renewed interest in social class has come in the form of the "sociology of consumption" (see Mochis 1981 for a review of consumer socialization). This tradition examines institutions, cultural values, and role structures to determine their impact on consumption (Bettman, Kassarjian, and Lutz 1978). Here, social class merges with topics such as consumption symbolism (Belk, Bahn, and Mayer 1986; Solomon 1983) and consumption's cultural context (Hirschman 1985).

LIMITATIONS DUE TO THE FOCUS ON BRANDS

In attempting to answer questions about choice, one could argue that research has followed a rather specific and narrow path. Sheth and Garrett (1986, p. 460) note the over-emphasis on *brand choice*. While there appears to be tacit agreement about the significance of brand choice, the extent to which the focus on brand choice has influenced consumer research has gone largely undetected. Consider the diversity of models founded upon a brand assumption. The Howard and Sheth model is a brand choice model and while Engle, Kollat, and Blackwell do not make such an assumption explicit, their model also deals mainly with brand choice. Extensive, limited, and routinized decision-making behavior differ to the extent of prior knowledge of product category, and brand attributes. Clearly, the multiattribute models deal with brand attitude, preference and choice. Moreover, the demographic/personality literature began by trying to distinguish categories of brand owners. Finally, while research into exogenous variables as they relate to choice is often at the product form level

(Westbrook and Fornell, 1979), here, too, brand choice plays a significant role.

We believe the implications of this brand focus have not been fully explored. While brand decision-making may represent a large portion of consumer decision-making, it only explains part of consumer behavior. Consumers in the position of making brand choices must be so aware of their needs, that brand attributes tend to become synonymous with *needs, benefits, and consequences*. Attributes, then, are defined as "outcomes, consequences or benefits people obtain from a product" (Wilkie 1986, p. 438) and might be used interchangeably with values and consequences, as some of the multiattribute literature uses attributes (see Cohen, Fishbein, and Ahtola 1972, p. 456). Then, brands tend to be viewed as the means and attributes as the ends of consumer behavior (Wilkie 1986, p. 460).

The ramifications of this simple brand assumption become enormous when one recognizes that modeling consumer behavior in this way narrows the focus of research. If attributes are synonymous with needs, benefits and consequences, then understanding consumer behavior becomes an overly simple matter. The reasoning might be as follows: If a researcher understands the attributes and attitudes toward attributes, it should be possible to predict brand behavior (choice or purchase) and thus understand consumer behavior. However, this scenario might accurately describe the theoretical "never-never land" against which Kassarjian (1987) rails.

Research to date in many fields of consumer behavior has provided an exceptional view of brand choice. Research results have been of much use to individuals in developing sales and promotional strategies, and short term marketing plans. However, the propensity of modeling of brand choice explains much of the discontent in the consumer literature. Clearly, it turns out that the evaluations of attributes only partially explain choice behavior. And while arguably cultural values and life-styles are important, they do not add to our ability to predict brand choice because (as attributes are defined in the literature) values and other variables are often defined and modeled in ways that tend to repeat the information contained in attributes.

Therefore, in attempting to advance the literature, researchers have concluded that we must be

missing any number of other variables: the situation (Belk 1975), reference group pressures, the family influence, emotions (JCR "Call for Research on Emotions, 1985), feelings or affect (Zajonc 1980, Zajonc and Markus 1982), hedonic tendencies (Holbrook 1981), irrationality (Sheth 1979), collecting behavior and having behavior (Belk 1982), and materialistic tendencies (Belk 1985).

DIRECTIONALITY AND DYNAMICS

Directionality. What may be missing in consumer research is an understanding of how a product becomes part of a consumer's life. This is implicit in Jacoby's call for a look at processes and "consumption" and in Sheth's suggestions about consuming life-styles. In other words, part of the explanation for why people buy might be found in how the product will fit into a consumer's life. Rather than ask why people buy or on what basis people make their choice of products, one might inquire *how* the choice of a product, and its constituent attributes, contributes to a person's life.

In addition to being focused on choice, all conceptual schemes of consumer decision making assume that consumers move toward choice of a brand or product. It is noteworthy that in all of the grand conceptualizations of consumer behavior, the arrows representing consumer decision making, move in the direction of choice. With the possible exceptions of the satisfaction literature and the dissonance literature, little consideration is given to what occurs after the purchase. Only recently has a small body of literature sprung up concerning what consumers do with products after purchase (see Belk 1982). While all models include feedback loops, these generally deal with feedback to evoked sets, decision rules, satisfactions, and perceptions. Notably conspicuous by their absence in consumer decision making models are feedback loops to life-style, social class/status or cultural values.

Dynamics. For grand consumer behavior models, since exogenous variables are largely taken as given for the type of consumer decisions under study, change is not relevant to the research. At the extreme, one moves from one given state of the environment to another given state of the environment. The dynamics are captured, as it were, in a series of "shapshots" rather than a motion picture. Rather than understanding the process of change, the level of analysis becomes what Frankenberg (1967, p. 83) would call exogenous comparative statics.

Implications. Taken as a whole, the problems outlined -- the lack of feedback and dynamism, along with the focus on brand choice -- may account for the consumer research focus on rational decision making, and the inability to answer questions about macro consumer behavior, as well as to incorporate the influence of exogenous variables.

PROPOSED NEW MODEL

To ease the restrictions imposed by brand research, the solution is to posit that underlying

single occasion consumer behavior is a dynamic, circular, long-term process. If such is the case, brand decision making becomes a special case of that more general model. The purchases of consumers are related to one another in nontrivial ways, which do not depend on the typical assumption of a rational consumer. The suggested changes are, first, to recognize consumer behavior as encompassing those processes that occur after (as well as during and before) purchase, but to shift focus to those processes that occur *after* purchase; second, to incorporate assortments into consumer behavior models; and, third, a detailed look at the information contained in the attributes of products.

Current models of consumer behavior assume a flow from culture to values to life-styles to beliefs to attitudes to purchase and its outcomes of satisfaction or dissatisfaction. Many streams of research, such as those discussed in an earlier section, look for a simple relationship -- demographics to purchase; life-style to purchase; attitude to purchase, and so forth. Marketers are interested in purchase and consumer theorists have tended to seek the reasons for purchase. But, in their search consumer researchers have asked what factors *result in* purchase. By posing the question in that form, the search tends to focus on the antecedents of purchase.

In the past, authors have suggested a change in focus from buying behavior to consuming behavior (Alderson 1957; Jacoby 1976; Nicosia and Mayer 1976). Alderson (1957; p. 166), for example, posits that buyer behavior is derivative of consuming. However, "derivative" implies that buying behavior *results from* consuming behavior. Here again, one might be led to search for the *antecedents* to purchase.

A number of scholars have also called for a change in the focus of marketing from brands to assortments (Wind 1977; Nicosia and Mayer 1976), but thus far little change has been forthcoming. Green, Wind, and Jain (1972) discuss measurement of item collections, but they look at a single purchase occasion (a meal) and implicitly assume that each item contributes one characteristic (attribute) to that occasion. Within the framework of the multiattribute models, McAlister (1979; 1982) developed a technique for looking at assortments of substitute brands in an inventory (different brands of soft drinks), but she did not extend her model to assortments of apparently disparate items. The challenge is to develop a framework for incorporating the notions of feedback and assortments into a model of consumer behavior.

The perspective proposed here is that choice and purchase could be viewed as *inputs* into a process, *not* merely the end of consumer decision-making efforts. In this way one recognizes the feedback from choice to other consumer behavior variables. Such a feedback loop has been suggested by Carman (1978). He has proposed that values,

FIGURE 2
Dynamic Model of Consumer Behavior

subculture and consumption actually form a "closed loop." While his insight is significant to the model proposed in the next section, Carman doesn't specify the nature of the feedback. Nicosia and Mayer (1976) also outline a circular process whereby consumption activities feed back to cultural values and institutions.

The outline of the proposed model of consumer behavior might appear as shown in Figure 2. If, indeed consumer behavior is a circular process, then why not view choice as the beginning of the process? As depicted choice is not solely the output of a discovery and evaluation process as in many consumer behavior theories. Rather, choice is viewed as an input, a *means*, not an end. Although the arrows go in both directions, we believe the field would be best served by focusing on the new direction, i.e., choice to consumer variables, as opposed to the reverse. Furthermore, the model as shown is tentative; other relationships are not precluded and remain to be explored.

The following two new theoretical units help to form the basic building blocks of a new theory. The initial definitions provide an indication of the nature of these constructs. Tighter theoretical definitions and operational measures remain to be developed.

Consumption Set: the assortment or portfolio of complementary and substitute attributes and attribute combinations that a consuming entity holds at a particular point in time.

Consuming Style: the manner in which a consuming entity furnishes the requirements of the consuming behavior aspects of life.

The long-term nature of the consumer behavior process can be made explicit by considering the individual prior to his/her first choice, and then following the individual through time. Every individual is born into a world surrounded by sets of products; e.g., that chosen by his/her family (the household consumption set), which is a subset of all the attribute combinations available in society (a societal consumption set). If one were able to focus on the individual's first choice/purchase of a good, the scenario in Figure 3 would depict that. Familiarity with other sets provides the context for the decision. The consumption sets encountered

during a consumer's childhood act as a reference point for the current purchase. Over time, the individual fills in the empty consumption set; the second choice is partially contingent upon the first and so forth. Consequently, as depicted in the new model, choice is not merely the *output* of a process, but rather, an *input*. Choice is not an *end*; choice is a *means* toward the end of accumulating a workable consumption set. The process of developing a consumption set should be considered an ongoing process whereby one continually creates, renews, replenishes and destroys the set.

The theoretical model, as briefly outlined, would enable consumer researchers to incorporate aspects of culture, social class and values, captured in consumption sets and consuming style, into models of consumer behavior. In the scenario depicted in Figure 3, culture (i.e., the material and symbolic aspects of culture tied up in the attributes found in the societal consumption possibilities set) is shown to have a direct influence on the individual's purchase decision. Moreover, different social classes would be expected to have somewhat overlapping, yet distinct consumption sets. Furthermore, demographic variables (e.g., geographic location and income) should be related to a person's exposure to aspects of the societal set. Likewise, life-styles help define the constituent components of a set. Thus, as posited, the model is able to incorporate the influence of groups and the influence of other products (those already part of a consumption set) on choice. More importantly, the model enables one to study consumer behavior as a process rather than an isolated event of brand choice. So that brand choice models become a special case of a more general model of choice. Dynamism enters this formulation of consumer behavior in the sense that the set is continually changing due to new acquisitions and the deterioration of old acquisitions.

Assortments and Attributes. The model calls for the incorporation of assortments, defined here as a consumption set. Alderson (1957, pp. 198-99) observes that products are not useful in themselves; utility arises in an assortment of complementary goods.

While the discussion so far has been couched in terms of goods, by convention in marketing, goods are defined as "bundles of attributes" (for example, Kotler 1988, p. 187). Thus, the fundamental element of a consumption set is an

FIGURE 3
Choice in the Context of Sets

attribute. *Attributes* can be thought of as descriptive characteristics sought by consuming entities. The terms feature, aspect, property, and element are alternatives for the word attributes. Earlier in the paper it was noted that thus far little attention has been given to the question of *why* attributes are important. According to the present line of reasoning, attributes are important because they provide the building blocks or ingredients of sets. Thus, attributes take on significance because of their place in a set and are therefore not the ends of consumer behavior, as in some multiattribute models. Perhaps the set issues, i.e., recognizing the significance of other products and of the entire set in choice, would help improve our understanding of multiattribute decisions.

CONCLUSIONS AND IMPLICATIONS

In the present model, consumer behaviors would be viewed, in the main, as instrumental to the development of a consumption set and a consuming style, which in turn enable the consumer to produce desirable outcomes. Consumption sets and consuming style produce utility for consumers because, in the process of developing a style, consumers take a meaningless variety of isolated goods/attributes and turn them into a meaningful, workable consumption set. Consuming need not be considered an end in itself; clearly it is only one possible end. Consuming may facilitate other goals, including learning, creating, resting/sleeping, exploring, nurturing, educating, and worshipping.

If choice is an *input* into a process of creating sets and styles, then what is the output? Any answer to this question by consumer researchers would include: creating a life-style (perhaps harmony, order/disorder); creating a personality/self; playing role(s); surviving (in a physiological sense); being an individual; belonging to a group; expressing oneself; signaling membership; entertaining oneself, and so forth. Ultimately, in creating a consumption set and developing a consuming style, the consumer creates possibilities to deal with life's multiple demands.

Based on the model as outlined, research directions could take the field down many avenues. First and foremost, one must determine whether consumers actually do create sets and/or think about products/attributes in set terms. If they do, then a whole series of unanswered questions remain. How

do consumption sets and consuming style affect one another? How are attributes combined? What determines whether an element of a set remains or is destroyed? What are the most important determinants of consuming style? Are different styles possible, do styles evolve, is there a typology of styles? Certainly the model has important implications for incorporating learning/maturation into consumer research. Moreover, the satisfaction literature may benefit from considering the set effects on satisfaction.

Capricious Consumption and the Social Brain Theory: Why Consumers Seem Purposive even in the Absence of Purpose

Joseph Cherian, University of Illinois - Chicago
Barbara Harris, University of Illinois - Chicago

ABSTRACT

Research on the consumption process is fueled by many viable theoretical traditions. Even so, there are aspects of the consumption experience that are destined to be inaccessible partly because of physiological reasons. One reason stems from the Social Brain Theory which posits, in contrast to previous thinking, that there are several modules in the human brain, all of which can work in parallel, not all of which are capable of verbalizing, and the one capable of verbalizing imputes a purposiveness to the self that may not exist. The required shift in consumer research is both ontological and methodological.

INTRODUCTION

The methodologies that are used to investigate phenomena, including consumer behavior, are directly linked to the investigators conception of the phenomena (Hirschman and Holbrook 1986, p. 213; Laudan 1977). Thus, even in consumer research, 'consumption communities' develop; they subscribe to different worldviews, and use different methods to look at their inter-subjectively validated world(s). Conversely, one may speculate that the more investigators are committed to one method the more locked in they become to one theory about a phenomenon. Further, when different investigators studying a common phenomenon 'incontrovertibly' establish their particular views, the dilemma is particularly troublesome. In the context of physics, scientists are unable to conclusively show whether light is a particle or a wave, since choosing to look at it as a wave yields valid 'wave' results and choosing to look at it as a particle yields valid 'particle' results (e.g. see Capra 1976).

Several recent papers have argued for the acceptance of such multiple and concurrent realities in consumer research. Three such examples are reviewed next to highlight philosophical, pragmatic and psychological rationales.

(i) Hirschman and Holbrook (1986) propose that a consumers reality has many aspects since it involves a complex and reverberating network of thought, emotion, activity and value. This prompts the use of several methodologies that are consistent with their relativistic epistemology;

(ii) Belk (1986) argues for multiple and complementary orientations, e.g. art and science, in order to arrive at essential understandings. In a sense, this appeal for multiple orientations is made on a strictly utilitarian basis since limiting methods of

looking only reduces what can be known about the focal problem; and

(iii) Hudson and Ozanne (1988) propose that we entertain an interpretivist approach because, among other things, reality is socially constructed (Berger and Luckman 1967) and individuals create reality by distorting received stimuli so that they can make sense of the world (Burrell and Morgan 1979, Kant 1982).

Although these studies exemplify the research on the need for multiple approaches to multiple realities, none of them has argued that the interpretivist approach might be physiologically preordained. To make this point, this paper will first examine the perspective of an eminent brain researcher, Michael Gazzaniga; after examining his view of brain functioning some important implications for consumer research will be highlighted.

SOCIAL BRAIN THEORY (SBT) (GAZZANIGA 1985):

Several theories exist about the functioning of the brain; in fact Hampden-Turner (1981) illustrates over sixty notions dealing with how the brain has been thought to work. One unifying aspect of many of these models is the view that the brain is a unitary system with well-defined serial linkages among its modules; different tasks such as vision, movement, etc., use different modules. If such strictly serial linkages existed it would mean that the brain sequentially processed external stimuli and fabricated a consistent version of reality from these stimuli. Simplistically, this is similar to an assembly line programmed by the consciousness-module (CM) to transform a variety of fundamental inputs into a variety of intended outputs; all of the inputs are potentially discernable in the output. If the brain indeed functioned in this manner all outcomes, e.g. behavior, could be explained since the outcomes would be tainted with inputs. The consumer would be able to (i) be aware of and (ii) articulate all relevant influences on a purchase decision.

Social Brain Theory (SBT) does acknowledge that the brain has specialized modules for different tasks. The primary distinction is that the processing of information is parallel, not sequential; in this respect it is much like a social network. When reading this sentence, some modules in this 'social' network are processing the symbolic content of the letters and words, some modules are sensing the colors and textures, etc., independently of each other (Minsky 1986). In other words, these modules are not aware of each others processing efforts or

results, and therefore have multiple and simultaneous processing of sensory inputs. CM then puts together the outputs to form a consistent image of reality.

The differences between the two notions of brain functioning are dramatic. In the first, a purposeful CM pulls together a consistent view of reality by harnessing the talents of appropriate processing modules; for example, to read this sentence, CM harnesses (lets say) the symbol-recognition module and the interpretation module to get to desired results. SBT says that the various modules do their processing undirected, and the consciousness-module is left to put the results from relevant modules together, in a consistent manner. To vividly see the difference, use the following metaphor: the former models say that consciousness builds the house of reality brick- by-brick and layer-by-layer; SBT says that consciousness puts this house together from prefabricated walls that are made by unsupervised and independent units in the social system.

Under the SBT scenario, consumers would be able to consult CM in order to account for their behaviors. Unlike the earlier models, SBT would predict that consumers might (i) not be aware of the influences on their behaviors and (ii) not be able to articulate the rationale for their behaviors correctly. In other words, a consumer could become conscious only of a vague sense of dislike for a blue car without knowing the reason; CM senses a negative valence from the memory-module but does not get the reasoning. Furthermore, if pressured for the reason behind disliking the car, CM would impute a logical rationale which may or may not be correct. Specific instances of these behaviors are amply illustrated later in the paper; before that, SBT must be differentiated from what appears to be a similar theory -- hemispherical lateralization.

SBT AND LEFT BRAIN/RIGHT BRAIN THEORIES

The left brain/right brain theories, which were in vogue in consumer research in the early 80's, envisaged complete lateralization in the tasks performed by the brain. At the very extreme, an incoming stimulus would be marked for the hemisphere that specialized in doing the necessary task. Such specializations were viewed as being both beneficial (Zajonc 1968; Lindzay and Norman 1977) and deleterious (Hansen 1981).

The left cerebral hemisphere is typically depicted as rational, realistic, a linear processor, specializing in verbal, mathematical and symbol-related tasks; and the right cerebral hemisphere is depicted as intuitive, metaphoric, a holistic processor, with noncognitive gestalt perception (Bogen 1971); for a more comprehensive overview see Hansen (1981).

In the consumer behavior context, the right hemisphere has been hypothesized to control the continual environmental scanning part of the attention process; the cognitive left hemisphere is activated only when the right hemisphere gives a

stimulus significant enough to warrant detailed and concentrated attention. Similarly, recognition is believed to be a right hemisphere function, while recall is attributed to the left hemisphere (Broadbent 1977; Krugman 1977). Studies involving EEG recordings report a high level of bilateral activity in subjects watching television rich with verbal, rational variables and low levels of bilateral activity in subjects watching advertising with emotionally-based and non-verbal variables, indicating the involvement of both hemispheres only when the task demands it (Rothschild et al. 1988).

Elements of choice behavior are similarly attributed to separate hemispheres. The right hemisphere is the primary determinant in low involvement purchase decisions for which past behaviors, holistic and pictorial information and emotion are determining factors; brand loyalty is therefore a right hemisphere phenomenon. The left hemisphere is responsible for high involvement consumption decisions in which information must be processed and a deliberate choice made (Krugman 1977).

Although SBT agrees that the cerebral hemispheres, each modular in composition, differ in the nature of their processing of information, there are three important distinctions: (i) SBT credits only one module with verbal activity; all other modules must be accessed through CM in order to bring their outcomes into awareness; (ii) The processing within the nonverbal modules is not UN-conscious but CO-conscious. Information is processed in several modules, within each hemisphere, simultaneously and differently; unless the consciousness-module is involved the processing lies outside of conscious awareness; and (iii) All the independent modules are capable of producing behaviors; those behaviors activated by modules in the right hemisphere may occur outside of conscious awareness. There is extensive empirical support of sorts for these three claims (Gazzaniga 1984). The next section examines some of the non-conscious elements in consumer behavior.

NONCONSCIOUS ELEMENTS OF CONSUMER BEHAVIOR

Consumer behavior researchers have often noted the non-conscious and non-cognitive aspects of experiential consumption, attitude formation, and precognitive preference development; often these approaches seem to have parallels to hemispherical lateralization type notions. Let us consider three specific examples from literature and highlight the differences between the nonconscious processing explicated by them and SBT.

(1) *Experiential Consumption*: Holbrook and Hirschman (1982) went beyond the logical, problem-solving approach adopted by the information-processing model to find an explanation for the consumption of nonutilitarian goods and services. They developed an 'experiential' view of consumption in which products were imbued with attributes such as 'symbolic meanings, hedonic responses, and aesthetic criteria'; all these attributes

are typically appealing outside the logical consciousness of the consumer. The drives behind experientially motivated consumption behaviors are believed not to be unconscious and therefore unrecoverable; but rather, the drives are believed to be preconscious or subconscious and could be recovered. Some techniques like participant observation and projective interviewing techniques could circumvent sensitive or covert motivations behind the behaviors which a consumer is hesitant to admit (Hirschman and Holbrook 1982).

This 'experiential view' focuses primarily on aesthetic products -- films, arts, 'fun'-products. This limits the nonconscious elements discussed by Hirschman and Holbrook (1982) to specific product categories. SBT would anticipate non-consciously deliberated purchase in all categories; indeed, impulse buying behavior has been noted to include high-priced, high-involvement products such as appliances (Rook 1987).

(2) *Preferences without Inferences*: Zajonc and Markus (1982) consider patterns for preference development other than what was expected by traditional theory (i.e. cognition leading to affect leading to preference). They showed that affect-based preferences could precede cognition-based preferences; indeed, affect and cognition could operate independently in some cases. Reasons given by subjects to explain a preference may merely be a rationalization since the individual could be unwilling to admit emotion-based attachments. Note that neither familiarity, nor subjective recognition, nor frequency of exposure is given as the basis for preference even though these variables have been empirically demonstrated to 'cause' preference. Clearly, the reasons given by subjects to explain a preference are not entirely credible.

Self-reports on nonconscious processing presents problems. Even if the individual is willing to report on the motivation for a behavior, or the affect behind the formation of a preference, or the preconscious antecedents to conscious attitude formation, s/he may be unable to do so. The nonverbal modules can process information, retain results, and activate behaviors -- all outside the awareness and control of the conscious mind (Gazzaniga 1985).

(3) *Preconscious Processing*: Janiszewski (1988) approaches the noncognitive aspect of attitude formation from a preconscious-processing perspective; the antecedents to the formation of an attitude are not necessarily related to the conscious deliberation involved. Preconscious preferences can be generated independently of conscious thought. Once preconscious processing has occurred the preference that is developed, prior to conscious thought, may actually have the ability to reinforce the preference that is developed during conscious processing. Because this influence occurs outside the conscious awareness, the consumer may not be aware of any preconscious antecedents.

According to SBT, some sorts of information can be processed and stored in the brain in the nonconscious modules; CM, the 'speaker' of the

bicameral mind (Jaynes 1977) can take advantage of the result of the nonconscious processing, but be unaware of the nature and mechanics of the calculation that produced it. Further, these nonconscious modules can activate real behaviors; SBT allows for the possibility that CM will be aware that a behavior activated by a nonconscious module has occurred and yet CM may not know the purpose beneath the behavior. The conscious mind sees this behavior to have come out of nowhere, out of pure caprice! How does the mind respond to such caprice?

WORKING WITH CAPRICE

All creatures are capable of being classically conditioned but the human brain is singular in its ability to make inferences about happenings in the external environment (Gazzaniga 1985). Pavlov's dog merely salivates when the bell rings; however, when Pavlov hears his wife slam the kitchen door, and then sees that she is late, and he surmises that dinner will also be late. Consumer behavior recognizes this inference-drawing ability. Perhaps, one curious extension of this is the notion of Symbolic Interaction. Essentially, symbolic interactionists assume that consumers do not merely regard a thing purely in and by itself; rather they imbue it with personal symbolic meaning. The ensuing behavior vis-a-vis this thing is partly a reaction to the objective reality and partly a reaction to the symbolic, subjective reality (e.g Solomon 1983). In other words, the individual does not react to a thing per se; rather s/he first changes the idea of the thing, then infers the correct interaction with this thing, in the given context, and only then does the individual act (Perinbanayagam 1985).

Just as the brain is capable of drawing inferences about the outside world, the brain should be capable of drawing inferences about the inside world. Symbolic consumption theorists have noted the consumers ability to send and to receive messages, through products or services consumed, both to self and others (Belk 1988; Solomon 1983; Hirschman 1983). If an action occurs the brain is compelled to interpret it through inferences. Thus, if a nonverbal module activates a novel and somewhat surprising behavior, tasting caviar for example, the mind will surmise: if I'm trying caviar, there must be a logical reason for it -- I guess I want to expand my horizons (Gazzaniga 1985).

According to SBT, the only module capable of drawing inferences about external or internal environments is the CM. This module is built to make inferences such as 'what is the purpose of this action?'. If no relevant data exist, this module will impute a purpose, thereby creating a motivation that never existed. This little module tirelessly generates these plausible conscious purposes to explain every action whether these purposes existed in reality or not. In this sense of explaining action, the mind relentlessly 'explains' even what it cannot explain. The constant need to maintain a consistent view of

the self and the constant imputation of rationality has interesting consequences for consumer behavior.

IMPLICATIONS FOR CONSUMER BEHAVIOR

SBT has one major implication for research on consumer behavior and one major implication for research methodology. First, for theory, the primary impact of SBT is to upset the theory of self. It is usually believed that people seek, express, confirm and ascertain a sense of self through what they consume. Indeed, philosophers have believed that possessions exist solely for the purpose of self-definition (Belk 1988). This sort of self definition rests squarely on the assumption that all behaviors are consciously and freely willed by the self. In other words, first there is purpose and then there is behavior. According to SBT, this need to feel that the self is in control is so strong that the CM is willing to 'fudge' a purpose if no purpose is apparent. In other words, there is purpose (P), then there is behavior (B), and if purpose (P) is not easily understood or surmised, CM readily provides a plausible purpose (Pp) as a reflex.

Although this inference-making keeps the sense of self intact, it jars the theories of consumer behavior research as a science. Researchers are essentially presented with the possibility of a subject who (1) cannot account for the motivation behind some, or perhaps even a great deal, of their consumption behavior; and (2) cannot discern what was a real motivation and what was a contrived motivation. This raises the very real question of whether the self is different from who the self implies it is; in other words, *am I different from who I imply I am?* Among other issues, one theoretically fascinating issue is the illusion of consistency. For example, what does it mean if for each time that motivation P occurs, behavior B follows, and the subject consistently *states* that the purpose was really Pp? Does this consistency mean that a theory based on Pp is validated since it seemingly leads to correct predictions? Even more complex, what happens to theory-testing when, for a variety of purposes (P1-Pn), the subject behaves the same way (B) and attributes the same purpose Pp?

This problem has been dealt with for some product categories. Hirschman (1983) noted that in the consumption of aesthetic products the consumption is a means to a goal rather than the goal itself. The consumption of aesthetic products is mainly experienced internally; therefore, identifying the rationale for a purchase could be extremely difficult due to the private nature of the experience. One way to get a handle on such fuzzy phenomenon might be to find the salient attributes. However, it would probably be impossible to identify an attribute such that there was (i) consensus, i.e. everyone agrees what any attribute is; and (ii) completeness, i.e. enough attributes of the phenomenon are captured. Further SBT suggests that even if such attribute description were in some way available, it would still be extremely difficult to

find what the importance of each of them were. Asking the consumer for a self report could result in the consumer either (a) knowing, (b) not knowing, (c) not knowing about not knowing and thus end up merely imputing an importance value. Again, what is theoretically disconcerting is that there seems to be no work done to enable a subject or a researcher to tell these three situations apart; the subject could answer with equal alacrity and aplomb in each of the three situation described above.

The second SBT implication is for research methodology. Although SBT precludes conclusively knowing what lies within, the interpretivist approach may offer a substitute for direct access to the nonconscious modules. The essence of interpretivism is that reality is essentially mental and perceived (Hudson and Ozanne 1988). Just like SBT states, the interpretivist school maintains that individuals "create devices, such as theories and categories, to help them make sense out of their worlds" (p.509). The interpretivist research focuses on discovering these 'devices' which help the individual create their environment.

An absolute understanding of the research subject and the 'devices' is never achieved in interpretivist research; rather, a temporal understanding susceptible to change emerges as the research process unfolds. The main thrust is to understand the individual from the individual's own perspective. This entails the use of tools such as empathy, intuition and translation (Hirschman and Holbrook 1986; Hirschman 1986). The methodology does not lead to predictive power; rather the focus is shifted to one of better understanding the problem at hand (Lincoln and Guba 1985).

CONCLUSIONS AND FUTURE DIRECTIONS

SBT primarily showed that there are structures in the brain that make it difficult to trust any consumer self-report. Even without desiring to deceive, a consumer can find it extremely hard to provide an honest answer to questions. The primary reason for this is that there is a module in the brain that ceaselessly provides the self with plausible rationales for behavior if a real one is not immediately apparent. In short, the mind explains even when it cannot explain. The primary outcome of SBT for consumer research is that the notion of self needs to be rethought. Specifically, three areas of work can be suggested: (i) how does the self relate to the self? e.g. how do you 'catch' a consumer imputing reasons instead of discerning the real reasons in a consumption context? (ii) how does the self relate to others? e.g. how can do you read the motivation of symbolic purchases? how do you read into the elaborate rationales that are used to justify purchases as simple fabrications? how can 'discovered' goals be separated from bona fide a priori goals? (iii) how does the self relate to decision-making? e.g. what are the idiosyncratic attributes used in individual purchases? do the decision-models really have a physiological basis? In the area of research methodology, SBT suggests

that the interpretivist scheme be used as often as possible since a consumer's behavior may be more easily intuited than measured. To the extent that SBT can be a reasonably correct model of consumer behavior, we must view the usual representations of consumer-decision making with even more skepticism than we did ten years ago when we were asked "Consumer Decision Making -- Fact or Fiction?" (Olshavsky and Granbois 1979).

A Commentary on New Theoretical Perspectives on Consumer Behaviour

David W. Stewart, University of Southern California

ABSTRACT

Research on consumer behavior has tended to focus on a narrow range of phenomena. Although the range of phenomena has expanded in recent years and new approaches for the study of consumer behavior have been developed, the full richness of consumer behavior has yet to be realized. Three papers suggest that consumer researchers broaden their agenda by focusing on aspects of consumer behavior that have not been widely investigated. Although each paper suggests a different focal point, they are complementary. A model of consumer choice is used to show how the approaches suggested in three papers can be integrated with other research in the field. The model also helps identify other dimensions of consumer behavior that have not been widely researched.

INTRODUCTION

Human decision making is the nexus of the study of consumer behavior. The factors that lead to the need for a decision, the processes by which decisions are made, and the development of decision strategies through experience are the elements from which we attempt to build an understanding of consumer behavior. Consumer researchers have also examined a wide range of other factors, life-style, attitudes, value systems, personality, information processing, cultural differences, and so forth. There is always at least an implicit recognition that these factors are related to decision making in some way, and we frequently find empirical demonstrations that differences in decision outcomes are related to these other factors. Despite many years of research on consumer behavior, the papers we have heard today (Cherian and Harris 1989, Duncan 1989, and Rassuli and Harrell 1989) remind us that much remains to be done before we have a full understanding of consumer behavior. Further, these papers remind us that there are dimensions of consumer behavior that have not been well explored and that our traditional views of the processes of consumer choice may not always be appropriate for all types of consumers and situations in which we find consumers. Let us consider what each of these papers suggests.

THE IMPORTANCE OF BELIEFS

Duncan (1989) reminds us that consumers have a host of beliefs that influence consumer behavior. These beliefs have an impact on information search and shopping behavior, on decision rules, and even on problem recognition. Beliefs have not been ignored entirely by consumer researchers, but much of the research on beliefs has been in the context of models of attitudes where the focus of study has most often been beliefs about product attributes. Beliefs about other aspects of the market place such as sales personnel, ability as a shopper, usefulness of search activity, and so forth have received more limited attention. Yet, those

studies that have examined the impact of more general consumer belief systems have consistently found them to have a very strong influence on consumer behavior.

THE DIRECTIONALITY OF CONSUMER CHOICE PROCESSES

Rassuli and Harrell (1989) remind us that the assumptions about the direction of causality in consumer behavior may be overly simplistic. The notion that the end point of consumer behavior is purchase overlooks the fact that purchase may, on many occasions, actually be more appropriately regarded as the beginning point of consumer behavior. In fact, the notions of beginning and end in an on-going system involving reciprocal causality are not particularly meaningful. In such a system the points of entry and exit are dictated more by the purpose of the researcher than the nature of the process itself. The frequent focus on purchase as the end of the process is the result of the fact that most previous and current consumer research is carried out in a marketing context that is specifically oriented toward influencing purchase behavior. This does not mean that this is the best way to view consumer behavior, even when the purpose of the research is to inform marketing action. Starting the process at different points may yield some interesting and useful insights that could not be obtained by always looking at purchase as the end of the process. For example, one might look at the purchase process as the beginning of a process that gives rise to the identification of new beliefs or new problems for solution. In fact, if we assume some degree of purposefulness on the part of consumers, purchase is neither the beginning nor the end of this purposefulness. It is only a means to an end that falls somewhere in between the identification of a problem or need and its solution. This, of course, raises the question of whether consumers are always purposeful.

ARE CONSUMERS PURPOSEFUL?

Cherian and Harris (1989) offer the intriguing notion that consumers are not fundamentally purposeful. Rather, they suggest that the verbalizing component of the brain serves to impute purposefulness to all activities even though many activities are not, in actuality, purposeful. If by purposeful Cherian and Harris mean consciously purposeful, rational, and able to articulate purpose, then I would certainly agree. There are of course other meanings of purposefulness and I believe that all life forms are purposeful in at least some sense of the term. Rather than quibble with terminology, however, I would rather focus on the implications of the view of Cherian and Harris. First, I would note that their view is not new, nor is it necessarily irreconcilable with the broad view of consumer rationality. Nisbett and Wilson (1977) review

evidence that makes a compelling case for the fact that people often do not know the reasons for their own behavior, though they also often feel obliged to make up reasons when pressed. More recently, Etzioni (1986) has suggested that people may make a rational decision to behave irrationally in situations in which the costs of rational behavior may be too high given the anticipated consequences. In these types of situations an individual may still feel compelled to provide an explanation for behavior that is more rational rather than admit that they have decided not to be rational. It is also quite likely that in many such cases individuals are not even aware that they made a decision to be irrational because the decision to be irrational is so automated. In fact, we know that a great deal of decision making and behavior is automated and defies simple explanation.

Cherian and Harris (1989) suggest that because people impute purposiveness when none actually exists, self reports should not be trusted. I would modify their conclusion and suggest that self reports should not be relied upon exclusively. Neither should "experiments" that are constructed to produce outcomes consistent or inconsistent with the rational model (a number of researchers in consumer behavior appear to be sufficiently clever to produce all sorts of odd behavior through skillful manipulation of the decision environment, but this also tells us little about how consumers actually behave). I am equally uncomfortable with the suggestion of Cherian and Harris (1989) that because consumers do not know what they are actually doing, and why, it is better to have a researcher interpret the intent of a consumer. There is a logical fallacy in the assumption that someone who is incapable of understanding his or her own behavior is better able to understand someone else's behavior.

What I really think all this means is that we need multiple approaches to the study of consumer behavior. I also think these multiple approaches should be applied by the same researchers. Rather than one group of researchers doing experiments, another doing naturalist observation, and still another using self reports, the discipline would profit from having the same phenomenon investigated by several means. Thus, self reports might be complemented by observation and interpretation. "Interpretations" might be checked against self-reports or against the results of carefully designed experiments. Experimental results might be checked against the subjective perceptions of both the subjects of the experiment and other knowledgeable judges. This would make it somewhat more time consuming to do research, and require facility with numerous approaches to research, but it might lead us to a more complete understanding of consumer behavior.

THE NEED FOR AN INTEGRATED PERSPECTIVE

Although I agree with many of the conclusions of the authors of the three papers we

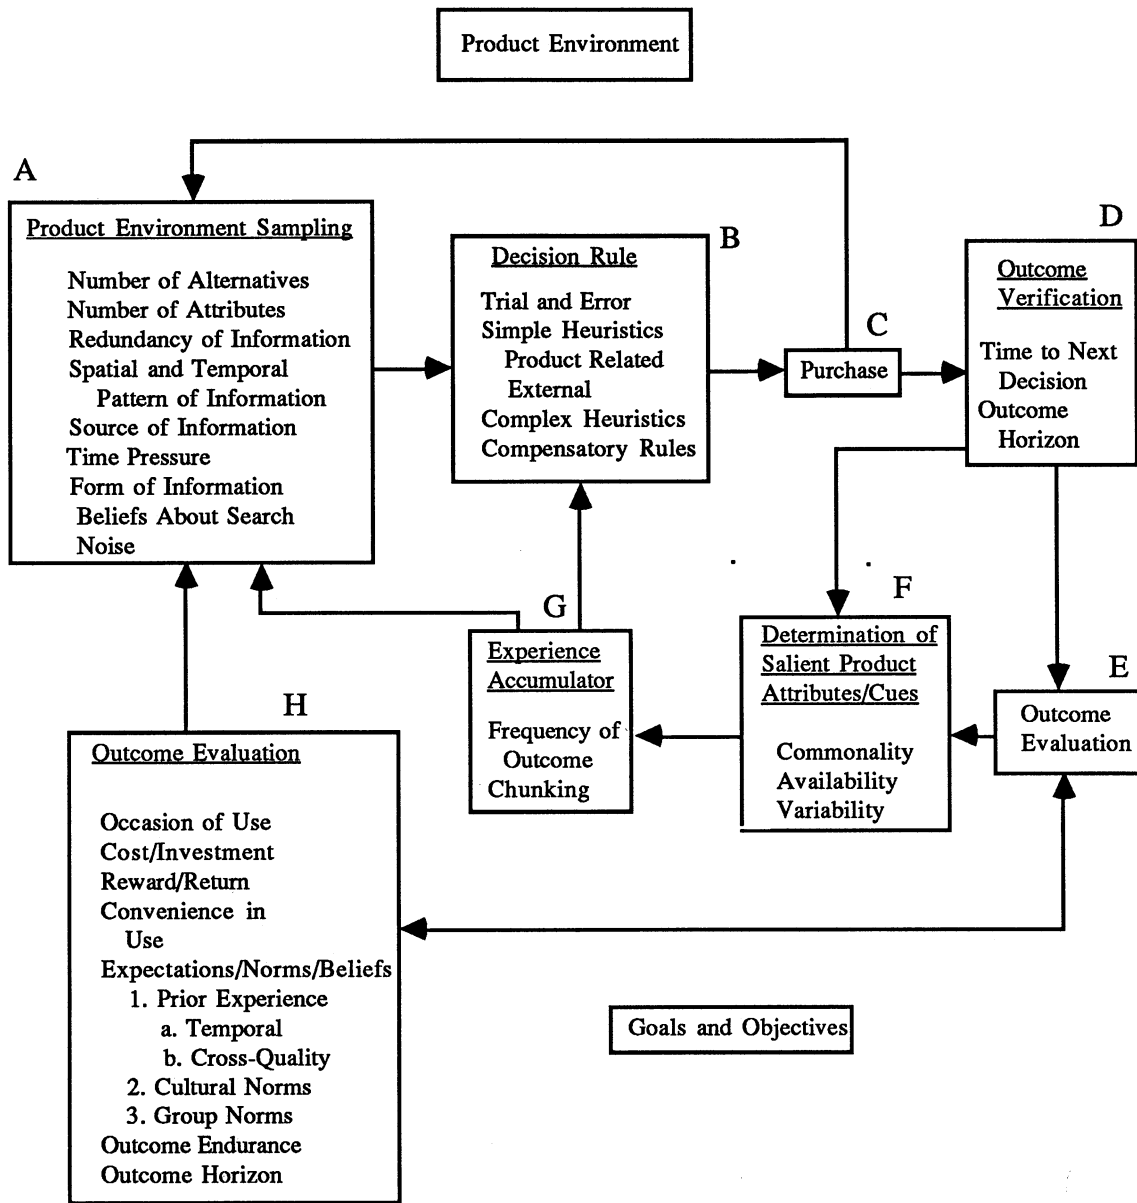

have heard today, I am concerned that each of the approaches we have heard is yet another opportunity for the fragmentation of the field of consumer research. Consumer researchers have borrowed quite liberally from other disciplines, but most of this borrowing has involved theories, concepts, or methods that are appropriate for a narrow class of phenomena. The more general phenomenon of consumer behavior gets lost as a result. While I do not think it is yet time for the development of new grand theories of consumer behavior, I do think it is time that we began to place specific studies, approaches, and theories in the more general context of consumer behavior.

At the risk of being accused of introducing yet another flow chart into a discipline that is already replete with them, I wish to try to illustrate what I mean by such integration using the three approaches suggested today. At the same time, I hope to point out some additional areas of neglect in the study of consumer behavior. Figure 1 is a simplified diagram of consumer decision making. Notice that there is no obvious beginning or ending. For purposes of illustration, let us enter the process in Box A-Product Environment Sampling. When a consumer recognizes a particular need, there is a search for a solution. Much of the consumer information processing literature has focussed on this aspect of the decision process and we have identified a wide range of factors that may influence the acquisition of information-the number of alternatives available, the number of attributes associated with each alternative, the spatial and temporal pattern of information, and so forth. The role of beliefs in determining the extent of this sampling has also received some attention, but far less than some of the characteristics of the information environment itself.

Social judgement theory and related theoretical perspectives have provided some understanding of this part of the process, particularly when the quality of information is not perfect and there is redundancy of information. Research on beliefs about the search process itself, sources of information, and the utility of particular types of information would also tell us a great deal about this type of consumer behavior. In fact, conceptualizing the process as a sampling process facilitates thinking about all of the determinants of the process. It also directs the focus away from the information environment itself and toward the sampling decisions being made by the consumer.

Ultimately information obtained in the search process may be used in a given decision rule (Box B). Decision rules have been the province of normative and behavioral decision theory, and more recently multiple criteria decision theory. Let me suggest that there have been few real efforts to link what goes on in Box A with what goes on in Box B. There must be a relationship and it is not so simple as more information leads to more complex decision rules. It is easy to find examples of extensive information search followed by the use of a simple heuristic, though it may be more difficult

FIGURE 1

to find examples of little search followed by more complex rules. On the other hand, we do know that decisions can be automated with experience. More experienced consumers tend to make global, brand based decisions and do relatively little information search. This process of automation (represented in Box G) is not well understood though information integration theory provides a means for modeling the process.

Whatever the decision rule employed, the decision may or may not be followed by an action that implements the decision (Box C in Figure 1). The impact of situational factors which may prevent

implementation of a particular decision is well documented. What is less well studied is the impact such factors may have on future search strategies and/or decision rules. For example, does a strategy or rule that frequently produces decisions that the consumer is unable to implement give way to other rules? In which situations are the decision rules actually used by a consumer known to the consumer and in what situations do the decision rules remain hidden from the consumer?

Post-purchase evaluation is well documented and a number of factors that influence it have been identified. I would like to suggest, however, that

there are really two distinct types of post-purchase evaluation. The first, represented in Box D, I have called outcome verification. In this process the consumer merely verifies that an outcome sought has been obtained—the aspirin relieved the headache, the soft drink quenched thirst, the life insurance policy provided a sense of security. There is no question about whether the outcome is desirable or not. The evaluation of the desirability of the outcome has been made at some previous point in time and the consumer needs only to verify that the expected outcome did in fact occur, or did not occur. In other situations it may not be so clear whether an outcome is desirable. This is particularly likely when the outcome has not been experienced before. Consider the first time you tasted beer or a pickle. You probably had to decide whether you even liked the taste (and that may have required several trials). This facet of the decision process has largely been neglected by all theories of decision making, yet it is at the very heart of the process. Some of the factors that may influence this process are listed in Box H, but we still don't understand preference formation. Motivation has not been a hot issue in consumer psychology for a long time. While I am not suggesting a wholesale return to motivation research, this is a dimension of consumer decision making that has not received its due attention.

For some products this experiential dimension may be all that is important to the choice process, and this has important implications for information search and for the selection of a decision rule. Part of information search may be experiential, involving product trial and outcome verification (the chair "feels" comfortable, the tennis racket or golf club "feels" right in one's hand, the drink was "refreshing"). This type of evaluation is distinctly nonverbal and has received scant attention. Our theories of decision making have tended to be largely cognitive, and it is not clear how experiential outcomes or attributes fit. This is perfectly consistent with the perspectives articulated by Rassuli and Harrell (1989) and by Cherian and Harris (1989).

Attribution theory suggests that consumers seek a theory to guide their behavior in the future. Such theories represent belief systems. These belief systems have also received some attention from consumer researchers, but more needs to be done. In particular, the development of these belief systems over time would be a particularly fruitful avenue for research. For example, having experienced a given outcome associated with a product, the consumer may attempt to identify distinguishing characteristics of the product—"Products with x produce y". This is depicted in Box F along with factors that have been shown to influence this process. The distinguishing characteristics identified by the consumer are likely to become more prominent in search activities and decision rules in the future. In effect these factors are believed to be important. Social judgment theory would also suggest that some situations provide better distinguishing information than

others, though the lack of a product characteristic that clearly differentiates superior from inferior products does not preclude the consumer from inventing one. In time, these differentiating characteristics may be abbreviated or combined, making it difficult to sort out the original distinguishing attributes. Indeed surrogate attributes may be used that have no relationship to the original benefits sought or experienced.

NEED FOR LONGITUDINAL RESEARCH

I have now walked through the decision process, indicating where various approaches appear to make their contribution and where gaps seem to exist. I would note one other problem in studying consumer decision making. We almost never begin with a naive consumer. We study consumers who generally have a very long history, so we are looking at a well developed process rather than a developmental one. This tends to introduce some significant biases into our way of thinking about consumer decision. A little reflection will suggest the nature of those biases—the decision process will tend to be more abbreviated and more cognitive than would be the case for a truly naive consumer. This is because purchase decisions tend to become more automated with experience and because the experiential aspects of consumption (and the outcome evaluation process) tend to be subordinated to verbal surrogates with experience.

CONCLUSION

I believe we have much to learn about consumer decision making. We can advance our knowledge quickly by doing two things. First, we must integrate the multiple perspectives on the phenomenon and identify the linkages among them. This also means bring multiple methodologies to bear on the study of the same events and processes. Second, we must look at the development of consumer behavior over time through well constructed longitudinal studies. This work is long overdue, and it is time to get on with the task.

The Effects of Situational and Intrinsic Sources of Personal Relevance on Brand Choice Decisions

Simeon Chow, University of South Carolina
Richard L. Celsi, California State University
Robin Abel, University of South Carolina

ABSTRACT

In the present study, the effects of subjects' intrinsic sources of personal relevance (ISPR) and situational sources of personal relevance (SSPR) with using fragrances (perfumes and/or colognes) on their brand choice intentions were examined through the use of multivariate profile analysis of repeated measures. ISPR and SSPR, individually as well as together, were found to have significant influences on individual brand choice intentions. These results emphasize the importance of examining both variables concurrently in consumer research.

INTRODUCTION

Consumer researchers have reached a general consensus that views the involvement construct as the degree of personal relevance an individual perceives in a concept such as a product or product related behavior (Petty, Cacioppo, and Schumann 1983; Zaichkowsky 1985). Personal relevance is defined as "the perceived linkage between an individual's needs, goals, and values and his/her product knowledge (i.e., product attributes and benefits)" (Celsi and Olson 1988, p. 211). Key to this perspective is that the overall amount of personal relevance an individual experiences or feels at any particular point in time is determined by situational and intra-personal factors (Houston and Rothschild 1978). Celsi and Olson (1988) defined these factors as situational and intrinsic sources of personal relevance.

Situational sources of personal relevance (SSPR) are specific cues or contingencies in a consumer's immediate environment that are perceived as personally relevant in the context of that particular situation. For example, price promotions, the presence of significant others, or the perceived importance of an event create contingencies in consumers' immediate environments that may activate personally relevant goals or values such as "be thrifty" or "look good" (Celsi and Olson 1988). SSPR are transitory and decline in relevance when the personal goal is achieved. In contrast, intrinsic sources of personal relevance (ISPR) are "relatively stable, enduring structures of personally relevant knowledge which are stored in memory and concern objects or behaviors that are intrinsically relevant to the individual. For instance, wine connoisseurs and computer buffs tend to perceive consumption activities associated with these products as personally relevant across situations" (Celsi and Olson 1988, p. 212).

To our knowledge only two studies have specifically considered the combined effects of situational and intrinsic factors on consumer behavior. First, Richins and Bloch (1986) examined

the effects of situational and enduring involvement (i.e., SSPR and ISPR, respectively) on consumer information acquisition behavior. Then, Celsi and Olson (1988) demonstrated the effects of SSPR and ISPR on consumers' attention and comprehension processes. Both, Celsi and Olson (1988) and Richins and Bloch (1986) demonstrated that situational and intrinsic factors combined to affect consumers' behaviors and concluded that future consumer research should examine the effects of both factors on consumers' thought processes and behaviors.

Therefore, in the present study, our objective is to extend this stream of research by examining the effects of SSPR and ISPR on consumers' brand choice intentions.

Research Issues

As discussed above, ISPR and SSPR have been demonstrated to affect consumers' attention to and search for product information as well as their elaboration of that information. However, to our knowledge, no study has examined the combined effects of SSPR and ISPR on brand choice decisions. For example, consider the product class of fragrances (perfumes and colognes) which is characterized by many competitive brands and low brand switching barriers. Do women who use fragrances have a single brand of perfume and/or cologne that they wear in most or all circumstances, or, does the perceived level of SSPR in a situation affect their choice of brands? Does the level of a woman's ISPR with fragrances also affect her choice of brands? Moreover, do SSPR and ISPR interact? For instance, do women with low levels of ISPR with fragrances tend to perceive usage situations differently than women with higher levels of ISPR?

We would expect the answers to these questions to be yes. The situation should affect brand (e.g., fragrance) choice to the extent that the situation is perceived by the individual to be personally relevant and leads to the activation of goals such as the maintenance or enhancement of one's self-image. ISPR should also affect brand choice across situational frames by heightening the perceived instrumental value of the product class to enhance, accentuate, or maintain one's self-image. Finally, we would expect to observe an interaction between ISPR and SSPR since women with different levels of ISPR with the product class of fragrances are likely to have different perceptions of the same situation. This interaction would most likely occur when individuals are confronted with situations independently judged to be of moderate or ambiguous importance. For example, in a study concerning the sending of greeting cards in various situations, Walker (1988) found that women with high levels of

ISPR tended to perceive moderate situations (e.g., sending a greeting card to a non-significant other on a common occasion) as more personally relevant than did women with lower levels of ISPR.

In summary, we propose that SSSPR and ISPR will demonstrate significant effects on individuals' brand choice intentions. Furthermore, we propose that SSSPR and ISPR will interactively affect individuals' brand choice intentions. In the following study, we empirically test the above propositions.

METHODOLOGY

Overview

A study was designed to examine the effects of SSSPR and ISPR on women's brand choice behavior in the product class of fragrances. A questionnaire was given to 450 subjects to determine their level of ISPR with fragrances and brand usage intentions under different situations. A total of 200 subjects responded (response rate of 44%), of which 55 subjects were dropped due to missing data. The analysis to be reported here is based on a sample of 145 respondents, representing a usable response rate of 32%.

Subjects

The subject population was comprised of undergraduate and graduate university students from a large southern university. The subjects' ages ranged from 17 to 27.

Measuring Intrinsic Sources of Personal Relevance

In the present context, ISPR refers specifically to the self-relevant meanings stored in long-term memory that individuals associate with fragrance. Thus, measures of ISPR must capture or reflect the personal relevance individuals perceive in perfume/cologne. In this study, the subjects' ISPR with fragrance was measured with Zaichkowsky's Personal Involvement Inventory (cf. Zaichkowsky 1985). This scale was selected because it was developed to measure "a person's perceived personal relevance of the object based on inherent needs, values, and interests" (p. 342). This scale contains 20 7-point items each labeled with bipolar adjectives (e.g., important/unimportant; irrelevant/relevant; essential/unessential). Subjects were asked to think about what colognes/perfumes meant to them and then to complete the scales. By use of the Cronbach alpha, the internal consistency of this multi-item scale was found to be quite good with a reliability of .97. Moreover, the item-to-total correlations ranged from a low of .61 to a high of .87.

Situational Sources of Personal Relevance

Each subject was presented with 13 situations that varied in their levels of SSSPR relative to the product class of fragrances. A previous focus group was conducted and used as the basis for generating usage situations for the questionnaire. Most

situations revolved around typical activities of student life.

Ranking of the Situations. Three female college students served as a panel of judges and ranked-ordered the 13 situations on the criterion of importance of the situation for wearing a perfume/cologne. Three of the situations gave divergent rankings across the panel and were dropped from further analysis. For the remaining 10 situations, an interjudge reliability of .76 was achieved.

The situations were then divided into three groups representing differing levels of SSSPR (low, moderate, and high). The following are examples of low SSSPR (L-SSPR), moderate SSSPR (M-SSPR), and high SSSPR situations, respectively:

L-SSPR You are going to participate in a physical activity, like volleyball, at the beach.

M-SSPR You are going to the mall with a group of friends, both male and female. There are NO boyfriend/girlfriend relationships in the group.

H-SSPR You plan to study for exams with a group of female classmates at the library. A few members of the group and yourself have made plans to go to Five Points (an area with a number of college bars) after studying and will be leaving directly from the library.

The Dependent Measures: Shifts in Usage Intentions

In the questionnaire each respondent was asked to list her three (or fewer if she does not own at least three) most preferred brands of fragrances that she owns and the percentage of time that she uses each of them. Each of the subjects three brands were then rank-ordered according to their percent usage, where the most used brand was ranked number one, the second was ranked number two, and the third was ranked number three. This rank ordering of each subject's brands produced a baseline or "average" likelihood usage for that respondent which served as a point of comparison. In addition, each brand of fragrance listed by the subjects was classified into four categories (1 = high, 4 = low) representing the "prestige" image of the brand. Membership to each "prestige" category was determined by consensus opinion of two industry observers (the first author and an executive from an international cosmetic company) and was consistent with instrument variables such as price and exclusiveness of the distribution of each brand.

In the questionnaire, each subject was presented with each usage situation and was required to state which if any of her listed fragrances she would mostly likely use in that situation and in what order. Each response made by a subject in each

situation was then compared to the subject's baseline to derive whether, in a given situation, the respondent would shift upwards or downwards with respect to fragrance prestige. A negative shift of value -1 was assigned to situations when the respondent selects a lower prestige brand over a higher prestige brand. Conversely, a positive shift of value 1 was assigned to situations when the respondent selects a higher prestige brand over a lower image brand. If there is no change in response with respect to the baseline, then the shift has value zero. Finally, if the respondent chooses to wear no fragrance in a situation, the shift value assigned is -2. For example, consider the case where the baseline is (2,1,3), where the respondent's most often used brand has prestige value 2, her second most often used brand is of higher prestige than her most often used brand, and her third most often used brand is lower in prestige than her first brand. If her response to a situation is (3,2,1), then we would consider this a negative shift because in this situation she has stated an intention to use a lower prestige brand over her usual brand. If the response is (1,2,3), we would consider this a positive shift because the respondent has stated that she is more likely to use a higher image brand over her usual brand of prestige value 2. Similarly, we would consider a response of (2,3,1) as a shift of -1.

For each respondent, an average shift for each set of situations is computed. That is, for every respondent j , we compute $L\text{-SSPR}_j$, $M\text{-SSPR}_j$, and $H\text{-SSPR}_j$, where $L\text{-SSPR}_j$ is the mean shift across situations in the L-SSPR group, $M\text{-SSPR}_j$ is the mean shift across situations in the M-SSPR group, and $H\text{-SSPR}_j$ is the mean shift across situations in the H-SSPR group, respectively.

Research Design

The purpose of this research is to compare the effect of ISPR and SSPR on behavioral intentions. Subjects are given a questionnaire which they were asked to complete and return. Each subject is presented with all usage situations and asked to choose from her 3 listed fragrances, which ones she would most likely use in that situation. A research design employing multivariate profile analysis of repeated measures on different situations is chosen to control for individual differences between respondents. In particular, differences between respondents could be quite large relative to differences in ISPR and SSPR effects and, therefore, we hope to account for this within subject variations by the selection of this design. To minimize the carry-over effects across situations, the order in which the situations are presented to the respondent is counterbalanced.

METHOD OF ANALYSIS

Since each respondent has repeated measures of brand usage intentions as measured by shifts from her baseline, Winer (1971) suggested treating the trials factor (differing levels of SSPR) as a multivariate profile and conducting contrasts across

the estimates for the profile effects. The repeated measures model used in this analysis is presented below, where the situation (L-SSPR, M-SSPR, H-SSPR) is a fixed factor and the subjects are random:

$$X_{ij} = \alpha_i + \beta_i \text{ISPR}_j + \epsilon_{i(j)}$$

where

- i = situation treatment subscript (L-SSPR, M-SSPR, H-SSPR)
- j = respondent subscript, $j=1, \dots, 145$
- X_{ij} = shift in brand usage intentions for respondent j within situation treatment i
- ISPR_j = level of intrinsic sources of personal relevance for respondent j
- α_i = effect of situation treatment i
- β_i = effect of ISPR nested within situation i
- $\epsilon_{i(j)}$ = random error for respondent j within situation group i .

The multivariate profile analysis of repeated measures computations for this model is carried out using the MGLH program included in the SYSTAT software package (Wilkinson 1984).

RESULTS

The research hypotheses are tested by a series of multivariate profile hypotheses. We begin by testing the ISPR main effects first, then the SSPR effects, then the ISPR-by-SSPR effects. The main effect of ISPR is tested with a univariate F statistic. For all of the tests involving situations, the test statistic is a multivariate F. Furthermore, hypotheses contrasting adjacent pairs of profiles are tested with univariate F statistics. The homogeneity of covariance matrices hypothesis is supported by the data (Bartlett's Chi Square = 2.60 with 6 df).

Parameter Estimates

The above model was estimated and provided the following results:

	L-SSPR	M-SSPR	H-SSPR
α_i	-2.443	-2.182	-1.726
β_i	.011	.016	.013
adj R^2	.133	.216	.163

The profiles corresponding to these estimates are shown in the Figure. These profiles indicate that the effect of ISPR on shifts in intentions differs - low and high ISPR respondents behave in different ways depending on the relevance of the situation.

ISPR Effects

The first hypothesis we test is that ISPR would have a significant effect on brand choice intentions (i.e., β_i is not zero for all i). This hypothesis is supported by the data ($F_{1,143} = 44.34, p < .01$). Referring back to the parameter

FIGURE
Profiles of shifts in brand choice intentions as a function of ISPR for three SSPR levels

estimates, we conclude that as the respondent's level of ISPR increases, she is more likely to shift towards more prestigious brands.

SSPR Effects

The next hypothesis we test is that the personal relevance subjects perceive in different situations (SSPR) affect their brand choice intentions. The results support this hypothesis with the multivariate SSPR effect found to be significant at the .02 level (Wilks' $\Lambda = .94$, $F_{2,142} = 4.59$, $p < .02$). From the Figure, we can see that as the perceived SSPR increases, the respondents state intentions to use more prestigious fragrances. The univariate F statistics for contrasting the adjacent profiles are $F_{1,143} = .98$, $p < .33$ and $F_{1,143} = 6.41$, $p < .01$ for the contrast of L-SSPR to M-SSPR and M-SSPR to H-SSPR, respectively. The univariate F tests indicate that this multivariate effect is substantially due to the second contrast.

ISPR-By-SSPR Effects

The third hypothesis we test is the multivariate ISPR-by-SSPR interaction. This effect is found to be significant at the .10 level (Wilks' $\Lambda = .97$, $F_{2,142} = 2.39$, $p < .10$). These results indicate that a person's level of ISPR has a differential effect on brand choice intentions which is dependent on the perceived level of SSPR. The univariate F statistics for contrasting the adjacent profiles are $F_{1,143} = 3.30$, $p < .10$ and $F_{1,143} = 2.72$, $p < .11$ for the contrast of L-SSPR to M-SSPR and M-SSPR to H-SSPR, respectively. Here the univariate F tests indicate that the multivariate effect is due more to the first contrast than the second contrast.

DISCUSSION

The results of this study provide evidence that subjects' brand choice decisions are influenced by situational and intra-personal factors. First, the results demonstrated that the subjects' level of ISPR influenced their brand usage intentions. As ISPR increased, the subjects tended to use more prestigious fragrances across situations. Second, subjects exhibited a positive shift towards more "prestige" fragrances as the level of SSPR increased across situations. This indicates, as expected, that the personal relevance perceived in situations affects consumers' brand choice decisions. Finally, the most important and interesting finding is the significant interaction between SSPR and ISPR. We find that the subjects exhibited a similar pattern of results when stating their brand choice intentions in the low and high-SSPR situations. However, in the moderate-SSPR condition, the subjects displayed a different pattern resulting in the interaction. When the subjects were presented with situations previously judged to be moderate, those with low levels of ISPR tended to respond to the moderate situations the same as they did to the low-SSPR situations. In contrast, subjects with high levels of ISPR tended to respond to the moderate situations the same as they did to the high-SSPR situations.

Why should the relationship between brand choice intentions and intra-personal relevance change with situations? Possible behavioral explanations are that the subjects' responses in the moderate-SSPR situations occurred as a function of (a) perceptual bias, (b) conscious choice based on the variance of possible outcomes in the moderate situations, or (c) a combination of "a" and "b".

In the case of perceptual bias, the high ISPR individual's world view, for example, may be such that end-states such as "looking good" or

"maintaining one's self-image" are so highly valued that the individuals tend to perceive their world differently than low ISPR individuals. Individuals with high levels of ISPR may simply perceive a greater range of situations as highly relevant to these personal goals. In contrast, individuals with lower levels of ISPR may perceive most situations as having little relevance. Future research could examine this issue by having the subjects also rate the personal relevance of each situation.

In the case of the conscious choice explanation, consider that the SSPR in all situations is really an "expectation" or average of all possible outcomes that those situations will be personally relevant. If we view SSPR in this fashion, it is reasonable to assume that most people would view high and low-SSPR situations in a generally consistent manner. For instance, "going dancing" or "doing your homework" will be consistently viewed by most people as having high and low levels of SSPR, respectively, relative to the goals of "looking good". However, in moderate-SSPR situations a greater variance of potential outcomes are possible. For instance, "going shopping with a group of friends" could become highly relevant if one of these friends unexpectedly brings along another friend of the opposite sex. Thus the probability that a moderate situation might in fact turn out to be of "high" or "low" relevance is not clear. It is here that ISPR exerts its greatest influence on brand choice selection. For instance, high ISPR subjects may be simply less willing to risk the outcome that a moderate situation may turn out to be highly relevant. Here the variance of possible outcomes leads the high ISPR subject to treat the "expected" moderate situation as if it were a high relevance situation (e.g., better to be overdressed than underdressed). This model of decision making under risk is consistent with what Kahneman and Tversky (1979) termed prospect theory.

The same rationale may apply to the low ISPR subjects who respond to the moderate-SSPR situations as if they were of low relevance. This does not seem likely, however. It is doubtful that low ISPR individuals would expend the cognitive energies required to analyze the range of possible outcomes from moderate situations. It is just not that important to them. In this case, it seems more likely that low ISPR individuals simply categorize most situations as having low relevance. Therefore, option "c" may be the most plausible, that is, high ISPR subjects may tend to analyze moderate situations in a conscious, controlled manner because of their involvement, while low ISPR individuals may perceive little difference between low and moderate-SSPR situations.

Future Research Issues

The results of this study demonstrate the importance to consumer researchers to further understand the nature of situations. Future research could focus on and attempt to identify the specific cues and contingencies in situations that individuals

perceive and respond to. Such research would lead to a more complete spectrum of situations and to the discernment of perceived risk associated with specific situations. In addition, future research should attempt to understand further the relationship between personal factors such as ISPR and situational factors. Do individuals with differing levels of ISPR categorize situations differently? When might interactions be expected? How will they manifest themselves? Under what conditions can we expect different groups of consumers to respond differently to the "same" information? Are these interactions caused by perceptual biases or are they the result of controlled elaboration of the situational information?

CONCLUSIONS

We have extended previous research concerning the effects of ISPR and SSPR on consumers' behaviors to include brand choice intentions. SSPR and ISPR, individually as well as together, were found to affect individuals' brand choice intentions. The interaction highlighted the subtle way that intra-personal factors can affect the way individuals respond to and possibly perceive situational information. These results emphasize the importance of examining both variables concurrently in consumer research.

Effects Of Individual Difference Variables On Responses To Factual and Evaluative Ads

Meera P. Venkatraman, Boston University
Deborah Marlino, Simmons College
Frank R. Kardes, University of Cincinnati
Kimberly B. Sklar, Pugh-Roberts Associates¹

Previous research has shown that factual ads that contain logical, objectively verifiable descriptions of tangible product features are more effective than other message appeals (Golden and Johnson 1983; Kuritsky, et al. 1982). Our research demonstrates that this is true only for people with certain cognitive personality orientations. We find that people who enjoy thinking, problem solving, and other mental exertions are more persuaded by and have greater confidence in factual ads. In contrast, people who strive to simplify their environment and avoid cognitive stress respond to evaluative ads that contain emotional, subjective impressions of intangible aspects of a product.

BACKGROUND

A considerable body of research has examined the relationship between person factors and responses to advertisements such as recall, recognition, and persuasiveness. Persuasiveness has been defined in many different ways and as used here encompasses the believability of an ad and how convincing it is, amongst other dimensions. Much of the research focuses on demographic factors (Lipstein and McGuire 1978). Although the findings are inconsistent, which make definitive statements difficult, this research seems to indicate that age is negatively related and education and income are positively related to commercial recall (Schlinger 1983). While these findings have had considerable impact on research in advertising effectiveness (in the design of copy testing experiments, for example), in comparison with demographic factors the relationship of other person factors, such as personality, with responses to ads has been neglected.

The study of individual difference personality traits in advertising research is important for several reasons. From the methodological perspective, researchers interested in improving the statistical power of their experiments but not specifically interested in individual difference effects must control for these effects if they are demonstrated to be related to ad persuasion (Sawyer and Ball 1981). From the advertising research perspective, demonstrating that personality factors influence persuadability of ads has practical implications for copy testing procedures. Since existing procedures control for demographics and product purchase readiness stage in subject selection, they are based on the implicit assumption that personality factors

are not important. However, if personality traits are related to persuadability, it means that an advertisement which is effective with a specific personality type may not be effective with another. Understanding this will help tailor advertising messages to different target audiences, target it more effectively, and better utilize advertising dollars.

In spite of the considerable potential importance of personality factors in advertising research, there are several good reasons for its neglect. Primarily, these variables have been found to be relatively ineffective in explaining different facets of consumer behavior (Kassarjian 1971; Wells 1975). One possible explanation is that the personality traits examined in previous research were borrowed from standardized personality inventories originally developed to measure abnormal personality predispositions and therefore not specifically relevant in the advertising context.

Individual difference personality traits that can be theoretically related to persuasion may be more effective in explaining responses to ads. One objective of this research is to show that personality traits that capture an individual's cognitive orientation will be effective in explaining responses to ads which include the persuadability of and confidence in ads. Consider, for example, the style of processing scale developed by Childers, Houston and Heckler (1985) which differentiates verbally oriented people from visually oriented people. Verbally oriented people have a preference and propensity to engage in verbal information processing. They agree more with items such as "I enjoy work that requires the use of words," and "I like to think of synonyms for words." In contrast, people who have a preference and propensity to engage in visual information processing agree more with items such as "My thinking consists of mental pictures and images." Childers, Houston, and Heckler (1985) hypothesized and found that verbally oriented people have better advertisement recognition and recall as compared to visually oriented people.

The Childers et al. (1985) study suggests that traits that capture a person's cognitive orientation are related to responses to advertising. But is this equally true for different types of ads such as emotional and factual ads? Intuition and research suggest not. For example, Rossiter and Percy (1978) found that preference for engaging in imaginal processing as measured by the Visualizer-Verbalizer scale (Richardson 1977) was strongly related to positive affective reactions to visually oriented print advertisements. The findings of Childers et al. (1985) combined with those of

¹The authors are grateful to Robin Higie for her very helpful comments on an earlier version of this paper.

Rossiter and Percy (1978) suggest that in addition to individual differences, message content is an important determinant of responses to ads. The importance of message content in understanding responses to ads is supported by Holbrook and Lehmann (1980) who found that message content factors such as type of appeal are important predictors of advertising recognition over and above the predictive power of mechanical ad factors such as size and effects of product class.

In this context, another objective of this research, besides demonstrating the relationship between traits that capture a person's cognitive orientation and responses to ads, is to show that personality traits and ad content interact in affecting responses to ads. It is hypothesized that certain cognitive personality traits are related to responses to factual ads that contain objectively verifiable data and others are related to responses to evaluative ads that contain subjective, emotional appeals. The specific responses studied here are the persuadability of ads and confidence generated by the ads.

HYPOTHESES

This research studies the relationship between traits that capture facets of cognitive orientation such as *style*, preference for engaging, *effortful* cognitive activities, preference for cognitive *stimulation* and responses to factual and evaluative ads. Of the different traits that capture an individual's cognitive orientation this research focuses on: cognitive style, an individual's characteristic way of dealing with uncertainty (Cox 1967); need for cognition, an individual's tendency to engage in and enjoy effortful cognitive endeavors (Cacioppo, Petty and Kao 1984); style of processing, a preference and propensity to engage in a verbal and/or visual modality of processing (Childers et al. 1985); and cognitive innovativeness, an individual's preference for engaging in new activities that stimulate thinking (Pearson 1970).

Consider the cognitive style of people identified as "simplifiers" (Cox 1967) and that of visually oriented processors (Childers et al. 1985). Simplifiers strive to achieve cognitive structure by avoiding new information. According to Cox, they not only ignore new information, they also deny it, distort it, or in other ways defend themselves against its impact, thereby avoiding ambiguity and cognitive stress. Similarly, people who have a propensity to engage in visual processing (Childers et al. 1985) prefer watching demonstrations, using diagrams or pictures instead of reading instructions. Therefore, it is expected that simplifiers and visual processors should not respond to the objective, logical factual ads but should prefer evaluative ads that contain subjective, emotional impressions of products. In this context, it is hypothesized that simplifiers and visually oriented people should be more persuaded by and have greater confidence in the evaluative ad as compared to the factual ad.

People with high need for cognition, cognitive innovativeness and verbally oriented

people will respond differently from simplifiers and visually oriented people. According to Cacioppo and Petty (1982), people who have a high, as opposed to low, need for cognition are likely to acquire, elaborate on, and evaluate new information to which they are exposed because they enjoy effortful cognitive activities. Similarly, people who have high cognitive innovativeness enjoy thinking, pondering, and puzzling over issues and other mental exertions and seek new information that stimulate these mental activities (Pearson 1970). Also verbally oriented people enjoy reading, learning new words, thinking up synonyms for words, and doing work that requires the use of words (Childers et al. 1985). This suggests that people with high need for cognition and cognitive innovativeness, and verbally oriented people should be more persuaded by and have greater confidence in the factual ad as compared to the evaluative ad. In summary, the hypotheses are:

- H1. The cognitive style of simplification and visual style of processing have a significantly stronger relationship with the persuasiveness of and confidence in the evaluative as compared to factual ad.
- H2. Need for cognition, cognitive innovativeness and verbal style of processing have a significantly stronger relationship with the persuasiveness of and confidence in the factual as compared to evaluative ad.

METHODOLOGY AND ANALYSIS

The Factual and Evaluative Message

Factual and evaluative messages used in past research were selected as stimuli (Holbrook 1978). These ads describe six attributes of a fictional new automobile called the Vendome: (1) appearance, (2) handling and ride, (3) interior comfort and roominess (4) safety features, (5) service record, and (6) economy of operation. Pretests revealed that the two messages were perceived to be equivalent in meaning, favorability, length, and features described.

Procedure

Subjects were 78 undergraduate students attending a large north-eastern university. In two separate in-class sessions, subjects completed the cognitive style, style of processing, need for cognition, and cognitive innovativeness personality scales. In a third session, scheduled a week later so that the connection between the personality tests and their responses to the ads would not be made, the same subjects were randomly assigned to either the factual or the evaluative message condition. After reading the messages, each subject completed a questionnaire that measured responses to the advertising messages. Responses were measured on a nine-point scale ranging from (1) "not at all" to (9) "extremely" for 10 items used by Holbrook

TABLE 1
Loadings Of The Ad Response Variables On Two Varimax-Rotated Factors

Ad Response	Factor 1 Persuasiveness	Factor 2 Confidence
1. Well written	.76	.20
2. Coherent	.65	.28
3. Difficult	-.01	-.82
4. Interesting	.64	.41
5. Pleasing	.64	.45
6. Confidence	.10	.85
7. Believable	.71	-.01
8. Persuasive	.86	.05
9. Convincing	.85	.03
10. Certain	.41	.45
Eigen value	4.48	1.49
Percentage of Variance	45.70	14.90

(1978) which were found to tap persuadability of the ads and extent of confidence in the ad message (Items are shown in Table 1).

Preliminary Analyses

Responses to Ads. Of the 78 subjects, 37 were assigned to the factual and 41 to the evaluative message condition. Of these, 5 subjects were excluded from the analysis due to missing data. A principle components analysis was performed on ad responses yielding two factors that accounted for 60.6% of the variance in the original ten variables. The varimax-rotated factor loadings are presented in Table 1. These factors were interpreted as (1) persuasiveness, and (2) confidence. Factor scores were employed in all subsequent analyses involving responses to ads.

Reliability. All scales, except the verbal and cognitive style scales, satisfied the Nunnally (1978) reliability criteria of .70. The Cronbach's alpha for the need for cognition scale was .83, visual and verbal scales were .76 and .58, cognitive style scale was .42, and cognitive innovativeness scale was .88. Hence, in general, scale reliability is considered adequate. The correlations between the scales are reported in Table 2.

Hypotheses Testing

The statistical analysis used to test this hypothesis measured the differential effect of the independent variables (cognitive style, etc.) on the dependent variable (responses to ads) as a function of message content (factual/evaluative). Each ad response (persuasiveness and confidence) was regressed on the trait variable separately for the factual and evaluative message condition (Arnold 1982; Baron and Kenny 1986). If the unstandardized regression coefficients differ significantly, then the hypothesis is supported. The significance test is:

$$t = \frac{B_{21}-B_{11}}{(SE^2B_{21}+SE^2B_{11})^{1/2}}$$

with n_1+n_2-4 degrees of freedom

where

B_{21} = slope of Y on X regression line for those cases assigned to evaluative ad

B_{11} = slope of Y on X regression line of those cases assigned to factual ad

SE^2B_{21} = standard error of estimate of B_{21}

SE^2B_{11} = standard error of estimate of B_{11}

n_1 = number of cases assigned to factual message

n_2 = number of cases assigned to evaluative message

RESULTS

H1 is supported for cognitive style. The higher the cognitive style of simplification, the greater the persuasiveness of ($t= 1.94$, $df=73$; $p < .05$) and confidence in ($t=2.00$; $df=73$; $p < .05$) the evaluative as compared to the factual ad (Refer Table 3). However, H1 is not supported for visual style of processing. There are no significant differences in the relationship of persuasiveness and confidence with visual style of processing between the evaluative and factual ad.

H2 is supported for both need for cognition and cognitive innovativeness but not for verbal style of processing. The higher the need for cognition the greater the persuasiveness of ($t=4.18$; $df=73$; $p < .01$) and confidence in ($t=2.37$; $df = 73$; $p < .01$) the factual as compared to the evaluative ad. Similarly, the greater the cognitive innovativeness score the greater the persuasiveness of ($t= 1.74$; $df=73$; $p < .05$) and confidence in ($t=1.55$; $df=73$; $p < .10$) the factual as compared to evaluative ad. However, contrary to expectations, verbally oriented style of processing is not related to persuasiveness

and confidence in a factual as compared to evaluative ad.

DISCUSSION

The results suggest that different cognitive orientations are related differently with responses to factual and evaluative ads. The cognitive style of simplification is related with responses to the evaluative ad, and traits that capture effortful

cognitive activity are related with responses to the factual ad. The hypothesis, however, is not supported for style of processing. Contrary to expectations, verbal style of processing is not related with responses to the factual ad and visual style of processing is not related with responses to the evaluative ad. In the case of verbal style of processing, it seems reasonable to expect that people who have a preference for verbal information

processing would respond to the factual ad. Perhaps they respond by reading the factual ad and therefore they can recognize and recall it as found by Childers et al. (1985). But in the case of the ads used in this study, they do not believe what they read and are not convinced by it, therefore verbal style of processing is not related to persuasiveness of the factual ad. For the visual style of processing, the lack of support for the hypothesis may be due to the fact that the ads do not contain any visuals like pictures, charts or diagrams. Perhaps visual processors respond to pictorial ads more than ads that are factual and verbal.

These findings extend previous research on responses to factual and evaluative ads (Golden and Johnson 1983; Kuritsky et al. 1982). Previous research found that factual ads tend to be more effective than other message appeals. Our research replicates this finding for cognitive innovators and people who are high on the need for cognition. However, people who are not cognitive innovators and do not have a need for cognition do not respond to factual ads. Further, simplifiers respond to evaluative ads. However, since our study used student subjects before any generalization can be made to "all consumers" it must be replicated with a sample representing this population.

In addition to extending past research, our results have implications for procedures used to test ad copy. Existing procedures are based upon the implicit assumption that personality factors do not affect responses to ads. This study, however, provides some empirical evidence to the contrary. These findings indicate that an advertising appeal that persuades and generates confidence for one personality type might not do so for another. Hence, advertisers should carefully consider the personality characteristics of their message recipients, and tailor their persuasive messages to match the characteristics of their target audiences.

Situational Product Relevance and Attitude Persistence

Curtis P. Haugtvedt, Ohio State University
Alan J. Strathman, Ohio State University

ABSTRACT

Attitudes of subjects exposed to an advertisement for a bicycle were assessed immediately and two days later. Based on Petty and Cacioppo's (1981; 1986) Elaboration Likelihood Model, it was predicted and found that product attitudes formed under a condition of relatively high personal relevance showed less decay than product attitudes formed under conditions of relatively low personal relevance. In addition, it was predicted and found that individuals exposed to the critical ad under conditions of high personal relevance chose to spend more time thinking about the ad than individuals exposed to the same ad under low personal relevance conditions.

INTRODUCTION

In a recent ACR paper, Haugtvedt and Petty (1989) discussed how individual differences in need for cognition (NC) may be associated with different levels of attitude persistence. Because NC was developed as a dispositional operationalization of the motivation to process information construct in Petty and Cacioppo's (1981;1986) Elaboration Likelihood Model, Haugtvedt and Petty (1989) predicted and found that initial product attitudes of individuals high in need for cognition (HNC) decayed less over a two day period than did the attitudes of individuals categorized as low in need for cognition (LNC). That is, because HNC individuals tend to put more effort into carefully evaluating information and tend to be more influenced by the quality of arguments contained in a persuasive appeal (see Haugtvedt, Petty, Cacioppo, & Steidley, 1988), it was predicted that the attitudes formed by such individuals would be more durable. On the other hand, because individuals low in need for cognition tend to be less influenced by the quality of message arguments and more influenced by factors such as the attractiveness or expertise of an endorser, it was predicted that their attitudes would exhibit higher rates of decay. The underlying assumption was that attitudes would be more likely to persist if a broader cognitive base existed to support the attitude (multiple associations and cognitive responses for HNC individuals) than if attitudes were based on a lesser number of associations or thoughts (the single fact that an endorser was attractive or an expert for LNC, for example).

THE PRESENT STUDY

Despite the conceptual parallels between NC and the effects of situational variables that enhance message processing, no consumer study to date has examined the effects of situational motivations on the persistence of newly formed or changed attitudes. Thus, the present study was conducted to extend the Haugtvedt and Petty (1989) study by examining the

influence of the situational variable of personal relevance on the persistence of attitudes formed toward a consumer product.

Situational manipulations of personal relevance have been shown to affect the nature and amount of message processing in past research in both social psychology and marketing (see Petty, Cacioppo, and Goldman, 1981; Petty, Cacioppo, and Schumann, 1983 for examples). Existing studies have shown that under conditions of relatively low personal relevance, attitude change tends to be based on the quantity rather than quality of information (Petty & Cacioppo, 1984); celebrity status of product endorsers (Petty, Cacioppo, & Schumann, 1983); and the mere number of people supporting a position (Harkins & Petty, 1981). On the other hand, under conditions of relatively high personal relevance, attitude formation or change tends to be based on the quality of message arguments (see Petty & Cacioppo, 1986 for a thorough review).

In the only study to date to examine the effects of personal relevance on attitude persistence, Petty, Cacioppo, Haugtvedt, & Heesacker (1986, experiment 1) exposed undergraduates to the strong argument version of a message advocating the adoption of senior comprehensive exams (attributed to an expert source) under high and low levels of personal relevance. Based on previous research it was predicted that attitudes changed under conditions of high personal relevance would be based on evaluations of the arguments whereas attitudes changed under conditions of low personal relevance would be based more on the fact that the source of the message was an expert. Consistent with predictions, it was found that attitudes changed under high relevance conditions decayed less over a ten day period than did attitudes changed under low relevance conditions.

In addition to studying the effects of situational relevance on attitude persistence, another goal of the present study was to examine the idea that individuals presented an advertisement under high relevance conditions would, if given the opportunity, choose to spend more time thinking about or "reflecting on" an ad than individuals exposed to the same ad under low relevance conditions. This idea stemmed in part from Tesser's (1978) suggestion that the amount of time individuals spend engaged in what he has labeled "mere thought" can lead to greater attitude polarization. In research in this area, Clary, Tesser, and Downing (1978), for example, found that individuals who were given 90 seconds to reflect on their attitudes toward individuals were more polarized in their attitude than were individuals who were not given time to think. Whereas Tesser's research has examined the effects of assigning individuals various amounts of time to think, we were interested in whether the personal relevance of externally paced

advertisement would influence the amount of time individuals would choose to reflect on an advertisement. That is, we predicted that individuals exposed to an externally paced ad under conditions of relatively high personal relevance would choose to spend more time thinking about information contained in an ad after exposure than individuals exposed to the same ad under conditions of relatively low personal relevance.

METHOD

Eighty-six undergraduate students from an introductory marketing class participated in groups of two to six for extra credit. The students were informed that the study involved the computer presentation and evaluation of print advertisements. They were further informed that because of the number of ads to be evaluated, the study would involve two sessions. The ads were presented on one of six Macintosh SE computers using the application software HyperCard. A series of six advertisements were presented. An informational "card" containing the brand name of the product, where it was manufactured and where the product was to be introduced, appeared immediately before each ad. Importantly, the amount of time the information card and each advertisement remained on the screen was under computer control. After the presentation of each ad, a card (screen) with the statement "take a few seconds to reflect on the ad you just viewed. Click the button below when you are ready to move on" appeared. The amount of time between the removal of the ad and when the subject clicked the button served as a measure of "reflection time." Ads were presented for amounts of time varying from 15 to 22 seconds. The information card for the bicycle ad was presented for 10 seconds and was followed immediately by the bicycle ad. The bicycle ad was presented for 20 seconds. Personal relevance of the product was manipulated by informing subjects via the information card that the product would soon be available in the local or a distant market. The ad was specifically developed to contain strong arguments and positive cues (expertise of the endorser and sheer amount of information). After exposure to all of the ads, subjects were presented a series of questions via the same computer about the ads and products viewed. Among these were questions assessing their opinions of the products contained in the ads.

At the end of the first session, subjects were told to return at the same time two days later. In the second session, subjects' attitudes toward the products viewed in the earlier session were again assessed. They were then debriefed, asked not to tell other students about the nature of the study, and dismissed.

RESULTS

Analysis of attitude toward the bicycle assessed by agreement with the statement "Speedtour Bicycles are good" on a seven point disagree-agree scale revealed comparable attitudes in the low and high relevance conditions in the first session. The

mean attitude score of subjects in the low relevance condition was 5.06 and the mean attitude score of subjects in the high relevance condition was 4.72. Analysis of agreement with the statement "The bicycle advertised in session 1 is good" obtained in the second session revealed a significant difference in the attitudes of persons in the low and high relevance conditions ($F_{1,85} = 5.37, p < .02$). Mean delayed attitude of subjects in the low relevance condition was 3.68 whereas the mean delayed attitude of subjects in the high relevance condition was 4.42. As indicated by this pattern, a 2 (low vs. high relevance) X 2 (immediate vs. delayed attitude) mixed design ANOVA revealed the predicted interaction ($F_{1,84} = 7.71, p < .006$).

Analysis of reflection time revealed that subjects in the high relevance condition waited longer after the presentation of the critical ad ($F_{1,85} = 5.37, p < .02$) before moving on to the next ad than did subjects in the low relevance condition (mean reflection time in the high relevance condition = 6.38 seconds; mean reflection time under low relevance = 4.46 seconds).

DISCUSSION

Both the attitude and reflection time results are supportive of our hypotheses. Attitudes formed or changed under conditions favoring greater elaboration decayed less over a two day period than did attitudes formed or changed under conditions less favorable to argument elaboration. Aside from the Petty et al. (1986) study and the Haugtvedt and Petty (1989) study, very few studies have been reported on the persistence of communication-induced attitude change (see Cook and Flay, 1978, for a review).

Understanding the processes by which attitude formation or change situations influence the durability of attitudes would seem to have important theoretical and practical implications. While there has and continues to be interest in econometric studies on the duration of advertising effects on sales (e.g., Clarke, 1976) and the analytical modeling literature on advertisement scheduling (e.g., Balakrishnan & Hall, 1989), such approaches provide little insight as to the psychological processes at the individual level that may mediate the observed effects. We believe studies of the kind presented here have the potential to build a body of literature that might provide such understanding.

As discussed in the introduction, the Haugtvedt and Petty (1989) study provided evidence that the individual difference variable of need for cognition may be associated with different levels of attitude persistence and the Petty et al. (1986) study provided evidence that situational manipulations of personal relevance for a college exam can have an impact on attitude persistence. There are, however, a number of important differences to consider between the kind of message and situational manipulation used in the Petty et al. (1986) study and the current test of the basic principles in an advertising context. Students, for example, tend to hold very negative attitudes toward the issue of

senior comprehensive exams prior to message presentations and are thus very motivated in the high relevance conditions to engage in counterargumentation during message exposure. It is only when they are unable to successfully counterargue the very strong arguments contained in the message that attitude change takes place under the high relevance condition. On the other hand, most consumers would not hold such extreme negative views toward an unknown brand of consumer product portrayed in an advertisement. Additionally, the extent of personal relevance or strength of a personal relevance manipulation is likely to be very high for an issue like a college graduation requirement when compared to a personal relevance manipulation like the fact a product will soon be available in a local or distant market. Results of the present study suggest that even with the more subtle manipulations in an advertising context, situational personal relevance can have an important influence on attitude persistence.

The finding of differential reflection time is consistent with our idea of a subject's desire for time to "consolidate" their attitudes after exposure to an externally paced advertisement. Such a finding is also consistent with studies that have examined the distracting nature of rhetorical questions under high relevance conditions in persuasive audio messages (e.g., Petty, Cacioppo, & Heesacker, 1981) and past research on cognitive responses (see Wright, 1981). That is, previous studies have suggested that restricting an individual's ability to digest information from an externally paced presentation can influence cognitive responses. To our knowledge, however, the present study is the first to show that individuals under different situational motivation will take different amounts of time to think about an advertisement after it has been presented.

The impact of providing "reflection time," under appropriate conditions, is interesting and potentially very informative with regard to advertising practice. One might predict, for example, that ads likely to be processed under conditions of high personal relevance might have greater long term impact if individuals are given the opportunity to think about them after they have been removed. Having another ad follow too closely in time might disrupt thoughts and attitude "consolidation" presumably occurring during this time, ultimately reducing the impact of the ad. It should be noted that this suggestion may be quite different than one of simply keeping an ad in front of an individual longer. There may be some important advantages to having a person think about the ad without having the luxury of its presence. For one, such a process may be more effortful and lead to memorial advantages. Secondly, allowing one's own tendencies or schema's to influence or bias the information might lead to evaluatively more polarized and/or "stronger" attitudes (Sadler & Tesser, 1973). Future research designed to address this issue is currently being planned.

FUTURE DIRECTIONS

Although the results of the present study are consistent with predictions, little data at the process level of analysis was collected---largely do to constraints of the design. For example, one would ideally like to have collected cognitive response data from persons in the high and low relevance conditions to assess differential message processing. However, collection of such data immediately after the presentation of the advertisement may have caused individuals in the low relevance conditions to engage in more elaborative processing than they might "naturally" ---potentially artificially increasing the persistence of their attitudes. Additionally, previous research by the authors suggests that the collection of cognitive response data at the end of the second session (two days removed) yields little. The examination of such process measures, however, is being addressed in continued research on the topic of attitude persistence.

In addition to the study of attitude decay, fruitful future research might examine the effects of situational manipulations or dispositional tendencies on the extent to which an individual's newly formed/changed attitude will resist change when exposed to a later counterpersuasive appeal. One might, for example, present subjects who initially processed an advertisement under conditions of high vs. low personal relevance with a communication challenging the validity of their attitudes and beliefs. Individuals having a broader base of support (high relevance conditions) for their initial position would likely marshal that support to defend their opinions. Only when the "counterattack" is judged more cogent than their own supportive arguments, would such individuals change. On the other hand, individuals whose support of an initial position is based mainly on some simple cue association may be very susceptible to the influence of other strong cues associated with positions or ideas counter to their own. In any case, it is clear that much might be learned from an examination of attitude change processes over time as well as in multiple message contexts.

Further Validation of the Consumer Susceptibility to Interpersonal Influence Scale

William O. Bearden, University of South Carolina
Richard G. Netemeyer, Louisiana State University
Jesse E. Teel, University of South Carolina

ABSTRACT

Recently, a two-factor (normative and informational), 12-item measure of consumer susceptibility to interpersonal influence (SUSCEP) has been developed (Bearden, Netemeyer, and Teel 1989). The present paper summarizes a series of additional analyses designed to further examine the dimensionality and validity of this scale. These efforts include first, the results of correlating the SUSCEP measures with a number of consumer specific and general personality traits. Second, previously reported tests of the SUSCEP scale employing measures of attention-to-social-comparison-information and self-esteem are expanded to include comparison tests with interpersonal influence measures similar to those used by Park and Lessig (1977). The results of these efforts provide additional support for the validity of the two dimensional-SUSCEP scale.

INTRODUCTION

Interpersonal influence is viewed as an important factor in consumer decision-making (e.g., Ajzen and Fishbein 1980; Gatignon and Robertson 1985; Kiel and Layton 1981; Stafford and Cohanougher 1977). Only recently, though, have efforts been made to strengthen measurement in this area of consumer research. The objective of this paper is to present the results of additional validation research for the recently developed consumer susceptibility to interpersonal influence scale (SUSCEP) (Bearden et. al. 1989). First, a brief review pertaining to the interpersonal influence literature and the SUSCEP scale is offered. Second, the hypotheses, methods and results of research relating the SUSCEP scale to a number of personality characteristics are presented. Next, the hypotheses, methods and results of a follow-up effort which compares the SUSCEP measures to alternative self-report measures of interpersonal influence (cf. Park and Lessig 1977) are presented.¹

¹With a few exceptions, the results summarized in this paper represent additional validation tests not presented in the original manuscript describing the initial construction and validation of the SUSCEP scale. These exceptions include: the confirmatory factor analysis and reliability tests of the original scale briefly used to introduce the follow-up correlational validity tests; the correlations between ATSCI and the informational and normative dimensions for the student sample; and the two correlations between the SUSCEP factors and the behavioral indices reported as comparison to the Park and Lessig results.

Lastly, a brief discussion and suggestions for future research in interpersonal influence are offered.

Consumer Susceptibility to Interpersonal Influence

Consumer susceptibility to interpersonal influence is assumed to be a general trait that exists to varying degrees in different individuals. This construct is derived from McGuire's (1968) concept of influenceability and is consistent with early research demonstrating that individuals differ in their response to social influence (Allen 1965; Asch 1958; Cox and Bauer 1964; Janis 1954; Kelman 1961). Interpersonal influence has been conceptualized as being either informational or normative where informational influence is defined as the tendency to accept information from others as evidence about reality (Deutsch and Gerard 1955). Based on the work of Kelman (1961), normative influence has been viewed as either value expressive or utilitarian (Bearden and Etzel 1982; Burnkrant and Cousineau 1975; Park and Lessig 1977; Price, Feick, and Higie 1987). Value expressiveness reflects the individual's desire to enhance his or her self-image and is characterized by the need for association in terms of being similar to a reference group and feeling for another referent. Utilitarian influence is reflected in attempts to comply with the expectations of others in order to gain rewards or to avoid punishments mediated by others (Burnkrant and Cousineau (1975, p. 207).

Several consumer behavior studies support the existence of the three manifestations of interpersonal influence (i.e., informational, value expressive and utilitarian) (e.g., Bearden and Etzel 1982; Ford and Ellis 1980; Park and Lessig 1977; Pincus and Waters 1977; Price, Feick, and Higie 1987; Stafford 1966; Witt and Bruce 1972). Based on these manifestations, the consumer susceptibility to interpersonal influence scale (SUSCEP) was developed. However, the scale development procedures revealed that the value expressive and utilitarian factors were not distinct and hence, they were combined into one normative factor (Bearden, et. al. 1989). SUSCEP currently consists of 12 items--eight comprising a normative interpersonal influence factor and four comprising an informational influence factor. Though a number of validation procedures were performed, additional research is warranted to further establish SUSCEP's validity.

CORRELATIONS WITH RELATED CONSTRUCTS

Hypotheses

A number of measures assessing both consumer specific constructs and general personality traits were used to further evaluate the validity of the SUSCEP scale. First, two consumer-specific variables are hypothesized to be related to susceptibility to interpersonal influence, i.e., consumer confidence and consumer interpersonal orientation. Consumer confidence is defined as the individual's perceived ability to choose the best buy from available brands; consumer interpersonal orientation is defined as the willingness to interact with others regarding consumer related topics. These two variables represent likely antecedents of individual susceptibility to interpersonal influence. It is predicted that general consumer interpersonal orientation will be positively related to measures of susceptibility to interpersonal influence. In contrast, it is felt that confidence and susceptibility to interpersonal influence will be inversely related. These predictions are consistent with earlier findings that individuals high in consumer confidence should perceive less need for information from others and demonstrate less concern for the opinions of others (Locander and Hermann 1979). Formally stated, the first two hypotheses read:

H1: Both dimensions of SUSCEP (i.e., the normative and informational dimensions) will be positively correlated with consumer Interpersonal Orientation.

H2: Both dimensions of SUSCEP will be negatively correlated with consumer confidence.

A number of constructs in social psychology assess interpersonal relations among individuals. Three of these constructs, i.e., attention-to-social-comparison-information (Lennox and Wolfe 1984), inner-other directedness (Kassarjian 1962), and self-monitoring (Lennox and Wolfe 1984) are included here for further validation tests of the SUSCEP scale. Strong positive correlations are predicted for attention-to-social-comparison-information (ATSCI). ATSCI addresses the general tendency to conform and has been found related to the concern for reactions of others (Lennox and Wolfe 1984). Consequently, the measure should be strongly correlated with the normative factor and, although less so, positively correlated with the informational factor. Thus, the following hypothesis is offered:

H3: Both dimensions of SUSCEP will have a positive correlation with ATSCI. However, the normative factor of the SUSCEP scale will be more highly correlated with ATSCI than will the informational factor.

Inner-other directedness and self-monitoring represent generalized traits that deal with the

individual's interest in and responsiveness to others. For example, the frames of reference for other-directed individuals are the values and attitudes of others around them (Kassarjian 1962). Similarly, effective social integration and adjusting to what is situationally appropriate are the hall marks of the high self-monitor (Lennox and Wolfe 1984). These measures reflect operationalizations of generalized constructs that have some overlap with consumer susceptibility to interpersonal influence and, hence, modest positive correlations are predicted:

H4: Both dimensions of SUSCEP will exhibit modest positive correlations with measures of inner-other directedness and self-monitoring.

Method

Subjects and Measures. Two samples were utilized in the correlational tests. In the first, 220 adult consumers responded to the 12-item SUSCEP scale along with measures of consumer confidence and consumer orientation. The developmental procedures for the confidence and orientation measures began with an initial pool of 39 items. Similar judgmental procedures to those employed in the scale development literature (cf. Bearden, et. al. 1989) resulted in deletion of 15 of these items. Examination of corrected item-to-total correlations and an initial confirmatory factor analysis for the confidence and interpersonal orientation items resulted in deleting 5 confidence and 9 consumer IO statements. The remaining items were then examined in a subsequent two-construct confirmatory factor analysis. Although the χ^2 value was significant ($\chi^2 = 87.97$, $df = 37$), all items loaded as hypothesized and each t-value exceeded 7.27. In sum, these analyses resulted in 5 remaining items for the measures of consumer confidence (e.g., "As a rule, I have a great deal of confidence in my ability to evaluate products and brands.") and consumer IO (e.g., "I enjoy discussing products and brands with friends.") Internal consistency reliability estimates (coefficient alpha) were .81 and .79 for consumer confidence and interpersonal orientation, respectively.

In the second sample, 141 undergraduate students responded to the SUSCEP scale along with the three general personality measures. The scales developed by Lennox and Wolfe (1984) were used to measure attention-to-social-comparison-information and self-monitoring. Inner-other directedness was assessed via Kassarjian's (1962) scale. The top portion of Table 1 presents the summary statistics and reliability estimates for these measures.

Results

The factor structure and internal consistency of the SUSCEP scale was examined first (Bearden, et. al. 1989). (Only a brief summary of the factor

TABLE 1
Summary Statistics and Reliability Estimates for Measures and Correlational Results

<u>Summary Statistics and Reliability</u>					
Construct	No. of Items	Mean	SD	Range	Coefficient alpha Reliability
<i>Adult sample: (n = 220)</i>					
Consumer Confidence	5	28.50	4.90	5-35	.81
Consumer IO	5	21.69	6.34	5-35	.79
<i>Student sample: (n = 141)</i>					
ATSCI	13	39.01	8.81	0-65	.86
Inner-Other	36	84.89	8.39	36-144	.60
Self-Monitoring	13	43.19	5.91	0-65	.80
<u>Correlational Results</u>					
				<u>SUSCEP</u>	
				Info.	Norm.
<i>Adult sample</i>					
Consumer Confidence				-.15 ^b	-.53 ^b
Consumer IO				.50 ^b	.38 ^b
<i>Student sample</i>					
ATSCI				.24 ^b	.59 ^b
Inner-Other				.13 ^a	.37 ^b
Self-Monitoring				.14 ^a	.05

^ap < .10.
^bp < .05.

structure tests is reported here.)² For the adult sample, the hypothesized 2-factor structure (8 normative and 4 informational items) yielded a $\chi^2 = 79.83$ (df = 53) with a correlation between factors of $\phi = .37$. In comparison, the null model had a $\chi^2 = 845.58$ (df = 66) while the unidimensional model had a $\chi^2 = 167.84$ (df = 54). Thus, the two factor structure had a significantly better fit to the data than either the null or unidimensional model. The variance extracted estimates for the normative and informational factors were .53 and .55 and the square of the ϕ correlation between factors (.14) was less than the variance extracted estimates for

both factors. Thus, evidence for the convergent validity among items and discriminant validity between factors was provided (cf. Fornell and Larcker 1981). In addition, internal consistency reliability estimates for the normative and informational scales were .87 and .83. In the student sample, the two-factor model had a $\chi^2 = 107.41$ (df = 53) with $\phi = .44$. The competing one-factor structure had a $\chi^2 = 255.60$ (df = 54) and the null model yielded a $\chi^2 = 820.10$ (df = 66). The differences in fit, again, were significant. The variance extracted estimates for the normative factor and informational factors were .54 and .50 and were greater than the square of the correlation between them ($\phi^2 = .19$). The internal consistency estimates were .88 and .82 for the normative and informational factors, respectively. In sum, the dimensionality and reliability of the SUSCEP scale were largely supported.

The correlations between consumer self-confidence and consumer IO and the two dimensions

²The SUSCEP statements, the item-to-total correlations and factor loadings are presented in the original manuscript (Bearden, et. al. 1989, p. 477). Due to space limitations, they have not been reported in this paper.

of SUSCEP are shown in the bottom portion of Table 1. Confidence was inversely related to the two sub-dimensions and consumer IO was positively related to the sub-dimensions, as hypothesized. It is interesting to note that consumer IO was most strongly correlated (.50, $p < .01$) with the informational dimension, i.e., the factor most closely reflecting verbal communications with others. Similarly, consumer confidence was most strongly correlated (-.53, $p < .01$) with the normative factor, i.e., the dimension reflective of the expectations of others. In sum, H1 and H2 were supported.

Table 1 also presents correlational findings from the student sample. As predicted, ATSCI did correlate positively with the two sub-dimensions of the SUSCEP scale and was more strongly correlated with the normative factor than with the informational factor ($t = 6.02$, $p < .01$, for a test between dependent correlations (Cohen and Cohen 1975)) offering support for H3. Although not overwhelming, the correlations pertaining to H4 generally adhere to the anticipated pattern.

COMPARISON WITH PARK AND LESSIG ITEMS

One of the purposes of developing the SUSCEP scale was to provide consumer researchers with a general measure of consumer susceptibility to interpersonal influence (Bearden, et. al. 1989). Though other measures of consumer susceptibility to interpersonal influence exist, they are primarily product/situation specific (cf. Brinberg and Plimpton 1986; Park and Lessig 1977). Thus, it was predicted that SUSCEP should have stronger correlations with personality traits and other generalized indices of interpersonal influence than product/situation specific measures. To examine this premise, the SUSCEP scale was compared with the Park and Lessig (1977) measures of interpersonal influence in two separate studies. The first study examined the relationships between SUSCEP, the items of Park and Lessig and the ATSCI (Lennox and Wolfe 1984) and self-esteem (Eagly 1967) measures. The second study investigated the relationships between the Park and Lessig (1977) measures of susceptibility to interpersonal influence along with the SUSCEP scale and a series of aggregate indices of behaviors performed over multiple time periods (cf. Epstein 1979, 1980; Lastovicka and Joachimsthaler 1988). The following hypotheses are offered:

H5: The SUSCEP measures will exhibit stronger correlations with ATSCI and self-esteem than will the Park and Lessig measures.

H6: The SUSCEP measures will exhibit stronger correlations with an aggregate indices of consumer behaviors than will the Park and Lessig measures.

Method

In the original research of Park and Lessig (1977), 20 products were evaluated for each of their 14 items. For comparison purposes, five of these same 20 products were randomly selected for this study. Similar to their original procedures, the relevance of each item for each product was evaluated on a four-place scale ranging from "not relevant" (1) to "highly relevant" (4). Responses to their informational and normative items were averaged over products and then summed to form informational and normative interpersonal influence scales. The average internal consistency estimates were 0.55 and 0.86, respectively.

Park and Lessig (1977) computed scores for each product by assigning the highest score obtained on any one of the items representing a given dimension of susceptibility to interpersonal influence to that product. These high scores were then averaged across products to produce one score for each component of interpersonal influence. To enhance the comparisons between SUSCEP and the Park and Lessig measures, we summed their items and used this composite in a series of comparison tests. Since this approach differed from Park and Lessig's original scoring procedures, additional comparison tests were conducted using their original scoring procedures. The results of these analyses were similar to those found using the summed comparison measures.

ATSCI and Self-Esteem. A convenience sample of 47 undergraduate business students responded to a questionnaire containing the 14 Park and Lessig items for five products, the ATSCI scale, the twenty-item self-esteem scale described by Eagly (1967), and the SUSCEP scale. The internal consistency estimates for the ATSCI and the self-esteem measures were 0.82 and 0.88. Again, ATSCI was expected to be more strongly correlated with the normative factor than with the informational factor. However, it was predicted that the correlations between ATSCI and the Park and Lessig items should be lower than the ATSCI-SUSCEP correlations. It was also predicted that both dimensions of the SUSCEP scale would be inversely related to self-esteem (McGuire 1968).

Relationships With Behavioral Indices. Similar to the procedures of Epstein (1979, 1980), the alternative measures of susceptibility to interpersonal influence (i.e., the Park and Lessig measures and the SUSCEP scale) were correlated in a second study with an aggregate index of consumer behaviors. First, a convenience sample of 35 undergraduate business students was used to elicit 21 and 17 behaviors reflecting the definitions of the normative and informational dimensions of susceptibility to interpersonal influence. Example normative behaviors included worrying about what others thought of the respondent's selection of clothing to wear and copying the purchase behavior of someone the respondent admired. Example informational behaviors included discussing products with friends or relatives and/or seeking expert advice of others prior to making a purchase.

TABLE 2
Comparison with Park and Lessig Items and Correlations with Other Constructs

	Normative		Informational	
	SUSCEP	Park and Lessig	SUSCEP	Park and Lessig

<i>Stability Indices: (n = 43)</i>				
Behavioral Index (Normative)	.37 ^b	.05	--	--
Behavioral Index (Informational)	--	--	.15	.07

^a_p < .10.
^b_p < .05.

Following elicitation of these behaviors, a questionnaire containing the Park and Lessig items for 5 products along with the SUSCEP items was administered to a new sample of 43 subjects. Next, at four separate intervals, these same 43 subjects reported their performance regarding the 21 normative and 17 informational behaviors during the preceding 48 hour period. Similar to the methods used by Epstein (1979), the behavioral measures were averaged over administrations to form behavioral indices.

Results

The reliability and dimensionality of the SUSCEP scale were examined first. The results again show support for validity of the scale. For the sample examining the relationships between the two measures of susceptibility to interpersonal influence and ATSCI and self-esteem, the hypothesized two-factor structure for SUSCEP was again supported ($\chi^2 = 97.96$, $df = 53$). The differences between the two-factor structure and a null model ($\chi^2 = 348.28$, $df = 66$) and a one-factor model ($\chi^2 = 119.38$, $df = 54$) were significant. The variance extracted estimates were .41 and .55 for the informational and normative factors while the correlation among the two factors was .36 ($\phi^2 = .13$). In addition, the internal consistency reliability estimates were .72 and .91 for the informational and normative factors. Overall, these results are supportive of the dimensionality and internal consistency of the scale.

For the sample examining the relations between the behavioral indices, the hypothesized two-factor SUSCEP scale ($\chi^2 = 133.99$, $df = 53$) again had a better fit to the data than did the null model ($\chi^2 = 355.27$, $df = 66$) or a unidimensional model ($\chi^2 = 138.91$, $df = 54$). The internal

consistency estimates were .91 and .72 for the informational and normative factors.

Table 2 presents the correlational results for the comparisons between SUSCEP and the Park and Lessig measures. As reported in the original scale development, ATSCI was again more strongly correlated (for a test of differences between correlations) with the normative dimension of SUSCEP than with the informational dimension ($t = 4.37$, $p < .01$). Importantly, the normative factor of SUSCEP was more highly correlated with the ATSCI scale than was the Park and Lessig measure of normative influence ($t = 3.43$, $p < .01$). Furthermore, the correlation between the informational dimension of SUSCEP and self-esteem was greater than the correlation between the Park and Lessig informational measure and self-esteem ($t = 1.67$, $p < .05$). Though the correlation between the normative dimension of SUSCEP and self-esteem was stronger than the correlation between the normative measure of Park and Lessig and self-esteem, this difference was not statistically significant.

The correlation between the even and odd summary averages for the normative and informational behavioral indices were 0.72 and 0.80. As Table 2 indicates, neither correlation between the normative and informational behavioral indices and the Park and Lessig measures was significant. In contrast, the normative factor of the SUSCEP scale was significantly correlated with the normative behavioral index ($r = .37$, $p < .05$) and, although the magnitude of this correlation is modest, it compares favorably with the trait-behavior correlations reported by Epstein (1979, p. 1118). In addition, the correlation between the normative factor of SUSCEP and the normative behavioral index was significantly greater than the correlation between the normative factor of the Park and Lessig measure and the normative behavioral

index ($t = 1.89, p < .05$). Although the correlation between the SUSCEP informational factor and the informational behavioral index was stronger than the correlation between the Park and Lessig informational measure and the behavioral informational index, the difference was not statistically significant. Overall then, H5 and H6 were largely supported.

DISCUSSION

This research sought to provide additional evidence regarding the validity of the recently developed consumer susceptibility to interpersonal influence scale (Bearden, et. al. 1989). The first series of tests examined the relationships between the two dimensions of the SUSCEP scale and a number of consumer specific and psychological traits. Overall, the results supported the convergent and discriminant validity of SUSCEP. Subsequently, SUSCEP was compared to previously used measures of interpersonal influence (i.e., Park and Lessig 1977). The general pattern of correlations demonstrated that the SUSCEP scale was more strongly related to behavioral indices reflecting both normative and informational influence than the Park and Lessig measures. Again, since the Park and Lessig items were product specific and the SUSCEP items more applicable to a wider range of consumer behaviors, the higher correlations between SUSCEP and the behavioral indices were expected.

The SUSCEP scale should prove to be useful for a number of consumer behavior applications. First, studies examining the differences in susceptibility to interpersonal influences based on gender and age could be performed. Earlier research posited that females have a stronger interpersonal orientation toward others than males (e.g., Solomon 1963). It has also been suggested that females interact more frequently with their peers about consumption matters and are more susceptible to social influence (i.e., possess stronger social motivations for consumption) than males (Churchill and Moschis 1979). Overall, age might exhibit a curvilinear relationship with the highest levels of susceptibility to interpersonal influence occurring during the teen and early adult years. However, for informational influence alone, research indicates that the influence of others (largely the extended family) as sources of information increases with advancing age (cf. Phillips and Sternthal 1977). Lastly, the SUSCEP scale should be useful in experimental research. Studies that examine normative vs. informational influence in terms of referent similarity and expertise could be undertaken (Burnkrant and Cousineau 1975; Price, Feick, and Higie 1987). Also, experiments could be designed where subjects are exposed to either informational or normative influence, and then the extent of the influence observed and measured. This observed level of susceptibility could then be compared with self-report levels via the SUSCEP scale, offering a stronger validation test for SUSCEP.

The Conceptual Organization of Behavior and Attitude-Behavior Consistency

Mahmood M. Hajjat, Ohio State University

ABSTRACT

The attribute-processing perspective views behavior as being driven primarily by cognitions and as being instrumental to the realization of consumption objectives. Alternatively, the recent surge of interest in the role of affect in buying behavior suggests that behavior may be consummatory (noninstrumental) and driven by emotions. Therefore, the validity of the single-component perspective was tested against a two component (consummatory and instrumental) model of behavior. Additionally, the effect of focusing on an attitude component (affective/cognitive) on attitude-behavior relation was examined. Results indicate that the two-component model achieved discriminant and convergent validity whereas the single-component model did not. Moreover, attitude-behavior correlations were higher when attitude and behavior were influenced by the same attitude component than when they were influenced by different attitudinal components.

INTRODUCTION

A basic tenet of the attribute-processing perspective is that the comprehension of the brand attribute claims leads to a change in consumers' stored cognitions. Thus, consumers are postulated to be problem-solvers and rational buyers who "base their decisions on the persuasive information provided" (Day 1973). The logical flow of the stages of cognitive processing (e.g. attribute comprehension-attitude-behavior-problem solving) assumes causation and assumes that behavior is instrumental to the realization of enduring goals (e.g., problem solving). Although it continues to explain important consumption phenomena, the attribute-processing perspective has failed to produce consistent findings regarding attitude-behavior consistency (e.g. Ajzen and Fishbein 1977).

The restricted conceptualization of attitude and behavior in the attribute-processing perspective has contributed greatly to this failure. For example, it is frequently argued that attitude may not be formed from decomposable origins (e.g. physical attributes) rather it may "involve a gestalt, configural appraisal of the stimulus object, going beyond the assessment of the utility contributed by each individual attribute" (Batra 1986). It is also generally accepted that consumption may not involve solving a problem, or realizing other such enduring goals. It may involve instead some sensory pleasures, joy, and emotional responses (Holbrook and Hirschman 1982). It appears that there are situations in which attitude would be based on affect rather than cognitions and consumption goals would be transient rather than enduring. In such situations, behavior should be viewed as being consummatory (e.g. to obtain pleasure) and driven

by affect rather than instrumental (e.g. to achieve enduring goals) and driven by cognitions.

This article has two purposes. The first is to provide empirical tests of the validity of these conceptualizations by contrasting a single-component with a two-component (consummatory and instrumental) model of behavior. The second is to provide empirical evidence as to whether focusing on either attitude component (affective/cognitive) affects attitude-behavior relation.

The next section is a discussion of the conceptual organization of attitude. It is followed by a conceptual analysis of behavior and a discussion of the effects of thought on attitude-behavior consistency. Finally, an experiment designed for achieving the research objectives is outlined and the findings are thoroughly examined.

ATTITUDE ORGANIZATION

The attitude concept was originally defined as being a single-component entity of likes and dislikes (e.g., Bem 1970). This concept was subsequently reconceptualized to include cognition and conation in addition to affect (e.g., Kothandapani 1971, McGuire 1969). The latter definition has received some empirical support. In an experiment that was designed for predicting contraceptive behavior among low income Negro women, Kothandapani (1971) examined the discriminant and convergent validity of this tripartite classification. He found convincing evidence both to support this classification and to conclude that conation was a better predictor of contraceptive behavior than either of the other two components of attitude (Kothandapani 1971).

However, the inclusion of conation in attitude structure is not universally accepted. This is because the difficulty of directly observing overt behavior has resulted in the use of conation as a surrogate for behavior by many researchers. This conceptual equivalence explains findings of higher conation than affect or cognition-behavior correlations. Moreover, a behavior involving the use of a drug (e.g., contraceptive) that could produce genuine health problems might be more influenced by a medical decision (e.g., prescription) than by affect or cognition. Thus a midpoint position which contends that attitude is composed of only affect and cognition is adopted here. At the same time, conation is considered to be an evaluative response based on the more accessible, more salient of only two attitude components - affect or cognition (e.g., Bagozzi and Burnkrant 1979, Millar and Tesser 1986). The affective component of attitude toward a brand is thought to contain the feelings (e.g., pleasure, happiness, joy) that may be evoked by the brand and the cognitive component is thought to contain the encodings of physical attributes of, and beliefs about the brand (e.g., price, size,

effectiveness). Bagozzi and Burnkrant (1979) examined the validity of a single-component model of attitude and compared it to a two-component model. They reported evidence to support an affective-cognitive conceptualization and lack of evidence to support a single-component model of attitude.

BEHAVIOR ORGANIZATION

Much research indicates that all products, no matter how mundane, carry attributes such as packaging, color, or taste that are not central to the objective value (e.g., effectiveness) of the product - symbolic features. It is also known that people make decisions so as to experience an emotion or to realize some type of utility. For example, a person may drive to a shopping mall on a nice evening just to enjoy him/herself by looking at store windows while another may do the same thing to maintain good health by buying a needed prescription. Similarly, a customer may purchase a product (e.g., toothpaste) because its symbolic features (e.g., taste) are richer and more salient than its objective attributes (e.g., fluoride) while another may do the same thing for just the opposite reason.

It appears that purchase behavior can be differentiated along customers' expectations from consuming the product (e.g., freshness/healthy gums from consuming toothpaste). Thus, purchase behavior that stems primarily from the pursuit of sensory pleasures, happiness, or any emotional responses consummated coincident with consumption of the product is different from purchase behavior that stems primarily from the pursuit of objectives that last beyond the time of actual consumption. These two types of behavior depend on the primary stimuli, and are called consummatory behavior (primary stimuli are immediate consummatory emotional responses) and instrumental behavior (primary stimuli are enduring objectives).

Figure 1 shows path diagrams of a single-component and a two-component model of behavior. A confirmatory factor analysis using LISREL VI (Joreskog and Sorbom 1984) was used for testing the fit of each model.

The single-component model achieves convergent validity if (a) responses that differentiate consummatory from instrumental behavior exhibit high intercorrelations and (b) an insignificant chi-square is obtained. Discriminant and convergent validity of the two-component model will be achieved if (a) within-component correlations are high, (b) across-component correlations are logically consistent and significantly lower than within-component correlations, (c) rho-statistic (Bentler and Bonett 1980) is within an acceptable range ($\rho \geq 0.90$), and (d) root mean square residual (RMSR) is within an acceptable range ($\text{RMSR} \leq 0.10$). A final test of the overall fit of both models based on an inferential evaluation of nested models (Long 1988) could be carried out to determine which model fits the data better. Based on this analysis, the following hypotheses were tested:

H1: A two-component (consummatory and instrumental) model of behavior achieves discriminant and convergent validity whereas a single-component does not.

H2: A two-component (consummatory and instrumental) model of behavior fits the data better than a single-component model.

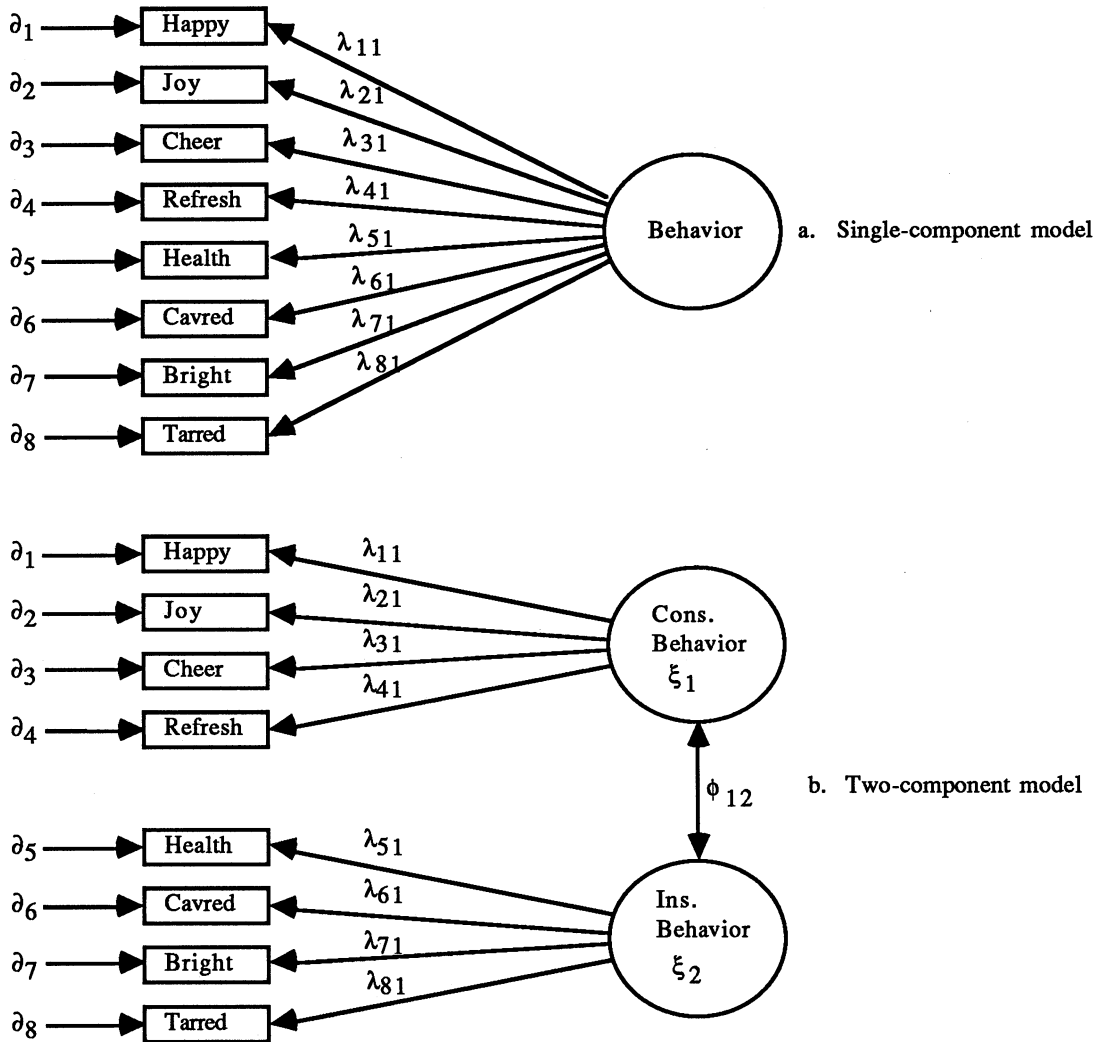

EFFECTS OF THOUGHT ON ATTITUDE-BEHAVIOR RELATION

In recent years, research in attitude-behavior relation has proliferated and has primarily examined the conditions under which attitude and behavior would or would not correlate (Wilson, Dunn, Bybee, Hymann, and Rotondo 1984). An area that has captured much attention, and is also the focus of this article, is the effect of affective and cognitive focus on attitude-behavior consistency. In one study, Fazio, Zanna, and Cooper (1978) stimulated their subjects to think about the attitude objects (puzzles) by instructing them to empathize with a similar individual on a videotape who was playing with the puzzles. Fazio et al. (1978) found that when subjects were instructed to think about the attitude objects (puzzles), the amount of salient information about the attitude objects increased. The attitudes of those subjects who were led to focus on the attitude objects were also found to be better predictors of behavior than subjects' attitudes in the control condition (who did not think about the attitude objects).

In contrast, Wilson et al. (1984), using a similar paradigm, found results that were contradictory to those reported by Fazio et al. (1978). Wilson et al. (1978) predicted that analyzing the reasons for one's own attitude (thinking in terms of why a person feels the way s/he does) would shift attitude in a direction away from behavior, thus attitude-behavior correlation would be low. In a series of experiments using puzzles, vacation scenes, and dating mates as attitude objects, Wilson et al. (1978) found that when subjects analyzed the reasons of why they would or would not like the attitude object, their self-reported attitudes accounted for only 1% of the variance of behavior while subjects' attitudes in the control condition were found to account for approximately 30%.

In an attempt to provide a resolution to the apparent contradictory findings, Millar and Tesser (1986) conducted an experiment in which they used puzzles, similar to those used in Wilson et al. (1978), as attitude objects. Millar and Tesser (1986) reasoned that if attitude report and behavior emanated from the same attitudinal component (either affective or cognitive), attitude-behavior correlation would be high. And, if behavior was initiated by an attitudinal component that would be different from that component dictating attitude report, attitude-behavior correlation would be low.

FIGURE 1
Path Diagram of a single-component and a two-component model of behavior

Note: Cons. Behavior-consummatory behavior; Ins. Behavior-instrumental behavior; Happy-happiness; Joy-joy; Cheer-cheerfulness; Refresh-refreshment; Health-gum health; Cavred-cavity reduction; Bright-brightness; Tarred-tartar buildup reduction.

In Millar and Tesser (1986), the time spent playing with each puzzle, the proportion of each puzzle chosen, and the order of choice in a free-play period were recorded for each subject. The play time for subjects in the cognitive and affective-focus conditions was correlated with their attitude reports. These correlations were higher when behavior and attitude reports were driven by the same attitude component (a match situation) than when each was driven by a different component (a mismatch situation).

However, one could argue that some methodological issues in Wilson et al. (1984) and in Millar and Tesser (1986) may have contaminated

their findings. In formulating a general evaluative response about an attitude object, some of its salient objective attributes or symbolic features would be more important than others. Thus, it is possible that subjects' attitudes toward the attitude objects (puzzles were used in both studies, and vacation scenes and dating mates were used in the first) might have had more symbolic or hedonic than physical or attribute origins. For example, the joy of triumph or the agony of defeat probably influences one's liking or dislike of a puzzle far more than the puzzle's contribution to one's analytic ability. Thus, since Wilson et al's (1984) subjects did not have a large number of cognitions to begin with,

they may have generated a biased set of reasons, just to appear more analytical, that might not have reflected their true attitudes.

Similarly, since Millar and Tesser's (1986) subjects in the cognitive-focus condition did not have many relevant attributes about the puzzles to start with, they may also have generated a biased set of reasons, but to a lesser extent than in Wilson et al. (1984). In fact, Millar and Tesser (1986) reported insignificant differences between affective- and cognitive-focus condition correlations when subjects' behavior was driven by cognitions, and the proportion of puzzles chosen and order of choice were used as behavioral measures.

Second, since Millar and Tesser (1986) did not include a control cell to compare with, it is difficult to conclude whether analyzing reasons in the cognitive-driven behavior condition increased attitude-behavior correlations or just did not decrease them. For the same reason, it is also difficult to conclude whether focusing on the affective component of attitude in the affective-driven behavior condition increased attitude-behavior correlations or simply did not decrease them. Third, considering the time span over which Millar and Tesser's (1986) study was completed (a few minutes), it could be argued that salient-attitude reports in the cognitive focus condition might have habituated subjects' behavioral responses when behavior was driven by the same cognitions. Thus, the observed consistency between attitudes based on cognitions and behaviors driven by these cognitions might have been inflated.

While taking these issues into consideration, the conceptual parallel between affective (cognitive) attitude that is based on feelings (cognitions) and consummatory (instrumental) behavior that is stimulated by symbolic (objective) attributes of the product was maintained in the present research. In the course of doing so, a research paradigm that is similar to those used by Wilson et al. (1984) and Millar and Tesser (1986) was utilized. Second, the attitude objects employed in this research were products (toothpaste brands) that would have different symbolic origins (e.g. packaging, color) for the hedonic component of attitude and several physical origins (e.g. fluoride, abrasive) for the cognitive component. Third, a control group was included and attitude-behavior correlations for all experimental cells were compared with those of the control group. Finally, subjects' actual behavior was observed one week after obtaining self-reported attitudes. The following hypotheses were tested:

- H3: If attitude report and behavior are influenced by the same attitude component (affective/cognitive), attitude-behavior correlation would be high; whereas if they are influenced by different attitude components, attitude-behavior correlation would be low.
- H4: Focusing on the attitude component that drives behavior would result in a high

attitude-behavior correlation; whereas the lack of focus on a specific attitude component would result in a low attitude-behavior correlation.

METHOD

Fifty six male and fifty two female undergraduate students from a marketing course at a major mid-western university completed a short questionnaire that was designed to measure initial attitudes and initial behavioral intentions. After collecting this instrument, subjects were randomly assigned to one of 2 (affective/cognitive attitude focus) / 2 (consummatory/instrumental behavior) cells and a control condition. Subjects completed another questionnaire (ostensibly for a different experiment), were thanked, and promised a gift (was intended to measure actual choice) in the coming days.

Procedure

On the first questionnaire, subjects provided some demographical data, recalled as many brands as they could from four different product classes including toothpaste, ranked the recalled brands, and indicated their preferences. The purpose of this instrument was to facilitate the contrast of subjects' initial to post-experimental attitude-behavior correlations. The second questionnaire contained the following regarding each of five toothpaste brands: (a) a black-and-white picture of the brand, (b) a 9-point bipolar scale for measuring the attitude toward brand, (c) eight 9-point bipolar scales for measuring behavioral responses that, based on a pretest, were found to differentiate consummatory from instrumental behavior, (d) a thought-listing question for measuring the degree of affective and cognitive focus, and (e) a purchase intention question. This instrument was designed to measure the differential effects of experimental manipulations.

Subjects were approached by an experimenter who, as a cover story, claimed that the purpose of the first questionnaire was to measure market share for the brands that subjects could recall. They were given two minutes for each product category and were instructed not to turn pages unless they were told. After collecting the first instrument, participants were approached by another experimenter who distributed the second instrument and asked them to read and follow all instructions carefully. They were given all the time they needed for examining the picture of any brand and for answering the questions.

Subjects were asked to keep a little numbered-post-it note from the first questionnaire, attach the note to the second questionnaire, write the number of the note on a little card attached to the second questionnaire, and keep the card to claim the gift. When gifts were claimed a week later, each subject deposited his/her claim card in the same box from which the toothpaste tube was chosen. Finally, the researcher matched the questionnaires and the card to isolate the responses of each individual.

Experimental Manipulations

An important issue in this research was whether to use fictitious (novel) or familiar and popular brands as attitudinal objects. The selection of well-known over fictitious brands was governed by a number of practical and theoretical considerations. These were: (a) an attempt to resemble a marketing situation as close as possible, (b) an attempt to measure overt behavior under the volitional control of subjects and correlate this index of observed behavior with attitude so as to properly illustrate attitude-behavior consistency, (c) an attempt to equate all recall cues across brands and subjects (the brand picture was the only cue), (d) an attempt to stimulate subjects to report real sentiments from their past experiential consumption episodes, and (e) an attempt to eliminate the likelihood of generating artificial (biased) inferential information, thoughts, and sentiments that would be otherwise increased if written attributes, needed with novel brands, were provided.

Subjects in the affective focus condition were instructed to focus on how they felt about each brand while they were viewing its picture, whereas those in the cognitive focus condition were instructed to think about the reasons that made them feel the way they did. The purpose of the brand picture was either to remind subjects of the sentiments and feelings they experienced whenever they used the product in the past or to aid in recalling the stored attributes of, and beliefs about the product. Subjects in the consummatory behavior condition were led to believe that they would receive a social sensitivity test (how well they would fit with others) at the end of the experiment, whereas those in the instrumental behavior condition would receive a brand and attribute-recall test (how much information they could recall). Neither group was actually tested. To get maximum help on the anticipated tests, subjects in the consummatory behavior condition should have heightened their stored feelings and emotions upon viewing the pictures. While those in the instrumental behavior condition should have accessed their stored belief and brand-attribute information. Subjects in the control condition were not given attitude focus and behavior manipulation instructions.

Attitude and Behavior Measures

Each subject indicated on 9-point bipolar scales how much s/he liked or disliked each brand. One on the scale indicated dislike very much and 9 indicated like very much. Behavior was observed one week after completing the questionnaires; each subject chose and received one tube of toothpaste from the five brands used.

Affective and Cognitive Focus Measures

Subjects listed all the thoughts that occurred to them while they were examining the picture of each brand. These thoughts were later coded by two judges into feelings and reasons. The two coding sets were highly correlated ($r=0.93$). The feelings

represented the affective focus and the reasons represented the cognitive focus.

Responses Differentiating Consummatory From Instrumental Behavior

Each subject indicated on 9-point bipolar scales how much s/he agreed or disagreed with four consummatory and four instrumental behavior statements regarding each brand. The representativeness of these statements to consummatory and instrumental behavior was established by a pretest of twenty subjects from the same population. Consummatory behavior statements tapped the degree of happiness (happy), joy (joy), cheerfulness (cheer), and refreshment (refresh) felt by each subject if the brand of toothpaste under consideration was used. Instrumental behavior statements measured the extent of belief that the brand of toothpaste might contribute to gum health (health), cavity reduction (cavred), teeth brightness (bright), and tartar-buildup reduction (tarred). On all scales, 1 indicated completely disagree and 9 indicated completely agree.

ANALYSIS AND RESULTS

Confirmatory Factor Analysis

For the single-component model to achieve convergent validity and provide a good fit, the variables differentiating consummatory from instrumental behavior should exhibit high intercorrelations and an insignificant chi-square should be obtained. The test of this model using LISREL VI gave zero correlations and a significant chi-square ($\chi^2_{28}=3629, p=0.0$). Thus, the single component model did not achieve convergent validity and it could not be accepted without testing a two-component model.

In the two-component model, the first set of these variables (happy, joy, cheer, and refresh) was hypothesized to have high loadings ($\lambda_{11}-\lambda_{41}$) on consummatory behavior and zero loadings ($\lambda_{51}-\lambda_{81}$) on instrumental behavior. The second set (health, cavred, bright, and tarred) was hypothesized to have high loadings ($\lambda_{52}-\lambda_{82}$) on instrumental behavior and zero loadings ($\lambda_{12}-\lambda_{42}$) on consummatory behavior. The correlation (ϕ_{21}) between the two components of behavior should not be high.

The correlation matrix used in the analysis (not included) showed that variables loading on consummatory behavior were highly correlated ($r=0.70$ to $r=0.94$) and variables loading on instrumental behavior were highly correlated ($r=0.61$ to $r=0.83$) while across-component correlations were low. LISREL estimates showed high loadings from the first set of variables on consummatory behavior (happy=0.962, joy=0.972, cheer=0.956, and refresh=0.735), high loadings from the second set of variables on instrumental behavior (health=0.918, cavred=0.877, bright=0.731, and tarred=0.800), low correlation between consummatory and instrumental

FIGURE 2
Mean feelings and mean reasons generated in thought listing protocol

behavior ($\phi_{21}=0.37$), high Bentler and Bonett's rho-statistic ($\rho=0.90$), and a low root mean square residual ($RMSR=0.1$). These results indicate that the two-component model (consummatory and instrumental) achieved discriminant and convergent validity.

The last goodness-of-fit test conducted here was an inferential evaluation of nested models. Since the free parameters in the single-component constitute a subset of the free parameters in the two-component model, it was possible to test a null hypothesis that the single-component fits the data better than the two-component model. If the null hypothesis could not be rejected (by obtaining an insignificant chi-square), then the single-component would be more desirable than the two-component model because the first would be more parsimonious than the second. The test resulted in a significant chi-square ($\chi_9=3472$, $p=0.0$), thus the null hypothesis was rejected and it was concluded that the two-component model of behavior (consummatory and instrumental) fits the data better than the single-component.

Attitude-Behavior Relation

The number of reasons for each subject was analyzed in a 2 (consummatory vs. instrumental) / 2 (affective vs. cognitive) / 2 (male vs. female) ANOVA. The only significant source of variation was thought focus, $F(1,86)=9.45$, $P=0.0028$. Subjects in the cognitive focus condition produced more reasons ($M=0.75$) than did subjects in the affective focus condition ($M=0.39$), $F(1,86)=4.58$, $P=0.0051$. The number of feelings produced by subjects was also analyzed in a similar ANOVA and thought focus was the only significant source of variation, $F(1,86)=17.77$, $P=0.0001$. Subjects in the affective focus condition generated more feelings ($M=1.15$) than did subjects in the cognitive focus

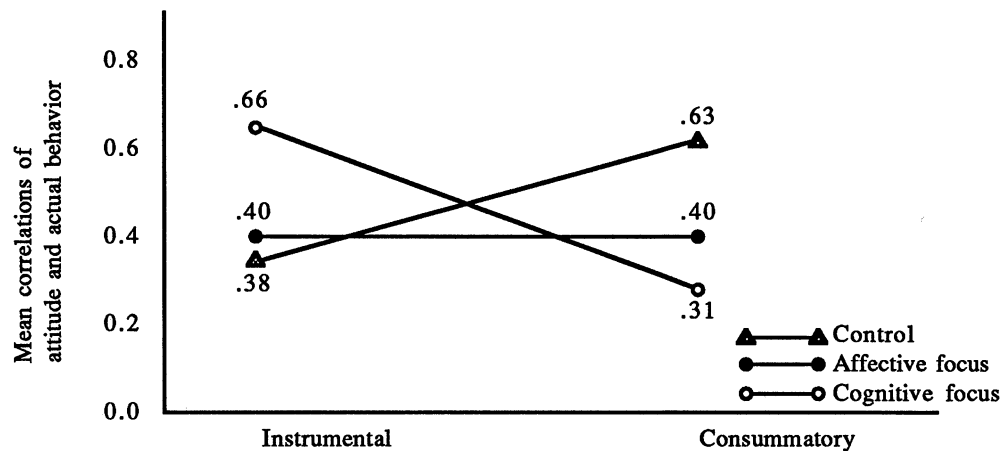

condition ($M=0.47$), $F(1,86)=6.96$, $P=0.0003$ (see figure 2).

Two measures of behavior were constructed and correlated with subjects' self-reported measures of liking and dislike of the five brands of toothpaste, actual choice of toothpaste and the tube size. Correlations were transformed to z-scores and analyzed in two separate 2 (consummatory vs. instrumental) / 2 (affective vs. cognitive) / 2 (male vs. female) ANOVAs. The two ANOVAs gave identical results. The only significant interacting effect was type of behavior / type of focus, $F(1,86)=16.9$, $P=0.0001$. Subjects in the instrumental behavior condition had higher attitude-behavior correlations when they focused on their cognitions ($M=0.66$) than when they focused on their feelings ($M=0.38$), $F(1,40)=2.77$, $P=0.05$. Similarly, subjects in the consummatory behavior condition had higher attitude-behavior correlations when they focused on their feelings ($M=0.63$) than when they focused on their cognitions ($M=0.31$), $F(1,44)=5.03$, $P=0.004$. It is interesting to note that subjects in the control condition had attitude-behavior mean correlations of $M=0.40$ (see figure 3).

DISCUSSION

This article has demonstrated that consumers' behavior can be differentiated according to consumers' expectations from consuming the product. A two-component model of behavior achieved discriminant and convergent validity whereas a single-component model did not. Focusing on the attitude component (affective/cognitive) that drives behavior (consummatory/instrumental) increased attitude-behavior correlation above that in the control condition (when subjects were not instructed to focus). Alternatively, focusing on the attitude component that does not drive behavior decreased

FIGURE 3
Mean correlations of attitude and behavior

attitude-behavior correlation below that in the control condition.

It is possible that subjects' age and purchase experience may have contributed to the observed differences in attitude-behavior correlations. This possibility was investigated in a number of additional analyses. First, a 2 (type of behavior) / 2 (type of focus) / 2 (sex) / 4 (purchase frequency) / 5 (age group) ANOVA indicated that significant differences between mean correlations at 0.08 significance level still existed and the only two-way interaction to reach significance was type of focus / type of behavior, $F(1,86)=5.36$, $P=0.02$. Second, a 5 (age group) / 4 (purchase frequency) / 2 (sex) ANOVA indicated that no significant main or interacting effect was produced by any of these variables, $F(25,62)=1.41$, $P=0.14$. Third, mean correlations of attitude and behavior, attitude and behavioral intention, and initial attitude and initial behavioral intention for experimental conditions, were compared to those for the control condition. This analysis showed that there were no significant differences between mean correlations of the five groups ($F \leq 1.87$, $P \geq 0.15$) except between attitude-behavior mean correlations. These findings clearly indicate that factors other than the type of focus and the type of behavior do not explain the observed differences in attitude-behavior correlations.

CONCLUSION

Though the attribute processing perspective has yielded valuable insights into consumer attitude-behavior relation, it falls far short of completely explaining the consumption phenomena. The findings of this research provide partial support to the notion that purchase behavior is largely dependent on the expectations of the consumer in consuming the product. Current findings are also consistent with findings in social psychology, and are apparent in some of the current advertising practices. For example, AT&T appeals to both

behavioral components by airing two different advertisements, "reach out and touch some one" and the "price of the call" ads. Toothpaste commercials are usually diversified to appeal to the majority of consumers by emphasizing the benefits (e.g. fewer cavities) and/or stressing the consumption experience (e.g. fresh breath) consumers can expect from using the brand. Even beef is advertised as a red, tasty, and delicious meat and as a good source of necessary nutrition.

Constructing A More Difficult Recognition Test For Television Commercial Scenes

Michael L. Rothschild, University of Wisconsin

Brian Deith, University of Wisconsin
Yong J. Hyun, University of Wisconsin

ABSTRACT

One of the disadvantages to using recognition as a measure of memory is that scores are often indiscriminantly high because the task is too easy. This paper investigates varying the length of time of exposure during the test, the length of the mask about the test stimulus, the number of exposures to the stimulus and the length of the decay period as variables that might reduce the ceiling effects often associated with recognition. Data show that controlling test scene length, its interaction with mask length, and decay period can increase the difficulty of the recognition task.

INTRODUCTION

Measuring memory of advertising is of interest to both academic and industry researchers. While recall has in the past been the most commonly used dependent variable in testing responses to television commercials, recognition has become more viable in recent years. It has been argued that recall may mask the amount of actual memory that exists, and that recognition is more appropriate to the level of learning necessary for in-store brand choice decisions (Bettman 1979).

While recognition measures may be more effective and appropriate in certain situations, one important problem remains. Recognition measures tend to produce ceiling effects, or indiscriminately high scores, especially for pictorial stimuli (Shepard 1967; Haber 1970), and even more so for dynamic pictorial stimuli (Goldstein, et. al. 1982) such as movies (their stimuli) or television commercials. These results make it difficult to use recognition to test memory for visual components of television commercials. The purpose of this paper is to investigate a method which will reduce these ceiling effects by making the task more difficult.

To date, a number of ways of avoiding ceiling effects have been developed. For example, (1) the memory decay period can be increased (Shepard 1967; Singh, Rothschild and Churchill 1988), (2) the number of distractor items in a forced choice recognition test can be increased (Singh and Rothschild 1983), or (3) the similarity of the distractors to the target items can be manipulated (Dole and Baddeley 1962). This paper will discuss manipulating the length of exposure to visual recognition test items as another method of avoiding ceiling effects. Using short test item exposure times, if effective, will have two advantages over other methods. First, less subject time will be required than for designs allowing either relatively long exposure to test items or long delays between exposure to commercials and test taking;

this will also reduce subject fatigue. Second, the need to invent distractor items of comparable difficulty will be reduced compared to designs employing multiple distractor items.

LITERATURE REVIEW

This section is organized into two parts which describe (1) the Search of Associative Memory (SAM) model and (2) factors affecting recognition test scores for pictorial stimuli.

The Search of Associative Memory (SAM) Model

There are several dominant models of recall and recognition memory in the psychological literature. Dissatisfaction with the validity of any current models led Gillund and Shiffrin (1984) to develop this model for both recall and recognition. Recall is assumed to involve a rather lengthy search of long-term memory plus a fast, often implicit, recognition-like process that allows a subject to decide that an item recovered from the sampled image is appropriate. Since only the recognition aspects of the model are important to this paper, the recall segments will not be explained further.

In the SAM model, recognition consists of a complex direct access process in which many memory images are contacted by a retrieval cue. It is assumed that in a "yes/no" recognition test the subject probes memory with two cues, the context cue and the tested item. Context is used in a broad sense here to include subject factors such as mood and alertness, as well as environmental factors such as time of day, other objects in the testing room, lighting, etc.

The number of images in long term memory contacted by the context and test item cues determines the familiarity of the tested item. If the familiarity is greater than some subjective criterion, the subject replies "yes", otherwise s/he replies "no". In "forced-choice" and "batch" recognition tests subjects generate familiarity values for all test items and choose the items with highest familiarities.

According to Gillund and Shiffrin the strength of long-term memory and hence the familiarities of items on a recognition test are functions of three factors: (1) rehearsal and coding processes that take place during the study of, or exposure to, the to-be-remembered material, (2) pre-experimental associations or memories for all test items, and (3) the match, or similarity, between the cue encodings at study and test.

Given these factors, Gillund and Shiffrin use Signal Detection Theory (SDT) to explain subjects'

performance in recognition tests. In SDT, the familiarity values for items are assumed to fall into two overlapping, roughly "normal" distributions. The distribution of old, or previously studied items, should be higher on the familiarity scale than the distractor items, although the tails of the distributions will probably overlap. Familiarity values for distractors in a recognition test will be influenced by pre-experimental memory for the distractors (factor 2 above), as well as similarity between distractors and target test items (factor 3 above). Familiarity values for target (previously studied) test items will be influenced by these two factors plus the amount of processing subjects perform during exposure to the study material (factor 1 above). Subjects are assumed to place a criterion or cut-off value near the intersection of the two distributions. Criterion values are assumed to be subjective and variable based on subjects' evaluations of the familiarity of the distractors as a group and the targets as a group. Test items evoking a familiarity value greater than the criterion elicit a "yes" response and other test items elicit a "no" response.

In the context of advertising, the SAM model predicts that using recognition to test advertising effectiveness can lead to indiscriminately high test scores. In general recognition scores will be highest when target and distractor familiarity distributions are farthest apart. Picture memory may be stronger and more enduring than verbal memory in this model if pictures tend to be more novel or to provide more information than verbal stimuli. At the same time, test item novelty causes pre-experimental memory for test items to be lower. Thus stimulus richness and novelty tend to push the distractor and target distributions apart.

High scores can be avoided by increasing the similarity of distractor and target test items, hence moving the two familiarity distributions closer together. One example concerns subjects' knowledge of an upcoming test. If subjects are unaware of an upcoming test, then they are less likely to try to remember the "study" material, their encoding during "study" may not be very effective, and the target and distractor test items should appear equally unfamiliar.

Factors Which Affect Recognition Test Scores

There are a wide variety of methods and variables that impact upon recognition test scores. One of the most common concerns the *length of time between study and test*. For example, Shepard (1967) presented subjects with 612 pictures to examine at their own pace. Subjects were then given two-item forced choice recognition tests after no delay, a two hour delay, a three day delay, a seven day delay or a 120 day delay. The average recognition accuracy scores ranged from 99.7 to 57.7%. Shepard explained these results in a Signal Detection Theory framework. In a two-item forced-choice recognition test, subjects presumably choose whichever item seems more familiar and call it

"old". Over time the familiarity of the truly "old" items fades, leading to more errors.

A study by Singh and Rothschild (1983) showed that manipulating the *number of distractors* in a forced choice recognition test and manipulating the *number of exposures* to study material also could affect recognition memory. In their study, subjects viewed segments of local news programs interspersed with commercials. Commercials were repeated 1, 2, or 4 times (a within subjects factor), and subjects received either a 5- or 9-alternative visual recognition test (between subjects factor). Significant main effects on recognition were found for repetition and for number of distractors.

Decreasing *length of exposure to test items* may also diminish subject performance. A study by Franken and Rowland (1974) found just such an effect for recognition memory of pictures. During study, 150 color slides were shown to subjects for 5 seconds each. Immediately thereafter a "yes/no" recognition test was given consisting of 15 slides randomly selected from the 150, plus 15 new slides. Eight exposure durations ranging from 120 to 5000 milliseconds (msec) were used. The corresponding recognition accuracies obtained ranged from 77.5% to 92.7%. At test exposure levels of only 120 msec, subjects performed quite well; scores reached an asymptote by 500 msec.

When considering using extremely brief test item exposures, the question of *masking* needs to be considered. Studies show that visual sensory memory or iconic store can last about 250 msec. (Sperling, 1960).¹ A visual mask following stimulus presentation will erase or interfere with images in the icon, hence shortening the time subjects effectively perceive the stimulus. Because iconic memory fades and because individuals differ with respect to rate of fading (Sperling 1960), using a mask following stimulus presentation should give better control over the effective length of the stimulus.

Forward masking is also of interest when stimulus presentation is very brief. A mask preceding the stimulus will have the effect of focusing subjects' attention on the screen. This is especially important in studies using variable presentation rates, relatively long interstimulus intervals, or any presentation device other than a tachistoscope. The length of the forward mask is not critical as long as it is more than 100 msec. Di Lollo (1980) has shown that at lengths of less

¹The iconic store or visual sensory memory holds visual information in an unidentified form for a brief time before higher mental processes recognize the information. Its function is to hold information during eye blinks so that sight seems to be continuous. A mask is a non-test stimulus that can immediately precede or follow the test stimulus and has the capability to disrupt or enhance the iconic storage process depending upon its length and placement. Operationally, the mask often appears as a random pattern.

than 100 msec forward masks interfere with perception of stimuli so that the mask and the stimuli appear to overlap; as a result subjects see both at the same time. This work also implies that if a stimulus interval is less than 100 msec, a mask following it may be perceptually integrated with the stimulus. If the following mask is long enough to persist beyond the mask-stimulus integration, subjects may be better able to cognitively separate the two and more accurately judge the familiarity of the stimulus.

A study by Dole and Baddeley (1962) demonstrated that the *similarity of the distractors to the target items* also affects recognition test scores. They concluded that when memory is imperfect, only some of the relevant characteristics of the study material can be remembered. If the distractors and the target items on a recognition test are very similar, they will both be similar to the imperfect memory and subjects will be unable to tell which they have seen before. While the Dole and Baddeley study used numbers as stimuli, the results can be expected to transfer to studies using pictorial or verbal stimuli.

The studies reviewed above provide a number of methods of decreasing recognition test scores. While their authors did not use the Gillund and Shiffrin SAM model for recognition memory to interpret the results, they fit into the SAM model rather well. In the following section four hypotheses are developed concerning methods of reducing recognition test scores based on the SAM model of recognition.

HYPOTHESES

As suggested by Gillund and Shiffrin's model for recognition memory, test scores can be affected by manipulating the familiarity of distractors to target items in a recognition test. This can be accomplished by manipulating the processing that takes place during study of the to-be-remembered material, manipulating pre-experimental memory for test items, or manipulating the match between cue encodings at study and at test. In this section four methods discussed above are developed into hypotheses.

Manipulating the match between cue encodings at study and at test can be accomplished by manipulating the length of exposure during the test period. This may affect the match between the subject's internal representation of the test item and its corresponding memory from previous study. While such a notion may seem obvious, it has not been tested in advertising and rarely tested in psychology; it needs to be tested for quite brief time periods in order to be useful to advertising tests of recognition. Therefore:

- H₁: Increasing the test length of exposure to the recognition stimulus has a positive effect on recognition memory when dealing with brief time periods of exposure.

Forward masks of less than 100 msec may be perceptually integrated with the test item. Following masks may be perceptually integrated with test items of less than 100 msec. However if the following mask is longer than 100 msec minus the length of the test item, subjects may have an easier time of cognitively separating the two. Therefore:

- H₂: Increasing the length of the forward mask (up to 100 msec) and the following mask (up to the length of the test item minus 100 msec) will have a positive effect on recognition memory.

The match between cue encodings at study and at test can also be manipulated by varying the delay between study and test. This has been shown often in the past but needs to be observed within the present context of brief text exposures. Therefore:

- H₃: Increasing delay between study and test has a negative effect on recognition memory.

Multiple exposures to study material should create a stronger memory for that material and a "richer" context encoding. This also has been shown in the past but needs to be observed within the present context. Therefore:

- H₄: Increasing the number of exposures to study material has a positive effect on recognition memory.

Of these four hypotheses, the first two are concerned with issues that have not been tested in the advertising and consumer research literature, while the latter two will serve as replications and extensions of previous work. The first two represent the major thrust of this study.

METHOD

The experimental design was a 3 (scene length of 30, 60 or 90 msec) by 3 (scene plus mask length of 180, 300 or 420 msec) by 2 (15 or 30 minute delay between presentation of study material and recognition test) by 2 (1 or 2 exposures to the study materials) split plot design. The first two factors, length of scene and length of recognition task, were within subjects factors, while length of decay period and number of exposures were between subjects factors.

Subjects

Twenty undergraduate students participated in the study. Subjects were assigned to one of three conditions such that there were 10 subjects in one condition (one exposure, 15 minute delay) and 5 subjects in each of the other two conditions (two exposures, 15 minute delay, and 2 exposures, 30 minute delay). All subjects were exposed to all levels of scene length and scene plus mask length.

Procedure

Subjects were told they were part of a control group for a study measuring EEG (brain wave) responses to television programming, and were asked to watch a series of video tapes. To enhance the cover story, subjects were asked to sit as still and quietly as possible while viewing, as movement caused muscle artifact noise in EEG patterns and we wanted them to act in the same way as the actual EEG subjects. Subjects were allowed to move about as much as they liked between video tapes; they participated in the study one at a time. In actuality, the study was a pretest for a later EEG study; the issue of the recognition test discussed herein was the sole purpose for the pretest.

Subjects were not told specifically what they would be viewing, nor was there any hint that memory measures might follow. Subjects sat in a small room (12' by 13') about 6 feet from a 13" Sony Trinitron color television. They stayed in their seats for the duration of their participation except for a short 2-3 minute break between viewing of the final tape and the beginning of the testing period.

All subjects began by viewing a 10 minute acclimation tape. They then viewed a stimulus tape consisting of 12 different 30 second commercials. The commercials were separated by 30 seconds of blank tape. A tape recorded voice asked subjects to close their eyes 5 seconds after each commercial ended and to open their eyes again 5 seconds before the next commercial began. At this point, some subjects saw the set of commercials a second time. After viewing the commercials, all subjects viewed a 7 minute distractor tape, followed by a short 2-3 minute break.

Some subjects were then given an unaided recall test for the commercials which served as a distractor and 15 minute decay period. All subjects were given the recognition tests. Finally, subjects were debriefed and asked specifically not to discuss their participation with other students.

In sum, subjects were randomly assigned to one of three groups. Group 1 had two exposures to the messages during initial viewing and participated in the recall test; group 2 also had two exposures but no recall test, while group 3 had one exposure and no recall test. In all other respects, all subjects participated equivalently.

Stimulus Materials

Acclimation tape: This 10 minute tape consisted of 3 short segments of college sporting events. The purpose of the tape was simply to let subjects get comfortable with their surroundings.

Commercial tape: Twelve thirty-second commercials intuitively judged to evoke a variety of positive, neutral and negative emotions were selected. None of the selected commercials had ever been aired in the test city and none of the brands represented in the commercials were marketed in the test city.

Distractor tape: A 7 minute tape of a man making a vase on a potter's wheel was shown to all

subjects after final viewing of stimulus commercials to allow memory to decay.

Measurements

All subjects judged two practice and thirty-six actual pictorial test items as presented on video tape. Each item consisted of 1, 2 or 3 frames (33, 67 or 100 msec) from a commercial preceded and followed by a random dot pattern mask. Half of the items were scenes from the test commercials and half were foils from another group of similar, previously unseen, untested commercials. The items were imbedded in one of three scene plus mask lengths (200, 333, and 466 msec).

In constructing the recognition test video tape, the masks were laid down first for the scene plus mask length period, and then the test scenes were recorded over and in the middle of each mask. As a result, the length of the scene and the length of the scene plus mask were controlled, but the length of the forward and following masks took on the value of the time remaining after the other values were controlled. While not necessarily optimal, this construction was dictated by editing equipment capabilities. The test items were recorded at 10 second intervals and a voice announced the item number of each test item. The ten seconds was ample time for subjects to view the stimulus and record the answer. Subjects recorded their responses on computer readable answer sheets based on a 5 point scale ranging from "definitely saw before" to "definitely did not see before."

RESULTS

Table 1 shows how each of the independent variables in the study affected recognition. Answers from the 5 point scale were summarized into binary responses with all midpoint "not sure" responses counted as incorrect. The value in each cell of Table 1 corresponds to the percentage of correct responses. Note that a proportion of 40% would indicate random guessing (2 values of the 5 point scale); overall, subjects performed significantly better than chance ($Z=4.50$; $p<.001$). Table 2 shows analysis of variance results.

Effect of Scene Length on Memory

There was a significant main effect for scene length (33, 67, or 100 msec) on scene recognition ($F=38.96$; $p<.001$). As Table 1 shows, there also were significant differences between correct recognition scores for scene lengths of 33 (.26 recognition) and 67 (.53) msec ($t=6.15$; $p<.001$), between scene lengths of 67 (.53) and 100 msec (.65) ($t=2.62$; $p<.005$), and between scene lengths of 33 and 100 msec ($t=8.87$; $p<.001$).

There was a significant interaction between length of scene and length of scene plus mask ($F=10.32$; $p<.001$) so that recognition scores were highest when the scene was relatively long but the scene plus mask was relatively short. When the scene was short, the length of the scene plus mask did not matter. There was no significant interaction between scene length and number of exposures

TABLE 1
Recognition Scores As A Function Of Independent Variables

	proportion of correct recognition	t	p	df
<i>Total Population</i>	0.49	4.50 ^a	<.001	719
<i>Length of Test Scene:</i>				
33 msec. scene length	0.26 ^c	8.87 ^b	<.001	(33 vs 100)
67 msec. scene length	0.53	6.15	<.001	(33 vs 67)
100 msec. scene length	0.65	2.62	<.005	(67 vs 100)
<i>Length of Scene Plus Mask:</i>

<i>Length of Delay:</i>				
15 minute delay	0.51			
30 minute delay	0.41	2.37 ^b	<.01	718
<i>Number of Exposures:</i>				
One exposure	0.49			
Two exposures	0.49	ns ^b		

^a one-tailed Z test

^b one-tailed t test.

^c df for length of test scene ranges from 458 to 498.

($F = .09$; ns). In calculating interactions, length of delay was suppressed due to the incomplete nature of the design.

Effect of Length of Delay

There was a significant main effect for length of delay ($F = 9.01$, $p < .003$). Subjects with a short delay were correct 51% of the time while subjects in the long delay were correct only 41% of the time. Interactions between length of delay and other variables were suppressed due to empty cells in the design. Length of delay period (15 versus 30 minutes) was determined by the absence or presence of the recall test.

Effects of Number of Exposures and Scene Plus Mask Length

There was a marginal main effect due to number of exposures ($F=2.78$; $p<.096$), and no effect due to scene plus mask length ($F=.05$; ns). There was no significant interaction between number of exposures and scene plus mask length ($F=1.30$; ns), nor was there a significant three way interaction between number of exposures, scene length and scene plus mask length ($F=.80$; ns).

DISCUSSION

The purpose of this study was to continue the investigation of the potential viability of recognition as a response variable in the study of memory for advertising. One of the key inhibitors to the widespread use of recognition has been the general tendency toward high scores during its use. It has been shown in other studies that the length of the decay period, the number of repetitions of the stimuli, and the similarity between the distractors and the test stimuli all can have an impact on lessening ceiling effects. In the current study, the variables of concern were primarily the length of the stimulus during the test and the impact of a surrounding mask.

By showing the test stimulus for brief periods of time, recognition scores, in the aggregate, were kept lower. In earlier work, a decay period as short as that used herein, coupled with an exposure period of as little as one half second would have led to levels of recognition above 90% and little variance across stimuli. It seems clear that the extremely brief exposure periods used in the present study have accomplished the desired goals.

Presumably the extremely short test exposure periods did not allow subjects to create clear internal representations of the test scenes. Consequently, a memory search using the imprecise internal

TABLE 2

representation of the test stimulus was less likely to contact memories of the studied material. When subjects' perceptions of the test stimuli were vague, they may have tried to fill in the missing parts, or cognitively create a clearer image using whatever memory they had of the studied material and any pre-experimental pictorial images.

The length of the scene plus the mask was not found to significantly affect recognition memory although there was a significant interaction between scene and scene plus mask length. A main effect due to mask and scene length may have been obscured by nonindependence in that the preceding and following masks were the same length for each test item. The interaction between scene and scene plus mask also could imply that forward and following mask lengths may affect recognition of different length scenes differently. This issue needs to be addressed more extensively in future work.

The major focus of this study was to shed light on the potential for seeing differences in memory as a function of the length of a test stimulus. In addition, by examining decay and repetition effects under the conditions of brief test stimuli, further insights could be gained.

Length of delay was found to affect recognition scores. As hypothesized, the length of delay between study and test had a negative effect on recognition. Even a fifteen minute difference was

found to significantly affect recognition memory for the pictorial stimuli. The delay allowed time for subjects' memories to fade, and also progressively altered the context. As the difference between study context and test context increased, the memory test showed poorer performance.

Number of exposures was found to only marginally affect recognition memory. Perhaps this was due to the phenomena of particularly strong memory for pictorial stimuli even after one exposure. It could be that the second exposure did not significantly increase memory for the visual aspects of the commercials. Even though memory after one or two exposures may have been quite high, recognition ceiling effects were avoided by using extremely brief exposure to test items. This would lead to the recommendation that one repetition be used (again to simplify things for the subject) when recognition testing involves extremely brief exposures to the test stimuli.

A test using a 30 minute decay with a 33 msec test would be incredibly difficult, and, as in the present case, would lead to mostly "don't know" responses. More realistic would be a 15 minute decay with a 67 msec test. This level of difficulty would allow subjects to respond at a low, but better than chance rate, and would also minimize the amount of time that a subject would need to be detained.

There were several potential design flaws in this study, yet the key finding concerning the value of extremely short test stimuli still emerged as significant. The potential flaws include the following: (1) *Small number of subjects*. While there were only 20 subjects in the study, there were 720 observations, given the within subjects nature of the design. (2) *Incomplete design*. The incomplete factorial design made it impossible to test for all the interactions; while that test will need to be repeated, the main effects still clearly remain. (3) *Confound*. The length of the decay period is confounded with the presence of the recall test; that is, in the 30 minute decay, there was a recall test which was absent in the 15 minute decay condition. This should not be a concern because other work (Darley and Murdock 1971; Postman, Jenkins and Postman 1948) has shown that a preceding recall test does not bias the results of a following recognition test. In the present case this is even less of an issue since the recall test was a verbal test of the entire message, while the recognition test was a pictorial test of scenes. In addition, the recognition scores after the recall test are lower than those without this test. The results, therefore, are consistent with the decay literature; the recall test of the whole seemed to act as a distractor for the parts.

The potential value of using these data is twofold: (1) to keep recognition scores from being so high that there is not enough variance to discriminate between memory for different stimuli, and (2) to allow the recognition test to be done more quickly and without the lags generally necessary to allow for the decay of memory.

Furthermore, as the need for more precise advertising tests becomes more prevalent, researchers are beginning to test component parts of messages rather than entire messages. As this trend increases, the issues discussed herein will become more relevant. Showing frames that represent scenes of commercials will allow advertisers to learn what is happening at various times in the commercial, and to then adjust the script to link well remembered scenes with key message points, or to rework those scenes that are remembered poorly.

Affect Intensity as an Individual Difference Variable in Consumer Response to Advertising Appeals

William D. Harris III, Ohio University
David J. Moore, University of Michigan

ABSTRACT

Recent research in psychology has identified stable individual differences in the level of intensity with which individuals experience their emotions. In other words, high affect intensity individuals, when exposed to an emotion-eliciting event or stimulus, consistently manifest more intense emotional responses. This paper reviews the literature on affect intensity and suggests a variety of advertising settings where this variable might be used to predict individual differences in emotional response and overt behavior.

INTRODUCTION

Just as the 70's can be described as the decade of cognitive theory development, the 80's can be viewed as the decade of affective theory construction by consumer behavior researchers. Beginning with the work of Holbrook (1978) and continuing to the present, researchers have been actively at work building a significant body of literature on the role of affect in consumer behavior. In the 1987 December issue of *The Journal of Consumer Research*, a special section titled, "Consumer Affect, Emotions, and Feelings," appeared demonstrating the importance of affect in our study of consumer behavior. Today the literature on affect in consumer behavior includes numerous articles, monographs, book chapters, and even a few complete books. We have found that, through the inclusion of affect variables in our models of consumer behavior, our understanding of how consumers behave has been enhanced. As a result of these studies, our entire perspective on how consumers behave has been modified (i.e., Holbrook et al. 1984, Zajonc and Markus 1982, Gardner 1985, Peterson et al. 1986).

Nowhere has this effect been more evident than in the study of how people respond to advertisements (Batra 1986, Burke and Edell 1986). Affect in the form of emotions can play an important role in mediating consumer responses to advertising (Holbrook and Batra 1987), and different ads can elicit different emotional responses (Edell and Burke 1987). Yet, as has occurred many times before in new areas of inquiry, one discovery leads to a whole set of new or related issues that are in need of investigation. For example, it has been observed that different people will respond differently to the same emotional ad (Aaker et al. 1986 and Edell and Burke 1987); however, we do not know why people respond differently to the same emotional stimulus.

Recently, Haugtvedt et al. (1987) have argued persuasively for the utility of individual difference variables as an aid in better understanding why different people have different reactions to the same

ad. Their work focused on the usefulness of the need for cognition personality construct in understanding how advertisements influence the formation of attitudes toward a product. According to Haugtvedt et al. (1987), individuals with a high need for cognition have a natural tendency to engage in and enjoy effortful cognitive activities.

The purpose of this paper is to further examine the usefulness of individual difference variables as moderators of individual responses to advertisements. However, unlike Haugtvedt et al. (1987) this paper will look at individual differences in affect reactivity rather than cognitive activity. The recent developments in the psychology literature on intensity of affect by Larsen and Diener (1985) holds considerable promise for increasing our understanding of affective processes that occur in response to advertisements.

Larsen and Diener (1985) developed the affect intensity construct to reflect the strength of a person's emotional responses to daily life events. Through the use of the affect intensity construct it may be possible to identify a type of individual who is more likely to respond favorably to an affectively oriented advertisement such as an emotional appeal than to a cognitively oriented advertisement such as an informational appeal.

THE AFFECT INTENSITY CONSTRUCT

In investigating individual differences in response to emotion-provoking stimulation, Diener, Larsen, Levine, and Emmons (1985) found that certain individuals consistently experience their emotions with greater intensity than others. Diener, Larsen, Levine, and Emmons (1985) related their findings to the theoretical work of Petrie (1967) on stimulus intensity modulation theory. According to Larsen and Diener (1987):

This theory suggests the existence of a stimulus intensity modulation mechanism located in the CNS (Central Nervous System). This mechanism functions to modulate the individual's responsiveness to sensory stimulation. It functions much like a "volume control" device, amplifying or augmenting the effects of stimulation for some individuals while damping or reducing the effects of stimulation for others.

From the perspective of stimulus intensity modulation theory, Diener et al. (1986) suggest that:

... some individuals modulate the intensity of emotional stimuli such that they consistently exhibit stronger or more intense emotional reactions. Other individuals are much less emotionally reactive to the same levels of

emotion-provoking stimulation. We refer to stimulus intensity modulation in the emotional domain as *affect intensity*, and we consider affect intensity to be a stable individual difference dimension.

Larsen and Diener (1987) have developed two methods for assessing an individual's characteristic magnitude of emotional responsiveness, affect intensity. The first method requires that a subject report their daily moods over a period of a month or longer. Although this approach has strong ecological validity, the reporting and subsequent calculations can prove to be extremely burdensome for both subject and researcher. Consequently, the development of an easier method of measurement was deemed necessary. The second method of measuring affect intensity, the Affect Intensity Measure (AIM; Larsen, 1984), was developed to address the awkwardness of the daily moods report measure. The AIM consists of a 40-item questionnaire designed to cover a broad range of emotions of both positive and negative tone such as joy, bad, troubled, happy, nervous, and peaceful (i.e., "I feel pretty bad when I tell a lie" and "When I feel happiness, it is a quiet type of contentment"). In addition, Larsen (1984) sought to capture specific physical sensations which accompany strong emotional responses such as having one's heart race, being sick to one's stomach, or having a shaky voice (i.e., "When I talk in front of a group for the first time my voice gets shaky and my heart races").

Another consideration in the development of the AIM was that the items should reflect intensity of emotional response instead of the frequency of emotional reactions. Therefore, Larsen avoided the use of items such as "I am very happy quite often" which contains both frequency and intensity elements. Instead, he developed items which tapped the intensity component unconfounded by frequency like "When I feel happy it is a strong type of exuberance." The complete questionnaire along with scoring instructions can be found in Larsen and Diener's (1987) article, "Affect Intensity as an Individual Difference Characteristic: A Review."

The intercorrelation of the AIM items was assessed with coefficient alpha to be between .90 and .94 across four separate samples, while test-retest reliabilities for the AIM have been reported to be .80, .81, and .81 over 1-, 2-, and 3-month intervals respectively (Larsen and Diener 1987). The validity of the AIM was assessed by calculating its convergence with the subject's daily mood reports and parental reports of the subject's emotional intensity. Across three separate samples the AIM correlated with subject's daily mood reports .61, .52, and .49 (Larsen and Diener 1987). When parental reports of the subject's emotional intensity were compared to the subjects' AIM, a correlation of .50 was found. Thus, it appears that the AIM is a reasonably reliable and valid measure of the typical intensity with which individuals experience their emotions.

General responses to emotional or non-emotional stimuli by individuals either high or low on affect intensity are given in the following figures.

Figure A illustrates how the affect intensity construct operates as a moderator of emotional response. When the stimulus is strongly emotional in character the high affect intensity individual will have strong emotional responses. An individual with low affect intensity will have emotional responses to the strongly emotional stimulus but these responses will be much weaker in strength. Thus, affect intensity is said to influence an individual's emotional responses to an emotional stimulus. However, as Figure B shows, affect intensity will have no discernible effect on an individual's emotional responses when the stimulus is non-emotional.

Rosenberg (1968) refers to the process of examining a relationship between two variables under different conditions as specification. Sharma et al. (1981) states that a specification variable is, "one which specifies the form and/or strength of the relationship between a predictor and a criterion variable." When the specification variable is related (correlated) to the criterion variable and interacts with the predictor variable, Sharma et al. (1981) refers to the variable as a moderator variable of the "quasi-moderator" type. In previous studies, the affect intensity variable has exhibited the characteristics of interacting with the predictor variable and being related to the criterion variable. Therefore, affect intensity appears to be a variable which moderates the relationship between a stimulus and a criterion variable. To gain a better understanding of the affect intensity construct, an examination of the literature on affect intensity is in order.

PREVIOUS STUDIES ON AFFECT INTENSITY

Temperament

In a study (Larsen, Diener, and Emmons, 1984) which measured the relationship of affect intensity to other temperament variables such as sociability, activity, arousability, and emotionality, it was found that affect intensity correlated significantly with each of these dimensions. This implies that persons who have relatively high affect intensity are more active, more sociable, more physically arousable, and more emotionally reactive.

Larsen (1984) further examined the relationship of affect intensity to other temperament characteristics by factor analyzing a battery of standard temperament measures along with measures of affect intensity. This factor analysis empirically demonstrated that there were two underlying factors among these measures. The first factor consisted of measures of sociability, activity level, and affect intensity. The second factor consisted of measures of emotionality, arousability, and affect intensity. What was most striking about this finding was that

FIGURE A
WHEN AFFECT INTENSITY WILL MODERATE AN EMOTIONAL RESPONSE

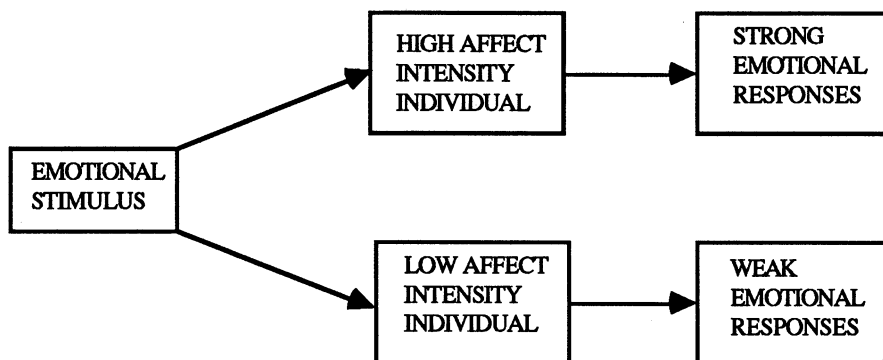

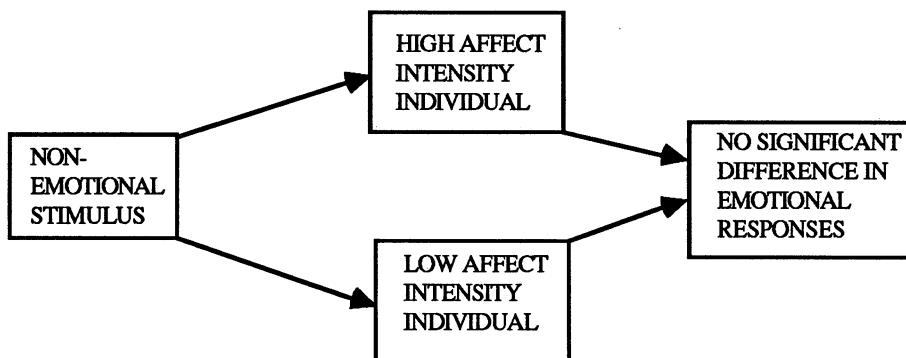

FIGURE B
WHEN AFFECT INTENSITY WILL NOT MODERATE AN EMOTIONAL RESPONSE

all the other temperament measures had simple factor loadings, high on one factor and low on all others, while affect intensity loaded on both factors. Larsen and Diener (1987) comment:

It is interesting that affect intensity loads on both of the temperament dimensions that emerged. It could be that affect intensity taps into some common underlying mechanism that contributes to both sociability/activity and arousability/ emotionality. Or it could be that affect intensity is an energizing force that drives or at least contributes to these temperament characteristics. ... (I)t appears that emotional response intensity is a component of various temperament dimensions that has previously gone unrecognized (p.20-21).

Daily Life Events

The relationship of affect intensity to daily life events has been investigated extensively. For example, Larsen and Diener (1987) have found that individuals high in affect intensity respond with stronger emotions to emotion-provoking events

which occur naturally in daily life (eg. success or failure at accomplishing a small task, seeing a violent scene on the evening television news). Although the severity of events experienced (how good or how bad) does not differ between individuals high and low in affect intensity, there is a tendency for high affect intensity persons to engage in day-to-day activities which are prone to provoke more emotion than low affect intensity individuals.

One implication for marketers is that certain types of television programs might attract high affect intensity individuals while other programs attract low affect intensity individuals. For example, high affect intensity individuals might be more prone to watch television news or television programs with emotionally charged plot lines than low affect intensity individuals. While the study of affect intensity as a segmentation tool is beyond the scope of this study, the potential for conducting this type of investigation in the future certainly exists.

Sensation Seeking

Because high affect intensity individuals are more prone to engage in daily activities with greater

emotion provoking potential than low affect intensity individuals, it has been hypothesized that affect intensity might represent a form of sensation seeking. However, Larsen et al. (1986) found that affect intensity had almost no correlation with the standard measure of sensation seeking, Zuckerman's (1979) Sensation Seeking Scale. Larsen et al. (1986) attributed their finding to basic differences in the nature of the two constructs. Sensation seeking refers more to behaviors which involve risk seeking, exciting, and thrilling activities which are different from every day life events, while affect intensity refers to having consistently strong emotional responses. Larsen and Diener (1987) state:

... One way to maintain this consistency is to engage more frequently in those ordinary daily activities, available to anyone, that provide a higher probability of provoking emotion. Thus individuals high on the affect intensity dimension do not seek out-of-the-ordinary experiences as much as they seek out an ordinary daily life that is more emotionally stimulating (p. 24).

Emotionally Relevant Cognitions

Another way to create consistently greater emotional responses to life events is to consistently engage in more emotionally relevant cognitions. It has been hypothesized by Epstein (1984) that cognitions can intensify emotional reactions to events when the person makes judgments about the stimulus event (i.e., intensified anger directed at a parent because that parent's child abuse behavior was viewed as irresponsible) and/or has beliefs about options of response (intensified anger because of the belief that parents who abuse children should be punished). Isen (1984) suggest that mood can prime associated cognitive material in memory, increasing the probability that these thoughts will intensify. Attribution theory (Weiner, Russell, and Lerman (1978)) suggests that attributions about the cause of an event will affect the intensity of a person's emotional reaction to the event.

Beck (1976) gave an account of certain cognitive operations that are relevant to emotional responses. Two of these are personalization and overgeneralization. Personalization occurs when an individual interprets experiences in a self-referential manner. Larsen et al. (1987) categorized personalization as consisting of two types of cognitive responses, personalizing statements and empathic statements. Overgeneralization occurs when a person takes a single event as being representative of how things are in the world. Larsen et al. (1987) categorized overgeneralization as consisting of two types of cognitive responses, global statements and fantasy elaboration.

It has been argued by Larsen, Diener, and Cropanzano (1987) that, when a high affect intensity individual personalizes the source of a negative event, he or she is making an internal attribution. However, when a high affect intensity

person overgeneralizes from a specific emotion evoking event, then he or she is probably activating additional emotion related material in memory. These cognitive operations are then thought to intensify a person's emotional response to an emotional stimulus. Larsen, Diener, and Cropanzano (1987) found that individuals with high affect intensity engaged in more personalizing and more generalizing cognitive operations than did individuals with low affect intensity in response to affective stimuli. When the stimulus was of a non-emotional nature, Larsen et al. (1987) observed no significant difference in emotionally relevant cognitive responses between high and low affect intensity individuals.

Figures C and D illustrate when affect intensity will and will not moderate emotionally relevant cognitive responses.

In summary, affect intensity refers to a stable individual difference characteristic defined in terms of a person's standard degree of emotional responsiveness. It appears to be closely related to both sociability-activity and emotionality-arousability temperament factors. It has been found that affect intensity is not related to the sensation seeking construct. In addition, it appears that high affect intensity individuals experience more emotionally relevant cognitive responses and strong emotional responses when exposed to emotional stimuli. Moreover, the affect intensity construct seems to capture an individual difference dimension which could be highly related to how an individual might respond emotionally to such daily life events as exposure to an advertisement.

FUTURE RESEARCH

The literature reviewed in this paper suggests that it would be worthwhile to pursue the study of the role of affect intensity as a predictor of emotionally relevant cognitive responses and emotional responses to advertisements using ads of different hedonic tones. For example appeals designed to produce fear, empathy, warmth, joy, and happiness could be worthy of study (Bagozzi and Moore 1989, Moore and Hoenig 1988). Such work might prove to be helpful in better understanding individual reactions to various emotional appeals.

Another avenue of investigation for researchers interested in the role of affect intensity in the processing of commercial messages would be the study of affect intensity's influence on the memory of emotional versus informational ads. In addition, one might investigate whether high affect intensity subjects experience slower burnout to emotional appeals than low affect intensity subjects.

Stayman and Aaker (1988) suggest that feelings may be strongest at early exposures to an ad having a direct effect on brand attitudes. The study of affect intensity's effect on emotions and emotions effect on attitude toward the ad and attitude toward the brand when the number of ad exposures are varied would be a valuable follow-up to Stayman and Aaker's work.

FIGURE C
WHEN AFFECT INTENSITY WILL MODERATE EMOTIONALLY RELEVANT COGNITIVE RESPONSES

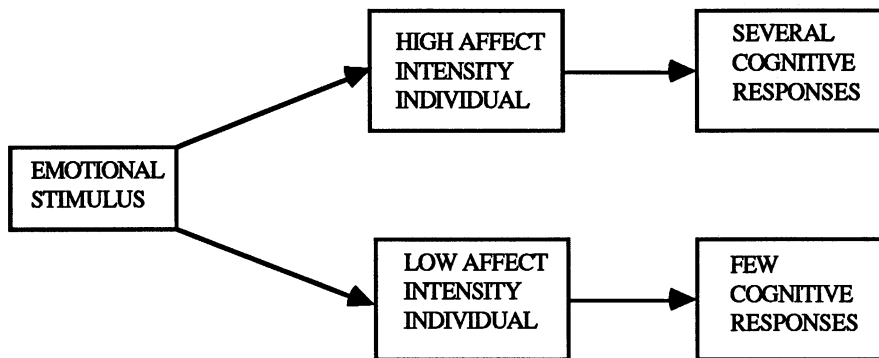

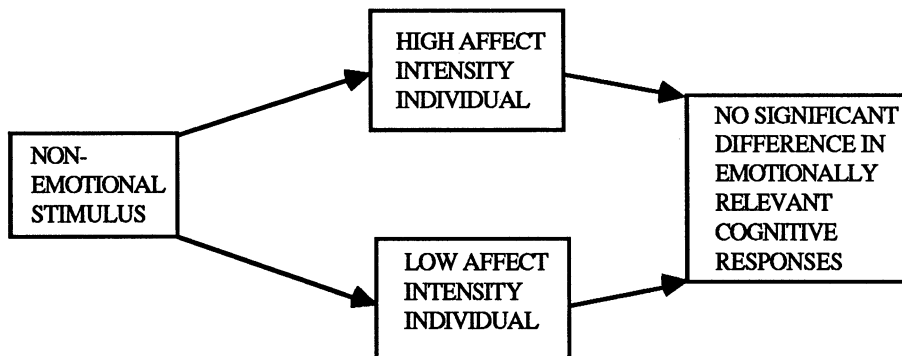

FIGURE D
WHEN AFFECT INTENSITY WILL NOT MODERATE EMOTIONALLY RELEVANT COGNITIVE RESPONSES

The opportunities for important work in this area appear to be great. We leave it to future research efforts to empirically confirm the usefulness of the affect intensity construct in enhancing our understanding of how advertising works.

Consumer Socialization Research: Content Analysis of Post-1980 Studies, and Some Implications for Future Work

Scott Ward, University of Pennsylvania
Donna M. Klees, University of Pennsylvania
Daniel B. Wackman, University of Minnesota

ABSTRACT

Studies of childhood consumer socialization since 1980 are content analyzed. Results show a high proportion of experimental research designs, participation by many authors from diverse disciplines, and multiple theoretical perspectives. In 14 sources surveyed, publications show a steady pace, at about 10 articles per year. Suggestions are offered for the next era of research in the field.

In 1979, an ACR paper asked: "Research on Marketing and Children: Upside or Downside on the Product Life Cycle?" Ten years later, that question is answered, because the question can be still be asked! This paper will overview sustained research in the area of "consumer socialization" since the 1970s, then present a content analysis of research since 1980, and, finally, suggest some fruitful areas for future research.

Our study is a rough set of the idea that Kassarian (1986) advanced: that stages of research can be likened to product life cycles, beginning with innovators, followed by mainliners, and, finally, by technicians. If the three types of researchers roughly correspond to the introductory, growth, and maturity stages of the life cycle, then our content analysis ought to provide a fix on where we are in the research scheme of things.

OVERVIEW OF CONSUMER SOCIALIZATION RESEARCH AND ITS ROLE IN CONSUMER BEHAVIOR

We define "consumer socialization" research in terms of three dimensions:

- (1) *Process Focus.* Most definitions of "socialization" refer to longitudinal processes by which individuals acquire skills, knowledge, and attitudes relevant to some area of social functioning. While studies of consumer socialization are usually cross-sectional, rather than longitudinal, the research interest is on intra- or inter-personal processes relevant to consumption. Some authors have examined populations such as the elderly, for example, but most research in the field has focused on children and adolescents.
- (2) *Economic Transactions.* Research in the area is concerned with economic exchanges, whether they are direct, or through othersDDmost often, through parents.

- (3) *Marketing Stimuli are Relevant.* Studies of children's use of television, family interaction, and the like are useful, but we believe the field is best defined by limiting it to phenomena involving marketing variablesDDthat is, commercials instead of programming, family interaction about consumption rather than general interaction patterns.

Using this definition, studies of consumer socialization can be traced to early pioneers: Guest's 20-year longitudinal study of brand attitudes(1972); McNeil's studies of child and family consumer behavior (1964); and Wells' pioneering work in measuring children attitudes and their influence in the family (1966). Nonetheless, these early studies were not the progenitors of a sustained stream of research. That stream began in the early 1970s and became sustained, in our view, largely because of "public policy" questions that were raised by consumer action groups, such as Action for Children's Television, and by federal regulatory agenciesDDmost notably the Federal Trade Commission. Policy questions were the *raison d'etre* for early research, and the focus was on television advertising's effects. Since age-related differences in children's responses to advertising were alleged, the most useful theoretical framework was Piaget's cognitive development theory, which poses age-related stages of development in children's perceptions and cognitive functioning. By the mid-to late 1970s researchers broadened their theoretical perspectives, and research issues were extended beyond television and the relatively narrow policy questions. New theoretical perspectives were brought to bear, including attribution theory, social learning theory, and theories about family communication patterns.

By the 1980s, significant work had been done to develop and validate measures for use in research with young people, beginning with Rossiter's validation of an attitude scale (Rossiter, 1977), Ward and Faber's multitrait, multimethod validation of purchase request attempts reported by both parents and children (1979), and progressing through contemporary work by Macklin and Roedder-John on a variety of measurement issues.

Throughout these 17 years, consumer socialization research has attracted researchers from diverse behavioral disciplines, and, within consumer behavior, has been usefully exploited by researchers seeking to apply concepts, theories, and measures useful in other areas of consumer research. In fact, we would argue that there are three primary reasons for sustained interest in consumer socialization:

1. The field is multi-disciplinary and multi-theoretical. As we will document in our content analysis, the field attracts researchers from a variety of behavioral disciplines, reflecting the fact that the breadth of consumer socialization phenomena invites the application of many theoretical perspectives.
2. The field has direct, readily-apparent relevance to "the real world." In addition to the concerns of public policy groups from government agencies to consumer groups and self-regulatory bodies, marketers who make appeals directly or indirectly to young people are a relatively defined group, and their questions about marketing effectiveness lend themselves to equally apparent research questions.
3. There are many opportunities for research. As we have suggested, individuals with diverse research interests can find some area in which to apply those interests in the field of consumer socialization, from intra-individual cognitive processes, to social processes, to longitudinal processes, to applications of advanced measurement techniques. Experimental, survey, and modelling approaches all have utility. In a way, the field is just the reverse of an earlier era in consumer behavior research, when the focus was on searching for suitable consumer behavior phenomenon for the application of particular theoretical perspectives (Ward and Robertson, 1973).

But where are we in 1989, and where should we go from here? We conducted a content analysis of research in the area of consumer socialization, beginning with the year 1980 and continuing through 1987 (not all 1988 journals were available at the time of our analysis). Previous reviews have focused on the pre-1980 period (Adler, et al, 1980). To try to answer the larger question, we focused on these questions:

1. Are we correct in our belief that the field has attracted many researchers, from diverse disciplines?
2. What is the nature of post-1980 research? Based on Kassarian's thoughts (1986), our working hypotheses were:
 - Younger (pre-school-aged) children would be represented in research, since almost all earlier work focused on school-aged children;
 - Lab or field experiments will predominate, moving beyond one-shot surveys and convenience sample research

that marked the early years of research in the field:

- The orientation of research would be more toward positive or "pro-social" consumer socialization outcomes, since there is less pressure to address public policy questions, which most often pose "negative" outcomes (e.g., deceptive advertising practices);
- There will be more "process-oriented" research than "stimulus-oriented" research, reflecting current trends in consumer behavior, and less concern with the policy questions that had prompted earlier research focusing on the effects of particular stimuli (e.g., effects of host selling in television commercials);
- Research will reflect a broad range of theoretical perspectives, and some studies would incorporate more than one theoretical base (the "multi-theoretical" perspective called for in earlier research);
- There will be little research oriented specifically to public policy issues.

While we do not have a before/after design since we do not have specific content analysis data from studies in the pre-1980 period, our expectations are shaped by our impressions of the pre-1980 period, and by general reviews of that research.

METHODOLOGY

We began by examining papers that reviewed research in the general area of "consumer socialization." We further limited our search to studies dealing with pre-teenage children. We derived a frequency distribution of referenced publications and examined the periodic indices of these journals to search for categories that met our criteria for the studies in consumer socialization discussed earlier. We identified the following as leading publications in the area and as a set containing over 90% of the published research in consumer socialization:

Child Development

Journals of:

Academy of Marketing Science
 Advertising
 Advertising Research
 Applied Developmental Psychology
 Broadcasting
 Communications
 Consumer Affairs
 Consumer Research
 Family Issues
 Marketing
 Marketing Research
 Public Policy and Marketing
 Proceedings, Association for Consumer Research

After identifying the articles in these publications that fell within our definition of "consumer socialization," we categorized them in terms of type of study. "Orientation" of the study was assessed: positive or "prosocial" orientation; "negative effects" orientation, or not applicable. "Positive" studies were those focusing on positive outcomes of exposure to marketing stimuli (such as sharing or positive sex-role attitudes as a function of exposure to television advertising stimuli), or those that portrayed children as learning positive aspects of consumer behavior. "Negative effects" were defined as studies dealing with outcomes of exposure to marketing stimuli that were identified as dysfunctional, such as materialism, parent-child conflict, and the like.

We also coded studies in terms of their topics. These were defined as:

- stimulus-related: dealing primarily with specific effects of particular marketing stimuli, such as host selling, public service announcements, program-commercial separators, and the like;
- process-related: dealing primarily with general processes, such as family communication process, information processing, attitude formation;
- general effects research: identifying studies investigating various effects as a function of undefined or general stimuli, or as a function of pre-existing states (e.g., descriptive studies of frequency of children's product requesting behavior, influence of product knowledge on comprehension of advertising);
- measurement studies: focusing on application of particular measures, or on measure validation.

Papers were also coded in terms of whether they explicitly mentioned a policy issue or not. A "policy issue" was defined as one that had been mentioned by a regulatory, self-regulatory, or consumer action group, e.g., the desirability or lack of desirability of hosts selling, amount of

advertising, program tie-ins with advertising products, and the like.

The academic affiliations of all authors on each study and the expressed theoretical base of each study were the final coding categories.

Two judges, working independently, coded the set of studies. With the exception of the academic affiliation of the authors, each of the measures were tested for interjudge agreement. Judges were in complete agreement for type of publication. Reliability for the remaining categories exceeded 90%, except for theoretical perspective, which had a reliability rating of only 73%. The latter category was difficult to code, because the stated theoretical orientations of the papers were not always comprehensive.

FINDINGS

We found 92 studies appearing in the 1980-87 *ACR Proceedings* and in the journals listed above. A reasonably steady distribution of studies through the years (shown in Table 1) suggests some "maturation," but no sharp decline of interest. A total of 155 different authors (65 first authors) contributed; 17 first authors contributed more than one study during 1980-87, with two authors contribution 6 studies each.

Over one-half (52%) of the authors listed Marketing as their academic affiliation; Communication or Journalism was the second most represented field (15%). Other fields included Psychology (10%), industry researchers (7%), and Advertising departments (5%). Education, Human Development, and Child/Family Studies contributed most of the remainder (a few affiliations were not ascertained).

Reflecting concentration of research in Marketing, and, more specifically, in Consumer Behavior, 19 of the 92 articles were published in the *ACR Proceedings* and 16 in the *Journal of Consumer Research*. Fourteen were published in the *Journal of Broadcasting*. These findings offer a mixed answer to our first research question: childhood consumer socialization research since 1980 shows concentration by researchers in marketing and publication in consumer behavior outlets, but the

field has attracted a high number of research contributors.

Next, we posed a series of expectations about the nature of research in the field. First, we expected researchers to include more younger children in studies than was generally the case in pre-1980 research. About 50% of the studies were based on empirical research with pre-teenage children (as opposed to conceptual or review papers, research with other family members as subjects, etc.), and, of these, 26, or about half, included children 5 years of age or less. This finding confirms our suspicion that researchers would venture down the chronological age continuum.

We also expected a prevalence of lab or field experiments, reflecting maturation of research approaches in consumer socialization. In fact, the data in Table 2 strongly support our expectation: about half the studies were experimental.

Next, we expected a substantial portion of research to be oriented toward "positive" or "prosocial" consumer socialization outcomes, such as attitudes toward sharing, saving, and the like, as opposed to "negative" outcomes, such as deception, nagging parents, and so on. We only coded studies in one or the other category when the orientation was quite clear, at least to the two judges scoring the studies. Table 3 indicates that of the 67 studies we could code in one category or the other, 42 were "prosocial," or "positive," while 25 focused on negative processes or outcomes.

We expected most research to be focused on processes, including intra- individual processes (e.g., information-processing perspective), inter-individual processes (in the family, among peers, siblings), and more general process notions, such as changes in consumption-related knowledge,

attitudes, and skills over time. We expected this trend toward process-oriented research in large measure because the relatively low level of public policy debate, as compared to earlier years, should shift the interests of researchers away from input-output designs to test for effects of specific stimuli (e.g., types of television advertising). This expectation was not supported (Table 4). Stimulus-related research accounted for 40% of total publications, versus 24% for policy-oriented papers.

Another perspective is the extent to which studies are designed to address specific policy questions, or, in the case of non-empirical research, the extent to which policy questions are the primary focus of the paper. Of the 92 papers, 33 (36%) were coded as "policy-oriented." Again, while we do not have prior data, we would suspect that number may well be somewhat less than in previous years.

Finally, we hypothesized that studies would reflect a broad range of theoretical perspectives, and that a substantial proportion would be "multitheoretical," in that they draw on more than one theoretical tradition in the formulation of hypotheses and/or interpret results in terms of multiple perspectives. Results are shown in Table 5. Of the 70 studies that could be coded in terms of our categories of theoretical perspectives, about one-fifth were "multitheoretical." Cognitive development theory is often one of the perspectives in multitheoretical works, and it is the theory that is most often the basis for single-theory studies. Alas, atheoretical papers account for 14% of the total. The fact that only 5 papers deal explicitly with "measurement" issues may mean that consumer socialization research is not yet as Kassarian's final stage, when the "technicians" move in. However, our perception is that many papers include detailed

TABLE 4

discussion of measurement issues as part of broader topics and objectives.

In summary, we find support for our expectations that: (1) the field of consumer socialization research is alive and well, attracting a steady stream of research over the past seven years; (2) the field attracts many scholars bringing a wide variety of theoretical perspectives, but the field of study which contributes the greatest number of papers is Marketing; (3) there is some trend away from policy-specific research, but many studies still focus on effects of specific stimuli; (4) there is some trend toward a truly "multitheoretical" perspective in that more than one theory or conceptual framework is brought to bear on consumer socialization phenomena.

THE NEXT TEN YEARS

Where does our analysis place consumer socialization on the "research life cycle" in 1989, and what does it suggest for future research directions? We believe consumer socialization research is in the "mature" stage of the product life cycle, exhibiting a reasonably steady pace of new research through the years. The diversity of disciplines and theoretical perspectives suggests that studies prior to 1980 cut a wide swath, while post-1980 research has focused on the specific issues early work exposed.

We believe that future research directions should build on the characteristics of the field that have attracted researchers to the field to this point in time—namely, that future research should remain multi-theoretical and multi-disciplinary, that research

questions continue to have significant implications for practice, and that researchers continue to explore various opportunities for research in the area.

We believe that these attractive characteristics remain, regardless of whether one believes that the most fruitful direction is to strive for a

general theory of consumer socialization, (e.g., Howard and Sheth, 1969) on the one hand, or focus on relatively narrow research questions such as policy issues—on the other hand. However, our belief is that the most fruitful directions for future research lie between the two extremes posed above. That is, we advocate "middle-range" research, or "micro-theoretical" notions—a position well established in behavioral sciences generally (Merton, 1957) and in consumer behavior specifically (Ward and Robertson, 1973; Ray, 1974). Future research should aim to specify and model reasonably discrete and specific sub-areas within the overall field. However, given the research to date, we believe that the marginal utility of additional studies in some areas is less than it may be in other areas. For example, the large pool of studies of children's information-processing patterns in recent years has greatly increased our knowledge in that area. As another example, so much research has been done based on cognitive development theory that there is little left to know about stage-related cognitive phenomena.

On the other hand, we believe the marginal utility of additional studies in the following areas is high, and that research can be oriented toward

deriving the following "middle-range" theories and models:

- (1) Children's influence on aspects of consumer behavior in the family unit, and conversely, the impact of family variables on children's consumer socialization processes. While many studies decry the fact that "family decision-making" as field of consumer behavior study focuses primarily on husband-wife dyads rather than on the entire family unit, relatively little research has been done in the last seven years on the expanded view of the family. The topic would seem to be especially important, given contemporary social and demographic changes affecting the composition of families, and their functioning as a social unit.
- (2) The durability of early consumer socialization processes. Virtually every definition of "socialization" stresses the idea that socialization processes involve learning that is applied in later situations. While we recognize the difficulty of specifying elements of learning for study, the prevalence of cross-sectional studies in the area leaves us begging for more information on not only what is learned and when, but also how long learning lasts and how it is changed.
- (3) Consumption as a relative experience for young people. Many authors discuss the fact that consumption is just one of many things children and adolescents experience, but the literature is silent on the relative nature and significance of consumption as a relative experience.

In conclusion, we believe consumer socialization research is maturing. We have gone through the "introductory" stage, when Kassarian's "innovators" exploited theoretical perspectives (e.g., cognitive development), driven by policy questions of the day. Research in the 80s is less tied to policy questions, and reflects a broad range of theoretical perspectives and more rigorous experimental research. The choice point now is if we continue to refine areas that have become "well-mined," attempt to construct broad, general theories, or seek to specify relatively specific areas of interest in this broad field and derive models and theories of the "middle-range" to satisfactorily explain and predict some circumscribed phenomena. We believe the field can enjoy a fruitful "mature" stage by pursuing the latter course.

A listing of the studies that were content analyzed for this research may be obtained by writing to the first author.

An Investigation of Mothers' Communication Orientations and Patterns

Les Carlson, University of Arkansas
Sanford Grossbart, University of Nebraska
Carolyn Tripp, University of Arkansas

ABSTRACT

This study investigated the efficacy of communication orientations and a typology of family patterns based on communication differences. Previous studies of these orientations and typology have been based on the responses of adolescents. Mothers served as the subjects in this investigation. Results from exploratory and confirmatory factoring as well as preliminary construct validation of the orientations and typology provided some support for their use with samples other than adolescents. Extensions and implications of the findings for consumer socialization are suggested.

INTRODUCTION

Marketers have sought to determine why differences in consumer behavior develop. Consumer socialization provides useful insights in this regard by attempting to identify and clarify those processes by which an individual acquires a consumer identity, complete with differential opinions, knowledge and skills. This study, by focusing on mothers' perspectives, provides additional insights on family communication about consumer learning.

Background

One research stream focuses on the influence role of various communication agents (e.g., parents) in consumer socialization (e.g., Moschis and Moore 1978; Moore and Moschis 1981; Moschis, Moore and Smith 1983; Moschis, Prahasto and Mitchell 1985; Moschis and Mitchell 1985). Since consumer socialization is the process "by which young people acquire skills, knowledge and attitudes relevant to their functioning in the marketplace," (Ward 1980, p. 380) understanding the nature of parent-child communication may provide an explanation for differences in consumer behavior and skills. In this context, Chaffee et al. (1971) and others (McLeod and Chaffee 1972; McLeod and O'Keefe 1972) provide a useful framework which describes family communication orientations and patterns in political socialization. This framework has been adapted to a consumer socialization context (cf., Moschis 1985; Moore and Moschis 1981). A review of the conceptual bases of these orientations and patterns follow.

Consumer Socialization Communication Orientations

These patterns are derived from two uncorrelated family communication dimensions. Socio-oriented parental messages promote deference to parents and monitoring and control of children's consumer learning while concept-oriented parental communications encourage children to develop their own consumer skills and competencies. These

dimensions can be arrayed to form a two by two typology depicting four parental communication patterns: Laissez-faire, Protective, Pluralistic, and Consensual.

Laissez-faire parents are neither socio- nor concept-oriented and hence little parent-child communication of either type occurs in these families. Protectives emphasize deference to parents, control and mediation of children's consumer socialization at the expense of building consumer competence and skills in the child. Pluralistics encourage the development of consumer skills without promoting acquiescence to themselves or controlling children's exposure to the marketplace. Finally, Consensuials stress both orientations. Their children are encouraged to take interest in ideas outside the scope of family beliefs and traditions, yet simultaneously are expected to learn and conform to parental consumer behaviors, values and ideas.

These patterns are believed to account for differential outcomes in offspring beyond those attributable to parent-child interactions such as modeling and reinforcement strategies and have been cited as directly or indirectly impacting consumer learning (Moschis 1984; Moschis and Moore 1978; 1983; Moschis, Moore and Smith 1983; Moschis, Prahasto and Mitchell 1985). Direct influences involve acquisition of consumption related information and formation of beliefs, norms and behaviors while indirect influences include affecting and mediating children's interactions with other sources of consumer influence, e.g., media (Moschis 1985).

Yet, while these findings provide understanding of the influence of these patterns on consumer learning, this research has been conducted almost exclusively on adolescents' views of family communication. In the only variations to this sampling frame, Moschis and Mitchell (1985) used mother and adolescent pairs; however, only the youngsters responded to communication orientation items. Similarly, Foxman et al. (1989), using mother, father and adolescent triads, found that family communication patterns were an influencing factor on consumption decisions. Again, while data were gathered from a variety of family members, pattern assignment was based on adolescent responses to socio and concept measures.

In summary, while these patterns have been related to consumer learning and family influence relations they have been investigated from the perspective of adolescents. Thus, only one partner (adolescents) of the communication dyad (i.e., parent-child) in consumer socialization has been studied. Likewise, validity assessment of these orientations and of the typology of family communication patterns has been limited to samples

of adolescents. Also, key assumptions across some research are the orthogonality and unidimensionality of the communication orientations which are essential preconditions for assigning individuals to the patterns in the typology. Thus, there appears to be several gaps in our understanding of these orientations and in their application. By focusing on mothers, this study sought to provide additional insights into these orientations and patterns.

METHOD

As part of a larger study, self-administered questionnaires were distributed to mothers via their children in three elementary schools from a variety of socioeconomic areas in a mid-western city. Mothers were asked to answer items with respect to their youngest school aged child to avoid multiple responses from the same family and because of previous research emphasis on adolescents' views of their family communication environments.

In addition to the need to study mothers' perspectives using the socio- and concept-orientations, mothers were selected for these reasons. In consumer socialization terms, mothers are important because of their greater familiarity with the marketplace and its relation to children (Aldous 1974), their roles as mediators of consumer socialization agent influence (Abrams 1984), and their long-term impact on the consumption choices of children (Alsop 1988).

Questionnaires were collected two weeks after distribution and the 46% response rate ($n = 499$) was similar across schools. Principals considered this rate to be normal compared to other take home items requiring a parental response and it was similar to rates reported previously (cf., Grossbart and Crosby 1984). 451 cases were retained for analyses, incomplete items occurred in a random fashion and there were no differences on dependent variables between respondents who did/did not complete all items.

Communication Pattern Variables

The most recent versions of the concept and socio scales (Moschis, Moore and Smith 1983) were slightly revised to allow mothers, rather than adolescents to serve as respondents. Six concept items reflected maternal emphasis on developing children's competence and skills as consumers (e.g., I tell my child to decide about things he/she should or shouldn't buy) while five socio items tapped maternal emphasis on monitoring and controlling children's consumptive behavior (e.g., I want to know what my child does with his/her money) (see Table 2). Responses were summed across items in each scale. One socio item (as cited in Moschis, Moore and Smith 1983) was deleted because it was deemed reflective of general parenting orientations rather than specifically oriented toward consumption issues (i.e., Parents say they know what is best for the child and he/she shouldn't question them).

As these measures were to be used to classify mothers per one of the communication patterns a check was performed on the potential impact of

responding to these measures in a socially desirable manner. Correlations were calculated between each index and a 19 item version of Crowne and Marlowe's (1964) social desirability scale. Social desirability accounted for less than 1% of the variation in socio-orientation and less than 2% of the variation in concept-orientation. Another correlation analysis investigated the possible confound of mothers couching their responses according to their youngest school aged child. However, neither communication orientation was related to birth order of the child or the number of children in the family.

Indicators of Media Mediation, Monitoring and Control

Moore and Moschis (1981) provided initial validity evidence for socio and concept indices by relating communication patterns (e.g., Protectives) to the adolescent's media use (e.g., amount of tv viewing). In an attempt to be consistent with procedures used by these authors, differences across patterns were examined for mother's reports of children's aggregate tv viewing, parent-child discussions about advertising, viewing tv with children and control of children's tv viewing. These variables appeared to be consequences and/or natural outcomes of fostering consumer competencies vs. controlling children's consumer learning (as tapped by the concept- and socio-orientations). Although differences across patterns were not hypothesized, certain relations were intuitively appealing. For example, Protectives and Consensuals ought to be higher on variables reflecting maternal control tendencies, i.e., amount and restriction of children's tv viewing, as they emphasize socio-oriented messages. Likewise, Pluralistics and Consensuals should be higher on tendencies to foster the development of the child's consumer skills and knowledge, i.e., parent-child discussions about advertising and viewing tv with children since they stress concept-oriented messages. Laissez-faires might be low on all tendencies as they refrain from either type of message.

Amount of children's tv viewing was indicated by number of hours a child viewed tv for a typical weekday and weekend. Mothers also noted the extent they discussed tv, magazine, newspaper and radio advertising with children. Coviewing tapped the frequency mothers watched tv with children on weekdays and weekends and the importance mothers placed on this activity. Finally, mothers cited extent of restrictions placed on children's tv viewing in terms of programming, times and amounts (see Table 1).

Analyses

The analytical procedure was composed of three parts. First, alpha and beta reliability analyses and exploratory factoring were used to examine item patterns and indicate whether item responses from mothers to the socio and concept scale items were similar to those obtained from adolescents in prior studies. Next, since the four

TABLE 1
Communication Pattern and Media Variables

Index	No. of Items	Scale	Alpha	Beta	Source
Concept	6	vo/n	.70	.50	Moschis, Moore & Smith (1983)
Socio	5	vo/n	.50	.49	Moschis, Moore & Smith (1983)
Amount of tv viewing	3	hours			Crosby & Grossbart (1984)
Discussions about advertising	3	vo/n	.84	.80	Crosby & Grossbart (1984)
Coviewing*	4	vo/n sa/sd	.90	.85	Authors
Control of tv viewing	3	vo/n	.82	.76	Ward, Wackman & Wartella (1977)
Social desirability	19	yes/no	.71	.50	Crowne & Marlowe (1964)

* The 3 coviewing items, e.g., I watch tv with my children on weekdays, Saturdays and Sundays were multiplied by a fourth item, i.e., It is important for my child and I to watch tv together so I know what kind of programs and ads he/she is watching and summed to tap the significance that mothers place on viewing tv with children. All other media items were summed across items.

Scales: vo/n = 5 point, very often/never; sa/sd - 5 point, strongly agree/ strongly disagree; hours = hours viewed for a weekday, Saturday and Sunday.

communication patterns are based on a theoretical orthogonal array of the two communication dimensions, confirmatory factor analysis was used as a test of this structure. Support for this array (versus competing depictions) would provide evidence for using it when investigating the impact of communication on consumer socialization. Finally, following previous investigations of communication patterns (e.g., Moschis and Moore 1979), median splits on the socio- and concept-orientation raw scores were used to place mothers into one of the four cells of the communication typology. Means on the various media variables were compared via oneway ANOVAs across communication patterns as an indicator of construct validity (cf., Moore and Moschis 1981).

RESULTS

Alpha reliabilities for the concept and socio scales using mothers (see Table 1) were very similar to those reported by Moschis and Mitchell (1985; concept alpha = .72; socio alpha = .51) for adolescent respondents. Initial exploratory factoring suggested a four factor solution accounting for 59.3% of the variation. Both concept and socio communication items loaded on two factors,

suggesting these orientations may be multidimensional. The socio beta of .49 also raises questions about its unidimensionality (Table 1). Loading patterns were relatively clean, e.g., socio items loaded primarily with other socio items as opposed to cross loading with concept items (see Table 2). Confirmatory factor analyses (as discussed below) suggested a four factor oblique solution, thus, rotated oblique results from exploratory factoring are presented in Table 2.

Confirmatory factoring via LISREL VI was used to examine several competing conceptual views. First, as noted, it could provide an indication of the appropriateness of the orthogonal array. Second, it might be argued that these orientations are not orthogonal dimensions but are merely end points or locations on a single continuum. That is, only one underlying consumer socialization communication dimension exists and mothers merely vary between controlling and fostering children's consumer learning. Finally, perhaps these items do not represent any underlying structure. Confirmatory factoring allows for comparing hypothesized models to each other and to a "null" model where complete independence is assumed between all indicators.

TABLE 2
Oblique Factor Results

Item*	Factor 1	Factor 2	Factor 3	Factor 4
1. I tell my child to decide about things he/she should or shouldn't buy. ¹	836	083	110	-125
2. I tell my child to decide how to how to spend his/her money. ¹	704	064	255	-305
3. I tell my child buying things he/she likes is important even if others don't like them. ¹	664	-105	417	181

4. Two factor oblique ^c	43	216.35	.87	.69
5. Four factor orthogonal ^c	44	255.11	.86	.64
6. Four factor oblique ^c	39	161.39	.90	.77

Note: Inclusion of the 4 factor orthogonal model for comparison was based on exploratory factor results

^a adjusted goodness of fit index

^b ratio of null model X^2 - comparison model X^2 divided by null model X^2 , see Bentler and Bonett (1980); Shimp and Sharma (1983)

^c as an initial step for model comparison, indicator/construct relation estimation was limited to those suggested by exploratory results and previous theory, i.e., the lambda γ parameter corresponding to the *highest* absolute loading for each variable from the exploratory findings was estimated; all other lambda γ parameters for that indicator across constructs were constrained to zero

Fit indices (i.e., Adjusted Goodness of Fit Index - AGFI) and a ratio using the null model as a reference (Bentler and Bonett 1980; Shimp and Sharma 1983) were used to compare models. Exploratory factoring (i.e., eigenvalues greater than one) suggested additional models to the null and two factor orthogonal possibilities. The results of these comparisons are presented in Table 3. The null model, postulating that each of the 11 items from the socio and concept scales are unitary constructs (i.e., that there is not a more parsimonious explanation for the data structure), served as a comparison for subsequent models. The one factor model represented the unitary communication construct possibility. The two factor orthogonal model was suggested by previous theory and represents the underlying structure of the four communication patterns. The four factor models were suggested by exploratory results. Both oblique solutions (models 4 and 6) were attempts to improve fit by allowing for intercorrelation (oblique rotation) between the dimensions.

All models, regardless of rotational methods or number of dimensions, were improvements over the null. In every case, both fit indices indicated improvement in fit between the data and a hypothesized model compared to the null. Allowing for intercorrelation between factors did not significantly improve the two factor model (model

4, Table 3) but did impact the four factor model (model 6, Table 3).

Finally, construct validity of the communication framework was assessed using a procedure similar to Moore and Moschis (1981). Four oneway ANOVAs were performed using communication pattern as an independent variable. Amount of tv viewing, discussions about advertising, coviewing of tv between mothers and children and mother's control of children's tv viewing were the dependent variables. These results are depicted in Table 4. No differences between communication patterns were observed for amount of children's tv viewing. However, Laissez-faires were lower than all groups except Protectives on discussions about advertising and were lower than Pluralistics on coviewing. Laissez-faires were also lower than Pluralistics and Consensuals on controlling viewing. Pluralistics were higher than Protectives on discussing advertising while Protectives and Laissez-faires were higher than Pluralistics on controlling viewing.

DISCUSSION

The objectives of this study were three fold. First, we attempted to explore the socio- and concept-communication orientations from the perspective of mothers due to their significance in the consumer socialization process. Second, we

TABLE 4
 Mother's Mediation, Monitoring and Control of Children's Media Use

Mediation Type	Laissez-faire ^a (n = 161)	Pluralistic ^b (n = 130)	Protective ^c (n = 80)	Consensual ^d (n = 80)	Univariate F
Amount of tv viewing	-.02	.05	.07	-.11	.64
Discussions about advertising	-.24	.31 ^{ac}	-.21	.19 ^a	9.68*
Coviewing	-.14	.16 ^a	-.16	.18	3.91*
Control of tv viewing	-.22	-.04	.33 ^{ab}	.19 ^a	6.89*

* $p < .01$; Wilks lambda multivariate test statistic for mediation variables = 0.872, approximate $F = 5.21$, $df = 12,1175$; table values are standard scores to enhance pattern comparisons across mediation types; superscripts^{abcd} indicate significant differences (Tukey pairwise comparisons, $p < 0.05$); for example, the superscripts^{ac} under Pluralistic for discussions about advertising indicate that Pluralistic mothers talk to their children about advertising more than Laissez-faire^a and Protective^c mothers.

investigated the efficacy of the four cell communication pattern typology (as proposed by Moschis and others), plus other depictions of parent-child communication. Finally, we studied the relations between communication patterns and mother's mediation, monitoring and control of children's media use as a preliminary step toward validation of the socio and concept communication scales. The following discussion considers each of these issues.

Maternal Communication Patterns

As noted, exploratory and confirmatory factoring suggested a four dimensional array. This model (model 6, Table 3) reflects splits in each scale, suggesting that mothers' communication orientations may be multidimensional (see Table 2). For example, one concept dimension reflects mothers' tendencies to instruct children to make decisions about purchases irrespective of the opinions of others (e.g., Item 1, I tell my child to decide about things he/she should or shouldn't buy). The other concept dimension reflects mothers' tendencies to solicit children's opinions regarding purchasing/consumption decisions that may or may not be related to the child (e.g., Item 7, I ask my child to help me buy things for the family).

The socio-orientation appears to be composed of maternal tendencies toward control of children's consumption (e.g., Item 4, I tell my child what things he/she should or shouldn't buy). Mothers also appear to be exerting control via cold indifference toward their children's consumption activities (e.g., Item 10, I tell my child he/she

shouldn't ask questions about things children do not usually buy and Item 11, I want to know what my child does with his/her money -- negative loading). The child may be expected to know that certain consumption activities are simply not discussed because the limitations on his/her behavior have been previously established and are nonnegotiable.

These splits may be due to differences in how mothers vs adolescents perceive communication orientations in a household, i.e., mothers may have a broader perspective on nuances in familial communication tendencies. As such, maternal orientation multidimensionality may suggest finer and more numerous communication pattern delineations than the four typically derived from adolescent responses. Specifically, this might be manifested in communication patterns defined by variations on the four communication orientations indicated in Table 2. Within construct multidimensionality may also suggest the need for scale revisions (e.g., addition of other items) for respondents other than adolescents.

Confirmatory Factoring

As expected, the null model depicted the worst overall fit. The best fit was the four factor oblique solution with the constraints on model estimation noted in Table 3 (superscript^c). Exploratory and confirmatory factor analyses all indicated the within construct multidimensionality of both orientations and multidimensionality of the socio-orientation is also suggested by its beta reliability of .49 (Table 1). Confirmatory factoring also suggested these orientations are not merely

locations on a unitary communication dimension as was depicted in the single factor model. Unfortunately, the two factor orthogonal array which was based on prior theory and used in past research to categorize adolescents' perceptions of their family communication environments into one of the four communication patterns, does appear to be "improvable". While this finding does not ease classification of mothers into communication patterns it may suggest mothers perceive communication about consumption issues differently than their offspring (although this study dealt with mothers of elementary school children).

Yet, even though these orientations appear to be multidimensional there *are* empirical and conceptual reasons to not discard the two dimensional orthogonal array. First, the exploratory factoring scree plot suggested a two factor orthogonal solution. Second, although the four factor oblique solution delineates a 56 point X^2 improvement compared to the two factor orthogonal array, the improvement in the AGFI and Bentler and Bonett (1980) fit indices is not substantial (see Table 3, models 3 and 6). Third, the correlations between factors for the four factor oblique solution are quite low (see Table 2). The highest correlation (i.e., between concept factors) indicates that less than 7% of the variation in one concept factor is accounted for by the other even though these factors were allowed to interrelate. Hence, although several analyses suggested within construct multidimensionality with intra-construct relationships, socio and concept dimensions are only marginally related. This supports the basic independence of the concept and socio tendencies but does not necessarily provide additional evidence for a two dimensional structure.

This evidence suggests a research dilemma, i.e., using multidimensional socio and concept scales which may be a more accurate depiction of how mothers perceive these constructs vs a concomitant loss of subject classification ease and model interpretability. Given these liabilities should researchers refrain from classifying mothers per the typical four patterns? To provide some guidance, as noted, we conducted additional tests of the typology's efficacy by investigating the relations between communication patterns and mother's mediation, monitoring and control of children's media use. These tests provide preliminary indications on the construct validity of these orientations and the typology.

Media Mediation, Monitoring and Control by Communication Pattern

Surprisingly, there were no differences between communication patterns on mother's indications of amount of children's tv viewing (see Table 4). This is contrary to previous findings (e.g., Moore and Moschis 1981) and may be a reflection of using mothers and querying them on the viewing habits of their youngest elementary age child. The lack of significant differences may also be a result of the within construct

multidimensionality issue cited previously. Our results indicate children's tv viewing does not vary by mother's communication type. What is not known is whether mothers report differences in adolescent viewing across communication patterns.

However, differences across patterns were found for other media use variables. Note that relations between these variables and patterns are not simple reflections of maternal response consistencies due to assumed similarities between the independent and dependent measures. For example, the discussions about advertising index asked mothers for the frequency they talk to children about the content of tv, magazine, newspaper and radio advertising. This variable is conceptually distinct from *either* the concept or socio indices (i.e., I tell my child to decide about things he/she should or shouldn't buy and I tell my child what things he/she should or shouldn't buy).

Laissez-faires, who by definition, are lowest on both communication orientations are also lower on discussing advertising with children than all groups except Protectives. Very little parent-child communication occurs in Laissez-faire families (Moore and Moschis 1981). Hence, it is not surprising that these mothers report few interactions with children about advertising. Likewise, this general lack of communication is also manifested in controlling tv viewing less than all other groups except Pluralistics though Laissez-faires coview less than Pluralistics.

Pluralistics might coview with children because this activity provides a springboard for parent-child discussions about advertising. Pluralistics foster consumer learning without emphasizing monitoring and control of consumption behavior. Thus, it's reasonable that Pluralistics discuss ads more than Protectives and Laissez-faires who both deemphasize concept messages.

Protectives emphasize control and monitoring of consumer learning via socio-oriented messages at the expense of building consumer skills. Not surprising then, Protectives are higher than all groups except for Consensuals on control of tv viewing but control apparently does not translate into differences on children's tv viewing. Both Protectives and Consensuals emphasize socio-oriented messages and hence might be expected to be similar on control of tv viewing.

Consensuals were higher than Laissez-faires on discussing ads and control of tv viewing. This is reasonable since Consensuals emphasize, while Laissez-faires deemphasize, the communication tendencies that might be related to these concepts, i.e., concept- and socio-oriented messages, respectively. Consensuals were higher on coviewing than all groups and the lack of significant differences may be a function of differential sample sizes (see Table 4). Like Pluralistics, they too may be using coviewing as a stimulus for discussions about ads.

The lack of additional media related differences may be due to the reasons previously cited for finding no differences on amount of

children's tv viewing (e.g., within construct multidimensionality). Still, even with these limitations, the differences that were found could be reasonably expected given concept and socio variations between the four communication patterns. Thus, researchers may have some confidence in the construct validity of these orientations and in the practice of assigning mothers to one of the patterns.

SUMMARY, EXTENSIONS AND CONCLUSIONS

Since past research has often used adolescent respondents this study attempted to extend communication pattern research by sampling mothers with elementary age children. We revised communication orientation items to facilitate their use by mothers rather than adolescents. We also investigated the efficacy of the pattern typology which can be constructed from these communication orientations and several alternative arrays. Finally, because of possible multidimensionality of concept and socio tendencies, we have provided other potential indicators of their construct validity (but with a sampling frame different from previous research).

This research may be extended in several ways. First, while these orientations and patterns have now been studied from the perspective of adolescents and mothers, their applicability to other family members, i.e., fathers, also should be investigated. Second, corroboration between multiple respondents within the same family unit would give additional insight into the true nature of communication within a household. This would help to answer a number of important questions. Do children confirm the type of communication about consumption that is reported by their parents? Do female and male heads of households note similar use of each communication orientation? If disagreement exists, how does it affect the consumer socialization process? Third, further refinement of these scales may be needed in order to address the within pattern multidimensionality issue. Additions, deletions and/or reexaminations of items may be necessary to obtain unidimensional constructs. Construct validation of these orientations might be enhanced with measure revisions.

Communication orientations and patterns are a rich area for additional conceptualization and research. The findings cited here are extensions to previous communication and socialization research. For example, our results suggest differences in mother's mediation, monitoring and control of children's media use may be a partial function of general communication differences. The orientations and framework investigated here and in other communication pattern studies should continue to provide new insights into the role of parents as socialization agents in children's consumer learning.

Children's Influence In Purchase Decisions: A Review and Critique

Tamara F. Mangleburg, Virginia Tech

ABSTRACT

Based upon a review of the literature, children's influence in family purchase decisions was found to vary by product- and decision-related factors, as well as by parental, child and family characteristics. A number of problems associated with previous research were also identified, including problems with construct validity, over-reliance on the survey method, and lack of theoretical explanations for observed patterns of influence. Finally, some possible avenues for future research were also discussed.

The issue of children's influence in family purchase decisions is beginning to attract the attention of researchers of family buying processes. In the past, research on family decision-making tended to concentrate on examining variations in *spousal* influence; the role of the child was often overlooked (Davis 1976; Ferber 1973; McDonald 1980; Miller et al. 1982; Scanzoni 1980). However, there has recently been an increasing recognition of the child's importance in family purchase decisions. Specifically, a number of studies have found children to have at least some influence in decisions for a wide array of products. Therefore, it seems that if researchers wish to fully understand family decision-making, children should be included in studies of family consumer behavior.

The purposes of this paper are to review previous research on children's influence in purchase decisions, and to evaluate the existing state of knowledge in this domain. Our goal is to point out some of the attendant strengths and weaknesses that characterize this area of research, and to offer some possible avenues for future research. The paper will be organized into three sections. In the first section, we will provide a brief overview of the substantive findings of previous studies. The review will be confined to examining studies which treat children's influence (attempts) or parental yielding as a dependent measure. The second section will be devoted to a critique of the existing literature. Finally, in the third section, we will discuss some possible directions for future research.

OVERVIEW OF SUBSTANTIVE RESULTS

In reviewing past research on children's influence, the results indicate that influence varies by a number of different factors. In this section, we will attempt to synthesize previous findings to

discover the sources of variation in influence.¹

Product Type. One important source of variation in children's influence is product type. In general, children seem to have significant influence in product decisions for which they will be the primary consumer (Table 1). For example, children have been found to have substantial impact in decisions for breakfast cereals, snack foods, toys, children's clothes and school supplies. Children also influence decisions about family leisure time activities (such as vacations, movie attendance, eating out and cable TV subscriptions), although their influence is less in these decisions than in decisions for products for their own use. One factor that may partially explain these results is the level of the child's product involvement. Children are likely to view products for their own use as the most personally relevant. Leisure activities should also be child-involving, but to a lesser extent than products that the child uses frequently.

In contrast to the significant role played by children in the child-related product decisions, children have less influence for products that are used by the entire family. This is particularly true when the family products involve substantial financial outlays. For example, children have been found to have little influence in decisions for cars, furniture, televisions and life insurance. Due to the financial risk associated with these family products, it appears that parents prefer to make these decisions without permitting the child to influence them. It is also likely that children perceive products such as furniture as having low personal relevance; therefore, they may not be motivated to influence these decisions. Intuitively, it seems likely that children's influence for any one product will depend on an interaction between the child's product involvement and the financial risks associated with that product.

Decision Stage. Another factor affecting the degree of children's influence in purchase decisions is the stage of the decision process. With one exception (Moschis and Mitchell (1986)), all of the studies examining children's influence across decision stages have used a three-stage model of the decision process. The three stages include problem recognition, information search and choice (Moschis and Mitchell (1986) also included an alternative evaluation stage). In general, children's influence is greatest in the problem recognition stage and

¹In addition to the substantive areas reviewed in this paper, the author initially had intended to include discussions of mass and personal communication effects. However, due to space constraints, these sections were deleted from the paper prior to submission. The reader is referred to Table 1 for a summary of studies which included these variables.

TABLE I
RESEARCH ON CHILDREN'S INFLUENCE

SOURCE	PRODUCTS	DEPENDENT VARIABLE(S)	INDEPENDENT VARIABLE(S)
Atkin (1978)	cereal	parent/child interaction	child's age, child's sex, SES
Belch et al. (1985)	car, TV, cereal vacation, appliance furniture	family member influence agreement in influence perceptions	decision stage, product, subdecision, respondent
Berey & Pollay (1968)	cereal	purchase of child's favorite cereal	child's assertiveness, mother's child-centeredness, mother's brand recall
Brody et al. (1981)	candy bars, chips, chocolate drink, jelly	child's influence attempts, no. of advertised brands requested	exposure to TV ads
Darley & Lim (1986)	movie, family outing, participant sports	children's influence	family type, child's age, locus of control, subdecision
Foxman & Tansuhaj (1988)	child-records, PC, clothes, magazine, bike, toothpaste; family-PC, groceries, cable TV, furniture, toothpaste, car	family member influence agreement in influence perceptions	product, product importance, respondent
Foxman et al. (1989)	same as above	relative child's influence, general child's influence divergence in influence perceptions	product respondent, father's age, family size, mother's work hrs., concept-oriented
Jenkins (1979)	vacation, appliance, car, life insurance, furniture, savings, groceries	children's influence	product, subdecision, demographics
Mehrotra & Torges (1977)	cereal, restaurant, child's clothes & shoes, chips, soft drinks	parental yielding	product, AIO vars., media usage
Moschis & Mitchell (1986)	soft drinks, school supplies, car repair, appliance, child-clothes, records, grooming products	children's influence in decision stages	concept- & socio-oriented family commun., child's age, child's money, child's sex, SES, peer communication
Nelson (1978)	restaurant	child's involvement	decision stage, income, family size, child's age

TABLE I (CONT.)
RESEARCH ON CHILDREN'S INFLUENCE

SOURCE	PRODUCTS	DEPENDENT VARIABLE(S)	INDEPENDENT VARIABLE(S)
Roberts et al. (1981)	children/pet food; gum; clothing/cereal/cookies; snacks	child's influence	mothers' attitudes
Szybillo & Sosanie (1977)	restaurant, family trip	child's influence	decision stage, product, subdecision
Ward & Wackman (1972)	relevant foods, less relevant foods, child-durables, toiletries, other	children's influence attempts	restrictions on child's TV viewing, mothers' time spent w/TV, mothers' adv. attitudes, mothers' ad recall, child's age

SOURCE	RESULTS
Atkin (1978)	Parents refuse younger children's requests more than older children's requests.
Belch et al. (1985)	Children's influence is greatest for cereal & vacation. Children's influence is lowest in choice stage. Child's influence lowest for how much & where for car, how much for vacation, what type of furniture, where for cereal. For cars, husband & child disagreed over child's influence for all subdecisions. For vacations, husband & child disagreed over child's influence in where, how much time to spend & where to stay subdecisions. For cereal, husband & child disagreed over what size, where & when to purchase subdecisions. For problem recognition, husband & child disagreed over child's influence for TV & over father's influence for furniture. Children believe they have more influence than their fathers think they do; children believe fathers have more influence than fathers think they themselves have.
Berey & Pollay (1968)	The more child-centered the mother, the less she's likely to purchase child's favorite cereal. The higher mother's brand recall, the more likely she is to buy child's favorite cereal.
Brody et al. (1981)	Children exposed to ads made more influence attempts than those not exposed to ads. Children requested more advertised brands under coviewing conditions than child viewing alone or no ad conditions.
Darley & Lim (1986)	For movies, external LOC parents perceive more child's influence than internal LOC. Single parents perceived more child influence for where than dual-parents. Older children have more influence for when & specific info. than younger children. For outing, older children have more influence than younger. Older children have more influence for how much to spend than younger children. External LOC parents perceive more child influence for specific info. than internal LOC. For sports, older children have more influence in when, what type, how much, info. gathering, and specific info. than younger children. Internal LOC single parents perceive less influence for all subdecisions except where than internal dual parents.

TABLE I (CONT.)
RESEARCH ON CHILDREN'S INFLUENCE

SOURCE	RESULTS
Foxman & Tansuhaj (1988)	Children have more influence for child than family products. The more important child's toothpaste is to mothers, the less influence children have. The more important is cable TV, the more influence the child has. Mothers & children disagreed over influence for child's records, clothes, magazine, & bike, furniture, groceries & family toothpaste. Children rated their influence as greater relative to parents than did mothers.
Foxman et al. (1989)	Children had influence in suggesting products, paying attention to new products and learning best buy. Children did not get to suggest price range. Family members disagreed over child's influence for child's dress clothes & tooth-paste. Children perceive themselves as having more influence than do parents. The older the father & the more concept-oriented family communication, the less the divergence in influence perceptions. The larger the family & the more the mother works, the greater the perceptual divergences.
Jenkins (1979)	Children have little influence for all products except vacations. Children's influence is lowest for how much, where to stay and transportation mode.
Mehrotra & Torges (1977)	Yielding varies by product.
Moschis & Mitchell (1986)	The more socio-oriented the family communication, the less is children's influence in the stages of alternative evaluation and choice. The more child discusses product consumption with peers, the greater child's influence in all stages but choice. The older the child, the greater the influence in all stages. The more money earned by child, the greater the influence in choice. Females have more influence than males across all stages. The higher the SES, the greater the child's influence in problem recognition.
Nelson (1978)	Younger children have less involvement than older. Older children have less involvement than parents only for choice and how much to spend. The greater the income, the greater child's involvement in choosing type and brand of restaurant. The larger the family, the greater child's involvement in providing info., selecting particular type and brand. Child's influence is greatest for problem, recognition & search, and declines by choice stage.
Roberts et al. (1981)	Children have less influence the more concerned mothers are about nutrition and family financial matters. Children had less influence the more traditional & conservative were mothers.
Szybillo & Sosanie (1977)	Children had more influence in problem recognition & search and less in choice. Children had least influence on how much to spend.
Ward & Wackman (1972)	Parents yield more to older than younger children's requests. Parental yielding decreases as parents place more restrictions on TV viewing. Yielding increases as parents have more positive advertising attitudes and as they spend more time watching TV. Children's influence attempts increase as parents spend more time watching TV and as their brand recall increases. Children's influence is greatest for relevant foods and durables for child's use.

declines significantly by the choice stage (Belch et al. 1985; Nelson 1978; Szybillo and Sosanie 1977).

These results should be regarded with some skepticism, as the range of products over which this pattern has been examined is limited. Specifically, Nelson (1978) and Szybillo and Sosanie (1977) used family restaurants as products. Belch et al. (1985) used a wider variety of products; however, this study included a number of products for which children's influence was low overall (i.e., television, car, furniture and appliances). Additionally, the one other study employing decision stages did not specifically compare influence variations over stages (Moschis and Mitchell 1986).

Subdecisions. In addition to product type and decision stage, children's influence has also been found to vary according to product subdecisions. The subdecisions investigated are adaptations of Davis's (1970, 1971) specific, as opposed to global, index of purchase decisions. The pattern emerging from these studies is that children's influence is lowest in the subdecisions of where to purchase (Belch et al. 1985; Jenkins 1979), gathering information (Darley and Lim 1986) and how much to spend (Belch et al. 1985; Darley and Lim 1986; Jenkins 1979; Nelson 1978; Szybillo and Sosanie 1977). Similarly, Foxman et al. (1989) found that both parents and children perceived that children had low influence in selecting price ranges. Children are more involved in subdecisions regarding color, make/model, and brand choices (Belch et al. 1985; Darley and Lim 1986; Jenkins 1979; Nelson 1978; Szybillo and Sosanie 1977).

Given that parents are the primary socialization agents of children, it appears that they attempt to set bounds on children's influence through decreasing children's roles in the choice stage of the decision process, and in the subdecision of how much to spend. Limiting children's influence in these areas may be one way for the parent to teach the child responsibility and appropriate consumer behavior. It also seems that parents reserve more instrumental (i.e., allocation and scheduling) activities for themselves, and permit more child's influence in the more expressive subdecisions (i.e., color and model decisions). Children may lack the experience necessary to make informed decisions for instrumental activities.

Parental Characteristics. A few studies have investigated how various parental attitudes affect children's influence in decision-making. For example, Berey and Pollay (1968) found mothers' child-centeredness to be inversely related to purchasing the child's favorite cereal. One reason for this may be that child-centered mothers are more concerned with the child's nutrition than are other mothers (Berey and Pollay 1968). Concern over nutrition may reflect these mothers' role perceptions of "what a good mother should do". Along this vein, Roberts et al. (1981) found that children had less influence in decisions when mothers were more traditional and conservative. It appears that parental characteristics, particularly those related to child-

rearing attitudes, may provide high explanatory power in examining children's influence.

Child's Age. Another group of factors having an impact on a child's influence in purchase decisions are characteristics of the child. The most commonly investigated variable here is the child's age. Most studies have found that older children have significantly more influence than younger children (Atkin 1978; Darley and Lim 1986; Jenkins 1979; Moschis and Mitchell 1986; Nelson 1978; Ward and Wackman 1972). This result is due partly to older children's greater cognitive ability, as compared to younger children. Older children also have more experience with products and have learned more about consumer roles. These factors, in addition to developmental level, probably contribute to older children's greater influence in family decision-making.

Family Characteristics. A number of family demographic characteristics may also affect children's influence, although the results are more conflicting here. Some studies have found children's influence to be greater with increased family income (Jenkins 1979) or higher socio-economic status (Moschis and Mitchell 1986). However, Atkin (1978) and Ward and Wackman (1972) found no statistically significant effect for socio-economic status on children's influence attempts. It seems intuitive that children will have more influence in higher socio-economic status families, given that such families are likely to make more purchases than lower class families. However, the literature is not clear on this point.

Another demographic variable that seems likely to affect children's influence is family size. Results here are mixed as well. Jenkins (1979) found children's influence to increase with family size; however, Ward and Wackman (1972) found no significant effect for number of children on children's influence attempts. Speculatively, one might expect family size to have a negative effect on any one child's influence, but that children's influence overall would increase.

CONCEPTUAL AND METHODOLOGICAL CRITIQUE

Based upon a review of the literature, it appears that children's influence varies by product- and decision-related factors, as well as by parental, child and family characteristics. However, there are also a number of problems associated with research in this domain. In this section, we will outline some of the more salient conceptual and methodological limitations of previous research.

Lack of Theoretical Explanation. One of the most glaring oversights in studying children's influence is the failure to provide conceptual justification for the observed patterns of influence. Previous research has been descriptive/relational and a-theoretical. Consequently, we may know that children's influence varies with a number of factors, but, without adequate theoretical development, we cannot answer "why" these variations occur. If we

wish to understand family decision-making, the need for sound theorizing cannot be over-emphasized.

Construct Validity. In addition to a lack of theory, another problem characteristic of research on children's influence has been the lack of attention paid to construct validity. The most noteworthy example of this is the failure to adequately define 'influence'. As Rossiter (1978) notes, there are two aspects to influence, an active and a passive dimension. In this instance, passive influence is characterized by other family members taking the child into account when making a purchase decision, as opposed to the child directly influencing the decision itself.

In spite of Rossiter's clarification, most studies have not distinguished between active and passive influence. For example, Jenkins (1979) notes that "the definition of 'influence' varied from one [respondent] to another. Some perceived only the 'active' dimension ... while others perceived the word to encompass both the 'active' and 'passive' dimensions." The fact that respondents can attribute varying definitions to a term is due to inadequate conceptual definitions in the first place. If the researcher is unclear as to the meaning of a construct, it is no surprise that respondents are unclear as well. It is noteworthy that most studies reviewed here failed to define "influence" conceptually. The net result of this oversight is that respondents assign their own meanings to the concept. As a result, their definitions may or may not be congruent with the researcher's notion of what a term means. In any event, construct validity is a serious issue under these conditions. The failure of most studies to carry out reliability analyses also supports this conclusion (Table 2).

Measures. Another issue related to children's influence is the type of measures used to assess influence. Studies have employed a diversity of operationalizations for influence (Table 3). With one exception (Jenkins (1979) used a constant sum scale), studies have used 3, 5, 6 or 7 point Likert scales to measure influence. Some studies have asked respondents to rate influence separately for family members (Belch et al. 1985; Darley and Lim 1986; Jenkins 1979; Nelson 1978; Roberts et al. 1981), whereas others have included all family members on a single scale (Foxman and Tansuhaj 1988; Foxman et al. 1989; Moschis and Mitchell 1986; Szybillo and Sosanie 1977). In this latter approach, respondents are essentially asked to think about a purchase decision and aggregate the influence of all family members into one global level evaluation in order to respond to the scale. The former approach of having respondents rate influence separately for family members has the advantages of (1) simplifying the cognitive tasks of respondents and (2) collecting data at a more disaggregate level. It is likely that significant information about influence is lost when respondents are asked to make global level evaluations.

Variation by Respondent. Results on children's influence also vary according to who is

the respondent. Many studies have used only parents as respondents (Table 2); therefore, these studies can only provide information about parental perceptions of children's influence. These perceptions may or may not be accurate. Those studies that have included children, as well as parents, as respondents have generally found that children attribute more influence to themselves than their parents attribute to them (Table 1). Differences in perceptions of influence may be due to perceptual biases and/or social desirability effects. Additionally, perceptual divergences may also be a methodological artifact. Surveys, in this instance, may reflect more subjective assessments, whereas observational studies may be more objective (i.e., an observer who is removed from the process independently evaluates "influence"). Clearly, the issue revolves around the interests of the researcher, whether one wishes to focus on subjective perceptions or behavior. Whatever the focus of the study, however, children should be included as they are the relevant unit of analysis in most studies of children's influence.

Method of Data Collection. Another issue related to research on children's influence is the method of data collection. All studies have used mono-method approaches to studying children's influence (Table 2).² With few exceptions (Atkin 1978; Brody et al. 1981), the method of choice has been the survey. The use of a single method within a research domain is problematic in that the results found may be confounded by methodological artifacts (McGrath 1982). The rival explanation that results are due to research method cannot be discounted when only a single method is used. Thus, the associations found between children's influence and various factors may be due to the use of surveys rather than to any "true" association. The observational study by Atkin (1978) mitigates against this conclusion; however, more observational studies need to be done before we can have confidence in the findings.

The use of surveys has a number of advantages, such as time and cost reductions, and the potential for large sample sizes. However, there are also a number of problems associated with their use. As previously mentioned, surveys may be more inter-subjectively biased than are observational studies. In addition, the use of surveys assumes that respondents have adequate recall of phenomenon and can report this information (i.e., they are capable of performing the "mental algebra" necessary to respond to the instrument (Nisbett and Wilson 1977)). Finally, the use of surveys is problematic in dealing with young children who generally lack the cognitive ability to respond to test items. Although it is possible to circumvent this problem by using interviews, the usual approach has been to exclude children as respondents and use only

²Berey and Pollay (1968) used different methods to assess different variables; only one method was used per variable.

TABLE 2
CHILDREN'S INFLUENCE: RELIABILITY, VALIDITY AND SAMPLE CHARACTERISTICS

Source	Sample	Method of Data Collection	Reliability	Validity*
Atkin (1978)	516 parent-child dyads; nonrandom; children 3-12 years	observational, cross-sectional	not reported	very low
Belch et al. (1985)	260 husband, wife, child triads; nonrandom; child over 13 yrs. living at home	survey, cross-sectional	not reported	very low
Berey & Pollay (1968)	48 mothers & children; nonrandom; children 8-11 yrs.	interview, survey, observation; cross-sectional	chi-sq. analysis on mother response x interviewer; no diff. found	low
Brody et al. (1981)	57 mother-child dyads; nonrandom; children 3-5 yrs.	experimental	.83 inter-judge agreement	high
Darley & Lim (1986)	106 parents (66% mothers, 33% fathers); nonrandom; children 1-17 yrs.; middle class	survey, cross-sectional	not reported	low
Foxman & Tansuhaj (1988)	193 mother-child dyads; nonrandom; children 11-18 yrs.; middle class	survey, cross-sectional	not reported	very low
Foxman et al. (1989)	161 husband, wife, child triads; nonrandom; children 11-18 yrs.; middle class	survey, cross-sectional	not reported	low
Jenkins (1979)	105 married couples; nonrandom; children 1-19 yrs.; middle class; recruited by marketing research firm	survey, cross-sectional	not reported	very low
Mehrotra & Torges (1977)	1,671 mothers; nonrandom; Market Facts mail panel	survey, cross-sectional	not reported	very low
Moschis & Mitchell (1986)	161 mother-child dyads; nonrandom; children in junior & senior high school	survey, cross-sectional	Cronbach's alpha ranged from .51 to .76	moderate
Nelson (1978)	84 parents (1 parent responds per family); nonrandom; upper- to middle-class	survey, cross-sectional	not reported	very low
Roberts et al. (1981)	1,150 mothers; nonrandom; Needham, Harper & Steers mail panel	survey, cross-sectional	Cronbach's alpha ranged from .51 to .78	low
Szybillo & Sosanie (1977)	190 wives, nonrandom; child at least 5 yrs. old; upper- to middle-class	survey, cross-sectional	not reported	very low

TABLE 2 (CONT.)
CHILDREN'S INFLUENCE: RELIABILITY, VALIDITY AND SAMPLE CHARACTERISTICS

Source	Sample	Method of Data Collection	Reliability	Validity*
Ward & Wackman (1972)	109 mothers; nonrandom; children 5-12 yrs.; upper & middle class	survey, cross-sectional	not reported	low
*NOTE: Very Low - lack of reliability; inadequate or absent construct definitions; no controls				
Low - reliability tested; constructs poorly defined OR reliability untested; constructs defined				
Moderate - reliability tested; constructs adequately defined; no controls, covariates, or random assignment				
High - reliability tested; constructs well-defined; controls, random assignment used				

parents. Thus, in some situations, other techniques such as interviews or observation may be more appropriate.

Statistical Techniques. A final consideration in this domain of research is the method of data analysis. Most of the studies have used chi-square analysis, ANOVA or MANOVA to test various associations. One problem that may occur in using these techniques is violation of the nonindependence assumption. The techniques are especially sensitive to this violation. When multiple respondents from the same family are used, one would expect their responses to be correlated with each other, and therefore, nonindependent. Yet studies examining divergences in family member perceptions use analyses of variance on these nonindependent samples in order to assess differences. It is not surprising that these studies find highly divergent perceptions as the type 1 error rate is seriously inflated when the nonindependence assumption is violated. Additionally, many studies test numerous relationships within the context of a single sample and study, while failing to adjust the alpha level accordingly. When one fails to adjust alpha in response to numerous tests, significant results may be due partly to chance. Therefore, it is small wonder that five or seven results are significant when the researcher has tested thirty or more relationships, a common occurrence in research on children's influence.

Summary. In summary, there are a number of problems associated with research on children's influence in purchase decisions. Inadequate conceptual definitions and lack of reliability raise serious construct validity concerns. Children are often excluded from the analysis even though children's influence is the subject of study. The use of a single method, usually surveys, gives rise to the rival hypotheses that results are method related. Additionally, surveys have a number of limitations that are especially problematic in this domain, including the inability of young children to respond to test instruments and potential subjectivity biases. Finally, this research domain is hampered by inflated alpha levels; consequently, some

associations found may be due to chance. It appears that many of these problems stem from a lack of sound theorizing (i.e., problems with construct validity, reliability, and inflated alpha levels due to testing numerous relationships instead of a few theoretically relevant relations). Others are more methodological in orientation (i.e., exclusion of children, use of single methods and surveys, misuse of statistical techniques). In conclusion, research on children's influence needs to be improved on both theoretical and methodological grounds.

DIRECTIONS FOR FUTURE RESEARCH

Although there are a number of problems associated with previous research, there are also a number of possible means of addressing the issues raised. Our goal in this section is to highlight some possible directions for future research, in order to build on past work and to increase our understanding of children's influence.

One means of contributing to our knowledge of children's influence is to incorporate stronger theoretical explanations in our research. There are a number of potential candidates in this regard. Within marketing, Corfman and Lehmann (1987) developed a model of spousal decision-making that could be expanded to include children. There are also a number of sociological approaches to studying the family that may also prove fruitful in this respect. Role theory, particularly the age-graded approach of Parsons and Bales (1955) and the more dynamic role orientations of symbolic interactionists, seems especially promising. Social learning theory may also offer high explanatory power in some instances.

Another direction for future research is concerned with issues related to construct validity. Clearly, construct validity will continue to be problematic until we conceptually define "influence". Rossiter's (1978) distinction between passive versus active influence seems to be a particularly useful one. Researchers must decide what dimension of influence they wish to probe and make this distinction clear to respondents. It also seems

TABLE 3
CHILDREN'S INFLUENCE: MEASURES AND SCALES

Source	Dependent Variable(s)	Independent Variable(s)	Measures & Scales
Atkin (1978)	parent-child interaction	child's age child's sex SES	initiation, response 3-5, 6-8, 9-12 yrs. middle, working
Belch et al. (1985)	family member influence	product decision stage subdecisions	6 pt. Likert (1=no influence; 6=all the influence); rated for each member for each product in all stages and subdecisions problem recognition, search, choice where & when to purchase, how much to spend, style, make and model decisions
Berey & Pollay (1968)	purchase of child's favorite cereal	child assertive mother child-centered mother's brand recall	pantry check; summed index (5 pts. for child's first choice, 4 pts. for second, 3 pts. for third, 2 pts. for other, 1pt. subtracted if out-of-stock) 3 pt. Likert (1=rarely, 3=often) for 4 components of assertiveness (verbal, leadership, persists, initiates) 3 pt. likert(1=rarely, 3=often) for frequency of participation in child activities summed index (5 pts. for each of child's brands recalled)
Brody et al. (1981)	children's influence attempts no. of advertised items requested	exposure to ads	observed; child's independent request for advertised item 3 conditions (child alone viewed, dyad viewed, control-no ads)
Darley & Lim (1986)	child's influence	family type child's age factor locus of control (parents) subdecision	5 pt. Likert (1=never influential; 5=almost always influential) for all products and subdecisions single- vs. dual parents high, low Rotter's Internal-External LOC Scale; 23 yes-no items (0-11 internals, 12-23 externals) when & where to go, how much to spend, what type, gathering info., specific info., initial suggestion
Foxman & Tansuhaj (1988)	family member influence		5 pt. Likert (1=parents alone, 2=parents more than child, 3=equal say -parents & child, 4= child more than parents, 5=child alone) for all products

TABLE 3 (CONT.)
CHILDREN'S INFLUENCE: MEASURES AND SCALES

Source	Dependent Variable(s)	Independent Variable(s)	Measures & Scales
Foxman et al. (1989)	relative child's influence	product product importance	6 pt. Likert (1=really import.; 6=really unimport.)
	general child's influence		5 pt. Likert (same as in Foxman & Tansuhaj) for products 5 pt. Likert (1=strongly agree, 5=strongly disagree) that child has influence for 7 activities (suggesting prices, stores, brands & products, co-shopping, learning best buy, paying attention to new products)
Jenkins (1979)	children's influence	product children's influence	100 pt. constant sum scale (100 pts. allocated between husband, wife, child for each product and subdecision)
Mehrotra & Torges (1977)	parental yielding	product subdecision (vacation)	info. collection, whether to take child, how long to stay, when, how to get there, how much to spend, lodging, where
		product AIO variables media usage	Not Reported 37 items (1 item arbitrarily selected from each of 37 scales) what TV shows watched & magazines read
Moschis & Mitchell (1986)	children's influence in decision stages	family communication	3 pt. Likert (1=parents, 2=child, 3=both) summed over products 5 pt. Likert (1=never, 5=very often); summed over 6 items for each of 2 types of family communication
		peer communication	5 pt. Likert (1=never, 5=very often); 8 items summed
		demographics money child earns	child's age & sex, SES
Nelson (1978)	child's involvement	decision stage	4 pt. Likert (1=not involved, 4=very involved) for husband, wife, child for all products and decision stages problem recognition, search, choice, restaurant type & brand, how much to spend
		child's age	age of youngest child (under 5 yrs., over 6 yrs.)
		family income family size	
Roberts et al. (1981)	child's influence		4 pt. Likert (1=almost all the time, 4=never) for products

TABLE 3 (CONT.)
CHILDREN'S INFLUENCE: MEASURES AND SCALES

Source	Dependent Variable(s)	Independent Variable(s)	Measures & Scales
		mother's attitudes	6 pt. Likert (agree to disagree) for 10 attitude scales
Szybillo & Sosanie (1977)	family member influence		7 pt. Likert (1=husband(H), 2=wife(W), 3=H & W, 4=child(C), 5=H & C, 6=W & C, 7=H & W & C) for all products, stages
		product decision stage subdecisions	problem recognition, search, choice when, what type, what brand, how much to spend
Ward & Wackman (1972)	child's influence attempts parental yielding	parent-child interaction mother's mass communication behavior	4 pt. Likert (1=often, 4=never); frequency of attempts for products % yielding parent-child conflict, restrictions on child's TV viewing mother's time spent with TV, attitudes towards advertising and ad recall

likely that the type of influence characterizing a purchase decision will depend in part on product type. Specifically, one might expect children's influence to be active in child-related product decisions, and passive in the more risky family-related product decisions. Making the conceptual distinction between active and passive influence will allow us to test these, and similar, propositions.

Another promising avenue for research on children's influence is further investigation of the effects of parental and child characteristics on influence. Up to this point, these variables have been given only a cursory treatment in the literature. However, one would expect these factors to be of primary importance in studying children's influence. Past studies on parental characteristics point to the potential contribution of parental attitudes in explaining children's influence. It seems likely that parental attitudes related to child-rearing practices would be especially critical, particularly for younger children. These sorts of relationships should be further clarified and developed. Similarly, for child characteristics, there is a need to go beyond merely examining the child's age, and to include other theoretically relevant variables, such as the child's product involvement and his/her attitudes towards parents. The explanatory power of many of these variables has remained virtually untapped; clearly, more work needs to be done in these areas.

Given that most of the studies reviewed here used surveys to investigate children's influence, another means of improving our understanding of the phenomenon is to make greater use of observational studies. This is not to say that

surveys should be abandoned, rather that the limitations of this method can be compensated for by observation, and vice versa. Observational studies may reduce subjectivity biases, and offer additional insights into how families actually make decisions. In any event, multiple methods are desirable in and of themselves in that they permit increased confidence in findings that are consistent across methods.

An additional means for improving our understanding of children's influence is to make more appropriate use of statistical techniques. As previously noted, inflated alpha levels have been problematic in past research on children's influence. When testing numerous relationships, researchers should control the experiment-wise error rate to avoid capitalizing on chance. If family members' responses are expected to be positively correlated, multivariate analyses which treat each member's responses as repeated measures can be employed. If the researcher is interested in assessing divergences in family members' perceptions, it may be appropriate to test at a more stringent alpha level, as non-independence tends to result in more liberal tests in this situation (see Judd and Kenny (1981) for a more thorough discussion of independence issues).

Finally, past research on children's influence has tended to use the nuclear family as the normative criterion of study. Only one study (Darley and Lim 1986) has examined children's influence under different family forms. This is surprising given a recent study's estimate that 60% of today's children will live in a single-parent household sometime

during their childhood (Norton and Glick 1986). What implications do alternative family forms have for children's influence? By failing to consider different family structures, we have in essence confined our analyses to one subset of children, namely those from intact households.

CONCLUSION

In conclusion, previous research on children's influence has been a-theoretical and empirical. Based upon a review of the literature, children's influence was found to vary with a number of factors. However, due to the limitations associated with past studies, we cannot explain why these patterns of influence exist. It appears that research on children's influence needs to be improved on both theoretical and methodological grounds. Until this occurs, our understanding of the phenomenon will continue to be incomplete and fragmentary. It is hoped that the proposals offered here will serve to stimulate future research and debate in this area.

Toward An Understanding of Social and World Systemic Processes in the Spread of Consumer Culture: An Anthropological Case Study

Janeen A. Costa, University of Utah

ABSTRACT

Recent theoretical discussions and empirical presentations concerning the origin and spread of mass consumer culture have asserted widely differing geographical and temporal sites for these developments. This case study explores the usefulness of a diachronic world systemic approach constructed by Wallerstein for analysis of production, applied here to consumption behavior. Consumption of non-essential products appears in upper, middle and lower classes at different points in time. The data indicate that a full understanding of these social and economic processes can be obtained only when production, distribution, and consumption are analyzed together.

The world system of the last four centuries has witnessed the spread of industrial production and an emphasis on material consumption. Historically, the "consumer revolution" occurred in certain areas of Western Europe at different times. The diffusion process of global consumer culture is one which is not yet complete. The case study presented here provides empirical support in an exploration of the following theoretical assertions: (1) Production, distribution, and consumption go hand in hand and cannot be analyzed separately; (2) Material accumulation in consumption behavior penetrates the social fabric unevenly, affecting people in different social classes at different times; (3) The data support the use of world systems theory as an analytical tool.

THEORISTS AND THEORIES CONSIDERED

Numerous theorists have addressed issues about the origin and spread of consumer culture. Following Braudel's *tour de force* on European life from the 15th to 18th centuries (1981, 1982, 1984), a number of scholars have analyzed in depth the social and economic features of European life during the rise of capitalism. Of particular interest are works exploring the geographic and temporal beginnings of mass consumption behavior. While many of these theorists present important data relevant to the issues at hand, they often lack a systemic diachronic perspective which, when utilized, illuminates both historical and present-day patterns of the origin and diffusion of consumer culture.

In reviewing recent literature on the topic, certain authors stand out as examples of the theoretical and empirical research typical of this area of exploration. All theorists in question mark the notable association between the rise of capitalism and the consumer revolution. As such, their focus on Europe is not surprising. They vary, however, in their interpretation of the role of consumer ideology in capitalism and the specific time and place for the

rise of mass consumer culture. Mukerji (1983) suggests that consumption was a prime moving force in the development of capitalism and existed prior to the rise of the capitalist mode of production; her data are drawn from the 16th and 17th centuries in the Netherlands. Campbell (1987) and McKendrick, Brewer and Plumb (1982) believe 18th century England was the original site of consumer culture, but Campbell relies on an exegesis of the "romantic attitude" whereby a utilitarian version of consumption was replaced by an "hedonistic outlook" which spurred the development of the "spirit of modern consumerism." McKendrick, Brewer and Plumb, on the other hand, emphasize the "commercialization of fashion" as the primary 18th century innovation responsible for the birth of mass consumer culture. Williams (1981) sees the 19th century French as pioneers in advertising and retailing and describes the Paris expositions of 1899 and 1900 as triggers to the development of department stores and the evolution of mass consumption behavior.

Unlike the other scholars described, McCracken (1988) addresses more directly the systemic nature of the rise of consumer culture. He explores the analyses of Mukerji, Williams, and McKendrick, Brewer and Plumb as "crucial moments in the history of consumption" (1988:28). McCracken implicitly recognizes the way in which various regions of Europe are integrated through production and consumption patterns, but he does not deal explicitly with world systems theory. The analysis presented in this paper indicates the usefulness of Wallerstein's (1974, 1980, 1989) exploration of the world-economy as an underlying theoretical construct in the analysis of the origin and spread of consumer culture.

While Wallerstein is concerned with capitalism as a form of production, his findings have important implications for the study of capitalist forms of consumption as well. Briefly, Wallerstein has asserted that the international or world economic system as we now know it was formed in the "long sixteenth century," when capitalism spread across political boundaries, and an unequal, diversified international division of labor evolved. The European world congealed into core, semi-peripheral and peripheral regions with specific political and economic characteristics. This system perpetuates itself and has continued to exist in similar form, albeit with varying details, to the present time. Core regions are those parts of the world system which have strong state machineries and manufacture and market industrialized goods; peripheral areas are characterized by weak central governments, the consumption of goods manufactured elsewhere, and the export of human labor and raw goods. In the 20th century, peripheral areas often host factories from the "developed" or

core portions of the world, without realizing many material benefits of the industrialized production sites located in their country by foreign capital. Semi-peripheral areas are former core regions of the world system, de-industrializing as the core of the system shifts from one locus to another.

Central to the core/periphery/semi-periphery distinction is the systemic interaction of the sectors. The relationship between the core areas and the peripheral regions serves to maintain the economic status quo and the uneven politico-economic power structure. Cores benefit as capital and inexpensive human labor flow into their sector of the international economy from the periphery and semi-periphery.

Importantly, this relative position changes over time, so that historically the "core" of the world economy shifted from Spain to France, Belgium and the Netherlands and eventually to England over time. The expanding production and capital accumulation in the Pacific Rim today may signal the ascendancy of that region into the "core" of the world economy. Similarly, patterns of mass consumption arose at various times in Europe and reflected the shifting position of regions and the intimate systemic interaction of those regions to the extent that changes in one area precipitated changes in other areas. Utilizing this approach, it is not surprising that the theorists mentioned have come to the conclusion that various sites were important in the origin and/or spread of mass consumption. Like McCracken, however, we must reach the conclusion that the development of consumer culture is an ongoing process, the specific details of which vary over time and space. (See Belk 1988 for an excellent discussion of mass consumer culture developing in the Third World.)

As in production, we can observe differences in consumption which affect and are affected by the relative position of the nation or region in the world economy as core, periphery or semi-periphery. In the fully developed economy of the core region, broad consumer choice is markedly evident. A full range of goods and services is available, with notable variation in price and quality within each product category. This variation accommodates the needs and desires of all classes and professions in the fully fleshed-out and complex social structure of the core area. Locally manufactured items are abundant, while raw goods and food often come from outside the industrialized region. In contrast, consumption in the periphery is marked by fewer overall total goods and less variety in the full product range as well as within a product category. Because manufacturing is limited or non-existent, items of local origin are not available and/or are undervalued in comparison with foreign-produced goods. Finally, as with production, the consumption patterns of the semi-periphery are transitional between those of the core and those of the full periphery. The availability of goods declines and consumer choice becomes more and more restricted over time.

In addition to gaining insight into patterns of consumption through the use of the core/semi-periphery/periphery distinctions, the case study presented here provides information on two other important theoretical issues. First, it is clear that the concept of social class is necessary in order to fully understand the reported behavior historically. The emphasis on material accumulation and the ability to accumulate penetrated the social fabric unevenly, affecting the lower class of landless laborers, the rising middle class, and the nobility at different times. Furthermore, an analysis cognizant of the dimension of class and the utility of a world systems approach addresses another important theoretical issue: production, distribution, and consumption *must* be analyzed together. Wallerstein over-emphasizes production, for example, while McCracken stresses consumption to a near exclusion of production. The "revolution" was one of all aspects of the socio-economic system, involving production, distribution and consumption, but affecting different regions and different classes at varying times. While this understanding is implicit in the analyses of these theorists, it must be made explicit. Marx, on the other hand, clearly points to the dialectical interactions of production and consumption in the capitalist system (1930). The concise description of these behaviors as they evolved socially and temporally in the case study presented here illustrates the intimate connections between changing patterns of production and distribution and forms of consumption.

THE CASE: METHOD AND SETTING

Information for the following case study was collected during several weeks in the summers of 1978, 1986 and 1987 and during a year-long period from November 1979 to October 1980. The author participated in and observed the changing lifestyle of residents of the island of Cephalonia as they were affected by circulating migrants and Greek and foreign tourists during these times, with particular emphasis on the village of Sami. With the help of a local research assistant, a demographic and socio-economic survey of the village was conducted for both the winter population of 600 and the summer population of 3,000, swollen by returning migrant family members and tourists. Lengthy and numerous depth interviews were conducted with key informants throughout the several phases of research as well. Finally, archival research was undertaken at the Corgialenios Library and Archives in Argostoli, Cephalonia and at the Gennadeion Library in Athens. In the following pages, the origins and spread of a consumption ideology emphasizing material accumulation over time in the developing social classes is outlined. The paper concludes with an exploration of consumer culture and two of its agents--the migrant and the tourist--in modern Greece. (See Aschenbrenner 1986 for a discussion of similar processes in another Greek village; see also Hughes 1943, Srinivas 1976).

The island of Cephalonia lies to the west of the Peloponnesian Peninsula in Greece and is the

largest of the islands in the Ionian Sea. Irregularly shaped and ruggedly mountainous, the island is approximately 15 miles wide and 25 miles long. The soil is relatively infertile and rocky, with few areas of cultivable level land. From early times, Cephalonia was an important strategic landfall, control of which became increasingly desirable as political powers vied with one another for domination of the Mediterranean and trade with the Levant. Later, Cephalonia became an economic asset in its own right with the introduction of the currant crop and the extensive reliance on the currant as an important part of the import and export ventures of the Venetians and the British (Goodisson 1822).

For several centuries leading up to the end of the 19th century, the larger valleys were owned by aristocratic families, members of a nobility which became entrenched during the lengthy period of indirect and direct Venetian rule. The majority of the island's inhabitants were landless laborers and small landowners who depended on the large landholders and their magistrates to provide seed, purchase crops, and facilitate access to markets. While the population of Cephalonia has fluctuated throughout the several thousand years for which historic and prehistoric evidence exists, it is unlikely that the population ever rose above 100,000.

Since the middle of the twentieth century, Cephalonians have emigrated in large numbers, and the census of 1981 registered only 27,649 inhabitants. Depopulation in this century is a result of the continuing spread of an ideology of consumption, combined with the perceived need to migrate in order to obtain sufficient income to meet expanding consumer needs and wants.

Attitudes and beliefs conducive to the eventual evolution of a mass consumer culture are evident in early historical periods in Greece. Mercantile capitalism and urbanization in Classical and Roman Greece combined to create a demand for certain consumer goods, and prestige was awarded to those who were able to undertake particular lifestyles associated with material accumulation. As the Greek distribution network spread, commercial ports were established along the coasts throughout the Mediterranean. The trade goods were primarily luxury, "non-essential" products, ownership of which required a certain amount of wealth and, in turn, conveyed status. Trading with Egypt and the Levant, Greek and Roman merchants returned to their homes with lapis lazuli, ivory, and glass. Precious metals and gems were acquired in exchange for surpluses of olive oil, wine and grain produced locally. Costly Roman funeral incense is an excellent example of an expensive, rare product utilized by the wealthy as an indication of prestige (Johnson 1987).

The number of people able to engage in the accumulation of such desirable objects was small and confined primarily to the wealthy class. Furthermore, the wealthy appear to have exploited their economic and political power during times of

general governmental weakness to maintain and increase their material wealth and consumption of luxury products at the expense of the poor (see Bon 1951, Costa 1983). However, there are indications that peasants and laborers sought the same consumer goods but found it difficult to obtain them. While an ideology emphasizing a certain consumer behavior pattern may exist, it cannot be enacted without the productive means, and such means did not exist for the majority of Greek society.

Distribution in the form of merchant shipping expanded in the Mediterranean in the eleventh century under Byzantine influence and the escalating activities of Norman conquerors. Into the 12th and 13th centuries, periods of rampant piracy, Cephalonia was sought as a strategic landfall with calm ports suitable for both military and merchant activities (Cosmetatos 1976:103). Under the various Norman and Frank rulers, the position of Cephalonia evolved from one of independence, to indirect rule as leaders were forced to ally with Venice for protection, to one of direct rule by the Venetian power.

The small middle class continued to trade in preciousness, as well as agricultural products, wine, and oil during this period. Land was being concentrated in the hands of a few, and a rigid upper class with distinctive consumption behaviors was developing. In the 14th century, some Cephalonian women were weaving silk, and their husbands were exporting the cloth (Froissart 1397). Tax revenues from the island were high and were an indication of general prosperity (Kirkwall 1864; Pratt 1978).

As Venice consolidated her hold over Cephalonia, production and consumption patterns and class formation responded. The period of direct rule, 1502-1798, witnessed the crystallization of a feudal system whereby individuals were granted fiefs and the nobility became entrenched in the rural parts of the island. Peasants produced surplus for the aristocratic landholders, who used the products to support a consumption lifestyle that can only be termed "lavish" when compared to that of the typical Cephalonian. Importantly, it was during the Venetian period in Cephalonia that the international or world capitalist economy described by Wallerstein was evolving in Europe. Prior to that time, empires, rather than world economies, existed, and it is not possible to characterize Cephalonia or any other region of Europe as core, periphery, or semi-periphery, since the international division of labor discussed by Wallerstein had not yet come into being.

With the introduction of the currant crop in the early 1500's, a shift from subsistence agriculture to commercial production for the international market occurred. This alteration had important implications for the lifestyle and consumption patterns of the nobility and evolving middle class of merchants and shopowners dependent on the currant trade for their livelihood. Using accumulated proceeds from currant production, large landholders purchased and consumed luxury foreign goods, "woollen or silk fabrics with caviar, coffee, and

spices from the orient" (Pratt 1978:37), as well as sugar and rice. Clothing varied by class, and, as in other parts of Europe, the type of clothing worn was proscribed for certain individuals in order to maintain distinct class identities; "wigs were worn in society" (Cosmetatos 1976:25). Nobles wore clothing made from fine imported fabrics and lace; trousseau lists indicate a similar reliance on foreign-made materials and objects among the wealthy. In the 1600s, the wealthy began to use imported linen from France, muslin from Constantinople, and Belgian lace in their clothing. Imported knitted stockings appeared in Cephalonia at the same time. Even during periods of economic decline, nobility continued to purchase and wear fine clothes in order to maintain social status. By the late 1800's, rich families often had their daughters' trousseaux prepared abroad (Ibid: 65).

In the 16th and 17th centuries, aristocrats who aspired to Venetian government posts were obliged to own houses in the growing towns, in addition to their country estates. By the late 18th and early 19th centuries, these homes were large and boasted extensive gardens. For the first time in Cephalonian history, the interiors were heavily decorated (Cosmetatos 1976). Italian artists were brought to the island to paint ceilings and murals. "Carpets, rugs, curtains, furniture, monumental bedsteads from Birmingham, paraffin oil lamps and China in the ubiquitous willow pattern were imported to stuff every room to capacity" (Ibid.: 50). Furthermore, "each of the houses contained a modern pram, as much a status symbol as was a knowledge of French for young marriageable girls" (Ibid.).

The rising middle class owed its existence to trade and consisted primarily of merchants, owners of ships, and ship captains. Their consumption patterns over time reflected growing affluence and a dependence on commerce, and their trousseau lists show the use of imported cottons and the late 16th and 17th century apron, fashionable throughout Europe by this time. As they continued to travel abroad for purposes of income production, they added more foreign products to their dowries, including furniture for their homes. In this consumption behavior, as with those discussed above, they emulated the patterns of the local and foreign nobility, who began to consume these "luxury" goods at an earlier point in time.

While the nobility and middle classes used their income from commerce to support comparatively lavish lifestyles, however, the peasants produced and sold the currants merely to survive. Throughout the Venetian and British periods and into the mid-20th century, the lower classes of the island continued to produce and consume at a near-subsistence level. Living in small one-room houses with dirt floors and few pieces of furniture, peasants wore home-spun clothing and ate simple diets of bread, olive oil, cheese and gathered greens. Meat was consumed perhaps once or twice a year at Christmas and Easter and only when an animal was available for slaughter. The consumption of any type of "luxury"

good was out of the question and well beyond the means of the majority of Cephalonians.

The data indicate increasing integration of the local level with extra-local levels, as the aristocrats and the middle class exemplify changes in production, distribution, and consumption associated with contact with European society and Levantine trade. During the Venetian period, however, Cephalonia was directly attached to a part of the world economy--Venice--which Wallerstein refers to as "semi-peripheral," a de-industrializing, formerly powerful sector of the international politico-economic system (1974, 1980). The decline would continue and accelerate through the British period, 1815 to 1864, and into the modern phase of Cephalonian history. As it did, relative wealth and affluence characteristic among the upper echelons of society during the early Venetian period declined as well. By the end of the British era, numerous aristocrats and merchants had emigrated from the island (Costa 1983, 1988b; Markopoulou 1967). In the modern period, Cephalonia and the other Ionian islands became part of a "peripheral" sector of the world economy--Greece. Utilizing world systems theory as it applies to Greece today, the weak central political organization, and the role of Greece as exporter of raw goods and, importantly, human labor, as well as importer and consumer of foreign manufactured goods, place Greece in this "peripheral" category.

As the focus narrows specifically to Cephalonia, it is clear that the island is now a peripheral *region* of a peripheral *country*. Cephalonia has "exported" 75 percent of its human population in this century. As that population returns periodically in the circulating migration pattern, Cephalonians become exposed to foreign manufactured products and, in turn, acquire the desire to obtain these products themselves. Eventually, local storeowners import the goods from companies located in Athens or Patras who have themselves imported the items originally from foreign sources. Like migration, tourism exposes Cephalonians to similar processes of change in consumption, distribution and production.

Feudalism began to decline during British rule from 1815 to 1864; land reformations and redistributions under the modern Greek government secured the total demise of the feudal system, as large landholders lost most of their land and the control of peasants attached to the land. Agricultural production in Cephalonia today is primarily to supplement income earned in other ways. In 1980, full-time agriculturalists made up only thirteen percent of the heads of households in the main village under study. Typical non-agricultural economic activities include shopkeeping, wage labor in construction, fishing and herding, employment in the merchant marine, and work in hotels, restaurants or other service-oriented businesses. The latter have become increasingly profitable as Greek and foreign tourists visit the island more frequently and in greater numbers since 1975. Employment in the merchant

marine has been a common pursuit for Cephalonians for several centuries. With respect to the issue at hand, various forms of migration and increasing tourism in Cephalonia are important factors in the spread of a consumer ideology throughout the social fabric of this island. For the first time in history, the lower classes have the productive means to pursue mass consumer culture.

The patterns of migration have had a particularly important impact on the consumption behavior of Cephalonians. Beginning at the turn of the 20th century, lower class Cephalonians joined the thousands of other Greeks migrating to the United States to take advantage of economic opportunities at a time when the local economy was collapsing (Costa 1983, 1988b; Saloutos 1964). The numbers involved in emigration from Cephalonia were not large enough to markedly affect local life as yet, and return migration either on a temporary or permanent basis was rare in this early period. By the 1950's and 60's, however, migrants were beginning to retire to the island, bringing with them savings accumulated during their lifetime abroad, as well as tastes for goods and services to which they had become accustomed. They often brought with them prized possessions in the form of clothing and household objects to be displayed prominently to the community (see Costa 1989a, 1989b). Infrequently returning male migrants seeking a bride earlier in the century also wore expensive clothing and jewelry and brought lavish gifts, such as gold jewelry and fine clothing, to their families and prospective in-laws.

It was only in the 1960's and after, however, that migration was so extensive and of a particular type that remarkable changes began to occur in the consumption behavior of the majority of Cephalonians, and a local "mass consumer revolution" occurred. At this time, the migration point of destination changed to Athens and other cities of Greece, as well as to parts of Western Europe, particularly Germany. These sites were comparatively closer to the island, and, especially as transportation networks developed and became more efficient, migrants began to engage in seasonal circular migration. In this pattern, migrants return during the summer and at Christmas and Easter holidays, visiting their families and bringing with them consumer objects from the world outside Cephalonia.

As did the permanently returned migrants, the circulating migrants bring with them their newly acquired tastes for goods and services heretofore unavailable on the island. Their consumer needs and wants have spurred the development of local businesses to cater to them. Furthermore, migrants have become a particularly effective avenue for the transmission of a consumption ideology to those who have not yet left the island. This ideology favors the acquisition and use of goods produced outside the island and, most often, outside Greece altogether. Such products include major and small appliances, Western-style clothing, stereos, televisions, radios and cameras, furniture, household

decorative items, distinctive foods and beverages, modern bathroom and kitchen fixtures, Western music and forms of entertainment including bars, discotheques, and movie theaters, and European or American cars, trucks and motorcycles (see Costa 1988a, 1988b, 1989a, 1989b).

The close connections between consumption, distribution and production behaviors are obvious here. Individuals undertake new production behavior through migration, transmit new consumer tastes to their families and friends in Cephalonia, who then undertake the consumption behavior themselves, as well as new production in the form of opening businesses to cater to local and migrant needs. Distribution systems develop and expand to respond to the increasing traffic in goods and people. In addition, Cephalonians who have not migrated previously may do so after contact with returning migrants in order to obtain adequate income to support new consumption behavior. Production, distribution and consumption clearly operate in a feedback system.

In addition to migration, tourism has been an important factor in exposure to new forms of consumption. Both foreign tourists and elite Greek tourists from Athens and Thessaloniki have increased in numbers in the last several years, and their influence on local consumption behavior is evident. Foreign tourists, primarily from France, Italy, the Netherlands and Germany, bring with them new fashions and new technology from outside of Greece. Local Cephalonians often admire the products and take steps to acquire them. Again emphasizing the intimate association of productive efforts, distribution and consumption patterns, some Cephalonians open stores or increase their inventories to make these items available to island residents, circulating migrants and tourists. Production in services expands as well, as hotels, restaurants, and entertainment sites increase in number, and transportation and communication networks develop. Greek tourists from Athens and Thessaloniki, like circulating migrants, become an effective avenue for transmission of consumer ideology from the urban to rural areas of Greece. Bringing with them desirable goods and a demand for certain products, they influence local tastes and are accessible models for emulation.

Throughout the periods in question, the *content* of the culture of consumption itself has varied by class. The nobility and upper echelons of modern Greece have made and make consumption choices on the basis of peer influence. In the past, aristocratic families created and maintained ties throughout various parts of Europe and shared consumption patterns involving luxury, high-cost goods prevailed. The modern consumer of the Greek upper classes today continues to maintain international ties, and his/her consumption choices reflect that contact. Purchasing and owning expensive, durable items from abroad is commonplace and not often singled out for comment by consumers. Members of this class participate fully in the consumption of services as well.

On the other hand, it is quite clear that ownership of items from foreign countries is still somewhat exceptional among lower-class Greeks, although it is becoming increasingly common and is a mark of prestige. These goods are often acquired through the productive efforts of migrants or members of the merchant marine (Costa 1989a, 1989b). There is a greater willingness to accept less expensive alternative goods which break easily or wear out quickly, and services are rarely used. Thus, villagers learn about and acquire valued goods through members of their own family, neighbors whose migrating kin have returned from abroad, or tourists.

In the past, the developing middle class seemed to emulate the wealthy in their consumption choices. Since a significant portion of this class, however, was and is productively based on commercial trade abroad, they have been exposed to and seek to acquire foreign goods to which they themselves have been exposed personally. In many cases, the members of this class were once aspiring lower class laborers and peasants of Greece who have become the migrating kin responsible for the transmission of consumer ideology and goods from outside the island to Cephalonia itself.

CONCLUSIONS

This paper has attempted a preliminary exploration of the development and spread of a consumer ideology among various social sectors in Cephalonia, Greece. While an attitude favoring consumption of non-essential products is evident among the upper classes of Greek society from an early period in history, the ideology and behavior in the middle and lower classes required the development of the productive means to support such a consumption pattern in these social sectors. As such, the evolution of truly "mass" consumer behavior cannot be said to have existed in Cephalonia prior to the middle of the 20th century. Furthermore, the case indicates the necessity of understanding consumption, distribution and production as interrelated systems.

In addition, the data are illuminated when Wallerstein's core/periphery/ semi-periphery distinction is applied. It is beyond the scope and page limitation of this paper to explore fully the implications of applying this construct to the case study at hand. However, the preliminary investigation points to shifts in consumption coinciding with historical changes in Cephalonian attachment to various sectors of the world economy which can be identified clearly as core, semi-periphery, or periphery. In the Venetian period in Cephalonia, Venice was a power declining from a core to semi-peripheral area, with increasing attempts to hold on to wealth through trade. The wealth once amassed by the nobility and merchant classes was threatened with the demise of the Venetian power. As the islands passed briefly through the hands of the British, members of these classes began to leave the island in search of

production and consumption opportunities elsewhere.

Eventually, with the cession of Cephalonia and the other Ionian Islands to the modern nation of Greece in 1864, the island became attached to a nation which was to become, quite clearly, a peripheral part of the European-based world economy. Industrialized core areas preserve their wealth and power at least partially through the use of labor and raw goods provided by peripheral regions. In addition, peripheral areas are excellent markets for the goods manufactured in core sectors. Consumption in peripheral regions is marked by an emphasis on foreign goods and a marked lack of variety in consumer products as well as product availability on the basis of class. Cephalonians and many other Greeks become foreign labor, send foreign capital home to their families, and purchase goods produced in foreign countries. As such, the data presented here support the use of a world systems approach, à la Wallerstein, to explicate events and behaviors occurring both historically and at the present time in the region under study.

An Empirical Update And Extension of Patronage Behaviors Across the Social Class Hierarchy

Scott Dawson, Portland State University
Bruce Stern, Portland State University
Tom Gillpatrick, Portland State University

ABSTRACT

This study provides an updated assessment of the extent to which social class differentiates patronage behaviors. After briefly reviewing literature concerning class and patronage, a study is described in which Coleman's (1983) objective measure of social class is used to differentiate patronage. In a second stage of analysis, this measure is embellished by encompassing class consciousness and relative class income within objective class levels. The results indicate that combining measures yields improvement in predicting department store patronage, and that significant differences in patronage occur within objective levels of class according to consumers' class identification and relative class income.

BACKGROUND

Social class refers to a group of people who share commonality in such social characteristics as prestige, education, occupation, social skills, status aspirations, community participation, family history, recreational habits, and physical appearance (Coleman 1983). Relations between such groups in terms of inferiority, equality, or superiority provide the basis for a social hierarchy. Coleman and Rainwater (1978) conceive of an American class structure which includes seven groups that can be described in descending order as "old family names" (Upper-upper class), "accepted new money" (Lower-upper), "collegiate credentials expected" (Upper-middle), "white-collar associations" (Middle), "blue-collar life style" (Working), "definitely below the mainstream" (Working poor), and "the welfare world" (Underclass). Marketers have found social class useful since it manifests a distinctiveness in life style (Myers and Gutman 1974) and, in turn, consumption (Sobel 1981). For example, social class is a natural variable for segmenting product-markets that satisfy needs related to such life style expressions as housing, travel, sports, and entertainment. Specific product categories in which consumption has been found to be distinctive across social classes include furniture, clothing, and housing (Laumann and House 1970; Schaninger 1981).

Differences in patronage behaviors across social classes were first empirically observed in proprietary studies conducted by Levy and Martineau. These and other researchers arrived at the general conclusion that social class is a salient dimension of store image and that patronage is the result of consumers seeking congruence between self-image and store image (Martineau 1958; Levy 1966). Studies have confirmed that department and specialty store patrons primarily are from upper social classes

(Rich and Jain 1968; Hirschman 1980), while discount stores tend to attract lower class consumers (Rich and Jain 1968). This pattern is more distinctive for purchases such as furniture or clothing (Schaninger 1981) which evoke higher social risk (Prasad 1975).

The goal of this study was to ascertain the extent to which an updated social class measure - Coleman's (1983) Computerized Status Index (CSI) - discriminates patronage in the current social milieu. An additional motivation of the study was to assess the degree to which relative income and class consciousness are factors which affect patronage within levels of objective social class. Scholars have found that relative occupational class income - income relative to the median within a class level - significantly differentiates consumption of automobiles (Peters 1970) and coffee (Klippel and Monoky 1974). While occupation and education strongly determine the commonality of values which typify social classes, variations in number of wage earners and age may produce disparate levels of income. A related phenomenon occurs when two individuals with the same approximate incomes are objectively measured as middle and working class, but spend their incomes quite differently. Relative class income, however, has not been investigated in the retailing literature. Overprivileged members of the working class may exhibit a higher level of patronage of mass merchandise stores (e.g., Sears, Montgomery Ward) than their underprivileged counterparts. Conversely, overprivileged members of the middle class may exhibit their emulation of the upper class by shopping at higher prestige specialty and department stores.

Class consciousness may also affect behaviors within levels of objective class. Though class consciousness tends to be a strong predictor of attitudes and behaviors related to political ideology (Centers 1949; Curtis and Jackson 1977), it may also help in better understanding patronage differences within objective levels of social class. The presence of factors such as prestige or status in a store's image may lead to patronage differences according to the saliency of these factors to consumers based on their class identification. Similarly, consumers who are objectively middle class but perceptually upper class may demonstrate patronage behaviors of a more upper class nature than individuals who are middle class both objectively and subjectively. In sum, patronage may differ between members of the same objective social class and consideration of class consciousness and relative income should yield an improved understanding of these differences.

STUDY DESCRIPTION

Sample

The population for this study was defined as adults residing in all private households (from single and multiple unit dwellings) in three metropolitan areas of the Pacific Northwest. The data were collected by trained interviewers through in-home, personal interviews. Eligible respondents were defined as the person renting, owning, or buying or otherwise residing in and responsible for the dwelling unit. In households where more than one adult met this criterion, interviews took place with the adult employed full-time. In the event that more than one adult was employed full time, the first adult contacted was the respondent. A multi-stage area probability sampling procedure was used to select the households. Up to three callbacks were employed to reach target households where adults were not at home. The households who refused to participate and who were not available after three callbacks were replaced in a random manner.

The final sample numbered 997 households.

The majority of respondents within these households were married (78.6%). Comparison with census data showed that the sample is not significantly different in terms of age, gender, or income, but is marginally higher in level of education ($p < .10$).

Measures

Given the results of previous studies, social class should be associated positively with patronage of higher status stores. Nine well-known stores were selected in the market area from which interviews took place, including 3 discount stores, 3 mass merchandise stores, 2 department stores, and 1 specialty store. Patronage was measured using a 4-point scale ranging from "frequently" to "never."

As noted above, the objective measure of social class used in the study was Coleman's (1983) Computerized Status Index (CSI). Based on measures of five household characteristics, the CSI provides an efficient and effective method for estimating social class in studies which involve large samples (see Coleman 1983, p. 267 for further explanation). Coleman (1983) claims that at least 75% of households are correctly classified by the CSI, where "correct" is defined as an expert's opinion after evaluating 10-times more information than is used in the CSI index. Overall, the CSI departs from early class measures in several respects. First, education's influence on household status is captured by including levels of education for both husband and wife. If the respondent is not married, education is doubled. Second, CSI reflects the strong impact of occupation on social class (cf., Snipp 1985; Giddens 1973) by doubling the weight of the head of household's occupation. Finally, the index includes total family income, rather than only husband's income. An interviewer's evaluation of residential area (i.e., "slum" area to "wealthy or society" area) is the final component of the index. The five items are then added and households are classified as Upper

American, Middle Class, Working Class, or Lower American (see Coleman 1983, p. 276).

Class consciousness is operationalized here as is common in the sociological literature and in a manner similar to that followed in studies of status crystallization; as one's self-designated social class (cf, Curtis and Jackson 1977). In order to facilitate comparability with Coleman's class structure, the question used here stated: "Which socioeconomic group or class would you say best describes you and your family?" Interviewers then read alternative responses including upper class, upper middle class, middle class, working class, and lower class. The top two categories were combined for data analysis in order to produce a structure comparable to Coleman's.

Comparison of the social structures produced from the CSI and self-report measures below shows that, though they are far from independent (Chi-square = 247.7, $p < .0001$), the two distributions

Social Class	CSI		Self-Report	
Upper American	109	10.9%	140	14.0%
Middle Class	367	36.8%	490	49.1%
Working Class	449	45.0%	298	29.9%
Lower American	30	3.0%	65	6.5%
Missing	<u>42</u>	<u>4.2%</u>	<u>4</u>	<u>4%</u>
Totals	997	100%	997	100%

share about 17% of common variance (Kendall's Tau B = .42, $P < .001$). This amount of shared variance is close to the correspondence Gilbert and Kahl (1982, p. 267) believe ought to exist between self-report and objective measures of class. Not surprisingly, a substantial number of objectively-assigned working class respondents appear to identify with the middle class as reflected by the self-report measure. This occurrence may be attributable to a myriad of factors including a resurgence of conservative, traditional and materialistic American values, a shift toward a greater percentage of white collar occupations, a negative stigma associated with lower than middle class identification, and a decline in the membership and power of working class unions.

RESULTS

The presentation of results examines differences in patronage, first across objective social class groups, and then through a combination of class consciousness and relative income within objective class. Analysis of variance showed that eight out of the nine stores produce statistically significant differences between social classes in frequency of shopping (see Table 1). Examining the mean scores shows that patronage differences between social classes tend to occur as predicted in the case of higher status specialty and department stores. The r-square values for these three stores are encouraging from a pragmatic standpoint and suggest that social class is a useful segmentation variable for higher end retailers. Post-hoc contrasts

TABLE 1
Frequency of Shopping by Objective Social Class

Frequency of Shopping in	Class Means (a)				F	R-sq.
	Upper Class	Middle Class	Working Class	Lower Class		
Specialty Stores						
Store 1	.68	.27	.10	.03	39.56b	.11
Department Stores						
Store 1	1.99	1.41	.74	.57	60.02b	.16

- c. p<.01

show that upper class respondents shop significantly more at the specialty store featured in the study than any of the remaining class groups (t=9.15, p<.001). Other significant contrasts indicate that upper and middle class respondents shop more frequently at both department stores 1 (t=9.43, p<.001) and 2 (t=8.29, p<.001) than working and lower class respondents. The absence of significant contrasts involving mass merchandise or discount stores suggests that social class is less effective in explaining patronage of these stores than in earlier studies (Rich and Jain 1968; Levy 1966). With one exception (mass merchandise store 3), no social class group differs substantively in patronage of mass merchandise stores. This result testifies to the expansive market to which mass merchandise stores appeal.

A crosstabulation between objective and self-report measures of class produced the ten class combinations seen in Table 2. The presence of differences in perceived social class versus objective class is apparent from the relatively high numbers in the non-matched categories. Not surprisingly, a high number of individuals feel they are middle class, though they are objectively categorized as working class. The tendency of some respondents to downgrade their class from a higher objective category may occur because of under-privileged income status (as shown below), or may indicate a problem with the objective class measure. Recall that the self-report "Upper Middle Class" group was previously combined with the "Upper Class" group. Without this collapsing the discrepancy between the

upper class self-report and objective categories would have been even greater.

Turning to patronage differences between the self-report/objective class groups, analysis was performed by first averaging frequency of shopping within each of the four store categories. The trend in means indicates that patronage in both specialty and department stores drops in a near linear fashion as both objective and perceptual social class declines. Mass merchandise patronage remains virtually flat across the ten class groups, while discount store patronage rises somewhat as class decreases from upper to middle class. Comparing Tables 1 and 2 shows that the expanded class model does explain approximately 8% more of the variation in department store patronage than the reduced class model. However, no differences in explained variation occur for the remaining three store categories.

The value of this analysis is perhaps best illustrated by examining patronage differences between class identification groups within levels of objective class. Within the objective upper class, patronage of department stores is significantly higher (F=6.17, p<.05) among those individuals identifying with the upper class than those identifying with the middle class. Several differences emerge within the objective middle class group as well. Both specialty store and department store patronage drop significantly (F=6.39, p<.001; F=11.85, p<.001, respectively) as class consciousness decreases within the objective middle class. Clearly, patronage within Coleman's middle class designation is quite heterogeneous and is better

TABLE 2
Frequency of Shopping Across an Expanded Class Consciousness - Objective Class Social Hierarchy

R-Square			.11	.22	.01	.01

a. $p < .001$
b. $p < .01$
c. $p < .05$
All others nonsignificant

differentiated by considering individual's perceived social class. The effect of class identification is also apparent from the higher specialty and department store patronage by objective middle class respondents identifying with the upper class, than respondents who are objectively upper class but perceptually middle class. Further breakdown of the objective working class yields improvement in understanding patronage of department stores as well as mass merchandisers. Within the objective working class, patronage of department stores drops significantly ($F=5.68$, $p < .01$) as perceived class drops from middle to lower. Also, mass merchandise patronage is significantly lower ($F=14.12$, $p < .001$) among those respondents identifying with the lower class than those identifying with either the working or middle class.

Coleman's (1983, p. 274) suggestion for designation of relative income groups within social classes was used to develop an expansive relative income class structure. This structure (not shown) is highly correlated with the class consciousness structure just described (Kendall's Tau B=.80), which suggests that relative class income is a salient

determinant of how people form perceptions of their class positions. As judged by the primary reason for undertaking this analysis - explication of patronage across social classes - the relative income breakdown yields a very similar set of findings. These two analyses produce close to identical results for overall F and R-square values, and for the pattern of significant differences within objective class groups.

CONCLUSIONS

Although this study did benefit from a large, representative sample, several limitations are notable. First, patronage of a relatively small number of stores was measured, especially in the case of specialty stores, which may have biased the results. Some consumers form intense loyalty to certain smaller and unique boutique-type shops, and such patronage was not measured here. Second, patronage itself was measured using a "frequently" to "never" scale, which is less valid than an exact measure of dollars spent over a period of time. However, the findings do suggest several conclusions regarding social class in the 80s.

Clearly, frequency of shopping at specialty and department stores increases with one's social class position. However, objective social class by itself is unable to predict patronage of mass merchandise or discount stores. These findings reflect the multitude of strategies pursued by retailers during the 1980s. Many specialty and department stores have carefully engineered a clear and stable store image targeted at upscale consumers. On the other hand, many mass merchandisers have attempted to make strategic adjustments in pursuit of this same upscale market, and in doing so have blurred their image. This has been particularly true for some of the major retailers. At the same time, many discount stores have traded up and other types of institutions, such as off-price retailers offering nationally-known durable goods and fashion labels, have emerged and gained popularity with both the middle and upper echelons of society.

Comparing the current value of social class as a retail segmentation variable with its value in earlier studies, and comparing Coleman's updated measure against earlier measures, is nearly impossible due to the absence of reported effect sizes in earlier studies. For example, although Martineau (1958) and Levy (1966) found patronage patterns across social classes similar to those reported here, neither provided any indication of explained variance. Other studies have tested for class differences in patronage-related behaviors and attitudes, but have used different dependent variables and not reported effect sizes (Prasad 1975; Schaninger 1981; Rich and Jain 1968; Foxall 1975). While multivariate models using gravitational and store image measures are able to account for roughly 40% of the variation in actual store choice (Nevin and Houston 1980), the results here show that from 10% to 15% of the variation at higher prestige stores is explained by social class alone. Further, the present study did not consider situational or risk factors associated with purchase occasions. Based on previous research, the inclusion of these factors would undoubtedly increase the extent to which social class explains patronage above that found here.

The usefulness of social class as a predictive variable in retailing is limited by the size of middle America. Over 80% of respondents in this study were objectively classified as middle or working class, making differentiation of mass merchandise patronage based on class particularly difficult. However, the results here also show that relative income or perceived class identification - when considered with objective social classes - do produce differences in patronage. The close correspondence between the expanded hierarchies suggests that relative class income may affect class identification. The embellishment of the objective class hierarchy with either of these criteria improves prediction of overall department store patronage. Further, a number of differences in patronage were identified within objective social classes. While these results were most present in the department store category, both relative class income and class consciousness

differentiate patronage of mass merchandise stores within the working class. Given the difficulty of identifying distinct consumer segments that shop in mass merchandise stores, this result is encouraging. The expansive approach to the American class structure taken here may prove useful to specialty, department, or mass merchandise retailers.

An Empirical Study of the Effects of Ethnicity on Consumption Patterns in a Bi-Cultural Environment

Chankon Kim, Concordia University
Michel Laroche, Concordia University
Annamma Joy, Concordia University¹

ABSTRACT

This investigation focused on the relationship between English-French Canadian ethnicity and consumption patterns. The study employed a communication pattern based ethnic classification scheme which accounts for the varying degrees of acculturation toward either end of the English-French ethnicity continuum. Four groups of varying degrees of English-French ethnicity were identified and then examined in terms of consumption differences for food and personal product items. Results indicated between group consumption differences for several product classes. However, the assumption of monotonicity between acculturation and consumption patterns was largely unsupported.

That consumption is a thoroughly cultural phenomenon is well established in the literature on consumer behavior (Belk, Sherry & Wallendorf 1988; Hirschman 1981; Mick 1986; McCracken 1986.) Yet the research on ethnicity and subcultural differences in consumption has not really explored the meaning of consumption for members of these groups. The underlying premise of the research on ethnicity has been that subcultures, while sharing the values and norms of the dominant culture, express certain significant differences of their own which may warrant differential marketing efforts (Nicosia & Mayer 1976; Zaltman & Bagozzi 1976). In these earlier studies, ethnic groups were identified using objective measures such as place of residence, last name, or language spoken at home and then compared with those of the dominant culture with respect to significant marketing dimensions. Clearly the validity of these studies depends on the soundness of the ethnic classification scheme used (Bergier 1986).

More recent measures use emic or subjective measures of ethnicity (Hirschman 1981). Although the term "degree of ethnic identification" is not equivalent to acculturation, its measurement enables researchers to indirectly assess the degree of acculturation. The term "acculturation" refers to the degree that values and norms of an individual or group correspond to those of the dominant group (Gordon 1964; Yinger 1985). Most studies of ethnicity look at immigrant adaptations to the host society (otherwise known as the assimilation hypothesis) and not vice versa (Glazer & Moynihan 1965). However, as Padilla (1980) notes, this is

dependent on the relative bargaining power of the groups in question and is determined within the context of relevant historical and political forces. More recent research in consumer behavior reflects this complexity in conceptualizing the myriad faces of culture (Deshpande, Hoyer & Donthu 1986; Guinn & Faber 1985; Valencia 1985; Wallendorf & Reilly 1983).

ACCULTURATION

Some support for the assimilationist hypothesis has been provided by Valencia (1985) and Schaninger, Bourgeois and Buss (1985), who found a monotonic relationship between acculturation and several consumption dimensions. On the other hand, the pattern of findings by Wallendorf and Reilly (1983) indicate that immigrant adaptation is neither like the culture of origin nor of the culture of residence but lies somewhere between the two.

One approach that has recently gained renewed attention is the importance of communication processes in general and the use of language in particular (Shibutani & Kwan 1965). In the study of consumer behavior, O'Guinn & Faber (1985) develop a measure based on communication patterns. The underlying rationale for this measurement approach is that communication is the most fundamental means by which individuals develop their understanding of a new culture (Kim 1985). Communication involves interaction with the environment. As strangers interact with people in the host environment, they learn and acquire the acculturative capacities in their cognitive, affective, and behavioral processes (Kapoor & Williams 1979; Pedone 1980; Shibutani & Kwan 1965; Tzu 1984; Wen 1976).

Of particular relevance to this study are two forms of communication - interpersonal and mass communication. A person's interpersonal communication can be observed through the degree of his/her participation in interpersonal relationships with members of the host society (Kim 1985), whereas individuals participate in mass communication processes through such media as radio, television, newspapers, magazines, movies, theatre, museums, lectures and posters (Tzu 1984).

RESEARCH OBJECTIVES

The focus of this research is on the relationship between English-French Canadian ethnicity and consumption patterns. While much of Canada is rooted in the English culture, French and English cultures co-exist as the two dominant forces in Quebec, exerting influences on each other. Conscious political efforts by the Government of

¹The authors would like to thank the Committee of Aid to Scholarly Activities, Concordia University for providing the research funds.

Quebec to preserve and expand the influence of French culture imposes an assimilation force on the English perhaps to a similar extent to which the English impose on the French. In recognition of this two-way process, English-French Canadian ethnicity in this study is viewed as a continuous concept with the two polar extremes corresponding to "strong English Canadian identity" and "strong French Canadian identity." The middle portion of this continuum would then represent various degrees of acculturation either French Canadians or English Canadians have experienced toward the other side.

French-English Canadian Consumption Differences

While there is a large volume of research investigating English-French Canadian consumption and lifestyle differences (Schaninger, Bourgeois & Buss 1985; Saint-Jacques and Mallen 1981; Tigert 1973; Vickers & Benson 1972), nearly all these studies use a dichotomous classification scheme based on a single indicator and, furthermore, many of them are post hoc in design.

Most of these studies indicate that the French are more oriented toward cooking and baking, less reliant on instant or convenience food, prefer soft drinks, sweet beverages, and consume larger quantities of alcoholic beverages (Barnes & Bourgeois 1977; Clifford 1979; Mallen 1973; Saint-Jacques 1981) than English Canadians do. In terms of life-style profiles, French Canadians seem more concerned with personal appearance and fashion, and are more oriented towards their home and cleanliness and are more likely to own washers, dryers, and other home appliances than their English counterparts are.

METHODOLOGY

Data

Data used in this study come from a survey of residents in various districts of the Greater Montreal Area performed in 1986. A quasi-probability sampling procedure was chosen for the reasons of cost and speed. Fourteen census tracts with a high concentration of population of English and French ethnic origin were included in the first sampling stage. Within each census tract, streets were chosen randomly. Interviewers knocked at the door and asked for the lady or the man of the house. Then, after the introduction, a filter question screened those respondents who did not overtly identify themselves as either French Canadians or English Canadians.

Qualified respondents were asked their preference of a French or English questionnaire. The self-administered questionnaire was left with the consenting respondents to be picked up at a later time. In total, 600 completed responses were obtained, of which 200 were English and 400 were French. The non-respondents did not differ significantly from the respondents in terms of demographic characteristics.

Measurement

In the beginning of the questionnaire, respondents were asked to indicate the degree of preference for the language of the questionnaire on a scale ranging from 1="I always prefer French questionnaires" to 9="I always prefer English questionnaires". This particular question is also considered as a communication variable, and will be used in conjunction with others in the ethnic classification scheme. Measurement of communication patterns in interpersonal and mass media use situations required the subjects to estimate the percentages of the times they use French, English, and other languages (adding up to 100) in the following contexts: 1. with spouse; 2. with children; 3. with relatives; 4. at work; 5. when watching television; 6. when listening to radio; 7. when reading newspapers; 8. when reading magazines or books; 9. when shopping; 10. with close friends; 11. when in school.

The next section of the questionnaire contained questions for consumption frequencies of 35 personal and food items. Also included in the questionnaire were various life style questions using 10-point likert scales as well as those requesting the respondent's demographic information.

Analysis

Methodologically, this study employs a cluster analysis based taxonomic procedure which allows for the detection of groupings with varying degrees of acculturation toward one end or the other on the English-French ethnicity continuum. In contrast to the a priori classification scheme used in the past studies (Deshpande, Hoyer, and Donthu 1986; Valencia 1985; Wallendorf and Reilly 1983; Schaninger, Bourgeois, and Buss 1985), the cluster based approach does not assume in advance any particular number or descriptions of groups.

Since the focus of this study is on English-French Canadian ethnicity, the analysis included only those respondents who reported the use of only French and/or English for all of the eleven communication contexts mentioned in the prior section.

The first step in the analysis plan involved cluster analyzing the subjects with the twelve communication variables (including the 9-point scale question on the language preference for the questionnaire). For each of the eleven communication contexts, the percentage of times English used was subtracted from the percentage of times French used, and inputted into the analysis. Responses on the 9-point scale question of questionnaire language preference was transformed to match the ranges of the eleven communication variables (i.e., 1="I always prefer French questionnaires" was recoded to +100, 9="I always prefer English questionnaires" was recoded to -100, and middle scale points accordingly).

Clustering of the respondents was performed with the BMDPKM program (Dixon et al. 1983). Cluster solutions of two to six group partitioning were examined in terms of the average F-ratio

(average between group variance divided by average within group variance for the twelve variables). This average F-ratio is an indication of the degree of homogeneity among the subjects within each group in a cluster solution. In all of the five cluster solutions, the average F-ratios were very high - 12776, 932, 701, 585, 492 for two to six cluster solutions respectively. An examination of the successive drops in F-ratio (an elbow test) apparently indicated that higher number cluster solutions may still contain quite heterogeneous groups with respect to the twelve input variables. At this point, it was decided that, the four group solution containing two rather unacculturated groups, one French Canadian and one English Canadian, and two groups in-between on the acculturation continuum will be examined for reasons of parsimony in terms of the consumption patterns for the product items mentioned in the previous section.

The next phase of the analysis dealt with the validation of this cluster based ethnic identification with discriminant analysis. With the membership information of the four cluster solution, discriminant functions using the twelve communication variables as independent variables are estimated from a randomly selected half of the total sample (i.e., analysis sample) and are subsequently tested for their accuracy in predicting membership in the remaining half (i.e., validation sample). This process is followed by testing the predictive power of each of the twelve communication variables. This was also accomplished with split sample discriminant analyses incorporating one communication variable at a time as the independent variable and the classification membership as the dependent variable.

The final stage of the analysis involved comparisons among the four clusters with respect to the consumption frequencies for the selected items. The comparisons will utilize analysis of variance and multivariate analysis of variance incorporating several demographic and life style variables as covariates.

RESULTS

The Cluster Based Four Group Taxonomy

Profiles of the four clusters based on their mean values of the twelve communication variables are presented in Figure 1. First, the profile shown on the far left of the figure corresponds to the group which can be labeled as "strong English". They have been educated in English, and English is the predominant language for communications in family, social, and for media use. However, not all of them seem unilingual. On average, members in this group reported a fair amount of use of French at work and when shopping. It appears that some members in this group have acquired some level of competency in French language to facilitate their communication at work as well as in shopping situations.

The next profile to the right pertains to the "moderate English" group. While English appears to be the primary language for these people, the use of French at work, while speaking to relatives and

while shopping is considerably more frequent than the strong English group. It is likely that the moderate English group uses French with relatives primarily because of higher incidence of inter-marriage. Insofar as the communication patterns reflect the degree of acculturation, these respondents appear to have undergone a substantial extent of acculturation toward the French Canadian culture.

To the right of the moderate English group is the "moderate French" cluster. These respondents communicate mostly in French in the family, work, and social settings. On the other hand, they tend to watch English TV programs, listen to English radio channels, read English magazines more often than those of the French language, and read French newspapers slightly more frequently than English newspapers. Their profile is apparently quite distinct from that of the moderate English group in many aspects. This casts some doubt in the homogeneity of the "bilinguals" category employed by Schaninger, Bourgeois, and Buss (1985). Finally, the profile of the "strong French" group is presented at the far right of Figure 1. Similarly as the strong English group, French is the dominant language of communication at home, with friends, and for their formal schooling. However, they reported a sizeable extent of English media usage. In particular, nearly one fourth of their TV viewing is for English programs. Also noticeable is their fair amount of use of English in work places.

In the subsequent step, using the discriminant analysis, a split-half validation of the four group taxonomy was performed. Results showed that the classification functions developed from the analysis sample predicted the membership of the cases in the validation sample with a 93.2 percent accuracy. With respect to the predictive power of each of the communication variables, results of the twelve split-half discriminant analyses using one variable at a time as the independent variable are summarized in Table 1. Discriminating power of the individual variables, measured in the percentage of the correct assignments made in the validation sample, ranges from 62.5 percent for the language used at work to 80.4 percent for the language of the newspaper. Apparently, no single item matches closely the cluster procedure in its classification results. These findings indicate that the often used single language items (e.g., mother tongue or language most often spoken at home) in the French and English Canadian cross-cultural studies are likely of questionable validity as ethnic classification variables.

Between Group Differences: Food and Personal Product Consumption

The investigation of the between group differences in consumption patterns for food and personal items controlled for the influences of several covariates. As has been noted, there may be differences in various life styles between English and French Canadians which could lead to different consumption behaviors. Five life style dimensions were included in MANCOVA as covariates: traditionalism, financial conservatism, extravagance,

TABLE 1
PREDICTIVE ACCURACY OF EACH COMMUNICATION VARIABLE

<u>Item</u>	<u>% of Correct Assignment</u>
1. Questionnaire language preference	78.63%
2. With spouse	72.92%
3. With child	73.75%
4. With relatives	75.83%
5. At work	62.50%
6. Watching TV	71.25%
7. Listening to radio	71.25%
8. Reading newspapers	80.42%
9. Reading magazines	75.00%
10. Shopping	71.25%
11. With friends	79.17%
12. At school	65.83%

home orientation, and health consciousness. Also included as covariates were a group of demographic variables: age, household income, household size, working status, education, and sex of the respondent.

Results of MANCOVA on 35 personal and food items after removing the effects of the life style and demographic covariates are contained in Table 2. As shown at the bottom, multivariate tests of difference among the four groups produced a significant result ($p < .001$). A further examination of the univariate analysis results revealed ten items for which a significant between-group difference existed. Among these significant items, the strong English groups showed a highest consumption frequency for four (canned baked beans, popping corn, frozen vegetables, and headache/pain relievers), the moderate English group in two (lamb and paper plates), the moderate French group in one (pasta), and the strong French group in three (maple syrup, frozen pies/cake, and electric shaver).

Partially supported by these results is the French Canadian's liking for sweets. The most frequent consumption of maple syrup and frozen pies/cakes reported by the strong French group confirms the past findings. However, the group showing the second highest average consumption frequency for both of these two items was the moderate English group, closely followed by the moderate French, and then by the strong English. The data in this study does not show a monotonic consumption trend among the four groups in this instance. For the other sweet items included in the analysis, chocolate/candy bars and cola, no significant difference was found in the consumption frequencies of the four groups.

The results also provide some clues to detecting differences among the groups in convenience food consumption. On the basis of the existing knowledge, the strong English are expected to be most convenience oriented in food consumption. The results, again, provides only a limited support for this expectation. The strong

English reported the highest incidence of consuming frozen vegetables and canned baked beans, but no significant between-group differences were found for other convenience food items such as frozen TV dinners, canned soups, and ready-mix cakes. Frequency patterns among the four groups for frozen vegetable and canned baked bean consumption do show increasing consumption trends from the strong French to the strong English.

Another finding of interest is the strong English group's highest consumption frequency for headache/pain relievers, followed by the moderate English, and then by the two French groups. This is contrary to the earlier finding by an industry study by J. Walter Thompson Co. Ltd. (1969). However, the study is 20 years old, and some consumption patterns of both English and French Canadians may easily have changed. What may be reflected in the present finding is the stronger emphasis by French Canadians on *Joie de vivre*. The relatively more pleasure oriented and relaxed life style of French Canadians may be associated with a less need for these remedies.

SUMMARY AND CONCLUSION

Several outcomes of this paper are worth noting. In particular, the cluster analysis based procedure using interpersonal and mass media communication variables proved to be effective in identifying four groups of varying degrees of English-French ethnicity (or acculturation). It provided a basis for a more rigorous examination of the effects of varying levels of acculturation on consumption behavior in the bicultural Quebec environment. It was also shown that no single communication variable was capable of producing classification results comparable to those obtained from the twelve item cluster procedure.

The ethnic classification scheme employed in this study incorporated a realistic assumption that acculturation is a two-way, reciprocal process affecting both cultures in consideration. A look at the profiles of the classified groups revealed that

TABLE 2

^ap<.01, ^bp<.05, ^cp<.10

English Canadians were acquiring French communication skills perhaps nearly as much as French Canadians were acquiring English communication skills.

Substantively, the analysis on the consumption differences among the four groups of different English-French ethnicity indicated significant multivariate results for food and personal product items. First, without the strong and moderate categorization of each group, results produced some supporting evidence for the French Canadian's liking for sweets, highly limited support for the English Canadian's stronger convenience orientation in food consumption. Results also showed a higher dependency on headache and pain relievers by English Canadians. The tests of between group differences made in this study controlled for several demographic and life style variables, thus, are more rigorous than those made in the past.

With regard to the monotonicity in the consumption differences among the four groups on the significant consumption variables, the overall patterns of findings provide weak support. For almost two thirds of the significant items (9 out of 14), mean levels of the moderate ethnicity groups either fell outside the range defined by those of their strong ethnicity counterparts or when in the middle range, did not show the monotonicity between themselves. Thus, these observations are more congruent with those of Wallendorf and Reilly's study (1983) on Mexican Americans' consumption behavior, which did not corroborate the linearity assumption between acculturation and consumption patterns. Yet, while Wallendorf and Reilly observed the Mexican Americans' consumption of several food items exceeding both the Anglo Americans' and Mexicans in Mexico, this was not a noticeable pattern in this study. Also to be noted here is that the test of monotonicity using 4 groups is more stringent than the 3 group classification used by Schaninger, Bourgeois and Buss (1985).

In conclusion, this study has demonstrated that the traditional approach to ethnic identification, especially in the study of English and French Canadian consumption differences, is too simplistic, and that within group differences in each major subcultural group resulting from varying degrees of acculturation are strong and warrant a closer examination.

Cultural Interpenetration: A Critical Consumer Research Issue for the 1990s

Alan R. Andreasen, California State University, Long Beach

ABSTRACT

This paper introduces the concept of "cultural interpenetration" and suggests that it is a rapidly growing societal phenomenon that ought to occupy the attention of consumer behavior researchers concerned with macro issues. Several central research issues are proposed.

INTRODUCTION

Consumer behavior researchers are typically concerned with micro and "somewhat macro" processes of consumption behavior. At the micro level, we study how individuals seek information, evaluate alternatives, develop affective responses, plan actions and then decide, act and evaluate. At the "somewhat macro" level, we attempt to understand group behavior of households, neighborhoods or lifestyle segments. For the most part, our methodologies develop explanations of phenomena that cover either one point in time, as in cross-section studies, or relatively short periods, as in studies of scanner-recorded purchase patterns over one or two years.

Focus on these narrower approaches restricts the field's potential to contribute to our understanding of broad, sweeping trends that characterize our modern society or have characterized it in the past. In his 1986 Association for Consumer Research Presidential address, Russell Belk admonished the field that: "Our mission as consumer researchers should in fact be . . . to examine the relationship between consumer behavior and the rest of life." (Belk 1986, 1). Among other things, Belk was urging that we not get so close to our models and our data that we do see the "broader picture." We need consumer behavior studies at the macro level of the entire society and studies that look at formative processes that may take decades to work themselves out. Such studies can focus on either the past or the present and should frequently attempt to understand evolutionary phenomena that will have major impact on our collective futures.

Cultural Interpenetration as a Macro Issue

Three papers at this conference touch upon a macro consumer behavior issue that has received little attention in the field, yet that is going to have a dramatic effect on both local and international social relations over the next fifty years. I refer to what I have termed "cultural interpenetration." By cultural interpenetration I mean the exposure of members of one culture (or subculture) to another through direct experience and/or indirectly through the media or the experiences of others. This, of course, is not a new phenomenon. Over many centuries, a major impact of wars, conquests of new continents, political alliances, religious crusades, and many and diverse trade developments has been to provide opportunities for particular populations

to be exposed to -- sometimes in extremely unpleasant ways -- the influences of other peoples and cultures.

In a very specific example, Costas (1989) describes how the little Greek island of Cephalonia over the years came under the dominance of a number of Western European cultures, most prominently the Venician and Greek cultures. These experiences have had lasting effects on the social structures, values and consumer behavior of residents of the island today. Costas also points to examples of other kinds of cultural interpenetration that have been taking place in the last several decades. For one, Cephalonians have been exposed to Western European cultures when they or members of their families or villages have gone abroad to serve as migrant workers. More recently, they have had contact with mainland Greeks, Europeans and some North Americans who have come to their island as tourists. And, finally, although Costas does not focus on it, there has been the growing exposure of island natives to such exotica as Hollywoodian and British culture through radio, television, magazines and newspapers.

While Costas focuses on geographic interpenetration, Dawson, Stern and Gillpatrick (1989) have studied relationships among social classes within a specific geographic area in terms of their consumption behavior. These authors investigated social class norms and the extent to which the availability of income to acquire the consumption norms of a class affects store choice. Obviously, one important determinant of this process is whether specific consumers identify with others at their own social class level or aspire to be like their "betters." It is certainly a hallmark of the late 1980s that members of all classes are now increasingly able to penetrate vicariously the inner workings of higher social class cultures through television programs like "Dallas", "Dynasty" and "Lifestyles of the Rich and Famous" and through upscale magazines such as *Town and Country* and *Architectural Digest* (see also, Hirschman 1989).

Kim, Laroche and Joy (1989) focus on a third kind of intercultural penetration, namely the horizontal interpenetration of two cultures in a relatively small geographical area that differ primarily in language. Their paper explicitly looks at the extent to which French and English cultures in Quebec Province are involved in the culture of their opposites, at least in terms of speaking in the other culture's language and reading their newspapers. These authors found newspaper readership to be a strong indicator of a person's language grouping, confirming that cultural interpenetration has both direct and indirect causes and consequences.

A Growing Phenomenon

Intranational and international cultural interpenetration is a phenomenon that has heretofore been little explored in consumer behavior research. It is also a phenomenon that is destined to grow significantly in the next quarter century. Two sweeping changes, one under way, one in the offing, make it essential that consumer behavior researchers pay it particular attention. The first change is the accelerating rate of in-migration of new immigrant groups into the United States. In the last two decades, the U.S. has had a major shift in the inflows of other nationalities into the culture. In the first half of the century, the principal immigrant groups were from cultures not greatly different from that already here. These include the Irish and Italians in the 19th and early 20th centuries and the Central Europeans in the late 1930s and 1940s. However, since the late 1960s, the United States has experienced a major shift in the source of its immigrants. The new immigrants are heavily concentrated in six major Asian cultures that are dramatically different from that with which most Americans are familiar.

In the 1960s, families and individuals from Western Europe comprised 37 percent of all immigrants to the U.S. and Asians 13 percent. However, in the period from 1981 to 1986, 11 percent of immigrants were from Western Europe and 47 percent were Asian (*Statistical Abstract of the United States* 1988).

The United States is also being impacted by the growth internally of another, very different culture, the Hispanic. Between 1980 and 1985, the Hispanic population grew at five times the pace of the population as a whole. Hispanics now comprise one in every fourteen Americans, a ratio that is expected to continue to grow until they become the dominant racial and ethnic minority in the country. It is estimated that Blacks and Hispanics will together make up 37 percent of the population in 2080. (What Lies Ahead, n.d.)

The aforementioned statistics understate the impact of the cultural penetration of the Asian and Hispanic cultures since they are not spread evenly throughout the country but, rather, are heavily concentrated in specific areas. Seventy-five percent of Asians now live in five states, California, Hawaii, New York, Illinois and Washington. Hispanics are even more concentrated: 60 percent live in just three states, California, New York and Texas.

The second major broad social change that will dramatically affect future world cultural interpenetration is the removal of economic and social barriers between the European Common Market countries in 1992 and potentially within the Eastern bloc beginning in 1989. Levels of permanent and temporary migration may be expected to increase dramatically, as presumably will short-term culture sampling through intra-European vacationing and exposure to other European media.

Implications for Consumer Researchers

If cultural interpenetration is to be one of the most striking characteristics of the United States and Europe in the next decade, consumer researchers owe it to both their discipline and to the society as a whole to attempt to describe and explain both the nature of this interpenetration and, perhaps most importantly, its consequences for both the cultural groups doing the "penetrating" and the cultural groups being "penetrated." Not only is it important from the society's standpoint that we study cultural interpenetration, it is also important for the advancement of our knowledge at the micro and "somewhat macro" levels. For example, I have argued elsewhere (Andreasen forthcoming) that the opportunity to study aspects of consumer behavior that are *extremely involving*, such as occurs, for example, when a peasant flees from Cambodia to Los Angeles, can put into stark relief basic consumer behavior processes that are difficult to see in the slower moving, less dramatic evolution of our typical middle class "native" subjects.

Among the topics that merit attention are the following:

1. Just to what extent is a cross-section of a given population exposed to other cultures, directly or vicariously, on a long-term or short-term basis? How many different cultures does this involve and what is the "depth of exposure"?
2. Just how do we measure "depth of exposure"? What are the relevant dimensions? How does one calibrate them? Are some dimensions more lasting than others?
3. Is the effect of going to a culture (even by TV or a movie) different from having it come to you (i.e. having a Cambodian move in next door or join your business or religious group)?
4. What differences are there across individuals in the extent of intercultural penetration? Are these related to personality traits, economic circumstances, chance?
5. For those who chose to enter another culture on a reasonably long term basis, what is the *process* by which acculturation takes place? What aspects of the new culture (e.g. products and services) are adopted rapidly, which ones slowly? What aspects of the former culture remain? What "blending" of former and new cultures takes place (and how do we describe it)? (An issue of particular interest to social marketers would be the impact of the nonsmoking U.S. culture on immigrant Asian teenagers and adults. The latter are notoriously heavy smokers; anything we might learn that could accelerate their adoption of healthier lifestyles would produce major social benefits.)

6. Do migrants enter the new culture at the same social class level as they held in the former culture? Do people from poorer countries (e.g. Thailand or Costa Rica) enter the new culture at a lower level and move up? Do those moving to a poorer culture move up in social status?
7. If cultural interpenetrators move to a different social class in the new culture, do they really have to learn *two* cultures (i.e. how to be a Mexican resident and how to be a relatively affluent businessperson in the Mexican culture)? If they do have to learn a new class (up or down), do they adopt the class norms (e.g. in consumption) from their old culture or from the new?
8. How does vicarious and first-hand experience differ in the way it is processed or in the memory traces and structures it leaves? Fazio and Zanna (1978), for example, suggest that direct experience has a greater effect on attitude and eventually behavior. Does this explain, for example, individual differences in willingness to visit or work in a particular country or region or to seek to interact with members of a particular culture?

Consumption Styles of the Rich and Famous: The Semiology of Saul Steinberg and Malcom Forbes

Elizabeth C. Hirschman, Rutgers University

"Maybe it's a little understated."
(Corporate raider Saul Steinberg, on his birthday party which featured a tent full of exotic birds, tapestry tablecloths and nude models posed as Flemish paintings.)

INTRODUCTION

An aspect of consumer behavior receiving increased attention in recent years is acts of an *obsessive* or *compulsive* nature (cf, Faber and O'Guinn 1988; O'Guinn and Faber 1989; Rook 1987; Holbrook 1987; Lehmann 1987; Pollay 1987a). The consumer may go on shopping, gambling, eating, or drinking binges, often with destructive consequences to self and family. Often the consumers who engage in these activities do not have the financial (or emotional or mental) resources to fund their behaviors, and the results are seriously dysfunctional from both a societal and personal perspective (Faber, O'Guinn, and Krych 1987; Moschis, Cox, and Kellaris 1987).

The present study examines obsessive and compulsive consumption from a different vantage point by detailing the behavior of two of the world's wealthiest and most prodigious consumers -- Saul Steinberg and Malcolm Forbes. Steinberg is 50 years old, is worth over 400 million dollars and is currently ranked in the top ten on the *Forbes'* list of affluent Americans (*Forbes*, October 24, 1988, p. 219). Forbes is 70 years old, is worth approximately 400 million dollars and also is currently ranked in the top ten on the *Forbes'* list (*Forbes*, October 24, 1988, p. 219). In addition to achieving celebrity status for their many accomplishments in business, both have also become popularized through their notable acts of consumption.

The present study proposes that through examining the consumption styles of highly affluent consumers, we may better come to understand some of the rationales underlying obsessive or compulsive consumption. It will be argued that in Steinberg's case such consumption acts are purposeful attempts to attain upward social mobility. It will be proposed that in Forbes' case, his seemingly random acquisition of objects may indicate a deep-seated desire for public recognition and environmental mastery, especially of a technological-mechanical nature.

METHOD

The study focused upon two recent articles featuring Steinberg and Forbes, respectively, in media directed to the affluent. The Steinberg article, "Barony on Park Avenue," appeared in the November, 1985 issue of *Town and Country* (Moonan 1985). The Forbes article appeared in the March 1988 issue of *Architectural Digest* and was titled "Malcolm Forbes at Timberfield" (Buckley

1988). These articles were chosen as illustrative of their subject's consumption style and values in that both Forbes and Steinberg had to invite the journalists to their homes, agree to be interviewed, and pose for several photographs of themselves and their possessions. Their willingness to permit themselves to be thus subjected to public scrutiny (and their presentation of self-identity and possessions while under such scrutiny) reveals much about their ideology, both as consumers and people. In essence, they are "showing off" themselves and their possessions with the intent of accomplishing some social identity goal. By examining what and how they attempt to "show off," much can be learned about them.

The present author had recently conducted a large-scale study of the ideology of the affluent (Hirschman 1989), which surfaced some of the general themes and images common to this group of consumers. The present effort, by focusing more tightly on two specific, affluent consumers, is intended to provide a more detailed glimpse into how the ideology of affluence may be manifested in individual lives.

A hermeneutical approach based on the philosophies of Barthes (1964), Baudrillard (1981), and Dilthey (1976) was used to interpret both the text and visual imagery in the two magazine articles. Extensive excerpted material and photographs from each article are included to permit the reader to assess directly the quality of the interpretation rendered.

SAUL STEINBERG

The headline to the first article reads "Barony on Park Avenue," creating a metaphorical allusion between the Steinberg residence and royalty and nobility, as well as linking the locale of the residence to a well-known Upper-class street, i.e., Park Avenue in New York City. The subheading states, "Saul P. Steinberg and his wife Gayfryd have transformed a triplex once owned by John D. Rockefeller, Jr., into a baronial home boasting one of the country's best collections of old masters [paintings] (Moonan 1985, p. 235)." This brief introduction provides several semiotic clues as to the consumption identity of the Steinbergs and initiates some themes which are carried throughout the article.

First, the Steinbergs are associated (through their residence) with legendary industrialist and philanthropist, John D. Rockefeller. By acquiring the apartment once owned by Rockefeller's son, the Steinbergs are signalling their desire to follow in Rockefeller's social footsteps and thereby gain entry to the Upper class. (Steinberg grew up in a middle-class Brooklyn family.) The primary route by which the Steinbergs plan to make their ascent is also identified in the text: they possess "one of the

country's best collections of old masters." Thus, the Steinbergs intend to use the tried-and-true route of aesthetic bequests and collecting to achieve upward social mobility.

The introductory passage also alludes subtly to the Steinbergs' somewhat ostentatious and overstated manner of publicizing their intentions -- their 'baronial' home 'boasts' the collection of prominent paintings. Thus, we are told by the writer-observer, the Steinbergs are still perhaps too much in the *nouveau* stage of their monetary life cycle. They have not yet settled into a comfortable familiarity with their wealth.

The first print image presented in the article largely reiterates the textual message. It depicts a portion of the Steinberg living room centered around a large Titian painting in a heavy gilt frame. On either side of the Titian are several smaller old masters paintings; the room setting also includes tables inlaid with elaborate marquetry, gold encrusted candlesticks, a pair of gold sconces mounted with white porcelain birds, crimson-colored brocade wallpaper, and a crimson couch. The caption reads, "Walls covered in crimson Fortuny [fabric], chairs in silk, and gilded French appliques are the opulent setting for paintings like the ravishing Titian in the Steinberg living room." The imagery of both the photograph and caption suggest the lavish display of wealth centered around important works of art.

The article's text moves on to provide some insights in Steinberg's motivations for acquiring art. "... [Steinberg] moves into a description of his last visit to the Tate [gallery] in London, where his *Triptych* by Francis Bacon was recently shown to rave notices... 'It was a great thrill to own the centerpiece of the exhibition,' Steinberg notes (Moonan 1985, p. 238)." This excerpt portrays Steinberg's search for international social acceptance vis a vis his remarkable art possessions. Still, his personal insecurity in the role of art patron is evident in his "thrill" of owning (and *being*) the center of so much aesthetic acclaim.

As the text continues, it outlines in greater detail the role of *novice aesthetic scholar* which Steinberg (and his wife Gayfryd) play. They are eager to seek information on artistic and intellectual subjects as a way of furthering themselves socially and also are anxious to display their new-found sophistication. For example, the text notes, "[Steinberg] eagerly asks about French architects who might renovate the Grand Hotel in Cap Ferrat, a new acquisition (p. 237)." He later comments, "I thought about becoming an architect once" and then describes in detail his "contemporary and starkly elegant Charles Gwathmey-designed corporate headquarters on Park Avenue (p.237)." The text suggests that Steinberg is anxious 'to do the right thing' aesthetically. Lacking confidence in his own inherent taste, he seeks out references to others who can make the socially correct design decisions for him.

Steinberg also appears anxious to exhibit the intellectual knowledge he has acquired -- to portray himself as a capable and enthusiastic student of the

Upper-class ideology. The text notes, "... He launches into a five minute monologue on Winston Churchill, what a great statesman he was; what an outstanding leader, ... [Steinberg] is now collecting first editions of Churchill's books (p. 238)." This form of collecting permits him to associate himself with an eminent political figure, while also demonstrating the appropriate intellectual appreciation for Churchill's talents.

Steinberg's goals in collecting art and scholarly possessions are vividly embedded in a second photograph taken from the article. It is captioned, "In the great English country homes, they live with extraordinary art and make a house a home," says Gayfryd Steinberg (p. 240)." The photograph depicts Saul and Gayfryd in formal evening attire in the front right-center of their living room. A seated Gayfryd wears a gold silk Scaasi dress and diamond jewelry. Saul, in evening formal wear, stands behind her; hands in his pockets. They both gaze at the camera. Behind them is an antique harp and music stand; to the left is an ebony Steinway grand piano, its keyboard open and sheet music laying on the bench. The crimson silk walls of the room are hung with several large gilt-framed masterpieces. Crystal and porcelain figures trimmed in gold leaf rest atop virtually every vertical space. Recessed lighting highlights the most significant possessions. The Steinbergs are effectively ensconced in their art. Their home is their social showplace; an exhibition of acquired 'good taste' *in extremis*.

Following the hallowed route to Upper-class acceptance through philanthropy (Aldrich 1988), Steinberg has donated both funds and art works to the Metropolitan Museum of Art in New York City. "[His] contributions to the Met -- the Fortuny on the gallery walls, the Frank Lloyd Wright room, the reinstallation of the Greek and Roman treasury, several educational programs, and even the half-million dollars necessary for the museum to do a catalog of its own collection... have totalled millions of dollars (p. 241)," notes the text.

These activities have endeared Steinberg greatly to the director of the Metropolitan Museum, who is shown with the Steinbergs in one photograph in the article. The caption to this photo states, "In the magnificent library, Saul discusses paintings with friend Phillippe de Montebello, the director of the Metropolitan Museum of Art, Saul's favorite 'charity.' Gayfryd sits under Joachim Wtewal's *Annunciation of the Shepherd*, 1606, the first old master Saul bought (p. 242)." There are several notable aspects of this photograph. First, the fact that the museum director was willing to drop by the Steinbergs' house while photos for the magazine article were being shot signifies that Saul's patronage of the arts has also bought him the services of significant art personnel. Perhaps more significant, however, is the positioning of the three figures in the photo. Both Saul and Gayfryd are seated upon the library couch attentively looking upward toward Mr. Montebello,

who stands, gesturing, in front of them. The image is very much one of a student-teacher relationship.

The library, itself, does not appear to be heavily furnished with books -- much of the available shelf space is given over to porcelain figurines and photographs. Two incongruous furnishings in the library are the enormous red draperies, which accent an enormous red couch, and blue, hi-tech track lighting mounted on the ceiling. These elements seem to be out-of-proportion-to and out-of-synch-with, respectively, the rest of the room and reinforce the inconsistent success with which the Steinbergs have communicated their social class goals through their choice of possessions.

A final photograph, also intended to demonstrate the Steinberg's commitment to Upper-class ideology, communicates once again their missteps, as well. This is a picture of the dining room and is captioned "Jacob Jordaen's *The King Drinks* over the sideboard sets a joyous mood for formal dinners (p. 245)." The dining room is dominated by a long, dark wood table set very formally for ten diners. Each place setting is marked with an ornate silver card holder naming the guest to be seated. The head setting of the table is designated "Saul." The other dominant image in the photograph is the long, dark painting, *The King Drinks*, whose central figure is a fat, jovial man with crowned head and full mouth -- an unwitting metaphor for the present host; (Steinberg is a large, heavy-set man).

It is evident that much effort has gone into the presentational qualities of the room. The chandelier chain and dining chairs have been wrapped in brocade cloth, as is the current fashion; fresh-cut flowers have been placed as a centerpiece; each setting has three cut-crystal goblets; a large oriental rug bedecks the floor, and an elaborate oriental lacquered screen stands nearby. There are lit candles in the candelabrum, and a pepper mill and salt bowl are used instead of shakers. In the photograph Gayfryd carefully instructs a servant, who holds a silver tray, in the correct placement of each goblet.

Into this concerted attempt at refined tastefulness, however, creep two notes of inauthenticity. Above Gayfryd's head glitters a constellation of hi-tech, industrial-style track lights, brightly beaming down to provide more sparkle to the opulence below. Their incongruity with the otherwise traditional setting is jarring. And below Gayfryd's carefully posed hand lies the other etiquette faux pas -- beside each dinner plate is a lavishly embroidered dinner napkin colorfully emblazoned with the initials S.P.S., announcing too boldly their owner's name.

In closing, some additional comments are appropriate. The above analysis was not intended to either laud or demean Saul Steinberg and his consumption patterns, but rather to demonstrate how consumers reveal their obsessions through their consumption. What Saul Steinberg wants -- as evidenced by his behavior as a consumer -- is to achieve social acceptance into the Upper-class. He

is an avid collector both of art and knowledge in his quest for this goal. He is an avid philanthropist for the same reason. And there would seem to be no fault or shame in pursuing this obsession; many of us do the same, with markedly less success than Steinberg has achieved.

In fact, it is somewhat ironic that it is Steinberg's chronic *overachievement* (he was a graduate of Wharton at 19; a multimillionaire at 29) that most often gives away his implicit intentions and goals. Typically, he *overacts* his commitment to art, culture, and scholarship by too eagerly trying to impress others with his paintings, his crimson wallpaper, his knowledge of architecture and Winston Churchill, and his monogrammed table napkins. Quick and capable learner that he is, however, Steinberg will likely soon learn that subtlety, modesty, and the art of understatement are the values he now needs to acquire to reach his goals (cf, Aldrich 1988).

MALCOLM FORBES

The article is titled, "Malcolm Forbes at Timberfield: The Publisher's New Jersey Estate" signalling at once the celebrity prominence of the featured consumer and the socially significant nature of his house: an estate named Timberfield. The article opens with a description of a social event hosted by Forbes which encodes several cues as to his consumption style and obsessions:

"When he threw a party for twelve hundred of his closest friends last May..., Forbes had to hire a free-lance air traffic controller to keep order among the thirty-three helicopters. *People* magazine concentrated on Forbes' two escorts for the evening, Elizabeth Taylor and Jerry Hall; the *New York Times*, sensing that a new status symbol had been born, focused on the air traffic controller (Buckley 1988, p. 95)."

The opening phrase "twelve hundred of his closest friends" suggests the central irony in Forbes' behavior as a consumer: he is a consummate collector -- of friends, houses, automobiles, toy soldiers, motorcycles, and sensory experiences (e.g., hot air ballooning) -- but appears to establish few enduring, intimate relationships either to people or possessions.

The helicopters used to ferry guests to his party signify a second aspect of Forbes' obsessions in consumption -- a fascination for things technical-mechanical in nature. (This will become more evident in subsequent textual excerpts and visual images taken from the article.) Finally, Forbes is obsessed with media attention. Reporters from several magazines and newspapers were invited to document the party cited above; and all of his various residences, as well as his yacht, the *Highlander V*, have been featured in articles in *Town and Country* and *Architectural Digest*. It is as if he desires not only to consume copiously, but to have

that consumption acknowledged and documented publicly.

The article continues to reinforce these themes by cataloging Forbes' achievements as a consumer: "[He] owns a [French] chateau, a [Moroccan] palace, a house in London, a quarter-million acre ranch in Colorado, a mountain house in Montana, and an island in Fiji. But Timberfield... is the place he [goes] most weekends, assuming he is not ballooning across the Peoples' Republic of China or motorcycling across Germany... Forbes is to art, bric-a-brac, toys, and anything collectible what a magnet is to iron filings (p. 95)."

Thus Forbes' obsession with collecting is extremely diverse and eclectic. Unlike Steinberg, whose collecting is focused almost exclusively on high quality, high-visibility art works, Forbes at times seems to acquire objects almost randomly, simply because 'they are there.' The text notes, for instance, the presence of a plate of plastic shrimp salad and noodles carefully stashed atop leather volumes in his library.

A prominent aspect of Forbes' consumption style is his fascination with motors, technology, and machinery. The opening visual image in the article provides a signifying cue for this; its caption reads, "A spectacular 1932 Packard dual-cowl phaeton [automobile] is parked in front of the garages and group of guest cottages at Timberfield, Malcolm Forbes forty-acre estate in the verdant New Jersey hunt country (p. 92)." A smaller photo of Forbes, himself, crisply dressed in a navy blazer, white shirt, and white pants is inset into the right hand corner of the larger image. The predominance of the elegant-but-jaunty, British-green Packard automobile (an old but still very potent machine) in the front left of the photograph forms a visual metaphor for Forbes, the man, also advanced in years but still (the image and text suggest) very virile in spirit.

Mechanical imagery is also carried over very distinctly to the text's discussion of Forbes' recently re-designed bedroom: "[Forbes] gave the commission to noted yacht designer, Jon Bannenberg, who had previously designed Forbes' Boeing 727 and his motor yacht... [The bedroom] has leather-upholstered ceilings, flamed and polished Italian granite, bird's eye marble panelling, raw linen, spot lighting, mirrors, and enough chrome to plate a '57 Caddie... Hot water flows continuously through the oversized bathtub rails, the shower nozzle might have been designed by McDonnell-Douglas, the bed rotates 360 degrees, Roman shades lower electronically, and the lighting comes in four moods (p. 97)."

The photograph accompanying the text description of the bedroom provides additional evidence of Forbes' affection for the mechanical. The predominant colors of the room are machine-colors: blue, gray, gray-green, and beige. The room is lit by industrial-style ceiling lights; in the room's center is an enormous stacked collection of media equipment (VCR's, television, radio receiver, c.d. player). The gray granite walls and pillars

evoke a corporate building. One glass wall is imprinted with blueprint designs and technical renderings. And above the granite fireplace is a portrait of Forbes, by Salvador Dali, astride a motorcycle. The prevailing semiotic image is one of man-and-machine, or perhaps even more aptly, man-as-machine.

Like Saul Steinberg, Forbes has enhanced the social presentation value of his house by utilizing the services of well-known, elite designers and by acquiring and displaying objects which he feels will effectively communicate his sense of self. The article's text states, "In the living room, [designer] Mario Buatta has brightened the general mood with chintz and a carpet the size of the Nimitz's flight deck... [A painting over the fireplace] is an early Toulouse-Lautrec work, formerly in the collections of Somerset Maugham and Huntington Hartford... The stag over the window bears a little plaque attesting to its having been shot within sight of Windsor Castle by Lord Talfer Smollet in November 1832 (p. 97)."

The objects displayed by Forbes are more eclectic than those collected by Steinberg, perhaps indicating Forbes' greater diversity of interests and desire for a sense of adventure. But, like Steinberg, they are also intended to demonstrate to visitors his association through acquisition with celebrity achievers (e.g., Huntington Hartford) and prominent artists (Toulouse Lautrec).

A photograph of the living room is captioned "'Sunken living rooms were an [architect] Musgrave Hyde signature,' says Forbes. The painting over the mantel is *Wedding Feast* attributed to David Vinckboons. In the rear bookcase are models of four of the five Highlander yachts that Forbes has owned since 1957 (p. 97)..."

There are some marked differences between the Forbes' living room and that of the Steinbergs. The decor in the present instance is much more muted and subtle, with predominantly pastel shades. There is a large collection of bound leather volumes exhibited in built-in book shelves, signifying Forbes' attention to intellectual pursuits; (recall that fine art, not literature, were present in the Steinberg living room, which also was much more vivid in hue). The photograph also shows a large, unordered collection of family photographs atop an ebony grand piano. This signifies the importance of lineage and kin to Forbes and also suggests that the piano is there for display purposes only, as playing it would require removal of the entire photo collection. Art books also are placed on the coffee table, as in the Steinberg library, to signify arts patronage; although the relative paucity of Forbes' art collection -- as compared to that of the Steinbergs -- suggests that art is not his social strong suit. As in the Steinberg house, Forbes' living room displays fresh-cut flower bouquets to indicate his appreciation for beauty and nature.

The photograph of the dining room also encodes several cues as to Forbes' particular values and obsessions as a consumer. It is captioned, "The Regency dining table is set with a circa 1810

Chinese Export service. The painting is *The Forbes Family at Easter Lunch, 1983*, by Julian Barrow (p. 98)." The caption includes three significant semiotic elements. First, it denotes Forbes' acquisition of expensive antique furniture (i.e., the Regency table), his fascination with collecting foreign exotica (the 1810 Chinese Export table service), and his apparent reverence for familial ties. This latter cue is expanded by visual inspection of the family painting hung in the dining room. The portrait depicts three generations of the Forbes family gathered in the dining room around the Regency table. Forbes is the predominant, central figure (recall the "fat king" depicted in the Steinberg dining room painting), and is clearly signified as the patriarch of this large, assembled clan. His wife is a distant figure at the back of the painting's perspective. Her 'distance' from Forbes was apparently emotional, as well, as they divorced only a few years after the painting was made.

The present photograph of the dining room (in which the painting is hung) shows some markedly revealing changes since the painting was made. The *current* place settings at the dinner table show that a place card titled Elizabeth Taylor has now been set in his wife's former place; next to that is a place setting designated for Walter Annenberg. Significantly (both semiotically and socially speaking), it seems that Forbes' wife and family have been replaced in recent years by celebrity lovers and prominent business associates.

The table setting also suggests some interesting contrasts with that of the Steinberg dining room. The room is lit by two candelabra on the dining tables and candles on the sideboard. Track lighting is notably absent. Dining room chairs are not 'wrapped' in fashionable fabric; and the napkins are unembossed plain white linen. The one ostentatious note on this otherwise consistently understated table setting is the gold-filigree-rimmed crystal goblets.

Thus, Forbes' 'obsession with possession' appears to be more diversified and less overtly aimed toward social climbing than Steinberg's, although Forbes seems more bent on achieving notoriety among the general public. He displays his possessions more publicly (e.g., the invitation of press coverage to his 'private' parties) and seems intent on achieving visibility with his choice of escorts -- the article notes his recent liaison with Elizabeth Taylor three times: as his party companion, as his dinner guest, and finally by observing in the text: "[There is] a cashmere blanket over [his] bed embroidered 'Malcolm, my sweet, With my love, Elizabeth,' a gift from Miss Taylor, whose purple Harley-Davidson is parked in the garage, along with Forbes' thirty motorcycles (p. 98)." That statement seems to sum up well the essence of Forbes' consumption obsessions: celebrity, machinery, and quantity -- not necessarily in that order.

DISCUSSION

Most studies which examine obsessive consumption have focused upon consumers whose personal resources were overwhelmed by their obsessions, and who subsequently suffered negative consequences -- as did their families (cf, O'Guinn and Faber 1989; Faber and O'Guinn 1988; Faber, O'Guinn, and Krych 1987). This form of obsessive consumption is easily categorized as normatively dysfunctional both for the individual and society, because its consequences are clearly destructive.

When we encounter consumers such as Saul Steinberg and Malcolm Forbes, however, the traditional framework for dealing with obsessive consumption is not so helpful. Clearly, Steinberg and Forbes are classifiable as 'obsessive' consumers. One (Steinberg) has turned virtually his entire residence into a museum; valuable paintings and sculptures are found in every room of his triplex apartment. He expends millions more on donations to the Metropolitan Museum of Art -- philanthropy which, these, days, does not even provide him with a substantial tax write-off.

And yet, there is clearly method to his madness. Steinberg's fascination with fine art is likely driven by two not-irrational motives. First, as the text makes clear, he does *enjoy* his paintings; they have aesthetic value to him. Clearly also, he recognizes that a refined aesthetic sensibility is a prerequisite to social acceptability among the upper reaches of the Upper class. To be truly accepted requires not only vast quantities of money (which Steinberg has), but also evidence of 'refined' taste, which he is avidly pursuing (Aldrich 1988).

Malcolm Forbes' motivations for his obsessive pursuit of celebrity, machinery, and apparently just about everything else *in quantity* are different from those of Steinberg and more difficult to identify. Perhaps they are expressions of an extraordinary level of sensation seeking (cf, Zuckerman 1979). Perhaps they are the strenuous efforts of one man to accumulate a material sense of self identity, as in *Citizen Kane* (cf, Hirschman 1990).

Regardless of their psychic origin, however, the consumption obsessions of Forbes -- like those of Steinberg -- create a challenge to current theorization on obsessive behavior, because they are not clearly categorizable as destructive to the consumer or to society. They may even have some psychic and social benefits. Just as Steinberg derives both pleasure and social mobility through his art collection, Forbes appears to enjoy his hot air balloon excursions, his motorcycle rallies, his parties for 1,200 people, and his dates with Elizabeth Taylor. Is it possible that obsessive consumption can be both functional and fun? Could those consumers who have adequate resources to pursue their obsessions actually enjoy and benefit from them?

It is possible that the answer may be 'yes.' Recent works by Holbrook (1987), a self-confessed jazz fanatic, Lehmann (1987), a self-confessed body-building fanatic, and Pollay (1987b), a self-

confessed obsessive advertising collector (and, we presume, all thoroughly sane and rational consumer researchers) each report several benefits they have derived from their obsessions. Like Steinberg and Forbes, they seem to have found ways of *controlling* their obsessions and guiding them in personally productive ways, rather than being *devoured* by them financially and emotionally, as so many other consumers have been.

The point of all this is simply that consumer obsessions, in-and-of-themselves, may not necessarily be dysfunctional; indeed they may serve some beneficial social and personal functions; (visitors to the Metropolitan Museum, for example, have certainly benefited from Steinberg's bequests). Thus, a fruitful avenue for future research would appear to be examining consumers who have gained positively from their obsessive behavior. By doing so, we may learn their methods for controlling the potential for obsessive destruction and instead extracting the potential for obsessive good.

A Relational Model for Category Extensions of Brands

Peter H. Farquhar, Carnegie Mellon University

Paul M. Herr, Indiana University

Russell H. Fazio, Indiana University

ABSTRACT

This paper introduces a relational model for studying the effects of brand-category, category-brand, and category-category associations on the potential success of extending a brand to a new category. The paper describes the managerial significance of category extensions, considers methods for measuring the different associations, and discusses the implications of recent research on category extensions.

BACKGROUND

Many firms capitalize on brand names that are well-known in one category by extending them to products in other categories that are new to the firm. For example, Tauber (1981) cites Jello Pudding Pops, Bic Disposable Lighters, Woolite Rug Cleaner, and Clairol Hair Blow-Dryer as successful extensions of familiar brands to new categories.

Farquhar (1989) describes two types of "brand extensions". A "line extension" applies an existing brand name to a product in one of the firm's existing categories. On the other hand, a "category extension" applies an existing brand name to a category that is new for the firm (Tauber, 1981). Our interest here is the study of category extensions of brands.

Potential benefits of category extensions include immediate name recognition and the transference of benefits associated with a familiar brand. For example, Chipman-Union's introduction of branded deodorizing athletic socks in 1980 was helped by licensing the "Odor-Eater's" name used originally by Combe, Inc. for its successful line of deodorizing foot-pads.

Moreover, category extensions eliminate the high costs of establishing a new brand and often reduce the costs of gaining distribution (e.g., Morein, 1975; Kesler, 1987). Such advantages have even led some companies to resurrect "has-been" brands; Pfizer revived the Barbasol brand and extended it first to a new line of aerosol-foam shaving creams (Saporito, 1986) and then to shaving gels and anti-perspirants.

A well-known brand name does not guarantee a successful extension. Abrams (1981) points to Arm & Hammer anti-perspirant, Life Savers gum, and Welch's prune juice as extensions that failed. Indeed, an extension can weaken the parent brand in the original category (Tauber, 1981).

Therefore, leveraging a brand's equity through extensions to new categories carries both opportunities and risks. The opportunities are represented by the firm's growth potential in the new category. Risk comes not only from a new product failure, as noted above, but also from the success of a category extension. Success carries the risk that the entire brand franchise can be diluted.

Ries and Trout (1986) describe many of the dangers of over-extending a brand name, and generally advise against category extensions.

THE RELATIONAL MODEL

Farquhar (1989) defines *brand equity* as the "added value" that a brand endows a product; this added value can be viewed from the perspective of the firm, the trade, or the consumer. Brand equity from a consumer perspective is reflected by the increase in the strength of associations an individual has for a product using the brand.

This paper specifies more precisely the structure of these associations and seeks to identify the processes which mediate consumers' judgments of a category extension of a brand. Herr, Farquhar, and Fazio (1989) implement the relational model by measuring (a) the strength of associations between brands and product categories, (b) the relatedness of different product categories, and (c) the transferability of features between a parent brand and a new item in a different product category. Some of their key findings are summarized here.

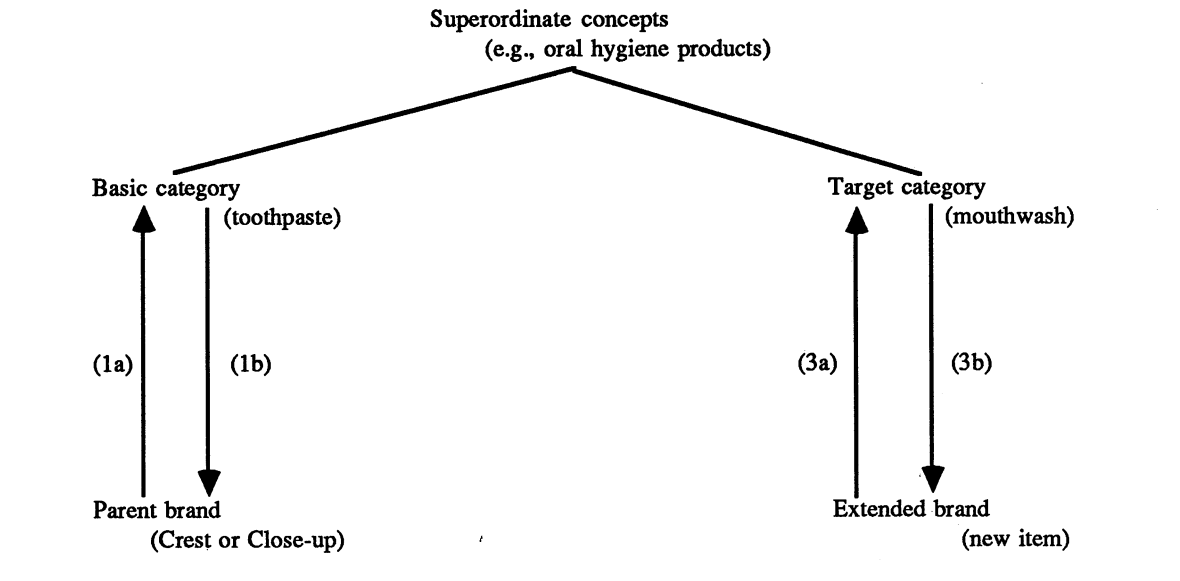

Figure 1 describes the *relational model* for investigating product categorization and brand extensions. The "parent brand" is presumably associated with only one product category, called the "parent category". Thus the basic model considers neither "family brands" used across several categories, such as IBM or Kraft, nor "ambiguous brands" that evoke multiple, unrelated categories, such as Cadillac (automobiles and pet food) or United (airlines and gasoline). The relational model can be modified later to accommodate these generalizations if necessary.

The *brand-to-category association* in (1a) measures the likelihood that observation of the parent brand activates various features that characterize the basic category. For example, Crest is strongly associated with the features of toothpaste, while for many consumers Close-up is weakly associated with the toothpaste category. We refer to the "brand-to-category associative strength" as *typicality* (Smith and Medin, 1981). Barsalou (1985) discusses possible determinants of typicality, while Loken and Ward (1987), Ward and Loken (1988), and others describe recent consumer studies of typicality.

One measure of brand-category associative strength or typicality is the time subjects take to respond correctly to the query, "Is a product with brand X sold in category Y?" By comparing response latencies within a given product category, we can establish the relative typicality of a given pair of brands.

On the other hand, the *category-to-brand association* in (1b) considers the ease with which the brand will be retrieved from memory given

FIGURE 1
The Relational Model of Brand Extensions

exposure to the category (Shiffrin and Dumais, 1981; Fazio, 1989). We refer to the category-to-brand associative strength as *cognitive dominance*. Thus, a "heavier" or "more dominant" brand is more likely to be recalled in a category than a "lighter" brand.

Fazio (1987) compared different measures of cognitive dominance for various brands in 25 product categories and found high convergent validity among the measures. One method measures response latencies to correctly identify a brand as belonging to a product category. The query is, "In category Y is a product sold with brand X?" Faster correct responses indicate stronger category-brand associations.

One distinguishing characteristic of the relational model is the directional nature of associations between a brand and a category. A strong brand-to-category association (e.g., the "Ferrari" brand with the category "automobiles") does not necessarily imply a strong category-to-brand association (e.g., the "automobile" category does not usually activate "Ferrari"). Thus a "typical" brand, in the sense defined, need not be a "dominant" brand in a given product category. Conversely, a "dominant" brand in a category need not be a "typical" brand (e.g., "Haagen-Daz" is a super-premium ice cream). The asymmetric relationship between a category and a member is discussed further in Tversky and Gati (1978) and Smith and Medin (1981). An analogous pair of relationships exists for (3a) and (3b).

The *category-category relatedness* in the relational model in (2) depends upon the strength and accessibility of superordinate concepts linking the two categories. For example, Aaker and Keller (1990) discuss three factors that contribute to

relatedness from a longer list of factors given by Albion (1985): *complementarity* (e.g., a common usage situation - tennis racquets and tennis balls), *substitutability* (e.g., a common function - wine and beer), and *similarity* (e.g., common features - automobile and motorcycle). There are obviously other factors that relate two product categories from a consumer's perspective.

RESEARCH WITH THE RELATIONAL MODEL

The likelihood of activating a memorial representation of the product category and its defining features when encountering a brand name presumably increases with the typicality of the brand. We hypothesize that typical brands in a product category are more easily extended (in the sense of learning new associations) to closely related target categories than to distant target categories. Furthermore, we conjecture that dominant brands will be difficult to extend to unrelated target categories, because of the exemplary nature of such brands in their original product categories.

Fazio's (1987) investigation of cognitive dominance provides a standard set of stimulus materials that are well calibrated on category-brand associative strength. For each of 25 different product categories, Fazio identified brands that vary in the strength of their association with the product category.

Herr, Farquhar, and Fazio (1989) used a subset of these brands and categories as stimulus materials in testing various aspects of the relational model. One study measured typicality by examining subjects' latencies to respond correctly to queries about a given brand belonging to a parent category.

Comparisons with Fazio's (1987) category-brand queries for dominance confirmed the hypothesized asymmetric relation between typicality and dominance.

Another study tested the hypothesis that relatedness influences the time subjects need to identify a product category as *not* being sold by a particular brand. The results provide overwhelming support that the less related the target category and the parent category, the faster subjects could identify the target category as not being associated with the brand.

Herr, Farquhar, and Fazio (1989) further demonstrated that the learning of new brand to target category associations depends upon the effects of the brand's cognitive dominance and the parent to target category relatedness. For example, subjects memorized one of several lists of brand-category pairs. Subjects were then given a cued-recall test where a brand was presented and they were required to retrieve the target category with which it had been paired in the list. Subjects were able to retrieve significantly more target category terms when those categories were closely related to the parent category than when the target categories were distantly related.

Tauber (1981) notes that feature transfer from the parent brand to the category extension is a critical element in the success of a newly introduced item. Herr, Farquhar, and Fazio (1989) also addressed this issue using the relational model. The focus, however, shifts from the typicality and dominance in (1a) and (1b) to the analogous relations in (3a) and (3b). Nedungadi and Hutchinson (1985), Ward and Loken (1988), and others have conducted preliminary studies showing positive correlations between typicality and preference for a brand, but did not identify the underlying processes for transferability of attitudes from the parent brand to an extension.

Herr, Farquhar, and Fazio (1989) found that subjects expressed greater liking for brands extended to closely related rather than distantly related categories. Moreover, dominant brand extensions were liked significantly more than their weak counterparts when extensions were to closely related categories. Similar results were found with "intention to buy" as the dependent measure. Thus, "evaluative" associations of the brand were transferred to the category extension as well. Recent research by Fazio (1986, 1989), Herr (1989), and Herr and Fazio (1989) describes the cognitive processes involved in such feature transfers.

Additional studies have investigated the relationship between basic components of the relational model and market level variables, such as market share. Preliminary analysis of the Fazio (1987) brands reveals a very strong correlation between the strength of category-brand association and the market share held by a brand. For these product categories, "cognitive dominance" is indeed reflected by "market dominance". Data were also collected on levels of advertising expenditures per brand as a function of cognitive dominance. In

every case, the "strong" category-brand associate spent more on advertising than did the "weak" category-brand associate.

RELATED RESEARCH ON CATEGORY EXTENSIONS

Several researchers are developing somewhat different frameworks that focus on consumer knowledge, memory, and inference in category extensions of brands. These approaches share a common theme that emphasizes the importance of memory content and structure in evaluating brand extension outcomes.

Aaker and Keller (1990) hypothesize that consumers may hold four types of *associations* in long-term memory that bear on category extensions. These associations occur between a brand and (1) the attributes of that brand, (2) consumer attitudes toward that brand, (3) the attributes of the product category, and (4) consumer attitudes toward the product category. Aaker and Keller suggest that the presence and strength of these associations affect consumer judgments of the "degree of fit" between the existing brand and its potential extension to a new category. These intervening judgments are important in predicting success of a given brand extension.

Park, Lawson, and Milberg (1988) propose that the success of a brand extension is mediated by a consumer's *categorization* of the new item. They suggest that categorization is driven primarily by similarity judgments that depend on the memory structure for the specific brand in question. Park et al. identify three distinct structures for memory of brands and draw managerial implications for each type of structure.

Bridges (1989) suggests that a *brand schema* ("the bundle of associations, beliefs, and expectations that consumers have for a brand", p. 7) affects consumers' evaluations of brand extensions. She conjectures that the outcome of judgments of "fit" depends upon the brand schema, the relationship between the existing and the extended products, and additional information about the extension.

Given the recent attention on brand equity by the Marketing Science Institute and other research organizations (Leuthesser, 1988), the number of related approaches is likely to grow.

DISCUSSION

The relational model for category extensions of brands includes three types of associations: (i) brand to category, (ii) category to brand, and (iii) category to category. The strengths of these associations are called *typicality*, *dominance*, and *relatedness*, respectively. The possible asymmetry in the relationship between typicality and dominance is a distinguishing characteristic of the model.

Early research provides support for the relational model. In particular, typical brands in a product category are more easily extended (in the sense of learning new associations) to closely

related target categories than to distant target categories. Furthermore, dominant brands are not easily extended to distant target categories, because of the exemplary nature of such brands in their original product categories. Herr, Farquhar, and Fazio (1989) provide further details.

The relationship between typicality and dominance is of further practical interest for exploring the *limitations* of brand extensions. When the same brand has been extended to a wide variety of target categories, we do not expect the parent brand's dominance in the original category to diminish, but we would expect a dilution of typicality. The strength of association from the parent brand to the basic category should diminish as a direct function of the success, number, and variety of brand extensions. Thus, the relational model offers one way of measuring the potential for "brand confusion" from over-extension (see Ries and Trout, 1986).

The distinction between typicality and dominance in the relational model addresses another issue in brand extensions. Some brands are so typical of a particular target category that consumers mistakenly believe that the brand extension exists when it does not. For example, many respondents in aided awareness tests said they had heard of McDonald's onion rings and Wang pocket calculators. One firm reportedly found that a proposed brand extension was already thought to exist by about half of the customers surveyed (Goydon, 1984).

"Spurious awareness" of non-existent brand extensions is both a blessing and a curse for marketers (see Farquhar and Pratkanis, 1987). To the extent that a strong association already exists, a firm might well consider a brand extension to that target category. Less effort would be needed for creating awareness, and more could be spent on other activities. On the other hand, "spurious awareness" can lead to misinterpreting advertising effectiveness measures and mismanaging the introduction of the brand into a new category.

The relational model appears to be a useful conceptualization of the associations between brands and categories that influence the success of extensions from a consumer perspective. Continuing research will refine the basic model through further consumer experiments, field studies, and market analyses.

The Cognitive Representation of Services Varying in Concreteness and Specificity

Laurette Dubé-Rioux, University of Montréal
Dennis T. Regan, Cornell University
Bernd H. Schmitt, Columbia University

Researchers and practitioners have suggested that the inherent intangibility of services should be taken into account when designing marketing communications for services, but there is little agreement as to how this should be done. A reconciliation of the issue requires more detailed knowledge about how consumers cognitively represent services. We conceptually and empirically divide the concept of "intangibility" into the separate, but related, dimensions of concreteness and specificity. We then demonstrate that services differing on the former (but not the latter) dimension reliably call to mind salient attributes differing on both dimensions of concreteness and specificity. The results are a first step in understanding how different levels of concreteness and specificity should be used in marketing communications for services.

The elements or attributes composing services are typically more abstract and intangible than those of consumer goods (Fuchs, 1985). In fact, services have been described as "doubly intangible": not only do most services lack material substrates, but they are also difficult to grasp mentally, because consumers may be unsure what exactly they are purchasing when they receive a service (Bateson, 1979). Consequently, researchers and practitioners have suggested that marketing communications for services should take into account the inherent intangibility of services (George and Berry, 1981; Shostack, 1977).

However, researchers do not agree about how this should be done. In fact one can find two radically different views about communication strategies for services. Some researchers have argued that because services are intangible, they may be represented in the consumer's mind relatively abstractly and therefore should be advertised relatively abstractly (Rothschild, 1987). Others have argued that service advertisements should be made concrete and visual in order to overcome the inherent disadvantage of services' intangibility (George and Berry, 1981; Shostack, 1977). A reconciliation of the issue may require more detailed knowledge about how consumers cognitively represent services. Moreover, in generating the above propositions, researchers may have focused too much on contrasting consumer goods with services and may have overlooked the enormous variability that exists among services. Although services are generally more intangible than consumer goods, services differ widely among themselves on the dimension of intangibility. Some services, such as life insurance or college, are relatively "abstract" and typically associated with intangible attributes (e.g., security or knowledge).

Other services, such as health services and auto repair, are more "concrete" and invoke sensory experiences. Therefore, rather than proposing one communication approach for all services, different communication strategies may be needed for services that vary in degree of intangibility.

Further complicating matters, the concept of intangibility itself is not clearly defined when it comes to services. For both services and their attributes, the concept of intangibility has been frequently related to the dimension of abstractness/concreteness. But the concept of abstractness/concreteness itself is unclear, and researchers have investigated at least two different notions of it (for a review see Paivio, 1965). One definition -- which from now on we will call *concreteness*-- relates to accessibility to the senses (Paivio, Yulle, and Madigan, 1968). The other view -- which we will call *specificity*-- refers to subordination, the specificity of a word being inversely related to the number of subordinate words it embraces (Spreeen and Schulz, 1966). Because the two notions of intangibility are perhaps independent (Paivio, 1965; Kammann and Streeter, 1971), an intangible attribute such as a piece of legal advice, may be at the same time both specific and abstract. Research in marketing, in focusing on cognitive representations of durable and non-durable goods at the level of the specific brand and of the generic product category (e.g., Johnson, 1984; Johnson and Fornell, 1987), has thus far exclusively addressed the *specificity* view of the abstractness/concreteness concept. Yet the question of a possible effect of different levels of the *concreteness* of representations defined in terms of accessibility to the senses should also be addressed as it may be equally relevant for both goods and services.

In this research, we study how both dimensions (concreteness and specificity) affect the cognitive representation of services. Johnson and Fornell (1987) have already shown that the specificity of a product representation can affect the level of specificity of attributes that consumers have represented in conjunction with the product. For three superordinate category types (home entertainment, domestic appliance and transportation), they investigated the level of specificity of attributes generated under three levels of product abstraction (superordinate category, product category, and brand). In a free elicitation task, they found a significant difference between the level of specificity of attributes generated at the superordinate level compared to the ones generated at the product type and brand levels, which did not differ significantly. Given Johnson and Fornell's findings that specific product attributes are linked to brands while generic attributes are linked to product

categories, two research objectives arise: (i) to investigate whether cognitive representations of services have similar structures, and (ii) to extend Johnson and Fornell's research on the dimension of *specificity* to include the dimension of *concreteness*.

METHOD

Pretests

The stimuli for the experiment were selected on the basis of two extensive pretests. The purpose of pretest 1 was to generate a list of attributes for a number of services provided by the experimenter. In a free elicitation task, 42 graduate students in marketing were asked to write the first five attributes that come to mind when they think about the services. Attributes were aggregated across subjects, and the 18 most frequently mentioned for each service were retained for further study. In pretest 2, 18 psychology students rated the concreteness (1=very abstract, 7=very concrete) and specificity (1=very generic, 7=very specific) of 12 services and, in addition, the concreteness (i.e., the degree to which they can be experienced with the senses) and the specificity (i.e., to how many instances they refer) of the list of attributes that subjects had generated for these services in pretest 1. Subjects read the following explanations for the two dimensions:

Concreteness ratings: The degree to which we can experience services with our senses varies. A very concrete service is one whose features or outcomes can be seen, felt, smelled or tasted. A very abstract service is one that cannot be experienced by the senses as such. For example, "cleaning services" are very concrete; "airlines" deliver slightly less concrete services, and the services provided by "Place, Life Insurance Co." are the most abstract, i.e., they cannot be seen, felt, smelled or tasted.

Specificity ratings: One may refer to services in a highly specific or in a less specific way. The more specific a service is, the more words used to describe it are restricted to only one or two actual instances of the given type of services. For example, a highly specific word refers to a very particular instance, i.e., it can be applied usually only to one specific member of a class. The less specific a word, the more it becomes applicable to a larger number of services in that class, i.e., it is more generic. You should note that "cleaning services" is presented in a very generic form since there may be all kinds of cleaning services; that airlines is slightly more specific, and "Place, Life Insurance Co." is most specific, referring to a firm selling a particular type of insurance.

The following explanations of the concepts of concreteness and specificity for attributes were provided:

Concreteness ratings: Attributes are very *concrete* if they represent features or outcomes of a service that can be seen, felt, smelled or tasted. Attributes are very *abstract* if they refer to features or outcomes not experienced by the senses as such.

Specificity ratings: Attributes are very *specific* if they refer precisely to identifiable features or outcomes of a service. Attributes are very *generic* if they refer to more general aspects of features or outcomes of a service, or to general aspects of the service itself.

Based on the results of the pretests, eight services were selected as stimuli for the experiment: two abstract/generic services (college education and legal services), two abstract/specific services (*Morton College of Arts and Sciences and Thompson & Associates Divorce Specialist*), two concrete/generic services (healthcare and auto repair), two concrete/specific services (*Max Krauss, Doctor of Dentistry and Fix-it, Muffler / Brake Shop*). Thus services were selected according to a 2 (concreteness) X 2 (specificity) factorial design with one replication.

Procedure

Thirty-four graduate students in marketing (14 females and 20 males) participated in the experiment. The average age of the participants was 28.

To confirm that we had selected through the pretests services that indeed varied along the dimensions of concreteness and specificity, subjects who actually participated in the experiment were asked to rate again all eight services in terms of concreteness and specificity. In addition, for four services, subjects were asked to check (from a list of 18 attributes that had been generated in the pretest) those five attributes which first came to mind when they thought about the particular service. The four services were selected on the basis of a replication of a Latin square design, and four different sets of four services were constructed in order to eliminate the possible confounding effects of certain stimulus combinations. Finally, subjects were asked to rate on seven-point scales the complete list of attributes for each of the four services in terms of concreteness and specificity.

RESULTS

Preliminary analysis

Were the concepts of concreteness and specificity of services successfully operationalised as two independent dimensions? First, two 2 (concreteness of the service) x 2 (specificity of the service) ANOVAs conducted on the concreteness and specificity ratings of services, revealed a strong main effect of manipulated *concreteness* on the concreteness ratings and a strong main effect of manipulated *specificity* on the specificity ratings of services (both $p < .0001$). In addition, there was a

TABLE 1
Mean ratings of concreteness and specificity* of most salient attributes as a function of services' concreteness and specificity.

	Generic Services		Specific Services		Overall	
	Attributes Concreteness	Attributes Specificity	Attributes Concreteness	Attributes Specificity	Attributes Concreteness	Attributes Specificity
Abstract Services	3.42	3.88	3.47	4.00	3.44 _a	3.94 _a
Concrete Services	4.35	4.82	4.22	4.57	4.28 _b	4.70 _b

* 1- 7 scale with 7 being most concrete and most specific.

Means with different subscripts are significantly different at $p < .05$. The comparisons were done row wise and column wise.

significant, but weaker ($p < .05$) main effect of *specificity* on the concreteness ratings. More specific services tended to be rated as more concrete. Thus, while concreteness ratings were strongly affected by the concreteness manipulation, and to a lesser extent by the specificity manipulation, specificity ratings were uniquely and strongly affected by the specificity manipulation. Second, the average correlation between the two scales was assessed by backtransformed average Z score; it was modest ($r = .26$) and marginally significant ($.05 < p < .10$). Thus, although the two dimensions of concreteness and specificity of services were intercorrelated to some extent, the intercorrelation seemed to be low enough to justify the investigation of both variables separately. Finally, the interrelation between the two dimensions was assessed for the service attributes. The average correlation between the two scales of concreteness and specificity for attributes was .41 ($p < .01$), a magnitude consistent with previous findings (Spreen and Schulz, 1966; Kammann and Streeter, 1971).

Consistency of cognitive representations

To test the hypothesis that there is consistency between the representation of services and their attributes on both the dimensions of concreteness and specificity, a multivariate analysis of variance (MANOVA) was conducted on the concreteness and specificity ratings of each subject's five salient attributes. The results revealed a main effect of manipulated service concreteness on ratings of both attribute concreteness and specificity ($F[2, 70] = 14.50, p < .001$). The main effect of specificity of services and the interaction were not significant (means are presented in table 1). Thus when subjects think about abstract services such as education and legal services, the attributes that first come to their mind are both more abstract and generic than when the same subjects think about

concrete services, such as health care and auto repair. On the other hand, when they think about generic services, such as healthcare services, the salient attributes are neither more generic nor more abstract than when they think of a specific instance of the service, such as *Dr. Max Krauss*, Doctor of Dentistry.

Because the list of attributes differed between abstract and concrete services, but not between generic and specific levels of a service, this result could simply reflect the fact that the pool of attributes from which salient attributes were extracted was, as a whole, more abstract and generic for abstract services, and more concrete and specific for concrete ones. In this case, attributes randomly selected from this pool will show the same bias. To rule out this rather plausible alternative explanation, we conducted an idiographic analysis comparing, for each service, the concreteness and specificity ratings that a subject assigned to salient and non-salient attributes. An individual difference score was computed by subtracting, for each subject, the average rating of the five salient attributes from the average rating of the thirteen non-salient attributes. These difference scores indicated whether the two clusters of attributes were rated differently, e.g., as more or less concrete or specific. Nine subjects had provided concreteness and specificity ratings only for the five salient attributes. Their data were excluded from this idiographic analysis.

Average difference scores across all subjects are shown in Table 2 along with significance levels for relevant t tests. The results show that the effect of service concreteness on the ratings of salient attributes is not artifactual and may indeed indicate how subjects cognitively represent services. The idiographic analysis showed that, compared with concrete services, the salient attributes of abstract services were both less concrete and less specific (both $p < .05$). The idiographic analysis also

TABLE 2

confirmed the null effect of the specificity manipulation: no significant differences were found between salient and nonsalient attributes of specific and generic services. A closer analysis of this idiographic score shows that in absolute terms, at least for the list of services we presented to our subjects, *abstract* services call to mind salient attributes that are reliably more *abstract* than nonsalient ones, whereas *concrete* services call to mind salient attributes that are reliably more *specific* than nonsalient ones. Whether these results mean that in general one should highlight abstract attributes when communicating about abstract services, and specific attributes when trying to sell a concrete service, is a question we are currently studying.

DISCUSSION

The results of the experiment indicate that attributes that spontaneously come to consumers' minds when they think about services differ, depending on certain properties of the services. Abstract (as opposed to concrete) services, whether they are generic or specific, bring to mind both more abstract and more generic attributes. When individuals think about college education in general, or about a specific college, knowledge is more likely to come to mind than the comfort provided by a classroom or the location of the campus. The challenge faced by the advertiser of such a service is to preserve the "abstract" essence of this service--the reason why people use it--and then to communicate effectively its characteristics and benefits to the consumer.

Contrary to what we predicted on the basis of Johnson and Fornell's (1987) findings, the level of specificity of services did not affect either the level of specificity or the level of concreteness of salient

attributes. Can methodological artifacts explain the failure of the specificity manipulation to affect attribute salience? Perhaps subjects could not possibly be familiar with the artificially constructed names of the service providers. Therefore, the name may not have provided any diagnostic information so that subjects may have relied solely on the category attributes. A more psychologically interesting cause of the null effect of the specificity manipulation may be intrinsically linked to the "doubly intangible" nature of services. As we said previously, most services -- and the most abstract ones in particular -- lack material substrates and are difficult to grasp mentally. As a result, consumers may be unable to perceive and to describe services in highly specific terms, even when they consider individual brands or service providers. The idiographic comparison of the concreteness and the specificity ratings of salient and nonsalient attributes seems to converge in that direction: for abstract services, salient attributes are significantly more abstract -- and not more generic-- than nonsalient attributes whereas for concrete services, salient attributes are significantly more specific but not more concrete than non salient ones. Thus, consumers may cognitively represent concrete services in a way very similar to physical goods. What seems to matter for concrete services and physical goods is the specificity of the attributes rather than their degree of concreteness. On the contrary, more abstract services are cognitively represented by abstract, but not necessarily less specific attributes.

The ultimate goal of our research is to understand how different levels of concreteness and specificity should be used in marketing communications for services, and we believe that an important first step is clarifying how services and

their attributes are cognitively represented. The present study has concentrated on mental representations of services and has shown that abstract and concrete services are cognitively represented differently. One possible strategy may be to strive for a match between the specificity and concreteness of the mental representations of services and the content of marketing communications. A test of this proposition requires comparison of the effect of a match and of a mismatch between specificity and concreteness of services and attributes or benefits featured in their advertisement (or other communications), using measures of persuasiveness, recall, and recognition as dependent variables. A study on marketing communications for services that vary along the abstractness/concreteness and genericity/specificity continuum is currently in progress, using a variety of judgement and memory tasks.

Testing a Theory of Crowding in the Service Environment

Michael K.M. Hui, Concordia University
John E.G. Bateson, The London Business School

ABSTRACT

Perceived crowding is important to the managers of retail service settings. With a fixed area of space (the physical capacity), service managers need to know the maximum customer density level their customers will tolerate (the effective or physical capacity). This paper presents an empirical test of the control theory of crowding which suggests that perceived control is an important intervening variable between physical density and perceived crowding. The results confirm the theory and show that perceived choice is associated with perceived control and hence can modulate the effect of density.

INTRODUCTION

Retail services can be thought of as services that are produced through interactions between customers and the contact personnel, environment and physical support provided by service firms (Eiglier and Langeard, 1977; Langeard, Bateson, Lovelock, and Eiglier 1981). For example, to deposit \$10 into a bank account, a customer has to go to a branch of his/her bank (the physical environment), fill in a slip (the physical support) and give the money and the slip to a teller (the contact personnel). Obviously, in order to produce a service, customers must be present in a milieu, usually the retail outlet of a service firm so that these interactions can occur.

One important characteristic of retail services is that they are produced and consumed simultaneously and hence cannot be inventoried (Eiglier and Langeard 1977). Meanwhile, the demand of any retail services is rarely smooth over time. Since stocks cannot be used as a tool to buffer the fluctuation in demand, crowds are unavoidable for retail services. One of the major determinants of the capacity of a service firm is the total area of that part of the premises accessible to the customers. When the demand level approaches or exceeds the service firm's capacity limit, there will be a high density of customers, being served or waiting to be served, in its premises. A huge crowd of people or long queues in banks, subways, supermarkets and other common service organizations is no longer a strange feature to consumers in the 1980's. The pervasiveness of crowding in retail services makes it an issue which deserves research attention from consumer researchers.

Stokols (1972) has contended that there is a need to distinguish between two terms "density" and "crowding". Density is defined by Stokols as "the physical condition, in terms of spatial parameter" while crowding is a psychological experience characterized by stress. This paper draws upon the latest theoretical developments in environmental psychology which suggest the importance of perceived control as an intervening variable between

density and crowding. The procedures and findings of an experimental study conducted to test the control theory of crowding in the context of service delivery are presented.

THEORETICAL DEVELOPMENT ON HUMAN CROWDING

Findings from both laboratory settings (see, for example, Paulus, Annis, Seta, Schkade, and Matthews 1976) and real-life settings (see, for example, Mackintosh, West, and Saegart 1975) have indicated that crowding does have deleterious effects on human response such as interpersonal behavior and task performance. However, a number of other experimental studies have obtained the opposite findings. They have shown that crowding can have no, or even positive, effects on human behavior (see, for example, Freedman 1975). For a review, please refer to Sundstrom (1978).

The equivocal experimental evidence have forced theorists to revise their conceptualization of human crowding. Stokols (1972) is one of the pioneers who has tried to clarify the conceptual confusions in the study of human crowding. As noted earlier, he suggests that "density" and "crowding" are two different concepts. Density is a function of the area and the number of people in a setting. By contrast, crowding refers to the stress experienced by the occupants of a setting when there is an "excessive" number of people there. The term "excessive" needs to be elaborated. At least three different theoretical models have been developed to specify the crucial antecedents of crowding and explain why a certain number of people are considered as excessive or not excessive in a setting. The three models are commonly known as the overload model, the behavioral constraint model, and the ecological model.

The Overload Model

The main argument of the overload model is that crowding results when one's mental ability is unable to deal with all the impinging environmental stimuli. Altman (1975) has argued that crowding is an outcome of one's failure to maintain a desired level of social interactions through means like personal space and territoriality.

The Behavioral Constraint Model

The development of the behavioral constraint model draws heavily from Brehm's (1966) reactance theory which states that there is a basic desire among human beings to maintain their behavioral freedom. According to the model, a certain amount of people will be evaluated as excessive (and hence result in the perception of crowding) for a setting when one's desired actions are restricted or made impossible because of the presence of other people. It is conceivable that pressure and norms imposed

by other people can restrain one from performing some kinds of actions. The constraint can be physical and instrumental as well.

The Ecological Model

Manning theory has also been used to explain human crowding. According to the theory, an individual's behavior is determined by the supply and demand of social roles existing in a setting. An individual will perceive more crowding when a setting is "overmanned" (when the number of occupants of the setting exceeds that required for the normal functioning of the setting) than when it is "undermanned". Similar arguments have been proposed by a number of authors that the perception of crowding is a function of the supply and demand of resources available in a setting (Stockdale and Schopler 1976). Empirical support for the ecological model, however, is far sparser than for the other two models.

PERCEIVED CONTROL AS AN INTERVENING VARIABLE BETWEEN DENSITY AND PERCEIVED CROWDING

According to a number of authors (Baron and Rodin 1978; Schmidt and Keating 1979), however, all the three conceptual models of crowding (overload, behavioral constraint, and ecological) can be subsumed under the concept of control. A review of the concept of control is deemed necessary before its relationship with crowding is explored.

Three Types of Control

Control has been operationalized in various distinctive ways which have been grouped by Averill (1973) into three different categories: behavioral control, cognitive control, and decisional control. In Averill's own terms, behavioral control refers to the "availability of a response which may directly influence or modify the objective characteristics of an event" (p. 286). Cognitive control is "the processing of potentially threatening information in such a manner as to reduce the net long-term stress" (p. 293). Cognitive control does not require behavioral control, rather it refers to a sense of "feeling in control". This has been broken down into predictability and evaluation in the literature. Finally, decisional control is regarded as the extent of "choice in the selection of outcomes or goal" (p. 289).

Crowding and Control

Constraints on or interruption of behavior obviously reduce one's ability to deal effectively with the environment in the way one desires (behavioral control, as in Averill's terms). Moreover, the more the constraints, the smaller will be the number of options available to an individual in the selection of (a) situational goals, and (b) means to attain the goals (decisional control, as in Averill's terms).

When an individual's mental capacity is impaired by excessive stimulus, he/she is less likely

to collect and evaluate useful environmental information. As a result, environmental events will look less predictable and effective cognitive or behavioral coping (behavioral and cognitive control, as in Averill's terms) will become less likely.

In an overmanned setting, any marginal occupants are likely to be ignored by the majority and hence there is less chance for them to affect the social and physical characteristics of setting (behavioral control). On the other hand, any existing member is important to an undermanned setting and there is greater opportunity for an individual to claim the setting's resources and manipulate the setting in the way he/she desires.

It is conceivable therefore that all the harmful effects caused by behavioral constraints, information overload, or overmanning can be explained by Averill's three types of control as Baron and Rodin (1978) have noted:

"It appears that when density variation have no direct implications for control as in certain of the studies involving manipulations of room size ..., variations in density do not produce differential stress effects. Thus there is a preliminary indication that the density-control may not only be a sufficient condition for stress instigation but a necessary condition." (p. 181).

In other words, perceived control is suggested to be a crucial intervening variable between density and perceived crowding.

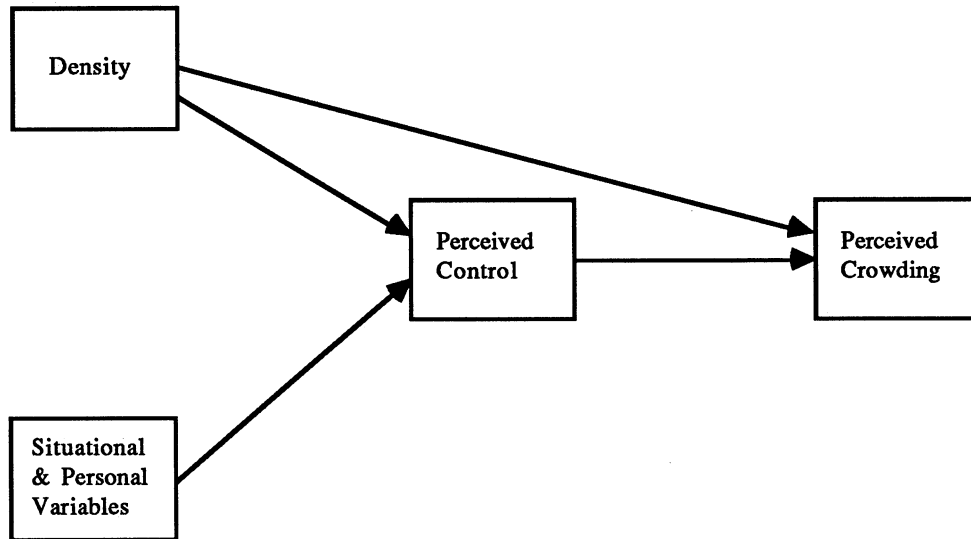

SITUATIONAL AND PERSONAL DETERMINANTS OF PERCEIVED CROWDING

Besides density, however, it has been shown that a large number of physical, social, and personal factors can also modify an individual's perceived control without any variation in environmental density. A logical conclusion from the argument is that for a fixed density level, perceived crowding can vary between situations and persons.

For example, architectural design of university dormitories has been found to be a key determinant of the residents' perception of crowding (Baum and Valins 1977). Other design variables such as partitioning (Desor 1972), signage (Wener and Kaminoff 1983), and even the shape (Desor 1972), colour (Baum and Davis 1976), and light level (Baum and Davis 1976) of a setting have also been demonstrated to affect human crowding.

From a social-situational perspective, empirical evidence has revealed that crowding is affected by the nature of activities within a setting - recreational versus work, interactive versus coactive, cooperative versus competitive (Cohen, Sladen, and Bennett 1973; Stokols, Rall, Pinner, and Schopler 1973). Moreover, acquaintance, group membership, and some basic social structure

FIGURE 1
The Control Theory of Crowding

developed within a group can also alleviate one's perception of crowding (Baum and Koman 1976).

Finally, demographic and personal variables like sex (Baum and Koman 1976), locus-of-control (Schopler and Walton 1974), and desire for control (Burger, Oakman, and Bullard 1983) have also been shown to affect an individual's perception of crowding.

It is difficult, if not impossible, to give an exhaustive list of mediating variables for crowding. However, a review of those variables which have been shown to affect crowding suggests that most of the variables actually affect one's perception of control. For instance, social structure has been shown to reduce perceived crowding (Baum and Koman 1976). The finding can be interpreted by suggesting that social activities will become more organized and hence more predictable when a simple social structure or hierarchy is developed within a group of individuals. Therefore, the first hypothesis is formulated as follow:

[Hypothesis 1] At a certain density level, perceived crowding is a function of all the environmental, situational, and personal variables which influence an individual's perceived control in a setting.

THE CONTROL THEORY OF CROWDING

As noted earlier, perceived control is suggested to be a crucial intervening variable between density and perceived crowding. Nonetheless, within a setting, manipulation of physical density has been found to exert a significant main effect on perceived crowding (see for example, Langer and Saegart 1977).

Alternatively, other things being equal, higher density is expected to lead to higher perception of crowding. As a result, the second hypothesis is formulated as follow:

[Hypothesis 2] Density is hypothesized to affect perceived crowding both directly and indirectly through perceived control.

Hypotheses 1 and 2 together can be represented by Figure 1 which is labelled hereafter as the "control theory of crowding". In the remaining parts of this paper, the methodological procedures and findings of a study conducted to test the theory are described.

AN EXPERIMENTAL STUDY

An experimental study was conducted to examine the validity of the control theory of crowding within the service setting: In essence, a 3 (high, medium and low density) x 2 (choice, no choice) x 2 (slide, video) factorial design was employed. The extent of choice available to an individual has been argued by Averill (1973) as a major situational determinant of perceived control. Moreover, customer choice has been suggested to be a crucial concept related to the strategic issue of service customization (Surprenant and Solomon 1987). Hence customer choice was selected as the situational variable (see Figure 1) to be manipulated in the study.

Customer Density Manipulation

Customer density was operationalized by slides and video tapes portraying three different numbers of customers in the ticket office of a major railway station in London, England. The

employment of two different representative media (slide and video) to simulate the same service setting allowed the researchers to detect any response bias caused by either media. The slides and video were taken at the station on two weekdays. On the first day, a photo camera, with a 24 mm lens, was fixed at one corner of the ticket office. On average, one picture was taken every 4 to 5 minutes and a total of 35 slides were obtained. Since the slides were shot by the same camera from the same location, the only difference between the slides is the number of customers present in the ticket office. On the second day, twenty-five 90-second video sequences were taken by a video camera, fixed at the identical spot where the photo camera was located.

The number of customers shown in each slide and video sequence was then counted. The slides which had the highest and lowest number of customers were selected to simulate the high and the low customer density environments. One more slide with a number of customers equal to the mid-point between the two extremes was selected to represent the medium density environment. Three video sequences which showed approximately the same numbers of customers as the three selected slides were also retained for the study.

The Choice Manipulation

Choice was operationalized through two different written scenarios, both of which described the service situation in the station:

[High choice]

It is ten o'clock on Saturday morning and Mr. Y is going by train to visit his friend. Tickets are sold in the railway station at both the ticket office and through an automatic ticket machine located next to the office. Mr. Y decides to buy the ticket from the ticket office. Of course, he can always change his mind and go for the machine. However, he sticks to his original decision throughout the process. The slide we are going to show you depicts the setting of the ticket office while Mr. Y is there.

[Low choice]

... However, the machine only sells normal fare tickets. Since Mr. Y wants a cheap day-return ticket, he can only buy it from the ticket office. The slide ... there.

The two situations described by the written scenarios can be regarded as the service analogues of the two treatment conditions employed in a series of studies conducted by Glass and Singer (1972). In the studies, a stressful stimulus (e.g. electric shock) was administered to the subjects. Half of the subjects, however, were given an option to avoid or escape from the stimulus but they were asked not to exercise the choice as long as they felt the stimulus was tolerable. As a result, no subject selected the escape or avoid option and hence all the subjects

went through the same stressful experience. Nonetheless, the choice subjects did feel and behave better than the no-choice subjects.

A similar approach was adopted in the design of the two written scenarios. In the high choice situation, Mr. Y can avoid the potentially stressful setting (when there are a lot of people there) by using the ticket machine but he does not take the available option. However, unlike the manipulations employed by Glass and Singer (1972), there is no guarantee in terms of the present manipulations that the alternative option (ticket machine) is a better one. Nonetheless, the mere existence of a similar option has been shown to increase an individual's perceived choice (Harvey and Johnston 1973) and hence is expected to elevate his/her perceived control as well.

Finally, Havlena and Holbrook (1986) have suggested that there are two advantages of using a hypothetical figure (Mr. Y) in a written scenario:

"... (a) to provide a projective task and thereby to discourage social desirability effects, and (b) to avoid problems involving individual differences in reactions to specific types of activities" (Havlena and Holbrook, 1986, p. 396.)

One hundred and twenty-three individuals, age between 17 and 57 were recruited from the streets of a coastal city in the south of England to participate as the subjects of this study. The subjects were divided into 24 groups of four to six people. Each group of subjects watched 1 slide or 1 video sequence, randomly assigned to each session. The slide was kept projecting on a screen while the video sequence was continuously displayed on a 21-inch monitor throughout the whole session. Before the subjects watched the slide or video sequence, they were asked to read one of the two the written scenarios. Half of the subjects within a session were given the high-choice scenario while the other half were given the low-choice scenario. The subjects then filled out an environmental rating form. They were asked to describe Mr. Y's feelings on the following scales:

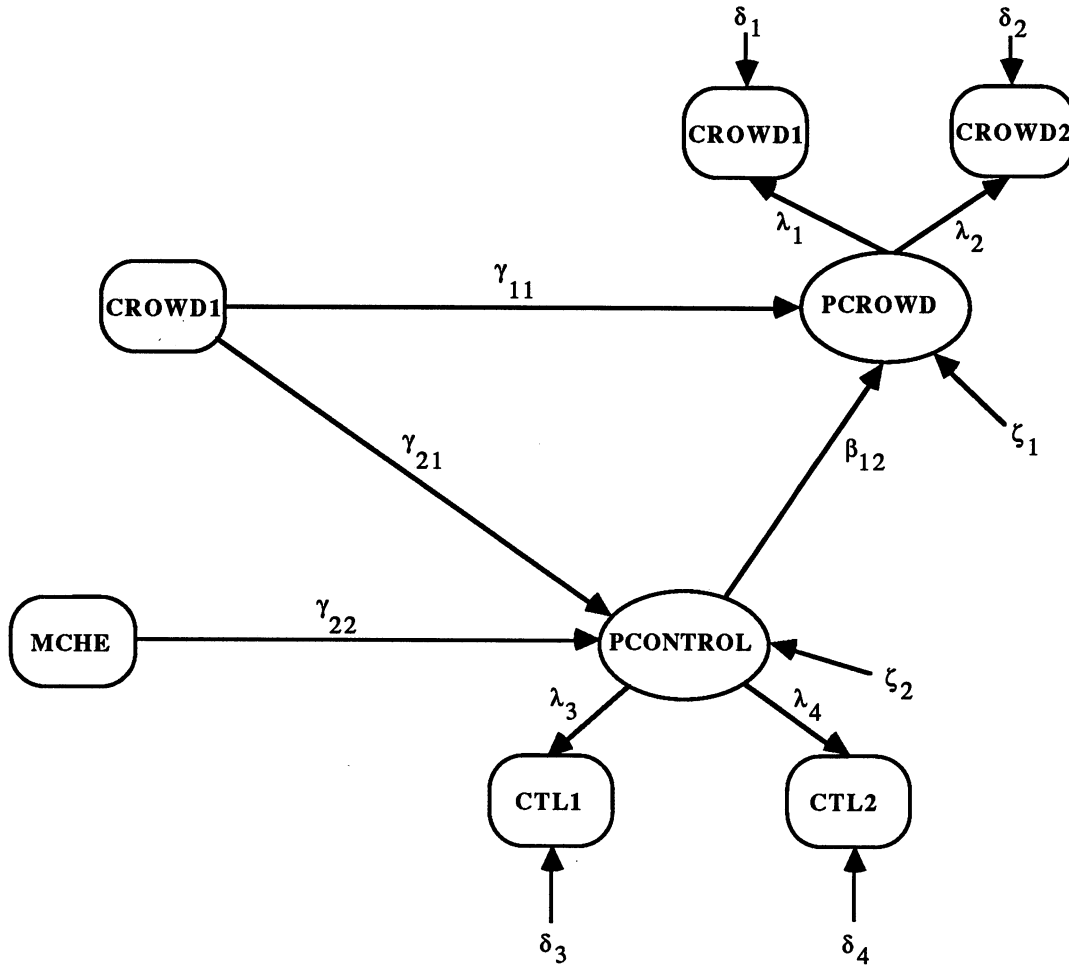

(1) CTL1:

A 9-item semantic differential scale, developed from a combination the Mehrabian and Russell's (1974) Scale of Dominance and Glass and Singer's (1972) Scale of Helplessness. Both scales have been suggested to be actually measuring perceived control (Bateson and Hui 1987).

(2) CTL2:

A 4-item Likert-type scale adapted from the studies conducted by Newcomb and Harlow (1986) and Fleming, Baum and Weiss (1987), was used as a second measure of perceived control.

FIGURE 2
The Hypothesized Structural Equation Model

DEN = Customer density (1-3)
 MCHE = Customer choice (0,1)
 PCROWD = Perceived crowding
 PCONTROL = Perceived control

CROWD1 = Semantic differential scale of perceived crowding
 CROWD2 = Likert-type scale of perceived crowding
 CTL1 = Semantic differential scale of perceived control
 CTL2 = Likert-type scale of perceived control

(3) CROWD1:

A 5-item semantic differential scale of crowding which is developed from the crowding literature. The items were: stuffy/not stuffy; cramped/uncramped; crowded/uncrowded; free to move/restricted and spacious/confined.

(4) CROWD2:

A Likert-type scale of crowding which includes three different items: (a) He would not feel crowded (negatively formulated); (b)

He would feel that there is almost no space for him; and (c) He would feel that there are too many people in the setting.

To avoid response bias, the direction of half of the items was reversed for the two semantic differential scales. The items of the two scales were then mixed together and put in one section of the environmental rating form. Similarly, half of the items of the two Likert-type scales were formulated negatively. The items of the two scales were also

mixed together and put in a separate section of the environmental rating form.

Findings

The 123 subjects produced 119 (60 for the slides and 59 for the video sequences) useful cases for analysis. Each subject's item scores were reversed when necessary. The scores were then summed to provide indices of perceived control and perceived crowding. The slide and video subjects were considered as two independent samples and the two sets of data were submitted to a multi-sample LISREL analysis (Joreskog and Sorbom 1984, Chapter 5) to test the model shown in Figure 2. Assuming both the slides and video sequences are valid simulations of the service setting, one will expect (a) the data obtained from either sample to support the structural equation model (Figure 2); and (b) the two sets of

data will produce identical estimates for the parameters of the model. Accordingly, in the multi-sample LISREL analysis, the parameters were specified in a way to test the model as shown in Figure 2. Moreover, all the measurement and structural matrices were also specified as invariant between the two samples.

A negative variance was obtained for the error term of the semantic scale of perceived control (CTL1) indicated the finding that there is a need to respecify the model (Bagozzi and Yi 1988). One possible explanation for the unexpected finding is that the error terms of CTL1 and CROWD1 were correlated because both scales consist of semantic differential items and were contained in the same section of the environmental rating form used in the study. Hence the covariance between the two error terms was set free in another multi-sample LISREL

analysis. The respecified model produced a chi-square of 22.47 with 29 degrees of freedom. The probability level ($p=.80$) of the chi-square value indicated an excellent fit. Moreover, the t-values also indicated that all the causal path coefficients were significantly different from zero (Table 1).

In short, the findings strongly support the control theory of crowding (Figure 1). Both density and choice affect perceived control which in turn shows a strong effect on perceived crowding. The direct causal link between density and perceived crowding is also consistent with the existing findings in the crowding literature.

IMPLICATIONS

The relationship between perceived crowding and psychological stress is a reasonably well supported relationship. In the context of a retail service firm such a relationship is important since it suggests that capacity will be constrained by consumers' perception of crowding. What this study has shown is the importance of perceived control as an intervening variable between density and perceived crowding. This raises important managerial implications since the finding shows that the impact of density on control may be moderated by the presence of other environmental and situational factors, for instance, the extent of choice available to an individual. This implies that when such factors can be manipulated by management, customers' perceived control and perceived crowding will remain at an acceptable level even when customer density is high. In other words, effective capacity (i.e. the maximum customer density level one would tolerate) may be extended without an increase in physical capacity (e.g. the area of the service setting). For instance, at the Disneyland, information (an important component of cognitive control) is posted at various points of a line so that people know how long they have to wait. With the given information, visitors are expected to feel better despite the length of the line is unchanged.

Methodologically, the present findings also provide evidence to support the ecological validity of slide and video as environmental simulations (McKechnie 1977). Since both sets of data (slide and video) support the same causal model and produce the same estimates for all the parameters, it can be tentatively concluded that the findings are not due to the artifacts of the two employed media. In other words, both media (slide and video) can adequately represent the service setting and the findings are expected to be generalizable to real life settings.

The Effect of Positioning on the Purchase Probability of Financial Services Among Women with Varying Sex-Role Identities

Lynn J. Jaffe, Northeastern University

ABSTRACT

This research investigates the advertising effectiveness for different positionings of financial services aimed at the women's market. Using an experimental design, it determines the impact of modern versus traditional positionings on the purchase probabilities of financial services among women with different sex-role identities. Analysis indicates that there is a significant two-way interaction effect between positioning and sex-role identity on the purchase probability of financial services. Women who score higher on masculinity have a higher purchase probability for the modern positioning compared to the traditional positioning, in comparison to women who score lower on masculinity who show no difference for the modern or traditional positioning.

INTRODUCTION

Deregulation in the financial service industry has intensified competition and forced financial service institutions to become more astute strategic marketers. Many marketers believe that financial service institutions will have to find market segments or niches with underserved needs and provide them with superior services, in order to survive the intense competitive climate that exists today (Donnelly, Berry, and Thompson 1985). While the financial service industry typically focuses its attention on upscale markets, some institutions will benefit from focusing on profitable segments with underserved financial needs in less competitively congested arenas such as the women's market.

In 1984 the Investment Company Institute, a national association of the mutual fund industry, conducted a comprehensive survey among a representative sample of 2,158 women to determine their financial attitudes. The major findings of the survey were:

- 1) Women are becoming more active in their personal financial management because it gives them a feeling of independence and achievement.
- 2) Women are developing more favorable attitudes toward those products that offer higher returns for higher risks, and are cooling off toward lower-yielding saving vehicles.
- 3) Many more women are working today and therefore have increased their ability to save. Forty-six percent of the respondents indicated saving regularly, with thirty-one percent saving as much as eight percent of their income.

In summary, deregulation has increased competition in the financial services industry

forcing companies to attract profitable new market niches. Women represent a viable segment due to their increased interest in investment decisions, their increasingly favorable attitudes toward higher risk/reward investment products and their greater ability to save. This research focuses on how to position financial services to attract the women's market. Specifically, it will determine that the optimal positioning varies as a function of a woman's sex-role identity. This paper extends our knowledge of sex-roles and consumer behavior in two ways: it explores the impact of sex-role identity on high involvement purchase behavior, and it separately measures the two components of sex-role identity, masculinity and femininity, allowing us to assess the unique contributions of each.

LITERATURE REVIEW

Women and Advertising

Women's sex-role identity has undergone enormous changes. Understanding these changes has tremendous implications for promotional and positioning strategies aimed at capturing the women's market (Debevec and Iyer 1986). Early research criticized advertisers for depicting women in well-worn stereotypes that many women found objectionable (Belkaoui and Belkaoui 1976; Courtney and Lockeretz 1971; Courtney and Whipple 1974; Lundstrom and Sciglimpaglia 1977).

Recently the focus has shifted to measuring the advertising effectiveness of modern versus traditional female roles. In 1982 the Equal Opportunity Commission supported an independent study by The Sherman Group and found that a modern positioning enhanced the advertising effectiveness in all tested product categories, among all segments of women. My view is that a modern positioning will enhance advertising effectiveness for financial services because investing is more likely associated with a modern women.

H1: The main effect of positioning will be statistically significant. Averaging across all other variables, the modern positioning will engender a higher purchase probability than the traditional positioning.

Two other studies examined the interaction effect of sex-role orientation and positioning (modern versus traditional) on the advertising effectiveness of ads for low involvement products (Jaffe and Berger 1988; Leigh, Rethans, and Whitney 1987). Both studies indicated that there is a strong two-way interaction effect between a women's sex-role orientation and positioning on advertising effectiveness.

Jaffe and Berger (1988) found that women who scored high on masculine personality traits (e.g., assertive, dominant) have a higher purchase intent for modern positionings than for traditional positionings, in comparison to women who score high on feminine personality traits (e.g., warm, tender) who favor the traditional over the modern positionings. Leigh et al. (1987) segmented women into groups of modern versus traditional based on a life-styles inventory which measured sex-role orientation. These researchers found positive association between the women's own sex-role orientation and the role she favored in the advertisements (e.g., women classified as modern in terms of their own sex-role orientation had a higher purchase intent when the ad portrayed a modern woman).

H2: The two-way interaction effect between masculinity and positioning will be statistically significant. Women who score higher on masculinity will have a higher purchase probability for the modern positioning than for the traditional positioning, while women who score lower on masculinity will not differentiate as strongly between the two positionings.

H3: The two-way interaction effect between femininity and positioning will be significant. Women who score *lower* on femininity will have a higher purchase probability for the modern positioning than for the traditional positioning; this differential (modern minus traditional) will be smaller for women who score higher on femininity.

Sex Roles and Behavior

If there are psychological differences between females and males (whether biologically or environmentally determined) sex-roles are inevitable (Vetterling-Braggin 1982). Sex-role is defined as "a role that is performed primarily by a person of a particular sex and that societal factors tend to encourage this correlation." Examples of this conditioning may be evident in the way parents guide children to behave in sex appropriate roles, or in the way schools direct students into occupations according to sex.

Masculinity is typically associated with instrumental traits, a cognitive focus on getting the job done, while femininity is typically associated with expressive traits, ones that show concern for the welfare of others (Bem 1974). Specific attempts have been made to empirically link these traits to behavior using sex-role inventories (Bem 1974; Spence, Helmreich, and Stapp 1974).

In this research, sex-role identity is measured by the Bem Sex-Role Inventory, a scale that exhibits not only a high degree of reliability, but also exhibits convergent and discriminate validity (Bem 1982; Lubinski, Tellegen, and Butcher 1983). In the Bem Sex-Role Inventory, respondents indicate

on a seven-point scale how well each of the masculine and feminine traits describes them. Typical masculine traits on the inventory are "aggressive" and "leadership ability;" typical feminine traits include "gentle" and "yielding." The inventory also has neutral items in order to disguise its exact intent.

In their seminal article, Lubinski et al. (1983) conclude that sex-role identity is best measured as two distinct constructs, masculinity and femininity. This allows researchers to assess the main effect of each of these constructs in addition to the incremental contribution of their two-way interaction (Hall and Taylor 1985). This methodology has been adopted for this research.

METHODOLOGY

This study consisted of a survey with built-in experiment undertaken in the real world among adult women. Each respondent was exposed to different stimuli (i.e., advertisements) based on an experimental design.

After a respondent agreed to participate, the interviewer read the respondent a product description and answered any questions about the product. Next, the interviewer handed the respondent a set of ads and asked her to study them carefully. The subjects indicated their purchase intent and their perceptions of the ads, and filled out the sex-role inventory. Finally, the data from the questionnaires was analyzed using hierarchical regression.

Development of the Stimuli

A portfolio of ads containing 10 purportedly modern and 10 purportedly traditional female role portrayals (i.e., visuals) was developed from a larger portfolio of hundreds of ads. Twenty women, marketing professionals and nonprofessionals, rated the ads on their ability to capture modern and traditional female portrayals, and the final portrayals were chosen for this study based on their ratings. In general, the modern portrayals show a career-oriented woman involved in making a decision, while the traditional portrayals show a woman in a more nurturing role, centering her attention on her family.

Next, headlines and body copy were developed and combined with the portrayals to form positionings that emphasized the modern/traditional dichotomy. Examples of the modern and traditional body copy respectively are:

"Behind every great woman, there should be a great company. Married or single, parent or single parent, the modern woman needs financial security."

"When a mother thinks of giving the best to her family, she needs a company she can depend on. We can help you plan for your family's financial security."

Sampling and Data Collection

The sample consisted of 200 women between the ages of 25 and 49. The procedure used was quota

sampling consisting of a systematic approach in which every fourth person who passed the interviewer (who was located at a specific point at the selected sites) was asked to participate. To ensure a heterogeneous and projectable sample, interviewers screened for different occupations, marital status and age.

The data was collected at four different locations, two in New York City (Manhattan and Queens), and two in the Boston vicinity (Chestnut Hill and Natick). One site in each city is perceived as a middle class location (or about average in terms of class) and one in each city is perceived as an upper-middle class location (or above average in terms of class). This scheme allows the obtaining of a variety of women with different incomes, occupations, etc. All site locations were malls. Naturally, days of the week and times of the day were varied, and interviews were conducted on both weekdays and weekends, starting at 10 a.m., 1 p.m., and 6 p.m., at each of the four selected sites.

Experimental Design and Analysis

The experimental design is a six factor complete factorial with a blocking scheme and partially repeated measures; the six factors are comprised of four within-subject factors (positioning, product category, institution and execution) and two between-subject factors (masculinity and femininity). Each subject viewed several ads, each with a different combination of the within-subject variables. Since she "repeats" a purchase probability assessment for each of the within-subject factors combinations, we have a repeated measures design. As is well known, a repeated measures design has several advantages: it not only reduces the sample size and costs by using the same subjects across treatments, but also reduces the overall variability by using this common pool of subjects (Howell 1982; Winer 1971).

As previously suggested, there are a possible 16 treatment combinations (i.e., 16 different ads) that each respondent could view (as a result of varying the two levels of positioning, product, institution and execution). Since each respondent would respond to 16 different treatment combinations there was a good possibility she could become tired, even resentful, and end up rushing her answers just to finish in a reasonable time frame, making the estimates of the effects of the factors less reliable. Also, experimental error might increase due to the sequence in which the treatment combinations are viewed (i.e., later treatments may be given less thought due to respondent fatigue).

An alternative solution was devised to negate this problem. By replacing the one large block of 16 treatments with four smaller blocks (each block containing four treatments [i.e., four ads]), each respondent viewed only four treatment combinations. This enabled respondents to complete the experiment in a more reasonable time frame and, hopefully, increased the reliability of the estimates. Consequently, 50 women were randomly

assigned to each of the four blocks and viewed the four advertisements comprising that block. Note that there is no reduction in the number of treatment combinations in the experiment; all 16 treatments are run (though now each treatment combination is seen by 50 women instead of 200 women).

The data was analyzed using hierarchical regression, a procedure routinely used with repeated measures designs (Baker, Ravichandran, and Randall 1989; Cohen and Cohen 1975; Pedhazur 1982). Additionally, hierarchical regression can handle the added complexity of this design's blocking scheme.

Dependent Variable

Intent to purchase was operationalized using an 11-point purchase probability scale. This scale has the advantage of inducing critical thinking and discrimination because it combines verbal definitions with purchase probabilities (Gruber 1970). To obtain an assessment of purchase probability, subjects were asked to respond to the following question: "Taking everything into account, what are the chances that you would buy this product?" The scale is anchored by the phrases, "certain (99 chances in 100)" and, "no chance (0 chance)."

Independent Variables

Positioning. The modern positionings exhibited a career woman in a leadership role, while the traditional positionings showed women focusing their attention on their families.

Product Category. The two product categories selected were Certificates of Deposits and Money Market Funds. They were selected because they use extensive print advertising, have reasonably high penetration rates among women and are relatively easy to understand. Moreover, they represent an interesting trade-off between liquidity and interest rates. Two product categories, as opposed to only one, allow us to generalize to other financial products.

Institution. Two financial services institutions were selected based on their similarity with respect to the following criteria: number of retail outlets, dollars spent on advertising and types of services offered. The two chosen were Merrill Lynch and Prudential-Bache Securities. It was important to choose financial services institutions that were fairly similar so as not to allow the factor "institution" to overpower the key factors of this study (i.e, positioning and sex-role identity). If one institution were considerably more well known, then respondents might choose it regardless of the positioning. Using two institutions instead of one makes the experiment more realistic.

Execution. There were two executions, with each execution containing one modern and one traditional positioning.

Sex-role Identity. Sex-role identity was measured with the Short Bem Sex-Role Inventory. This inventory contains (10) masculine traits and

(10) feminine traits, allowing one to assess the individual contributions of masculinity and femininity.

RESULTS

After manipulation checks indicated that respondents clearly perceived the positionings, each of the hypotheses was tested for significance (see Table 1). Although masculinity and femininity are continuous variables, in order to enhance clarity these variables were classified into "high" and "low" based on dichotomized frequency distributions (See Tables 2 and 3).

There is strong support for Hypothesis 1, which states that, averaging over all other variables, a modern positioning will engender a higher purchase probability than a traditional one. The main effect of positioning is significant at $p < .01$, and accounts for 9% of the variance in purchase probability (Table 1).

Further examination of the means shows that the modern positioning has a mean purchase probability of 5.45, while the traditional has a mean of only 3.84 (see row means in Table 2). This modern minus traditional positioning differential is 1.61, ($5.45 - 3.84 = 1.61$). *I will refer to this*

modern minus traditional positioning differential as the "modern positioning advantage."

There is strong support for Hypothesis 2; the two-way interaction effect between positioning and masculinity is significant at $p < .01$, and accounts for 13% of the variance (Table 1). Furthermore, the "modern positioning advantage" is indeed larger at high masculinity than at low masculinity. Table 2 shows that at high masculinity, the "modern positioning advantage" is 3.46 ($6.14 - 2.68 = 3.46$), while at low masculinity it is -.24 ($4.75 - 4.99 = -.24$). Evidently, a modern positioning appears crucial to attract women with high masculine sex-role identities; positioning does not seem to be significant for low masculine women.

There is also considerable support for Hypothesis 3. The two-way interaction effect between positioning and femininity is significant at $p < .01$ and accounts for 3% of the variance in purchase probability (see Table 1). Table 3 shows the mean purchase probability for the positioning x femininity combinations. Note, that when averaging over both levels of femininity, the modern positioning has a higher purchase probability of 5.45 compared to the traditional positioning of only 3.84 (See row means in Table 3). This is consistent with the findings of

TABLE 2
Mean Purchase Probability by Positioning by Masculinity

Positioning	<u>Masculinity</u>		Row Means
	High	Low	
Modern	6.14	4.75	5.45
Traditional	2.68	4.99	3.84

TABLE 3
Mean Purchase Probability by Positioning by Femininity

Positioning	<u>Femininity</u>		Row Means
	High	Low	
Modern	5.32	5.57	5.45
Traditional	4.36	3.29	3.84

Hypothesis 1. However, when we look at the "modern positioning advantage," we see that at high femininity this differential is .96 ($5.32 - 4.36 = .96$), whereas at low femininity it is 2.28 ($5.57 - 3.29 = 2.28$).

DISCUSSION AND IMPLICATIONS

For some time researchers have been suggesting that showing women in traditionally stereotyped roles no longer reflects the roles of many North American women and, consequently, is increasingly becoming less effective as an advertising tool (Courtney and Whipple 1983). Moreover, in addition to this study, a growing body of empirically based research about advertising to women has begun to appear in the marketing literature which shows that, in certain product categories, modern positionings will increase purchase intent.

This study found that, when averaging over all sex-role segments of women, a modern positioning enhances the purchase probability for financial services. In-depth interviews, that were conducted with 20 women after they had completed the experiment, provide insights into this finding. The consensus among these women was that when it came to financial decisions they would trust a modern woman to make a better choice than a traditional woman. They therefore related to the modern positionings more than the traditional positionings. These women expressed this opinion despite their feelings that the traditional positionings are indeed thoughtful and express a problem they face, that of providing financial

security to their families. This finding suggests that financial service institutions should use a modern positioning when implementing a mass advertising strategy to capture the women's market.

The second major finding of this research indicates that the impact of positioning on purchase probability varies for women with different intensities of masculinity and femininity. Recall, for example, that women who score higher on masculinity have the largest "modern positioning advantage," strongly preferring (in terms of purchase probability) the modern over the traditional positioning; women with lower masculinity scores show no significant difference between the traditional and the modern positioning. This suggests that it is crucial for marketers to use a modern positioning to attract women with strong masculine sex-role identities. Marketers, however, have more flexibility in their choice of positioning for female segments with low masculine sex-role identities.

This research extends the current sex-role research into the financial services sector. Future research will examine whether the relationship between positioning and sex-role identity is significant in other product categories. It will also explore these relationships among men, as well as women.

The Antecedents of Cognitive Age
Caroline Chua, National University of Singapore
Joseph A. Cote, Washington State University
Siew Meng Leong, National University of Singapore

ABSTRACT

Gerontological explanations for the disparity between cognitive age and actual age were explored. Life satisfaction, activity levels, health, and culture influenced the discrepancy between cognitive age and actual age. Family relationships were not related to the age discrepancy.

Age segmentation is popular because it is operationally simple and intuitively logical. Barak with others (1980, 1985, 1986, 1988) has suggested that cognitive age rather than chronological age should be used as a basis for segmentation since it better reflects an individual's identity and behavior. While chronological age may be related to life events and people with similar ages may have similarities in lifestyle, health, and mental outlook (Reynolds and Rentz 1981), chronological age merely indicates birth date and causes nothing to occur (Jarvik 1975). Therefore, chronological age may be an inadequate basis for segmentation since it merely describes the market but does not provide an understanding of underlying consumer motivations.

Past research on cognitive age has focused on the relationship between chronological and cognitive age. The level of agreement between them is low suggesting that cognitive age captures a separate dimension of age not revealed by birth dates (Kastenbaum, Derbin, Sabatini, and Steven 1972; Barak and Schiffman 1980; Barak and Gould 1985; Barak and Stern 1985, 1986). There is also evidence that cognitive age may predict behavior better than chronological age (Smith and Moschis 1984). However, consumer researchers have not examined how cognitive age is related to consumer motivations. In order to improve our understanding of how cognitive age might be related to consumer motivations, this paper examines the relationship between the predictors of successful aging and cognitive age. The paper builds on research in the gerontology literature which has examined the relationship of aging and life satisfaction.

**LITERATURE REVIEW AND
HYPOTHESES**

Gerontological research takes a developmental perspective toward the aging process, focusing on tasks (such as family relationships, activity levels, and physical well-being) over the life cycle (Havighurst 1972). These experiences vary during the life span and have varying effects on life satisfaction. Inevitably, aspects in the life course affect cognitive age for much the same reason they can affect life satisfaction. People able to cope with age transitions will not feel the effects of age as much as people unable to cope.

Life satisfaction depends on social interaction, which changes throughout the family

and career life cycle (Mass and Kuypers 1974, Havighurst 1972). Social role changes occur from life events like retirement and reduced incomes, death of a spouse, establishing an explicit affiliation with one's age group, and meeting social and civic obligations (Havighurst 1972). While life events and transitions may be similar for everyone, people's ability to adapt differs. People better able to cope with transitions will be more satisfied. Mass and Kuypers (1974) suggest four lifestyle patterns among the elderly. Among these, the "family centered person" and the "hobbyist" were found to be more adaptive and experienced greater life satisfaction than the "remotely sociable" and "disorganized" types. Specific social interactions (activity levels and family relationships) will be examined in more detail below.

Activity Levels

Although there is a tendency for old people to become less active, Neugarten, Havighurst, and Tobin (1964) found that life satisfaction was greater in older people who were socially active and engaged than those who were inactive and disengaged. Blau (1973) also found life satisfaction increases with new roles and other socially interactive alternatives. ". . . Aging involves an unusual amount of personal change and status ambiguity. . ." (Ward 1977). Periods of personal change often result in increased self awareness (Rosenberg 1965). As a person becomes less active the realities of the aging process are more likely to be recognized. Discrepancies between now and when they were younger will be more obvious, making them feel older. People who remain active will not experience increased self awareness and are less likely to "feel their age."

Family Relationships

Life satisfaction is also highly correlated with family interactions (Lohman 1977). Family relationships and roles provide a sense of continuity, personalized interaction, and affection during the life span. Family ties become increasingly important sources of satisfaction as other roles are lost (Cherlin 1983). The life satisfaction attained from better family relationships means greater fulfillment in those roles, leading to a younger cognitive age perception. In addition, better family relations will also increase general activity levels.

Biological Factors

Even healthy older people experience declines in: energy, muscular strength, speed of response, sight and hearing; and have difficulty in adapting to extreme heat or cold (Marsh 1980). Health affects the performance of basic tasks and expected social

roles as well as affects adjustments to changing life conditions (Birren 1964, Botwinick 1978, Bromley 1974). Since the body symbolizes a part of the individual's identity, illness has a negative effect on self-esteem and age perception. Moos and Tsu (1977) found a positive relationship between good health and satisfaction. In the same way, emotional health influences successful aging patterns; those who perceive themselves to be healthy are likely to be more satisfied than others (Neugarten 1968). Mutran and Reitzes (1981) observed that self-reported health status also affects levels of activity.

Less healthy old people need to adapt more to changing life conditions. Activities and food enjoyed at a younger age can be experienced less frequently, or not at all. How often do we hear, "I must be getting old" when simple physical activities result in aches or favorite foods cause indigestion. As health problems begin to affect the enjoyment of activities, people will begin to feel old. Conversely, healthy older people will continue to see themselves as young since health does not affect their lifestyle.

Culture

Adaptation to developmental tasks varies depending on the extent to which different societies give deference and prestige to the old. It was suggested by Lebra (1976) that increased age brings increased status in the Chinese culture. Conversely, Kimmel (1988) found that a negative connotation towards aging exists in Western culture. Given these characteristics, a chronologically old person would experience different age perceptions depending on the cultural context. Older Westerners prefer to perceive themselves as young because their actual age status is not respected. When age is respected, as in the Chinese culture, the elderly would accept their actual age more willingly.

Hypotheses

Based on the discussion presented above, five hypotheses will be examined.

- H1: Higher satisfaction experienced in life results in a younger cognitive age.
- H2: Higher levels of activity result in a younger cognitive age.
- H3: Closer family relationships result in a younger cognitive age.
- H4: More healthy elderly persons will feel younger than the less healthy.
- H5: Those inclined to the Western culture will have a younger cognitive age than those inclined to a Chinese culture.

RESEARCH METHODOLOGY

A convenience sample of 301 elderly Singaporeans was given a self-administered questionnaire in either English or Mandarin. The

Mandarin questionnaire was back translated to English to ensure its accurate interpretation in both languages. The sample, selected from diverse groups, included several associations for the elderly, (n=140 eg., Singapore Retirees Association, Singapore Action Group for Elders, senior citizens clubs in community centers, clan associations, Dying Aid Society, and religious organizations), outpatient clinics (n=70), lunchtime crowd of the Stock Exchange of Singapore (n=20), and grandparents of colleagues and friends (n=71). The sample appeared to be an adequate representation of the various socioeconomic class. All participants were 55 years or older. Although aging is a lifelong process, the elderly are defined as persons 55 years of age or older for empirical purposes (Neugarten 1968). In Singapore, 55 is also the official government retirement age. None of the respondents were institutionalized, a common sampling limitation of previous research on elderly consumer behavior (Bernhardt and Kinnear 1976). While the age range, cultural orientation, and non-random nature of the sample prevents broad generalizations, it was felt the sample was acceptable for a test of the theoretical relationships specified in the hypotheses.

Measures

Each of the independent variables was constructed by lifestyle questions encompassing the activities, interests, opinions (AIO) of each individual (Wells and Tigert 1971). Agreement with each AIO statement was assessed using 7-point Likert-type scales. There were both positive and reversed statements included to control for possible acquiescence bias. Some fill in the blanks were also used to enhance the validity of the findings. The items of the independent variables were generated from earlier studies of the elderly (Wells 1974; Schutz, Baird, and Hawkes 1979).

Life satisfaction was defined as the type of gratification that an individual's life circumstances make available to him and allows him to attain. Ten items, such as "I am happier now than I ever was before," were designed to assess the effect life satisfaction has on cognitive age.

Activity levels are reflected in the respondent's patterns and attitudes towards levels of activity. Daily activities such as group membership, solitary activity, and interpersonal relationships were examined using ten items such as "I often take an active part in local civic issues." Those who are presently working answered three additional AIO statements since their activity levels differ from those who are retired. Finally, nine fill in the blank questions on the number of times the respondents participated in different activities were asked. Both the Likert-type and objective measures were included to provide a measure for both attitudes toward activity levels and respondents' actual activity.

The family life measure estimates the satisfaction with family ties and number of activities done together with members of the family. The

scale consists of seven Likert-type items and six fill in the blank.

Health was assessed using eight AIO statements related to various aspects of health including general overall health, energy level, and speed of recovery.

Language was used to assess culture orientation since it is a major determinant of an individual's mode of thought (Whorf 1956). The respondent specified what language he spoke most on a 5-point entirely English - entirely Chinese scale. The level of fluency of each language was obtained on a 3-point scale ranging from fluent to poor. Although language is not a perfect measure of cultural orientation, it is a commonly used component of cultural orientation measures. A more comprehensive measure was not used because of space limitations.

Cognitive age was measured using four questions: 1) I feel as though I am in my ____; 2) I look as though I am in my ____; 3) I do things as though I am in my ____; 4) My interests are mostly those of a person in their ____ (Kastenbaum et al. 1972; Barak and Schiffman 1980). Cognitive age was calculated as an average of the four age aspects.

Analysis

Factor analysis was conducted to determine the component structure of the multi-item independent variables. Factor scores were then used in a multiple regression analysis. The dependent variable in the regression analysis was the difference between actual age and cognitive age (hereafter referred to as the age differential). The age differential was used since the objective is to determine the factors that lead to a younger or older age perception.

RESULTS

The correlation between chronological and cognitive age was performed to determine any significant differences between them. This was done separately for those below and above 65 years of age. The results indicate both chronological and cognitive age are different from each other ($r = 0.4729$ and 0.4736 for below and above 65 years respectively). This points to the fact that cognitive age is capturing aspects of age that are not adequately reflected in the elderly's chronological age. Further, the cognitive age was constantly younger than the chronological age in both age groups. Both these findings are consistent with past research.

Factor analysis produced three dimensions for life satisfaction (see Table 1). The factors were identified as contentment, attitudes, and daily encounters. There were also three factors for health signs of aging, physical health, and strength. The activity level measure had four factors for the Likert-type scales (inactivity, social, enthusiasm, and work). Family life had two factors for the Likert-type scales (affection and pride). Each factor was

used as a separate variable in the regression analysis, for a total of 13 independent variables.

Overall, the independent variables were able to explain 22.7% of the variation in the difference between actual and cognitive age (see Table 2). The age differential was negatively related to the attitude factor of life satisfaction supporting Hypothesis 1. A positive attitude results in respondents feeling younger than their actual age. Hypothesis 2 was also supported since the actual activity and enthusiasm factors were significantly and negatively correlated with the age differential. This indicates that respondents felt younger when activity levels were high. Hypothesis 3 was not supported. None of the family life factors were related to the age differential. Two dimensions of the health factor (signs of aging and physical health) were negatively and significantly correlated with the age differential supporting Hypothesis 4. The old person who did not experience diminished functioning associated with age felt younger than their actual age. Hypothesis 5 was also supported. English-speaking respondents were more likely to feel younger than their actual age as apposed to the Chinese-speaking respondents.

DISCUSSION

Previous research on cognitive age has shown it is different than chronological age and may better explain consumer behavior in certain circumstances. However, the reasons why this might be so, and how cognitive age can affect consumer behavior has not been examined. This paper has examined several possible antecedents to cognitive age. Cognitive age was found to be related to life satisfaction, activity level, physical health, and culture. Surprisingly, family relationships were not found to affect cognitive age. This may be due to the strength of family relationships in Singapore, which vary little across families. Since almost all families are close, the ability of family relationships to explain variations in cognitive age would be masked.

These findings suggest that cognitive age, as a distinct construct, may be used to partially reconcile several contradictory findings in the literature on elderly consumer behavior. For example, in the health care marketing context, differing levels of consumerist activities were found to be present among elderly consumers. In his review, Tongren (1988) suggested that studies revealing higher levels of elderly activism were linked to concern with fraud and victimization. Lower levels of activism involved elderly consumers who were unwilling to appear dependent or who did not feel they had control over the cost and quality of medical treatment.

While Tongren's (1988) account appears entirely possible, the present findings suggest another plausible explanation. In particular, it may be that variations in cognitive age, as they are related to the physical health and activity levels of the elderly, serve to reconcile the observed differences in consumer activism among the elderly.

TABLE 1
Factors And Factor Weights For the Independent Variables

<u>Factor</u>	<u>Weights</u>
<u>Life Satisfaction</u>	
<u>Contentment</u>	
I feel I have little to be proud of.	0.7323
I often have experiences which teach me new things.	0.7133
I am happier now than I ever was before.	0.6462
I am unhappy with my life.	0.6110
I feel I have a number of good qualities.	0.5475
My life involves interesting kinds of tasks and activities.	0.4574
<u>Attitudes</u>	
I take a positive attitude toward myself.	0.7264
I wish I were younger than I am now.	0.7126
<u>Daily Encounters</u>	
Most of my activities involve people whose company I enjoy.	0.8591
I really enjoy the things I do.	0.7561
<u>Activity Level</u>	
<u>Inactive</u>	
I prefer watching other people being active than being active myself.	0.7821
I have a very inactive social life.	0.7661
My days seem to follow a definite routine like eating meals at the same time daily.	0.7152
I seem to have fewer friends now than before.	0.6960
<u>Social</u>	
I like visiting new places on my own.	0.7937
I do volunteer work for service organizations or hospitals on a fairly regular basis.	-0.6737
I am an active member of at least one service organization.	-0.6386
<u>Enthusiasm</u>	
I often take an active part in local civic issues.	0.7772
I work very hard.	0.7692
I have never felt I was too old to take up new ways.	0.3678
<u>Work</u>	
I work to maintain my lifestyle and independence.	0.8620
Working leaves me less time for my social life.	-0.7878
I want to work for as long as I can.	0.5254
<u>Family Life</u>	
<u>Pride</u>	
I look forward to a family gathering.	0.6993
Nothing makes me more upset than to see my children and grandchildren in a rough patch.	0.6749
<u>Affection</u>	
I am unhappy with the relationship I am having with my children.	0.7341
I do not worry about my children.	-0.5592
I often do things together with my children and/or grandchildren, watching television, having meals, etc.	0.5467
<u>Health</u>	
<u>Signs of Aging</u>	
My daily activities are limited by my health.	0.8986
I appreciated my favorite foods better ten years ago.	0.7062
I get tired more easily now than ten years ago.	0.6466
When I fall ill nowadays, I take a longer time to recuperate.	0.6331
<u>Physical Health</u>	
I am as quick as I used to be ten years ago.	0.8168
I have excellent overall health.	0.6696
Strenuous work tires me less ten years ago.	0.5778
<u>Strength</u>	
I have as much energy as ten years ago.	0.9690
It takes me longer to regain my energy after an exhausting day now.	0.9690

TABLE 2
Regression Results

Hence, elderly consumer who perceive themselves to be cognitively younger and were more healthy and socially active may conceivably be less willing and interested to engage in consumer activism relative to those who perceived themselves to be cognitively older. Rahtz, Sirgy, and Meadow (1989), provide tentative empirical support for this contention when they found that individuals who felt younger were less likely to be active participants in the healthcare service domain as those who viewed themselves as older.

Future Research

The findings in this research also imply that future research in elderly consumer behavior should incorporate cognitive, in addition to chronological, measures of age. Such an approach may broaden extant understanding of this important segment as it would allow consumer researchers to draw out the effects due to cognitive age from those due to chronological age. This paper considers a more precise delineation of the conditions under which one or the other age construct possesses greater predictive and explanatory power with regard to important elderly consumer behavior outcomes.

Future research may also focus on determining other antecedents of cognitive age given the encouraging results of the present study. For example, it may be useful to explore in greater depth the relationship between cognitive age and life satisfaction. Several scholars (eg., Aiello et al. 1977; Andres and Withey 1976; Meadow 1988; Neugarten, Havighurst, and Tobin 1961) have posited that life satisfaction may be construed as a composite global satisfaction outcome resulting from the satisfaction derived from various individual domains. With regard to the elderly, such relevant individual domains as healthcare may be explored in connection with cognitive age. Finally, it may also be instructive to establish with greater precision particular antecedents of cognitive age which account for variations in specific elderly consumer behaviors.

Attitudinal and Leisure Activity Differences Across Modernized Household Life Cycle Categories

William D. Danko, State University of New York
Charles M. Schaninger, State University of New York

ABSTRACT

An updated family life cycle model, originally proposed in the consumer behavior literature by Gilly and Enis (1982), is empirically evaluated. The model produces strong significant differences across men's and women's sexrole norms, work and time pressure attitudes, self-fulfillment attitudes, traditional values, and leisure activities. Further, this model results in less than one percent of the sample classified as "other," and incorporates individuals into new classifications reflecting changing demographic trends as called for by researchers in multiple disciplines. Suggestions for future research and potential model modifications are also discussed.

The family life cycle has been a widely studied construct in the marketing and consumer behavior literature (Arndt 1979; Gilly and Enis 1982; Murphy and Staples 1979; Wells and Gubar 1966). Over the past two decades, there have been calls for updating or modernizing our definitions of the family life cycle, mainly due to demographic shifts such as later age at marriage, an increase in working wives, postponed child bearing, and increased divorces (Gilly and Enis 1982; Glick 1977; Murphy and Staples 1979). In the marketing and consumer behavior literature, two recently proposed updated models attempt to capture some of the aforementioned changes and trends (Gilly and Enis 1982; Murphy and Staples 1979).

Changing Values and Demographics

Yankelovich (1981) attributes new demographic trends such as staying single, postponing marriage, postponing or forgoing childbearing, having fewer children, as well as separation and divorce, to changing values, and the "search for self-fulfillment." Nearly 80% of the population is now engaged in this search, associated with a shift away from traditional values, greater individualism, greater concern with self improvement, careers, and creative life styles, and more modern sex role norms. That 17% of the population who evidence what Yankelovich terms the "strong form", are much more likely to lead alternative life styles and to forgo, postpone or depart from traditional family life cycle progression. They tend also to be younger, higher socioeconomic status, experience greater time and work pressures, and are more health conscious. This tends to result in different consumption patterns (e.g., greater use of yogurt, imported wines, herbal teas, fresh fruit, restaurant meals, lesser use of high calorie, high cholesterol foods). It also results in different leisure activity patterns: more frequent participation in active exercise such as tennis, skiing, jogging, and dance; as well as more frequent social entertainment

such as dining out, going to bars, concerts, movies, and travel. Thus, we would expect similar profiles for postponed, foregone, or nontraditional family life cycle stages, including younger and middle aged bachelors, newlyweds, delayed fullnest households, and childless couples.

Scanzoni (1975, 1982, 1983) also concludes that our society has become more individualistic then collectivistic or familistic. He views these changes as evolutionary, and as due to rapidly increased women's education and labor force participation, as well as more modern sex role norms. Scanzoni (1975) empirically demonstrates that women's education and sex role modernity lead to women's work force participation, to greater autonomy, independence, and achievement, and to delayed or non-progression through traditional life cycle stages. He suggests that marriages in which both spouses hold sex role modern norms are even more likely to evidence nontraditional lifestyles and life cycle progression, while those with a modern wife and traditional husband are likely to become divorced if they can't effectively resolve their conflict. The implications of Scanzoni's work for non-traditional family life cycle stages are quite consistent with those of Yankelovich (1981).

Duvall and Miller (1985) discuss new forms of transitions/departures from traditional family life cycle progressions, and also discuss role transitions which must occur at different stages due to forming a new dyad, having a first child, having children enter school, empty nest transitions, divorce, etc. Wells and Gubar (1966) and Reynolds and Wells (1977) review some of the consumption and leisure activity differences associated with traditional progression through life cycle stages. Presence of young children at home generally curtails the more external and socially active leisure activities which characterize bachelors, newlyweds, and childless couples, and results in an increase in home and family oriented activities.

Major Family Life Cycle Models

Three major family life cycle models (Gilly and Enis 1982; Murphy and Staples 1979; Wells and Gubar 1966) have been used by marketing/consumer behavior researchers. Each of these models is described and briefly compared next.

The models differ in the number of categories assigned. The Murphy-Staples and Gilly-Enis models each use 13 groups, while Wells-Gubar has 9 groups. All three models incorporate at least a portion of the singles category. Wells-Gubar includes older divorced and widowed; Gilly-Enis includes bachelors, widowed, divorced, and separated of all age groups. The Murphy-Staples model adds categories for young and middle aged divorced, both with and without children, distinguishes between

middle aged married without dependent children and middle aged married without children, and adds a category for middle aged divorced without dependent children. Middle and older aged bachelors, single parents, cohabitating couples, and young and middle aged widow(er)s are all classified as "other." The Gilly-Enis model adds categories for middle-aged and older bachelors (which include both childless and non-custodial divorced and widowed individuals), for young, middle aged, and older single parents (whether never married, divorced, or widowed), for childless middle aged couples (treated the same as empty nest), and for delayed full nest (middle aged, child under 6). Further, cohabitating couples are treated as married in all couple unit designations. Another distinction among the models is the age cutoff. Wells-Gubar uses one age cutoff, 45, to distinguish between older and younger families. Both Gilly-Enis and Murphy-Staples use an age cutoff at 35 for middle aged, and of 65 for older couples. The Gilly-Enis model, however, uses age of female head of household for age cutoffs, based upon the rationale that most (traditional) women stop active childbearing by age 35.

In the marketing/consumer behavior literature, Wagner and Hanna (1983) compared the Wells-Gubar and the Murphy-Staples models as well as multiple regression models incorporating income and family composition variables in an examination of aggregate family clothing expenditures. Fritzsche (1981) compared the same two models on their ability to predict energy consumption profiles. Both studies had to substantially modify their operational definitions of the Murphy-Staples model, resulting in their testing a model closer to the Gilly-Enis model. Due to the limited nature of the dependent consumption expenditure variables examined, we know very little about how modernized life cycle categories differ.

The high incidence of households classified as "other," is also problematic. The Wells-Gubar model assigns 28 percent as "other," Murphy-Staples 19 percent, Gilly-Enis less than 1 percent. In this paper, we focus on the Gilly-Enis model in part because it classifies a much lower percentage of other, but also because it results in meaningful consumption profile differences across categories. Schaninger and Danko (1989) compared these three models, as well as several others in greater depth. They found that the Gilly-Enis model outperformed the other models, and demonstrated a higher percentage of variance explained as well as stronger significance across a variety of consumption related areas. Danko and Schaninger (1989) provide a detailed examination of specific consumption differences for this model, including food and beverages, dollar value of major durable acquisitions, major and minor appliance ownership, and use of services.

The purpose of this paper is to empirically test the Gilly-Enis model across the attitudinal constructs developed previously (sex role norms, work and time pressures, strong-former attitudes, and traditional values), as well as leisure activities, for

both men and women. We hypothesize that both men and women, in stages indicative of delayed or non-progression through traditional life cycle stages (young and middle aged bachelors, single parent women, childless newly weds, and delayed fullnest households) will be more sex role modern, report greater work and time pressures, score higher on strong former attitudes, and have less traditional values. We also hypothesize that such households will report greater participation in more active leisure activities, as well as more external/social leisure activities than households with children (particularly young children) present.

METHODOLOGY

Questionnaire Development

The questionnaire consisted of eight type-set pages and was mailed using university letterhead. The first segment elicited household descriptors (demographics), food and beverage consumption, use of services, durable goods ownership, and value of select durables. Two additional pages ascertained individual leisure activities, and six-point Likert scaled attitudes regarding topics such as sex roles (Schaninger, Buss, and Grover, 1982), work and time pressures (House and Harkins, 1975; Robinson, 1977), "strong former" attitudes (Yankelovich 1981), and traditional values (Reynolds, Crask, and Wells, 1977; Wells, 1974; Wells and Tigert, 1971; Yankelovich, 1981).

Sample Development

A telephone directory from a widely used test market and top 50 SMSA located in a mid-Atlantic state served as the sample frame. The initial sample was recruited over a four week period via telephone solicitation with three call-backs, using a systematic random sample design. Of the 2,790 households we attempted to reach, 111 had telephones not in service, and 508 households were unreachable after three attempts. Of the 2,171 households reached, 1,160 (53.4%) agreed to participate, while 1,017 refused. Within four weeks of the mailing, 19 questionnaires were returned as address unknown, 10 were completed partially and deemed unusable, and 307 were usable.

To ascertain possible non-response bias, three additional subsamples of 500 households each (unreachable by phone, refusals, and non-respondents from the first mailing) were mailed a personalized letter with a questionnaire and cover letter. This resulted in an augmented sample of 137 households (approximately equally distributed across the three nonrespondent groups) and 74 non-deliverables, yielding 444 households with usable returns. This represents a response rate of 31.1% of those who originally agreed to participate, and 17.2% of the original telephone book frame with working phones and reachable by mail. No significant differences were found between our original and augmented sample with regard to family life cycle classifications. Some households were comprised of adults of the same sex, and in some

FIGURE
THE GILLY AND ENIS (1982) FAMILY LIFE CYCLE MODEL

Stage	Description	Sample	
		Size	Percent
B1	Bachelor 1: head is 18-34, single (never married, divorced, separated, widowed), no dependent children	35	7.9
B2	Bachelor 2: head is 35-64, single (never married, divorced, separated, widowed), no dependent children	59	13.3
NW	Newlywed: female head is 18-34, couple (married or unmarried), no dependent children	33	7.4
SP	Single Parent: head is 18-64, single (never married, divorced, separated, widowed), dependent children	26	5.9
FN1	Full Nest 1: female head is 18-34, couple (married or unmarried), dependent children	44	9.9
DFN	Delayed Full Nest: female head is 35-64, couple (married or unmarried), dependent children under age 5	17	3.8
FN23	Full Nest 2, Full Nest 3: female head is 18-64, couple (married or unmarried), dependent children over age 5	98	22.1
CC	Childless Couple: female head is 35-64, couple (married or unmarried), no dependent children	71	16.0
OC	Older Couple (Empty Nest): female head is 65 or older, couple (married or unmarried), no dependent children	26	5.9
B3	Bachelor 3: head is 65 or older, single (never married, divorced, separated, widowed), no dependent children	33	7.4
	Unclassified "other" (not used in the analysis)	2	0.5
	Total Sample Size	444	100.00

NOTE: Single parents 1, 2, and 3 were combined into single parents, and full nest 2 and 3 were combined due to sparseness.

cases an adult son or daughter lived with one of their parents. For individual attitudes and leisure activities on such households, each individual was classified to a family life cycle stage based on their age and marital status. Thus, totals of both women and men may exceed household counts for bachelor categories.

When the total sample (444 households) was compared to 1980 SMSA census statistics, no significant differences were found for proportions of single under 18, or married couples without children under 18, or individuals under or over age 45. To further examine the question of sample representativeness, we compared our sample to March 1986 national census statistics. Overall, our sample's distribution was not significantly different from the census distribution at the .05 level,

although it was marginally different at the .10 level. Our sample slightly overrepresented married couples with no children under 18, and underrepresented non-married over 65 households. The lack of significant differences between our original and augmented samples, over total sample and 1980 SMSA data, and our total sample and 1986 census data suggests that non-response bias is minimal.

Operationalization of Family Life Cycle Models

Household classification (single never married, single by divorce or separation, widowed, married couple, or unmarried couple) and the ages of all adults and children in the household were reported by an adult head of the household. The Figure

outlines the categories used in the analysis for the Gilly-Enis model.

In their original formulation, Gilly and Enis (1982) developed 14 categories, including "other." The three single parent categories had to be collapsed into one category, as did full nest 2 and 3, to avoid sparseness. Our sample sizes in these original categories were nearly identical to 1986 census data proportions. Full nest 2 and full nest 3 were combined based on the common attribute that all dependent children are over five years of age and on the lack of significant differences across a variety of consumption and expenditure areas as well as leisure activities and attitudes. Thus the model we tested consisted of ten categories, with only 2 households classified as "other."

Analyses

For men's and women's attitudes and leisure activities we choose to apply separate single factor models (MANOVA's for attitudes, and Pearson Chi squares for leisure activities). While a two factor design (FLC stage by sex) could have been employed, we were not concerned with testing for sex differences, and had to drop male single parents ($n=4$) due to sparseness, thus resulting in different degrees of freedom for men's and women's tests.

RESULTS

Individual Attitudes

Men's and women's sex role norms, work and time pressures, strong former aspirations, and traditional values, were strongly and significantly related to family life cycle stages, as shown in Tables 1 and 2.

Among women, newlyweds, young bachelors, and single parents held the most modern sex role norms, while older bachelors followed by older couples and childless couples were most traditional. Middle age bachelors held more modern views toward wife's career importance, while fullnest 1 households held more modern views towards sharing household responsibilities if a wife works. Surprisingly, delayed fullnest wives were more traditional than fullnest 1 wives. Single parents reported the strongest pattern of work and time pressures, while older couple wives and older bachelors (as expected) demonstrated an opposite profile. Delayed full nest wives reported the highest non-work related time pressures. Strong former aspirations were highest among young bachelors and single parents, followed by newlywed women. They were lowest among older bachelor, followed by older couple women, as expected. Older bachelors, followed by older couples, and childless couples, agreed most with traditional values, while young bachelors, followed by newlyweds, demonstrated an opposite pattern. In general, these results are consistent with those hypothesized, although delayed fullnest wives were not more sex role modern nor less traditional than other fullnest wives.

Men's attitudes demonstrated a similar pattern to those of women for older couples and older

bachelors. They tended to be most sex role traditional, experience less work and time pressures, have weaker strong former aspirations, and hold more traditional values. Childless couple men demonstrated a similar, but weaker profile. Newlywed, followed by full nest 1 men, were most sex role modern and strong former oriented. Young bachelors held relatively modern norms toward a wife working but not toward wife's career importance or sharing responsibility. They also held relatively high strong former aspirations and less traditional values. Delayed full nest husbands, contrary to our expectations, were not more sex role modern and did not hold less traditional values. They did, however, score highest, followed by fullnest 1 and fullnest 2-3 households, on work and time pressures, reflecting the conflicting demands of work and family (children) obligations.

Overall, most of the patterns were in the direction hypothesized for men and women's attitudes. The finding of more traditional sex role norms and values for delayed full nest couples compared to full nest 1 couples, probably reflects age effects. It may also reflect the inclusion of couples who continued to have children with couples who delayed having children. The finding of more modern sex role norms for newlywed and full nest 1 men than for young bachelors suggests that men's sex role norms change after marriage due to negotiation and conflict resolution, as suggested by Scanzoni (1982).

Leisure Activities

Strong Pearson Chi square results were observed for women's and men's leisure activities as shown in Tables 3 and 4.

Not unexpectedly, men and women demonstrated different leisure activity patterns across family life cycle stages. Among women, strenuous physical activities, including bicycling, skiing, tennis, and aerobic dance, were lowest among older couples and older bachelors, and highest among younger and middle aged bachelors, and newlyweds. Gardening was most prevalent among full nest 2&3 through older couple women. Volunteer work was most common in delayed full nest, full nest 2&3, and older bachelors. Bars, concerts, movies, and dancing were most popular among young bachelor, single parent, and middle aged bachelor women, with older couples and older bachelors scoring lowest. Probably due to presence of young children, full nest 1 and delayed full nest women reported heaviest usage, and older couples and older bachelors, least usage of rented movies. Dining out was highest among childless, older couple, newlywed, and middle aged bachelor women. Single parents, full nest 1 and delayed full nest households (due to presence of young children) were least likely to dine out. Thus, women's leisure activities demonstrate a pattern consistent with that hypothesized.

A similar pattern to that observed in women was found for physically strenuous activities among men, with lowest participation among older couples and older bachelors, and heaviest participation

among young bachelors. Delayed full nest men were most likely to jog and second most likely to exercise on a machine. Middle aged bachelor, newlywed, full nest 1, and delayed full nest men also tended to participate more in such activities than full nest 2 and 3 or childless couple men. Hiking and camping were highest among young bachelors and relatively high among middle aged bachelors. Gardening was lowest among young bachelors, highest among older couples, and high for full nest 2 and 3, childless couple, and older bachelors. External social activities (bars, movies, dancing) were highest among young bachelors. Middle aged bachelors also scored high on dancing, concerts, and movies. Movie rental was highest among couples

with young children (full nest 1 and delayed full nest) and lowest among older couples and older bachelors. Going to movies declines after the newlywed stage. Gourmet cooking was highest among young bachelors and newlyweds, and lowest among full nest 2 and 3, childless couple, and older couple men. Dining out (as a stated leisure activity) was highest among childless and older couples, and lowest among delayed full nest men probably reflecting the presence of children. Separate analyses showed that young and middle aged bachelors and newlyweds also eat out frequently at restaurants, although they may not have regarded it as a primary leisure activity. In general, the pattern

observed for both men's and women's leisure activities is consistent with that hypothesized.

SUMMARY AND CONCLUSIONS

The Gilly-Enis model proves to be a good predictor of individual attitudes and leisure activities. Because it classifies nearly every household (less than one percent are "other"), it is more applicable for examining today's "family" life cycle than the more widely used Wells-Gubar or Murphy-Staples models. Additional analyses (Danko and Schaninger 1989) demonstrate that this model is strongly and significantly related to food and beverage consumption, major and minor appliance ownership, dollar value of major household acquisitions (first

and second homes, automobiles, RV's, boats, etc.), and to dollar value of home entertainment devices (stereos, TV's VCR's, etc.), and furniture. An understanding of how life cycle stages differ both attitudinally and with regard to leisure activities provides us with a gestalt picture of these lifestyles. When coupled with consumption differences, this information should be of value in creating background themes for advertising specific food and beverage or durable products.

Based on the results reported here, it would appear that the Gilly-Enis model might be a useful predictor for additional areas of research such as family decision making, family interaction/conflict

resolution, household division of labor, use of time, or marital satisfaction.

Finally, although we view the Gilly-Enis model as fairly complete, there are a number of potential stages of the family life cycle that might be included in yet another updated version. For example, do second marriage individuals hold different attitudes than those in their first marriage? Do postponed newlyweds differ from those marrying earlier? While the Gilly-Enis model does include a delayed full nest, it encompasses both those having their first child after age 35 as well as those having additional children after age 35. Separate analyses on men's and women's attitudes based on using husband's rather than wife's age, found similar overall results, but resulted in a profile of delayed full nest couples closer to that hypothesized. Use of wife's age, rather than husbands, results in a larger proportion of full nest 1 households and smaller proportion of delayed full nest and older couple households. Use of husband's age, or retirement status might prove to be a fruitful modification. Additional research that incorporates such modifications may further demonstrate that, if properly formulated, the family life cycle construct can be both a valid empirical conceptual tool.

The Intensions and Extensions of the Time Concept: Contributions from a Sociological Perspective

Carol J. Kaufman, Rutgers University
Paul M. Lane, Western Michigan University

ABSTRACT

Time has long been recognized as an important consumer behavior variable (Jacoby, Szybillo, and Berning 1976; Hirschman 1987; Feldman and Hornik 1981). However, our conceptual understanding of time itself is necessarily drawn from a variety of disciplines, often resulting in a disaggregated set of terms and measurement techniques, devoid of a unifying paradigm. Because of this, it is often difficult to assess the intensions and extensions of time both within marketing and in other fields. A systematic review of existing paradigms is recommended to establish a "common" understanding of time studies, or a "chronosophy", as proposed by Fraser (1981). This paper begins the chronosophical process in presenting a paradigm for the sociology of time, and develops a vocabulary which can be usefully incorporated into consumer research.

INTRODUCTION

Time has long been recognized as an important variable in consumer research. As consumers, individuals spend much of their time in shopping for and using products, perhaps based on a brand preference learned in the past, or prompted by a present immediate need, or stimulated by the perception of a need in the future. Despite the pervasive influence of time in consumer behavior, investigations are often limited by our abilities to conceptualize, model, and measure time itself.

The concept of time is difficult to understand in its entirety when viewed within the limitations and constraints of specific disciplines. That is, certain aspects of time are developed and tested through accepted research methods, while other topics of investigation are classified as inappropriate or not fitting within the discipline itself. Thus, an economic approach to time is likely to emphasize constraints and tradeoffs, while a religious perspective instead would focus on personal experience and feelings.

Several prior reviews present organized summaries of the development of the time concept (see for example, Feldman and Hornik 1981; Hirschman 1987; Jacoby, Szybillo, and Berning 1976). However, existing approaches used in marketing do not seem to be complete enough to model some aspects of consumer time. A frequent argument centers on the need to incorporate perceptual, subjective, and experiential aspects of time within the more traditional economic framework which has largely characterized prior time research (Hirschman 1987; Hornik 1984). That is, the marketing-economics interface forms only a limited subset of the social culture in which time phenomena occur.

In applying the concepts of other fields to the study of consumer time, it is necessary to determine whether the discipline under review is able to account for the aspects of time use which are of interest to marketers. The present paper argues that the in-depth consideration of time paradigms in other disciplines must precede the incorporation of concepts, terminology, or measurement techniques into consumer research.

A paradigm, according to Deshpande (1983), is "a set of linked assumptions about the world which is shared by a community of scientists investigating that world (p. 101)." That is, it includes statements of the proper domain of a science, what questions it should ask, and the rules to follow in interpreting results; in effect, a paradigm can be viewed as the foundation of theory, directing theory building efforts (Arndt 1983). However, Anderson (1983) points out that "there are often paradigmatic conflicts as a result of the different philosophical methodologies and frameworks across disciplines (p. 22)." Time studies provide a case in point. That is, many investigations take a mathematical or economic approach for granted, which does not allow the subjective aspects of time to emerge.

An Example: Problems with Existing Approaches

In particular, the often-used fixed resource paradigm from economics is not sufficient to capture the social, perceptual, or experiential aspects of time use (Hibshoosh and Silver 1988). Although the economic approach is useful in some studies, the "Beckerian" tradition is oriented toward the economy, considering quantities of time, rather than their value to the consumer. That is, economic or fixed resource models identify fixed amounts of clock time among work, or household, or leisure activities, without examining the importance or enjoyment perceived by the participants.

For instance, time budgets are frequently used in social psychology, home economics, and sociology in order to study individuals' time use throughout their day. Respondents are required to record, usually in minutes, all the activities done throughout a specified time period, similar to a monetary budget. Along with the straightforward process of time or money measurement, however, are also a set of underlying assumptions regarding the variables being studied. In a monetary budget, a given sum of money is used for a specified purpose, mutually-exclusive of other uses. The same period of time, in contrast, can be used to accomplish multiple purposes, when time is used polychronically. This is borne out in empirical research, as respondents frequently indicate secondary or tertiary activities (Lane, Kaufman, and

Lindquist 1989). The assumptions of the budget analogy do not allow for additional uses of the same time, nor do they provide information of the context, value, and meaning of time use. Instead, an overriding constraint specifies that daily time is limited to 24 hours a day, and implicit in that constraint, is that the 24 hours are divided among mutually-exclusive activities. This is a problem, since many consumer-related activities are often combined with other activities, such as shopping and child care, and can be classified as polychronic.

In response, economic models may be extended or modified in several ways: the utilization of a psychologically-based theory of time equilibrium (Wilson and Holman 1984); the addition of "subjective preference propositions" in time use studies (Hornik 1985); the consideration of both objective and subjective needs of the individual in modeling time allocation behavior (Hendrix 1980); the development of explanations and predictions of the future (Holman 1981; Nicosia 1982); or the application of transportation research to time study (Hibshoosh and Silver 1988).

It is also necessary to extend time research to include interaction with groups outside the individual (Gronmo 1989), as well as to more fully investigate internal perceptual time processing (Settle, Alreck, and Glasheen 1978). That is, research has largely focused on measuring quantities of time expenditure per individual, rather than the patterns of time expenditure among both individuals and groups (Jacoby, Szybillo, and Berning 1976).

A Complementary Perspective

Gronmo (1989) argues that concepts of time are complementary, rather than mutually exclusive or completely independent of each other. Moreover, some perspectives on time have been underutilized, such as social time, perhaps due to unfamiliarity with paradigms which tap the perceptual dimensions of time, and overreliance on the economic model which has predominated since it was formally introduced and reviewed.

The present paper addresses this need by proposing that a sociological paradigm, suggested by Lewis and Weigert (1981), can be used in the conceptualization of consumer time phenomena. That paradigm incorporates perceptions of time, as well as the interaction between individuals' time and their membership in groups. Some theory building terminology will be introduced next, for use in the paradigm review.

BACKGROUND

Theoretical Suggestions

In learning, evaluating, and possibly combining alternative paradigms for use in any study, Zaltman, Pinson, and Angelmar (1973) recommend that the respective concepts from each specific discipline be examined to learn if they refer to the same set of phenomena. That is, it is necessary to insure that they have "intensional and extensional compatibility with another and that they

are rooted in identical or at least comparative assumptions (p. 96)." In order to avoid conceptual mismatching, the researcher must determine whether there is "compatibility between the nonmarketing context in which a concept or theory has been empirically tested and the marketing context in which it is to be applied."

The recognition that given paradigms are appropriate for certain aspects of the time phenomena, and not for others forms a central core of the present paper. A chronosophical approach, discussed next, can provide an organized method to evaluate the intensions and extensions of time paradigms which are under consideration for use in modeling consumer behavior.

Chronosophy

While Fraser (1981) argues that the successful study of time must be interdisciplinary, the extension of time concepts into marketing must be done systematically and carefully. Prior reviews encompass a vast background of research, generally found in economics, home economics, sociology, social psychology, and psychology, as well as marketing. In addition, other, perhaps-less consulted fields, such as biology, physics, religion, music, and child development also provide insight into additional time processes and uses. A systematic research program which investigates, presents, and unifies these "traditional" and "non-traditional" fields is likely to add depth and understanding to current efforts to examine time in consumer research.

Such an interdisciplinary and normative study of time is designated as "chronosophy" (Fraser 1981). Its purposes include the search for new knowledge regarding time, while developing methods to integrate the contributions from existing multidisciplinary knowledge. Particularly important is the conscious effort to identify and communicate across research boundaries to permit interaction of experience and theory construction.

According to Fraser, the chronosophical approach would include the following:

1. surveys of historical and current ideas of time in the sciences and in the humanities;
2. studies of the relation of time to ideas of conceptual extremities such as motion and rest, or the spatially very large and very small;
3. comparative analysis of those properties of time that various fields of learning and intuitive expressions designate unproblematically as "the nature of time";
4. inquiries into the processes and methods whereby man learns to perceive, proceeds to measure, and proposes to reason about time;
5. exploration of the role of time in the communication of thought and emotion;

6. search for an understanding of the relation of time to personal identity and to death;
7. research concerning time and organic evolution, time and the psychological development of man, and the role of time in the growth of civilizations; and
8. determination of the status of chronosophy vis-a-vis the traditional systems of knowledge (pp. 591-592).

Using the chronosophical process as a guide, the following sections are organized to review and evaluate the potential contributions of a sociological time paradigm, introduced next.

A PARADIGM FOR THE SOCIOLOGY OF TIME

The sociological perspective is particularly useful in incorporating the qualitative features of time. A paradigm proposed by Lewis and Weigert (1981) suggests that social time permeates every region of social life, and thus time use is tied to a social structural framework, given as the individual, group, subcultural, and cultural levels of analysis.

Each of these levels has its own form of social time: the individual-level "self-time;" the group level "interaction time," for informal interactions and "institutional time" for organizations; and the socio-cultural level "cyclic time," such as days, weeks, and seasons (p. 434). This typology enables the researcher to conceptualize and study the movement of individuals from one temporal structure to another in everyday life. Self-time quite naturally taps the time perceptions of the solitary individual, including remembered pasts, experienced presents, and anticipated futures. At some point, however, the individual interacts with others, whether in an informal situation, such as a family, or one that is formal, such as employment. Here norms of behavior and specific interactional rules partially govern the situation. In turn, the individual's self-time and interaction time are embedded within the macro structures of institutional time and cultural time. Institutions, such as schools, stores, and factories, make up their own rules. "Although they may take into account time structures of other organization with which they must conduct exchanges, the norms and sanctions governing the use of time in any particular organization extend directly only to its own members (p. 438)."

The time levels are not mutually-exclusive, however, as behaviors at one level may depend on behavior at another, such as husbands' and wives' activities being somewhat dependent upon the needs of their families. Individuals acquire social roles which constitute the points of intersection between the levels, coordinating their behaviors to avoid role conflict. As a result, individuals must schedule their time to match the time standard of the larger groups in which they must function (Lane and Kaufman 1989). When invited to a social dinner,

one customarily arrives close to the specified time, regardless if one becomes hungry several hours earlier. Similarly, consumers of mass transit may purchase the right to travel within days and times specified by a set schedule, rather than simply at their own individual discretion.

On a larger scale, cultural time demands that its members match their time use with the standardized time of the culture. For instance, Lewis and Weigert point out that the weekend has become the dominant temporal marker of the weekly routine, evidenced by special weekend shopping hours and Monday holidays. However, desired shopping services are often not available on late nights or weekends, which may be the consumer's self-time for shopping. When consumers cannot standardize to the schedules of existing market institutions, opportunities are created for new developments, such as automated teller machines and round-the-clock repair services.

As part of this paradigm, however, Lewis and Weigert argue that the types of time exhibit a well-defined stratification. That is, "organizational time demands precedence over interaction time, and interaction time, in turn, demands precedence over self time (p. 444)." Thus one does not shop when required to be at work, although polychronic time processing allows consumers to blend several of these levels of stratification, such as shopping at home while supervising children.

INTENSIONS: ASPECTS OF TIME IN THE PARADIGM

In order to determine whether the sociological paradigm possesses intensional compatibility with consumer phenomena, it is necessary to examine the properties of time within the framework. Lewis and Weigert propose three major dimensions: embeddedness, synchronicity, and stratification. In addition, related terms are also presented which are commonly used in other social settings and are used within the paradigm presented here.

Sociological Aspects

Social embeddedness. Social embeddedness refers to the fact that all social acts are temporally fitted inside of larger social acts (Lewis and Weigert p. 437). Basically, this aspect of time recognizes the "human life and the social actions which constitute it are a complex overlap of actions and meanings at various stages of enactment (p. 450)." For instance, a physician may schedule a series of appointments as a set of embedded acts, which are to be completed before hospital rounds or after surgery.

Synchronicity. A coordination of broadly recurring sets of meaningful events characterizes synchronicity. "A modern industrialized and rationalized society can function only if most of its members follow a highly patterned and dependable daily round (Lewis and Weigert p. 439)." The physician's patients must match, or synchronize, their schedules with that of their appointments. Similarly, retailers are likely to conduct business during certain hours deemed acceptable by the

society, or community, in which they exist. Lack of synchronization generally reduces the productivity of a group, as evidenced by problems brought on by a transit strike or inclement weather.

Stratification. In order to synchronize their time with the demands and schedules of others, individuals must be able to order their time use according to some established priority. Certain types of time can demand precedence over other types of time, based on the subjective value assigned by the individual, as well as the obligations the individual bears to both informal and formal groups. The sociological paradigm proposes that organization time has priority over interaction time, which in turn has priority over self time. Overall, people must synchronize their embedded times to attain temporal coordination, depending on the stratification.

Other Related Aspects of Time

Time duration. Time duration can be defined as the interval between separate events (Piaget 1981). That is, its measure answers questions such as "how long an event takes," or "how long until the next event," or "how long since a past event."

Relational time versus absolute time. In contrast, relational time is used when our experience is related to other events happening in time. Thus the individual can discuss time "speeding up" or "slowing down." In contrast, time duration can be measured objectively, without referring to its content. This is known as "absolute time," and has its origin in Newtonian physics (Benjamin 1981).

Subjective time. Individuals perceive time differently. Thus, durations can be affected by the individual's perceptual capabilities as well as their time orientation (Settle, Alreck, and Glasheen 1978). For instance, some events seem longer than others. Enjoyable tasks may appear to move quickly, while unpleasant chores may seem to last "forever." This unevenness in perception is likely to be situational, as a one hour block spent browsing in a favorite store may appear to pass at quite a different rate than an hour hurriedly searching for a last-minute gift.

Succession. Succession, or temporal order, deals with the sequence of events (Piaget 1981). Certain events precede others naturally (i.e., day-night cycles), while some are scheduled to occur before or after specific events. Thus "After Christmas" and "Back-to-School" sales tie their expectations to the passage of certain days, offering retail assortments which match the needs of consumers.

Time Standardization. Similar to the notion of absolute time, this concept refers to the specific schedule required by a household, community, organization, or government. Individuals are thought to standardize their internal time senses to match external conventions, when necessary. This manifestation becomes our public time (Lane and Kaufman 1989).

SOME PRELIMINARY PROPOSITIONS

In developing the sociological paradigm, Lewis and Weigert offer some preliminary propositions regarding the study of time. These appear to represent the general foundation for some specific consumer research relationships between activity and time.

Perceived Temporal Distance

P1: The greater the number of temporally-embedded events between two points in physical time, the shorter is the perceived temporal distance between two points.

A few studies in marketing have investigated consumers' perceptions of waiting time. For instance, using supermarket checkout lines, Hornik (1984) found that individuals exhibit a tendency to overestimate waiting time, perhaps because little is happening between entering the line and eventually paying for one's purchases. It is likely that the lack of other-embedded activities affects the overestimation. Common managerial strategies, such as providing entertainment or displays while in amusement or exhibit lines, embed "filler" activities between the two points of entry and exit, which presumably shorten the consumers' perceived wait. Comm and Palachek (1984) further extend the notion of perceived wait to consumer regret levels.

Synchronization

P2a: The greater the interdependence of actors, the greater the necessity for temporal synchronization.

P2b: The degree of difficulty in temporal synchronization is a positive exponential function of the number of timetables involved.

These two propositions appear to be directly related to the multiple time schedules inherent in interdependent groups, such as households. That is, rather than restricting time allocation models to the individual level, the explicit recognition of synchronization must be incorporated into consumer research. Perhaps difficulties in temporal synchronization are a key to the wives' employment area. Role overload, defined as conflict resulting from multiple roles, would appear to be directly related to the ability to synchronize multiple role expectations. The interdependence between husbands' and wives' employment constraints is likely to affect their individual and joint household responsibilities.

Stratification

P3: Social times are stratified in the following hierarchy (from highest priority to lowest): cyclic time, institutional-

organizational time, interaction time, self time.

Stratification enables consumers to prioritize their uses of time, allocating precedence to those activities which are deemed most important. For instance, a society typically establishes certain holidays, which affect customary employment schedules. Certain retailers are likely to close on those holidays, or perhaps offer additional incentive salaries as compensation for working on a holiday. Interactional time, such as that spent with one's family, is necessarily structured around one's employment obligations, leaving the remainder as time for self. However, priorities regarding one's time use are often established based also on the value of certain activities to the individual. As Hirschman (1987) indicates, consumers are likely to schedule their time in certain activities based on tradeoffs between the perceived pleasure of the experience and the obligations which constrain use of time.

EXTENSIONS TO CONSUMER RESEARCH

The underlying importance of time in consumer behavior stems from its inherent role in the purchase and use of products. Needs may be perceived in relation to past experience, present dissatisfaction, or anticipated future requirements. Those needs will be addressed in terms of consumer self-time, the consumers' interaction with others, the consumers' synchronization time with household and employment, and standardization with the environment.

Consumer researchers need to describe time involved in recognizing and searching for ways to fulfill needs. The simple economic assessment of quantities of time greatly limits our ability to describe the dimensions of time. For instance, needs may be recognized as part of consumer self-time. However, the consumer is likely to discuss those needs within family or social settings, engaging in interaction time. Moreover, overly-simplistic measures of institutional time, such as number of minutes spent shopping, reduces our understanding. Without in-depth questioning, it would be difficult to discern from present-day time budgets what amount of shopping time is spent in search, in negotiation, in discussion, and in complaints; moreover, no information is given whether the retail time is perceived as short or long. These fine distinctions enable us to describe the tradeoffs among temporal resources which characterize the dimensions of time discussed above. All the time use categories are additionally affected by cultural influence and perceptions of time.

In addition, time processing may vary among linear, procedural and cyclic perspectives across respondents in any given study. For instance, some individuals may shop after receiving their pay, in a linear sense; others instead may shop procedurally until the "right" product is found; while yet others may schedule weekly or monthly shopping trips in a

cyclical sense. Economic time budgets, however, would necessarily group time used in shopping in similar categories, without being able to investigate the underlying differences in the patterns of shopping time. Moreover, shopping may be done as a single, monochronic activity, or it may be combined with other tasks, such as child care, socializing with friends, or housework, if home shopping is chosen. The complexities of polychronic shopping behavior is also masked by research frameworks and measurement tools which implicitly assume that time use is a linear, separable, monochronic, individual phenomena.

The conceptual framework and terminologies provide clear implications for consumer research. The sociological perspective enables us to differentiate among time used solely by self, such as that in need recognition or internal search; various types of interaction time, such as time spent negotiating household activities or retail purchases; and culturally-determined time patterns, such as "appropriate" sales hours and holidays. For instance, consumers shop for "back-to-school" clothing or for holiday gifts and food, rather than just shopping for three hours in a given week in 1985.

A TIME VOCABULARY

In particular, the sociological paradigm can be used to propose the following time vocabulary with clear extensions to consumer research:

consumer self-time: experiential, subjective, perceptions of time use as interpreted by the individual

consumer interaction time: time spent in informal groups such as households, decisionmaking units; in retail settings; in work settings

consumer institutional time: employment or other organizational activity, volunteer time, etc.

consumer cyclical time: individuals have certain repetitive routines, determined by their subculture or culture, which may affect time spent in market exchange. Shopping for holidays follows a ritualistic pattern

market institutional time: consumers must conduct exchanges during standardized shopping hours, which may be culturally-determined - this may lead to dissatisfaction when needs occur during non-standard hours, such as supermarket delis and pharmacies which close at a specified early evening hour

cyclic time: defined in terms of repetitive structures, such as days, weeks, and seasons - blue laws result from the interaction of culture and market institutions

time embeddedness: consumer shopping and household production behavior take place within the confines of employment obligations. There may be only limited time for shopping. Rise of home shopping is one response. Problems occur in synchronizing market time and consumer time.

synchronicity: the matching of consumers' time schedules creates the necessity for scheduling in households. This may be a factor contributing to the role overload.

stratification: valuing time, enabling consumer to determine schedules through the setting of priorities

The interactions between the various levels and dimensions are useful in identifying opportunities and problems in consumer research. For instance, when the demands of consumers' institutional time limits their time spent in interaction with their households or friends, convenience products and household services may provide a needed supplement to reduce role conflict. Moreover, institutional demands may also make it difficult for consumers to synchronize their time with other household members. Products which enable time to be deferred, such as VCRs and telephone answering machines, can adjust discrepancies in time schedules. Employed parents' time is necessarily embedded within the demands of their households as well as those of their employers, creating new needs which face sometimes conflicting sets of stratified commitments. Similarly, when consumers cannot synchronize their institutional and market schedules because of priorities assigned by work, new retail modifications, such as home shopping networks, can provide a way to achieve synchronization.

SUMMARY

This paper presents a sociological time paradigm as a complement to the prevailing microeconomic/fixed resource framework. It has been argued that the latter paradigm is limited in its ability to integrate the experiential, subjective, or perceptual natures of time phenomena into consumer research. As a result, it is likely that current measures and models of time use are largely dominated by the assumptions of linear, separable, monochronic time.

Instead, the Lewis and Weigert framework provides additional tools for theory development in this area. In particular, the matching of individual consumer time with the interaction time of households and retailers provides a broader context which can accommodate the time tradeoffs (stratification) and schedule synchronization which occur. In addition, institutional time and cyclic time place additional constraints on the consumer's actual choices in using time, taking into account the notion of time embeddedness. The authors recognize that while these links with consumer research are

preliminary in nature, the proposed "time vocabulary" can provide a basis for incorporating additional dimensions of time use into existing models, and form a broader foundation for further theory development.

IMPLICATIONS FOR FUTURE RESEARCH

Several implications can be drawn from this chronosophical review and evaluation of the sociological paradigm. In applying the proposed framework, exchange theory can be extended to examine the retail interaction time spent in search, evaluation, and purchase activities. Moreover, the retail perspective can also help to identify mismatches of time processes: for example, consumers may spend time waiting for a repairman or in a physician's office for an appointment. That is, the lack of synchronization and stratification of social timetables can be investigated as a possible cause of consumer dissatisfaction. In addition, cyclic time appears to form part of the rationale behind some of the ritualistic behavior exhibited by consumers. Weekly shopping, holiday gift-giving, and seasonal "white" sales follow the consumer's apparent response to repetitive cycles held in regard by the larger society in which the individual resides, or is "temporally-embedded."

Perhaps a more far-reaching implication is the further consideration of other disciplines in developing a theory of time. The studies reviewed in this paper strongly support the notion that time is multidimensional, and that those dimensions are often the specific focus within a given discipline. For instance, a three-dimensional approach might involve a processing dimension, an activity dimension, and a level of involvement dimension (Lane and Kaufman 1989). Individuals would vary based on their use of linear, circular, or procedural processing; their capabilities for monochronic or polychronic activities; and their level of cognitive effort as they use time. It is possible that these dimensions can account for some of the variability in consumers' use of time.

Alternative frameworks, like the one reviewed here, are likely to suggest additional dimensions of time. For instance, time is culture-bound; disciplines in the laboratory sciences, such as physics and biology, may provide further insight into time dimensions since they are not as strongly tied to cultural bias as fields such as sociology. Disciplines which look across cultures, such as art, music, and biology, may also uncover additional dimensions, which transcend cultural boundaries.

Aging, Life Cycles and the Sociology of Time

Elaine Sherman, Hofstra University

A discussion of the three papers presented in this session could focus on any number of concerns. However, in exploring the "core" of each paper, the underlying dimension of time emerges. The three papers each deal with a variety of interesting consumer behavior related issues in their unique treatment of time. Although their viewpoints are very different, their approaches suggest a variety of implications for future consumer behavior research.

The first paper "The Antecedents of Cognitive Age" explores a personal and subjective view of the passage of time. Within the past decade, considerable research has examined older adults' self perceptions of their ages (e.g. Barak and Schiffman, 1980; Underhill and Cadwell, 1983; Sherman, Schiffman and Dillion, 1988). This research uniformly indicated that older consumers perceive themselves to be younger than their chronological ages. In addition, older consumers' subjective ages have found to be inversely related to several other self perceptions including one's self esteem, confidence and feelings of purpose in life (Barak, Stern, and Gould, 1988).

With such a subjective perspective, aging is a form of life passages instead of a chronological milestone. What does it mean to turn "40," or "60"? There is a need to expand our understanding of cognitive age, and to use it as a basis for segmentation since it better reflects an individual's identity and behavior. Cognitive age --suggests that the 65 year old may be more like the 50 year old, and thus time in the chronological sense of the measure is not as good an indicator for understanding consumer motivations.

The second paper "Attitudinal and Leisure Activity Difference Across Modernized Household Life Cycle Categories" empirically evaluates an updated family life cycle model, originally proposed in the consumer behavior literature by Gilly and Enis (1982). The family stages have often been considered similar to life stages of an individual. As the modern family (or household) changes, the traditional stages of the family life cycle increasingly fail to capture accurately and reflect the family life cycle as the same categories did twenty or more years ago. The old distinctions between life periods are blurring in today's society. Only a few decades ago, aging was closely defined with the family cycle. During that time period, when there were fewer children per family, and births spaced closer together, the signal for the emerging of "middle age " was the time when children left home, while the onset of "old age" was commonly acknowledged as the time following retirement.

Today's changing patterns have altered our perceptions of chronological age categories. Thus, we have greater difficulty measuring life periods when 20 and 40 year old women are both having first babies. In the past, empty nesters were often regarded as those family members in their late

forties. Today, yuppies often postpone having children, and now have a child in their late thirties and forties. With these changing cycles, it is important to reflect how the traditional family life cycle categories will be affected by these older parents, who are often the same age as their contemporaries who are often already empty nesters, and who sometimes are grandparents. Furthermore, those in the later stages of the family cycle are living longer, healthier lives and are even marrying and remarrying up through their seventies.

For consumer behavior, these changes have implications from both a research and a strategy point of view. A surprising finding of the Danko, and Schaninger research is that "delayed full nest" wives, do have very traditional values. They defined "delayed full nest" wives as those women having their first child after age 35 as well as those having additional children after age 35. These women also reported high non-work related time pressures. Not surprisingly, single parents also reported strong patterns of work and time pressures. The relationship of time pressure, work related stress, and family time will continue as important areas of exploration in the coming decade. Additional insights on these issues will be explored subsequently in this commentary.

The third paper by Kaufman and Lane(1989) presents a sociological paradigm that can be used to conceptualize consumer time phenomena. This paradigm incorporates perceptions of time, as well as the interaction between individual's time and their membership in groups. The authors suggest that time constraints pervade language and other aspects of consumer behavior. They recommend a systematic review of existing time paradigms to establish some common understanding of time studies or a "chronosophy" as suggested by Fraiser(1981). Using the chronosophical process, the authors proceed to review potential contributions of a sociological time paradigm and introduce us to a rich vocabulary of time concepts which can be incorporated into consumer research. The authors conscientiousness and attention to detail need to be commended.

While the general topic of time has been addressed in all three papers, a closer examination of some of the specific issues raised by the authors in this session needs to be addressed.

COGNITIVE AGE AND CROSS CULTURAL RESEARCH

The authors, Chua, Cote and Leong build on research in the gerontology literature which has examined the relationship of aging and life satisfaction. The relationship between the predictors of successful aging(i.e life satisfaction, higher levels of activity, closer family relationships, good health and western culture are explored. Although the concept of cognitive age is

interesting and important in our attempt to understand the older consumer, the paper raises several questions. Firstly, one problem was the use of the convenience sample of 301 "elderly" Singaporeans with a self administered questionnaire. Cultural differences are often particularly acute dealing with perceptions relating to such concepts as perceived age. For example, what does it mean to be 55 or older in Singapore compared to a comparable chronological age in the US? Furthermore, can any generalizations be made from the results found in this research? Differences in the cultures regarding age perceptions may make it precarious to do so. An illustration of these differences relates to the age of retirement in these two countries. Since in Singapore 55 is the official government age to retire, there can be major perceptual differences between older people in these two countries based on this factor alone. As the authors acknowledge, the age range, cultural orientation and non-random nature of the sample prevents broad generalizations as they relates to aging. One cultural phenomena that may make the results less generalizable to the U.S. is the authors suggestions that the lack of association between family relationships and cognitive age might be due to the strength of family relationships in Singapore, which vary little across families. None of the family life factors were related to the age differential, so their third hypothesis was not supported.

Other problems refer to the methodology used in this research. For example, although the authors attempt to measure life satisfaction, they define it as "the type of gratification that an individual's life circumstances make available to a person" is a nonconventional approach to measurement. One might wonder why some well established means of life satisfaction or well being such as Neugarten's (1961) measure was not used. The measurement of cognitive age was not clearly defined.

I agree with the authors that future research needs to focus on various relationships such as that between cognitive age and life satisfaction. Previous research by Sherman, Schiffman and Dillon, (1988), and Sherman and Forman (1988) both indicated positive relationships between life satisfaction and cognitive age. Further investigation of our knowledge of subjective age perceptions continues as an important avenue for research in the coming decade.

THE MODERNIZED FAMILY LIFE CYCLE

Danko and Schaninger's paper explored attitudinal and leisure activity differences across modernized family life cycle model, using the Gilly Enis model to empirically test perceptions of sex role norms, work and time pressure attitudes, traditional values and leisure activities. Our changing demographics certainly present a strong argument for the need for this research. The research suggest differences across sex roles norms and various attitudinal and leisure activities by

gender. Their findings indicate the need for future research to use women as head of household and compare these findings with men as head of household. Also using women's ages, instead of men's would suggest shifts in terms of the leisure activities of various stages of family life cycles. Other research issues might be to distinguish between those having their first children and those merely continuing to have children.

Furthermore, various categories need closer exploration. Although newlyweds, bachelors and single parents were categorized, it would be interesting to examine the views of other groups such as noncustodial parents, and true childless couples. In addition, future research which might compare the attitudes of those in second marriages with those in a first marriage and the attitudes of those who marry later with those who married earlier. Other interesting directions might be to explore attitudes and activities by types of career patterns of those who married later and those women who return to "work" and those who return to establish new careers with more education and training. The influence of other variables such as social class would be an interesting area for future investigation. The attitudinal and leisure activities explored in this research are interesting for giving us a gestalt perspective of life style patterns and suggesting new directions for future research.

THE TIME CONCEPT

Kaufman and Lane's paper presents an absorbing review of the time paradigms in other disciplines and how they can be incorporated into consumer research. The authors suggest that this in-depth consideration of time paradigm in other disciplines must precede the incorporation of concepts, terminology and measurement techniques into consumer research. The concept of time has often been characterized in a traditional economic framework. This mathematical or economic approach does not allow the subjective aspects such as the need of the individuals which may be interacting with other time phenomena. A "Chronosophy" approach which is an interdisciplinary and normative study of time.

Their point is well taken. Similar cross discipline analysis in other areas of consumer behavior, such as the two other areas of this session, aging and the family might be fruitful. This paper presents important avenues for consumer research and marketing strategy. While the authors suggest certain areas, others that come to mind for future research include the relationship of roles or the conflict from multiple roles and their relationship with time synchronization. An analysis of various family roles and the changing time perspective would be interesting (i.e. single families, and dual working families).

Another area would be the relationship of time studies and the consumer decision processes. For example, how does it relate to information uncertainty and consumer satisfaction? If the level of expectations and realized outcomes affect

consumer satisfaction, does consumer perceptions of the time involved in various consumer behavior activities affect their satisfaction?

The authors discuss the important implications of their paradigm for retailers. For example, the new opportunities created by the inability of consumers to standardize their schedules to existing market institutions which has led to the initiation of special week-end and late nite shopping hours, automated teller machines and round-the clock repair services. Further in-depth investigation of the associations between shopping time and its relationships to other time perspectives such as "social time" can be beneficial. Future research might compare the changing perceptions of time in the last five years and perhaps some speculation about future perspectives of time. Most importantly, consumer researchers need to explore how time concepts relate to consumer needs and fulfillment. The authors research in this area points out the many avenues for future research. For example, consumer "self time", such as age perceptions, consumer "interacting time", such as household roles and consumer's "cultural time", such as holiday celebrations and other events suggest potential areas for building richer time constructs and linking them to consumer decision analysis. Implications of these findings include incorporating gender perceptions and the extension of research (Schroeder, 1989) of the expectations behavior based on time use information. A variety of interesting directions for future research have emerged from this session.

Computer-Controlled Experimentation in Consumer Decision Making and Judgment

Merrie Brucks, University of North Carolina

ABSTRACT

Relative to other laboratory techniques for experimentation in consumer decision making and judgment, computers offer three major advantages to researchers: 1) potential for complex and dynamic task structures, 2) precise measurement and control of time, and 3) automation of experimental procedures and data file creation. Disadvantages are related to the artificiality of the task as well as user interface, software, and hardware issues. These advantages and disadvantages are discussed and directions for future research that is especially well-suited for computer-controlled experimentation are suggested.

INTRODUCTION

The growing availability and capability of the microcomputer has resulted in increased interest in computer-controlled experimentation in consumer decision making and judgment research (e.g., Brucks 1985; 1988; Brucks and Chakravarti 1986; Brucks and Schurr 1990; Drumwright 1986; Hoyer and Jacoby 1983; Johnson et al. 1986; Olshavsky and Rosen 1985; Ozanne 1988; Ozanne, Brucks and Grewal 1989; Painton and Gentry 1985; Rosen and Olshavsky 1987; Urbany 1986; Urbany, Bearden and Weilbaker 1988; Zeithaml and Brucks 1987). This article identifies major advantages and disadvantages of computer-controlled experiments in consumer decision/judgment research, and points out directions for future research that is especially well-suited for computer-controlled experiments.

ADVANTAGES OF COMPUTER-CONTROLLED EXPERIMENTS

Relative to other laboratory techniques for experimentation in consumer decision making and judgment, computers offer three major advantages to researchers: 1) potential for complex and dynamic task structures; 2) precise measurement and control of time; and 3) automation of experimental procedures and data file creation. Each of these advantages is discussed below.

Potential for Complex and Dynamic Task Structures

Typically, laboratory studies of information search behavior have examined only two factors: brands and attributes. Yet the information environment that consumers usually face is significantly more challenging. Consumers may obtain information of various types (e.g., attribute values, product class information, overall evaluations of alternatives) from various sources (e.g., brochures, advertising, salespersons, friends, consumer and hobbyist magazines) by various methods (phone, visit, incidental exposure). It is important to study decision making behaviors of

consumers in complex information environments since it has been shown that information search and processing is contingent on task complexity (Payne 1976; 1982).

Menu-driven computer programs offer a method by which to study large and complex information environments. The sequence and contents of menus may be structured in such a way as to simulate many of the complexities of real-life decision making. For example, the subject may first be asked to choose an information source and method of contacting that source (phone a friend, visit a store, etc.) Next, the subject may choose what type of information to request (recommendation, specific information about a brand, advice on important attributes). After that piece of information has been received, the subject may choose to continue requesting information from that source or to go to another source.

Obviously, the more complex a simulation is, the more programming and computer memory will be required. One must carefully consider how much task complexity is necessary for a specific experiment's goals. While one might be tempted to incorporate as much complexity as possible in order to achieve "realism," this may not be desirable. It is impossible to simulate the real world *exactly*, so descriptive data resulting from such studies are always suspect. For example, if one wants to learn the percentage of people who use each of several information sources, the simulation would have to match the real world exactly on the perceived relative costs and benefits of contacting each of the information sources in order to produce meaningful results. If we understood search costs and benefits well enough to do this, we would not need the simulation to learn about information source usage.

The task complexity associated with computer simulations is most useful for experiments and quasi-experiments in which the effects of the independent variables are contingent on task complexity. For example, research in cognitive psychology has shown that one of the major effects of expertise is on problem perception and representation (e.g., Chase and Simon 1973; Chi, Glaser, and Rees 1981). Thus, some of the information processing advantage that experts have over novices may not be evident in simple, well-structured tasks. A complex, ill-structured information environment provides a better test of expertise effects (Brucks 1985).

In addition to large task structures with a variety of stimuli, computers are ideally suited for dynamic task structures, i.e., tasks where the stimuli or task objectives presented to the subject depend on the subject's previous behavior or current status in the task. A dynamic task structure is useful when the researcher wants to place a manipulation, measure, or instruction at a specific intermediate

point in the task. For example, the effects of types and timing of unintentional exposure to information can be studied by interjecting various screen displays at predetermined points in the decision process. More specifically, the influence of personal selling, stockouts, and unintentional exposure to advertising on the consumer decision or judgment process may be more directly examined.

Measurement and Control of Time

Time may be measured to create dependent variables, or it may be controlled to create independent variables. As a dependent variable, time measurements are often used to infer amount of cognitive processing. For example, the amount of time it takes for an individual to agree or disagree with the statement "Car X is highly reliable" indicates whether this evaluation has been previously stored in memory (and must simply be retrieved) or whether an evaluation must be formed at the time the question is presented. Thus, response time measurements may be used to study memory content, memory structure, and also inference processes. In information search experiments, the time spent examining a piece of information, or information of a specific type (for example, the attribute price), indicates the amount of processing devoted to that piece of information or information type. Traditionally, response times have been measured with tachistoscopes - specialized equipment not always available to consumer researchers. The capability of microcomputers to measure response times makes this methodology widely accessible.

As an independent variable, time may be manipulated by varying the amount of time a stimulus or piece of information is visible (exposure time), by varying the amount of time before subjects' information requests are displayed on the screen (waiting time), and by varying the time allotted to the task (time pressure). Computers may be programmed to manipulate these time variables precisely and reliably within or between subjects.

In decision making experiments, waiting time may be used to represent search costs. The major advantage is that waiting time parallels the cost of search in actual purchase situations. In the real world of consumer behavior, information is collected by such activities as talking to friends, visiting showrooms, or making telephone calls. For most people the major cost associated with such activities is the time it takes to do them. Although most purchases are not made under explicit time pressure, consumers do have alternative ways to spend their time. Waiting time, then, represents the time cost of information search. A disadvantage of using waiting time to represent search costs, however, is that people have widely differing perceptions of the value of their time, and it is very difficult to control for this statistically or experimentally. Another disadvantage is that waiting in front of a blank computer screen may be much more or much less aggravating than spending time shopping in the real world. Other methods for operationalizing time costs may be used in conjunction with waiting time,

such as providing subjects with opportunity costs for time spent doing the decision-making task.

Although microcomputers control time precisely and reliably, mainframe computers do not. The number of other users and the jobs they are running affect the response time of the computer to the subjects' keyboard entries. Thus, time-sharing computer systems should not be used if time control is critical.

Automation of Procedures and Data Creation

Computers do exactly what they are programmed to do (assuming reliable hardware). Thus, multiple administrations of treatments and tasks will be identical each time, eliminating unwanted variations due to differences in experimental procedures. Furthermore, depending on hardware availability, many subjects may be run simultaneously - a big advantage for process-oriented experiments.

The data generated from process-oriented experiments are notoriously difficult to analyze. Computers can eliminate the need to manually convert the subjects' process traces into a quantitative data file. For example, Search Monitor (Brucks 1988) contains a program that keeps track of specific types of subjects' actions and outputs these data directly into a file that is in the usual format for input to a commercial statistical package. With some minimal knowledge of computer programming, the program can be altered to keep track of additional output variables.

DISADVANTAGES

It is often argued that the primary disadvantage of computer-controlled experiments is their artificiality. Specifically, computer simulations are not realistic depictions of real-world decision making, and they might encourage a more rational approach to decision making and judgment than consumers usually use. As mentioned earlier, this artificiality is certainly an important obstacle to using computer-controlled simulation for descriptive research. It may or may not be an issue for experimentation, however. One must suspect that the artificiality of the task interacts with one of the independent variables in its effect on the dependent variables in order to argue that artificiality is a serious threat to external validity (see Lynch 1982 for an expanded discussion of this issue).

The remaining disadvantages are related to user interface, software, and hardware issues. User interface refers to the communication between the experimental subject and the computer. Difficulty may arise if subjects are unfamiliar with computers, or worse yet, intimidated by them. These problems are minimized if the task includes early screens designed to reduce subject anxiety and explain simple commands. Subjects need to know what will happen if they press the "wrong" key and they need a chance to practice skills that will be needed in the experimental task, such as choosing options from a

menu. Difficulties may also arise if the task requires subjects to formulate and type in their own requests and commands (rather than choose them from a list). If the sample is drawn from a non-student population across various social strata, the resulting data set may contain excessive undesired variation due to differences in verbal and typing abilities of the subjects.

The expertise and time required to develop original software is a major disadvantage. Search Monitor (Brucks 1988) and Mouselab (Johnson et al. 1986) were developed by consumer researchers to handle task structures typical of consumer research experiments, thus avoiding the need to develop new software for every new experiment. Commercial user-interface software, such as HyperCard, also may be used instead of developing software from scratch. However, even these software packages take time to learn to use and to create specific experiments.

Hardware availability may also pose a problem. If a large number of subjects are required, it is helpful to have several computers (or terminals) available. Although it is certainly possible to run a one-computer study, it adds to the already lengthy process of implementing a computer-controlled study. Another potential hardware-related problem is the size and quality of the screen display. Computer screens are relatively small and may not be able to display simultaneously all the desired information or stimuli.

SUGGESTIONS FOR FUTURE RESEARCH

Almost any consumer decision-making task may be implemented on a computer, but it may not be appropriate to do so. For many research problems, the only major advantage of the computer is automation, which may not be important enough to offset the disadvantages - especially the time and expense of developing software for the task. In this section, some research problems that are particularly likely to benefit from a computer-controlled approach are discussed.

Complex Purchase Environments

The computer's capability to store and retrieve great quantities of information make it ideal for studying consumer information acquisition in complex purchase environments. It is relatively easy to include multiple stores, multiple information sources, and multiple purchase goals, as well as the usual assortment of brands and attributes in a decision-making task. Thus, for example, one can experimentally examine the relationship between store choice and brand choice or the effect of stores' inventory and pricing strategies on information search. Furthermore, the number of available stores, information sources, and purchase goals may contribute to perceived task complexity or information overload. Future research is needed to examine this possibility and its implications.

III-Structured Choice Tasks

Although much previous research has presented subjects with well-structured decision tasks, the consumer choice situation is often an ill-structured problem (Brucks and Mitchell 1981). Consumers do not usually know all the available alternatives and product attributes before beginning a decision-making task, nor are they certain which methods for obtaining information will be fruitful. It is suggested that consumers develop an internal representation of the decision problem based on these task characteristics during the decision-making task. What factors affect this process of problem representation? How do the (probably) concurrent processes of problem representation and problem solution interact?

Computer-controlled tasks may provide a method to examine these questions. By utilizing dynamic task structures, the task-defining characteristics do not have to be identified at the beginning of the decision process. To examine how problem representations are formed during decision making, the subject might be allowed to search for information on task-defining characteristics (e.g., number of alternatives, identity and importance of product attributes, number of available stores, and store characteristics) as well as attribute values. The amount and timing of search on task-defining characteristics might illuminate the development of problem representation, especially if coupled with concurrent verbal protocols.

Interrupts in Decision Making

The concept of interrupts is crucial to Bettman's information processing model of consumer choice (Bettman 1979). Bettman uses Simon's (1967) proposal that a scanner mechanism continually monitors the environment, looking for conditions that might require changes in current activities. When such conditions are found, the interrupt mechanism stops progress on current activities and initiates a response to the condition encountered. Bettman's model postulates that interrupts affect all parts of the decision-making process: motivation, attention, information acquisition and evaluation, decision processes, and consumption and learning processes. Yet little research has examined responses to interrupts and their effects on the consumer decision process.

Computer-controlled experiments can use dynamic task structures, which provide an ideal methodology for studying interrupts. Phenomena suspected of causing interrupts may be programmed into the task, presenting themselves to consumers at specific points in the decision process. Thus, consumers' responses to the timing and nature of various interrupts may be examined.

The major source of interrupts is a perceived departure of environmental conditions from those expected or anticipated. More specifically, interrupts result from impediments to goals, such as stockouts and unexpected negative information (e.g., high price). Interrupts may also result from unintentional exposure to information. For

example, unsolicited advice from a salesperson or another consumer may cause a consumer to rethink a purchase intention. Similarly, unintentional exposure to advertising or a competitor's display may also cause an interrupt.

Salesperson Influences

Although information from salespeople is a major influence on consumer purchase decisions (Wilkie and Dickson 1985), it has received little attention in the information processing literature. Little is known about the effects of information obtained from salespeople on the process of decision making and judgment. Such influence may occur in the form of an interrupt (unsolicited information), or sales influence may be actively sought by consumers. One direction for future research is to examine the effect of various aspects of salesperson-customer interactions on the formation of problem representation as well as problem solution strategies.

The computer provides a way to experimentally manipulate the timing and content of sales messages while providing access to the consumer's decision process. One might argue that presenting information on a computer screen and ascribing that information to a salesperson does not sufficiently capture the complexities of the face-to-face interaction between customer and salesperson. While this is a real limitation, it does not imply that computer simulation is an inappropriate method to study sales interactions. Rather it implies that independent variables must be chosen that do not significantly interact with this aspect of artificiality. As discussed earlier, purely descriptive research would be problematic.

A special aspect of sales influence research that computers can facilitate is the bargaining process. A simulated salesperson may be programmed to respond to various types of consumer influence attempts with specific messages and concessions (e.g., Brucks and Schurr 1990; Schurr and Ozanne 1985). Computer-opponent bargaining eliminates the need for a human experimenter to trade messages with subjects and allows clean manipulations of bargaining strategy (i.e., one doesn't have to depend on a research assistant to follow instructions). Although the researcher must be careful about generalizing results to face-to-face bargaining situations, it is possible to conduct experiments on independent variables that would not be expected to interact with the "humanness of opponent" dimension.

Memory and Inference

Because computers make response time measurements easily obtainable, research on memory and inference is facilitated. Response time measures provide insight on the organization and content of product information in memory and the development of cognitive structures (Gardner, Mitchell, and Russo 1978). They are commonly used to examine cognitive representations of category structures (Mervis and Rosch 1981). Since response times

help differentiate responses based on memory from responses constructed on the spot, these measures may also be useful for distinguishing product judgments made during choice from product judgments made in response to experimenters' questions.

CONCLUSION

While the computer facilitates or makes possible a number of interesting research endeavors, it is not well-suited for all decision-making or judgment topics. For many research problems, the only major advantage of the computer is automation, which may not be important enough to offset the disadvantages - especially the time and expense of developing software for the task. It is recommended that the researcher carefully weigh the advantages and disadvantages before embarking on a computerized course.

Product Category Perceptions, Elaborative Processing and Brand Name Extension Strategies

Dipankar Chakravarti, University of Arizona
Deborah J. MacInnis, University of Arizona
Kent Nakamoto, University of Arizona

ABSTRACT

This paper argues that consumers' judgments of fit between established brand names and new product extensions are determined by the associations that are activated and elaborated upon in a given situation. A pilot study explored the elaborative processing that occurred, both independently and when prompted by a cue, when consumers considered the extension of some established brand names into hypothetical product categories. The methodological and managerial implications of the results are discussed.

INTRODUCTION

When a firm attempts to penetrate a new product category, considerable managerial attention is devoted to the naming of the new brand. The importance of this decision is underscored by the substantial resources that firms are willing to invest in the process of naming a brand (Mamis 1986, Leuthesser 1988). One common recommendation is to extend a well-established brand name to the new product via a family branding or similar strategy. It is argued that the franchise enjoyed by the established brand name will transfer to the new product. Such a transfer may provide several potential benefits, e.g., easing the task of generating awareness for the new product, providing an instant image for the new product, enhancing acceptance of the new product by the trade, and allowing potential promotional efficiencies. These arguments partially explain why firms have increasingly tended to adopt a brand extension strategy when introducing new products (Erickson and Dagnoli 1988, Kesler 1987, Tauber 1981).

The prevailing wisdom is that the above benefits of brand extensions should be most pronounced when the original and new product categories are similar (Kotler 1988). However, little is known about the nature of these similarity assessments. Indeed, recent psychological research on the organization and structure of human memory (Mervis and Rosch 1981, Smith and Medin 1981) suggests that this prevailing view may be overly simplistic. Whether or not a brand name transfers as intended from an old to a new product category may depend on the associations that are activated and elaborated either naturally or by a marketing cue.

In this paper, we discuss and empirically explore some factors that may influence the cognitive processes underlying consumers' judgments of "fit" between the original product category and new extension. Specifically, we consider (1) the degree to which the associations between the old and new categories are shared versus

unique; (2) the implications of the relative salience or non-salience of these associations in memory and (3) the impact of the presence/absence of marketing communications cueing specific associations. We then describe a pilot study designed to provide some initial insights on these aspects of the brand name transfer mechanism. Finally, we discuss the methodological and managerial implications of the study findings.

FACTORS INFLUENCING BRAND NAME TRANSFER

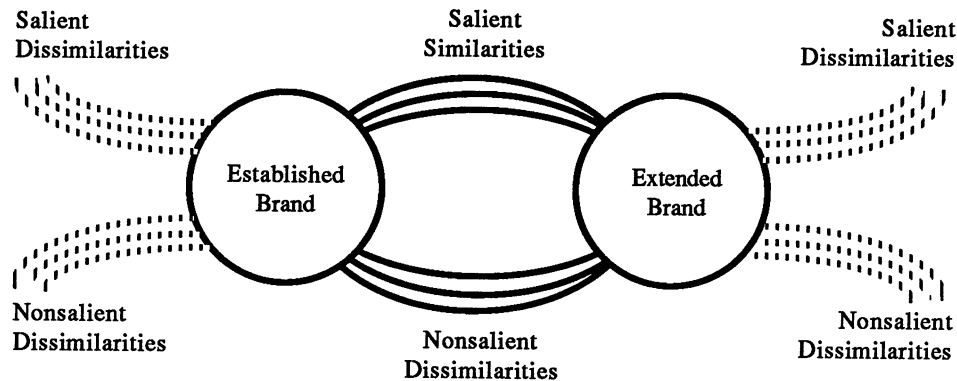

Recent discussions of the nature of product knowledge in consumer memory draw upon the cognitive psychology literature (Anderson 1983, Wyer and Srull 1986) and argue that knowledge of an established brand is represented in memory as a series of associations (Lynch and Srull 1982). Some associations may be generic to the product category whereas others may be brand-specific. Thus, associations for Haagen Dazs ice-cream may include generic features of ice-cream such as "cold", "sweet" and "high in calories", as well as features specific to Haagen-Dazs, such as "rich" and "expensive". Beyond product features, the associative knowledge structure for a brand or product category may also comprise of benefits, usage situations and skills pertaining to manufacture. We now consider the aspects of these associations that may influence the judged fit and evaluation of a new product that has been given an established brand name, i.e., the determinants of brand name transfer (Aaker and Keller 1988).

Shared and Unique Associations

The degree to which the old and new product categories have shared and unique associations is expected to be a factor that determines the likelihood of brand name transfer. Figure 1 represents this schematically. A brand name would be more likely to transfer when an old and a new product category *share* more associations (see the solid lines in Figure 1). Thus, Haagen Dazs sherbet may be a logical extension from a consumer's perspective, and may be seen as a good fit with Haagen Dazs name because the two products have common associations or shared features.

However the overlap between two products is seldom complete. Thus, for any given extension, the established and extended brand are likely to have knowledge associations that are not shared (see the dotted lines in Figure 1). For example, while Haagen Dazs ice-cream is made with butterfat, sherbet is not. Moreover, the two products often come in quite different flavors. Thus, the old and new product categories are also likely to have unique (distinctive

FIGURE 1
Associations Between an Established and Extended Brand

or dissimilar) features. The greater the extent of such unique associations, the lower may be the transferability of brand names across the two categories.

These ideas on brand name transferability are closely related to theories of categorization which suggest that the greater the feature overlap between items, the greater the likelihood that such items will be perceived to belong to the same cognitive category (Rosch and Mervis 1975, Rosch 1978, Mervis and Rosch 1981, Smith and Medin 1981). Other theories of similarity judgments (Tversky 1977) also propose corresponding ideas. Thus, Haagen Dazs sherbet may seem like a natural extension since ice-cream and sherbet share many physical features. However, to the extent dissimilarities become salient during the fit judgment, the extension may be viewed as less appropriate.

Shared benefits may be another basis for judging the appropriateness of a brand extension. Barsalou (1982, 1983) suggests that, in considering items linked by a common goal (e.g., things to eat on a diet), it is shared benefits rather than physical features that guides category judgments. Thus, although cake and ice-cream share few physical features, both may be linked to the same goal (i.e., things to eat for dessert). This may explain why a brand extension such as Haagen Dazs cake may be judged appropriate. By a similar logic, the Arm and Hammer brand name may transfer readily from baking soda to air freshener because the two products provide similar deodorizing benefits.

Usage complementarity among product categories may provide a basis for assessing the appropriateness of a brand name transfer. This type of complementarity between product categories is a special case of shared benefits in that it makes the joint benefits of the two products higher than the sum of their benefits viewed individually. Thus, the Haagen Dazs brand name may readily transfer from ice-cream to chocolate syrup because the two products are complementary in usage.

From a firm's perspective, the decision to produce an extended brand is often determined by marketing or manufacturing synergies between the two products. In some cases, these technological or manufacturing synergies are also obvious and meaningful to consumers and may provide the basis for a perceived similarity between the old and the new product categories. Thus, skills associated with the moulding of plastic products makes Rubbermaid a credible brand name across a number of disparate product categories such as floor mats and storage boxes. Thus, manufacturing synergies that are readily perceived by the consumer may also be a basis for judged fit of an extended brand name.

Salient and Nonsalient Associations

Associations among products may be differentially salient to consumers. Just as some associations come to mind very easily, others are less accessible in memory or more difficult to perceive in the environment. For example, it may make sense for Haagen Dazs to produce frozen vegetables because it already commands a developed technology for distributing frozen foods. Likewise, Heinz may be capable of producing high quality apple juice because the production technology for ketchup is akin to that used for making apple juice (extraction). However, despite marketing and manufacturing similarities between the categories, consumers may not focus on these similarities. Thus, Haagen Dazs frozen foods or Heinz apple juice may be viewed as inappropiate extensions of the brand names. Thus, in addition to considering the type and nature of associations between the established and the extended products, (i.e., shared vs. unique features), it is important to consider the salience of the associations.

Barsalou (1983) suggests that some attributes of items in a category are salient regardless of context, while the salience of others are context-dependent. Context-independent attributes tend to be those central to the meaning of the category. One may speculate that the basic features of product

categories, and those central to a product's ability to deliver its core benefit, would be context-independent and hence naturally salient. On the other hand, if consumers typically think of products based on their benefits or physical features, potential technological or commercial synergies between the products are less likely to be salient.

Figure 1 depicts associational patterns between an established and an extended brand, classified on the basis of whether they are shared/unique or salient/nonsalient. Thus, the two products may be (1) similar on both salient and nonsalient dimensions, (2) similar on salient dimensions but dissimilar on nonsalient dimensions, (3) dissimilar on salient dimensions but similar on nonsalient ones, and (4) dissimilar on both salient and nonsalient dimensions. This fourfold classification scheme permits us to consider the nature of the fit judgments and also the managerial relevance of each classificatory cell.

Cases 1 and 4 are straightforward and imply strong and weak fit judgments respectively. Cases 2 and 3 have significant managerial relevance. First, consider Case 2 in which an established and extended category pair have dissimilar salient associations but are similar on nonsalient dimensions (e.g., Heinz ketchup and apple juice). Because the two brands are dissimilar on salient features, benefits or usage, consumers may perceive Heinz apple juice as a poor fit and evaluate it negatively. The manufacturer then would have to ensure that previously nonsalient manufacturing synergies become salient to the consumer. Likewise, consider Case 3 where an established and extended product pair share salient associations, but there exist nonsalient issues that may raise legitimate questions regarding a firm's competence to manufacture the extension. For example, though Heinz relish may seem like a natural extension due to the perceived complementarity between ketchup and relish, the manufacture of the two products involve quite different processes (extraction versus pickling). A competitor pointing out these differences would lower the credibility of Heinz relish. These examples illustrate why one must consider both salient and nonsalient associations in judgments of fit between an established and an extended category.

Cueing Effects

The salience of associations is likely to be subject to a number of external and situational factors. One factor investigated in this study is the effect of a general, externally-provided cue that is designed to prompt elaboration of previously nonsalient associations. Advertising is particularly important in this regard. Advertising claims could alter the salience of particular associations or, more generally, shift the mental frame or set in which judgments take place, changing the set of associations that are salient.

HYPOTHESES

Given the above, one would expect that without elaboration, nonsalient similarities or dissimilarities would have no effect on the perceived fit of the extended brand with the established brand. Salient cues would drive judgments of the goodness of a brand extension. Thus:

H1: When elaboration is not cued, judgments of the goodness of an extension are best when the established and the extended products have similar features, benefits or usage, and are worst when the two products have dissimilar features, benefits or usage.

However, when an externally provided cue prompts greater elaboration, previously non-salient cues may begin to matter. Thus, two products which initially seem dissimilar may be more favorably evaluated as consumers come to find similarities that were not immediately salient. On the other hand, upon elaboration, a consumer may also find dissimilarities between two products on non-salient dimensions, even though the products initially seemed to be quite naturally associated. The identification of these distinctive features may change how well the established brand name is perceived to fit the extended product and may also change perceptions of the goodness of the extended brand.

H2: Cued similarities on nonsalient dimensions may reduce the impact of salient dissimilarities on the perceived goodness of the extended brand, while cued dissimilarities should reduce the impact of salient similarities on perceived goodness judgments.

In summary, we suggest that the basis for evaluative judgments regarding a brand extension lies in the associations that link the existing branded product and the new product class. Associations may be shared or unique (i.e., similar or dissimilar) and they may be either salient or nonsalient. Salient associations will affect judgment regardless of external cues. Other, initially nonsalient associations may become salient if they are cued. In the next section, we describe a pilot study that examined how the sharing and the salience of associations influences consumers' evaluation of brand extensions.

STUDY DESIGN AND PROCEDURES

A set of seven well-known brands were selected (Table 1). We expected that product category characteristics would be strongly associated with them (Carpenter and Nakamoto 1989). Each brand served as a replicate of the basic design. Five types of extensions were developed for each brand (Table 1). One extension was a control product actually produced under the brand name. Others were extensions to hypothetical categories that varied in

TABLE 1
Stimulus Product Categories

Established Brand	Control Category	Extended Product Category			
		SS/NS	SS/ND	SD/NS	SD/ND
Hunts	Tomato Paste	Tomato Puree	Dill Pickles	Apple Juice	White Wine
Kleenex	Napkins	Disposable Diapers	Sponges	Tree Nurseries	Furniture
Papermate	Pens	Markers	Staples	Disposable Razors	Auto Parts
Alpo	Puppy Food	Cat Food	Flea Collars	Canned Tuna	Shoes
Haagen Dazs	Ice-cream Bars	Butter	Chocolate Syrup	Frozen Dinners	Canned Peaches
Sheraton	Travel Lodging	Beach-front condos	Suitcases	House-keeping services	Tax services
Kelloggs	Corn-flakes	Oatmeal	Bread	Birdseed	Beer

SS= salient similarities (i.e., similar features, usage, benefits)

SD= salient dissimilarities

NS= nonsalient similarities (i.e., similar technological, marketing synergies)

ND= nonsalient dissimilarities

similarity or dissimilarity to the established brand. Some extension categories were picked such that the similarities or dissimilarities on dimensions that we presumed would be naturally salient. Operationally, these tended to be physical features, benefits, or usage characteristics. Other extensions concerned dimensions that we presumed would be non-salient. These mainly concerned technology or manufacturing dimensions.

Finally the study manipulated whether an external cue (elaboration instruction) was present or absent. If present, the cue was embedded in the study instructions. It suggested that in evaluating the extensions, subjects should beware of first impressions, and that technological synergies and shared marketing efficiencies could allow the company to produce a quality product at a reasonable price.

The study used a 2 (salient dimensions - similar or dissimilar) by 2 (nonsalient dimensions - similar or dissimilar) x 2 (cueing present or absent) experimental design. Since, for this pilot study, we had a limited number of students (97) in a

convenience sample, each subject judged only five of the seven extensions. The extensions were assigned using a balanced incomplete block design. In the no cue condition, each subject saw all four treatment combinations plus a control. In the cued condition, only the mixed similarity extensions were used, i.e., the salient similarity - nonsalient dissimilarity or the salient dissimilarity - nonsalient similarity cases. The subject judged two of one type and three of the other type.

For each of the five brand extensions, subjects provided four judgments on 7-point scales anchored by high and low. The judgments, (1) similarity to other products made by the brand, (2) fit with the brand's image, (3) quality of the new product, and (4) the extended brand's expected sales, were assumed to reflect the perceived goodness of the extension. After providing judgments for all five products, subjects provided some qualitative reasoning for their judgments of fit and quality.

TABLE 2
Judgments as a Function of Similarity/Dissimilarity on Salient and Nonsalient Dimensions.

Anova Table:

Source	df	Sum of Squares	F	p
Category	6	79.47	1.53	0.169
Salient Similarities	1	950.48	109.65	0.001
Nonsalient Similarities	1	152.61	17.60	0.001
Salient x Nonsalient	1	31.08	3.59	0.059
Residual	266	2305.87	8.67	

Pattern of Means for FIT Judgments:

		Nonsalient Elements	
		Similar	Dissimilar
Salient Elements	Similar	5.01	4.51
	Dissimilar	3.13	2.03

RESULTS

The judgments for the extended brand were analyzed in a repeated measures analysis of variance using the brand extension as the unit of analysis and the similarity manipulations on salient and nonsalient dimensions as factors. Our first hypothesis (H1) was that, in the absence of an external elaboration cue, judgments would be driven by naturally salient associations. The results were somewhat consistent with expectations (Table 2). For associations deemed to be salient, (physical features, benefit, and usage), similarity had a strong main effect ($p < 0.001$) on judgments. Unexpectedly however, similarity had a significant main effect ($p < 0.001$) for nonsalient associations as well. Moreover, as indicated by a marginally significant salient x nonsalient interaction, ($p < 0.06$), the effect of similarity varied by whether the associations were salient or nonsalient. For space reasons, Table 2 reports the means for only the fit judgments. However, the data for the similarity, quality and sales judgments showed similar patterns.

The interaction suggests that the impact of nonsalient similarities (technological synergy) on judgments was greater when physical feature or usage similarity was low. Thus, if consumers initially perceive that the established and extended products are dissimilar on salient dimensions, they may engage in greater elaboration to find similarities that may not be immediately obvious. These results suggest that in some circumstances, consumers may look for and "find" similarities on nonsalient dimensions even without an external cue.

It was also hypothesized (H2) that the presence of an elaboration cue increases the impact of nonsalient similarities and reduces the impact of salient dissimilarities on judgments. In an ANOVA on the four types of judgment, (considering only the mixed similarity extensions judged), the cue by extension type interaction was marginally significant ($p < 0.06$). However, the means were not ordered as expected (Table 3). When brands were similar on physical features, benefits or usage, the cue had no impact. Even when cued, the lack of technological synergy did not adversely affect judgments regarding these extensions. Only when technological synergy was present did the cue have the expected effect of increasing fit judgments. These results are consistent with the idea of a confirmation bias (Einhorn 1982). Specifically, these analyses, pooled over the seven brands used in the study, suggest that consumers primarily search for evidence of similarity on salient features. If brands are similar on these salient features, the impact of dissimilarities on nonsalient dimensions is minimal.

Brand-Level Analyses

In the preceding analyses, the effects of brand and of type of judgment were also significant and interacted with the salient and nonsalient similarity/dissimilarity manipulations. Because of our focus on fit perceptions, judgments of the fit of the brand extension with the brand's current image were of particular interest. We therefore considered these judgments in more detail at the brand level.

TABLE 3
Judgments as a Function of Cueing and Extension Type

Anova Table:

Source	df	Sum of Squares	F	p
Category	6	307.41	5.60	0.001
Cue	1	8.98	0.98	0.322
Extension Type	1	593.76	64.90	0.001
Cue x Extension Type	1	33.87	3.70	0.055
Residual	268	2451.91	9.15	

Pattern of Means for FIT Judgments:

	Cue	No Cue
Salient Similarities	4.51	4.60
Nonsalient Dissimilarities		
Salient Dissimilarities	3.13	2.44
Nonsalient Similarities		

These analyses provide further insight on the reasons for the patterns noted above.

We summarize these results without going into detailed descriptions of the data. In essence, the data for one brand and its extensions (Kellogg's) showed the pattern originally expected. In the absence of cueing, physical and usage similarity drove fit judgments. Thus, oatmeal and bread were both rated very high on fit, while birdseed and beer were rated poorly. The cue had the effect of increasing ratings slightly for birdseed (because of the shared production technology), and decreased fit ratings for bread. The qualitative reasoning explaining the fit judgments were also consistent with our expectations.

However, the remaining six brands reflected idiosyncratic patterns. In some cases, (e.g., Kleenex Tree Nurseries), products that were expected to be seen as naturally dissimilar were not seen that way. The presence of the cue seemed to intensify the impact of the physical feature/usage similarities. In other cases, (Haagen Dazs chocolate syrup), product-specific factors such as usage complementarity appeared to have strong effects, regardless of the cue. In some cases, (Alpo canned tuna), even the recognition of technological synergies did not change evaluations because of other salient inferences. Thus, although Alpo tuna uses many of the same manufacturing and packaging technologies as Alpo dogfood, consumers made inferences about the extension (i.e., would taste like dogfood) lowering fit perceptions. Moreover, though subjects recognized the potential sharing of equipment used to make both pet food and human

food products, this was perceived as disgusting by some.

DISCUSSION

While the study results did not conform to our expectations, they provided a number of insights on the varied inference processes that may underlie judgments about brand extensions. These suggest both methodological caveats and managerial implications for future research.

First, as may be expected, salient associations have a strong impact on judgments about brand extensions and similarity between the established and extended brands seems to have a positive impact on fit judgments. However, it is clear that perceptions of similarity can be based upon multiple dimensions and that the specific context may drive what is salient. Physical feature and usage similarity are two generally effective bases, but other bases (e.g., product complementarity) emerged as well, sometimes dominating the effects of physical disparity.

Cues to nonsalient dimensions had mixed effects. In the absence of other sources of similarity between the established and extension categories, the cue seemed to have had an asymmetric effect - increasing ratings if it cued a basis for similarity, no effect if it did not. However, if other more obvious sources of similarity were present, the cue, when effective, seemed to cause increased elaboration of these obvious sources. This increased their impact, but did not enhance the salience of the intended nonsalient attributes.

The first implication of these findings concerns the identification of "good" and "bad"

extensions. A complex cluster of associations may exist between an established brand name and an extension product category. Hence, it is difficult to specify a priori which of these are likely to be accessed and elaborated in a judgment situation. Thus, to the extent that a priori judgments of salience/nonsalience were inaccurate, it is difficult to predict fit judgments. Thus, for future research examining these effects, it may be necessary to develop a baseline set of associations for each brand pair. In theoretically-motivated empirical work, this may be done at the individual subject level and used to assign subjects to experimental groups. In other, managerial applications, one may look for segments of individuals who depict similar, stable clusters of salient and nonsalient associations for a product category.

Second, the effect of cues to nonsalient associations seems highly variable. In the present study, the cue was rather global and provided a general invitation to consider certain bases for comparison. Based on the verbal reports, the cue appears to have been successful only in some cases. Thus, self-driven elaboration took rather idiosyncratic directions. By contrast, advertising cues tend to be much more specific. Hence, associations cued by well-executed advertising messages may have a more uniform impact.

Third, the brand stimuli used here were established names that were perhaps prototypical and may have anchored the cluster of associations in their original categories. Relative to names that were less prototypical, the set of associations evoked by these brand names may have been difficult to overcome even with the help of a cue. Thus, with less stable associations and a weaker product category member, external cues may have stronger effects.

Finally, the judgments reflected a difference between the noting or comprehending of an association and the adjustment of a fit evaluation on that basis. In the Alpo Tuna case, it was clear that the cued associations (technological synergies in food processing and canning) were clear to many subjects, but were not compelling. The pattern of evaluations suggested that it was impossible for subjects to discount the incongruity between dog food and human food.

Thus, if a taxonomy of brand extensions is to be based on the idea of salient associations, it will be necessary first to develop some more detailed understanding of the classes of associations that may arise in relating an established brand and a novel product category. We are currently studying the structure of brand knowledge as a basis for predicting the natural or baseline perceptions likely to emerge when an extension is introduced. Despite the somewhat mixed findings here, it remains an intriguing possibility that ultimately, a brand name may enjoy greater credibility in a product category if it permits priming of deeper and more meaningful structural associations, even if the surface similarity is not judged to be great.
