Drawing on research on omission bias (Ritov & Baron 1999), which suggests that people will favor bad outcomes that arise from their own inactions compared to actions, we hypothesize that consumer choice for safety products with identical potential rates of failure will be affected by whether the failure is active or passive. Three hundred and forty one subjects participated in study one which served to examine the hypothesis as well as to replicate prior results of Koehler & Gershoff (2003). In all conditions subjects made choices between two automobiles with airbags. One was described as having a 2% risk of death in the event of serious car accident. The other was described as having a 1% risk of death in the event of a serious car accident plus an additional one in ten thousand (.01%) risk of death in the event of a serious accident that varied in its description by condition. In the active betrayal condition the .01% risk was described as coming from the force of the exploding airbag. In the passive betrayal condition the .01% risk was described as coming from the airbag failing to deploy. In the non-betrayal condition the .01% risk was described as coming from engine fumes due to a cracked engine block. Note that despite having identical risks, in the non-betrayal condition the additional risk is not directly caused by the agent of protection. Results replicate prior research and support the hypothesis. In the non-betrayal condition most subjects (60%) selected and rated as more preferable the airbag with the lower overall risk (1.01%) of death. In the active betrayal condition only 34% of subjects selected the airbag with the lower risk. Further, when the betrayal was passive as opposed to active, aversion to the betraying product was reduced, and significantly more subjects (50%) chose the lower risk alternative.

Study two examined whether the decision involved a status quo position or not. In study one subjects actively made choices between two possible safety product alternatives. Thus in this case, rejecting the lower risk, yet potentially betraying, alternative still involved some level of protection. However in many consumer circumstances the decision is whether or not to employ the safety product, not which one to employ. Fifty-nine subjects participated in study two. Identical materials to the active betrayal condition in study one were used, however in study two the choice was described between no airbag with a 2% chance of death and an airbag with a 1% chance of death plus a .01% chance of death from the force of the exploding airbag. While only 34% of subjects chose the lower (1.01%) risk airbag when the alternative was a higher (2%) risk airbag, 69% of subjects chose the lower (1.01%) risk airbag when the alternative was a higher (2%) risk associated with no airbag at all.

Effects of interpersonal betrayal involve visceral and intense emotional reactions (Strauss 1994). Visceral reactions have been described as being weighed extremely heavily in decisions by the individual experiencing the reaction, but that they tend to be underweighted or even ignored when making decisions for others (Loewenstein 1996). Study three examined the impact of having others make a safety decision in the face of a potential safety product betrayal. Sixty subjects participated in study three. Mate-

rials were identical to the active betrayal condition in study one (potential risk from exploding airbag) except that subjects were told that they were making the decision for another person who they did not know and would never meet. Supporting the hypothesis, the betrayal effect was moderated by whether the decision was self or other focused. While only 34% of subjects chose the lower risk airbag for themselves. 63% of subjects chose it for some one else.

The Collective-Relational Paradox in Consumer Trust Judgments: Framework and Propositions

Jagdeep Singh, Case Western Reserve University
Rama K. Jayanti, Cleveland State University

EXTENDED ABSTRACT

Rarely in its long history has the marketing discipline faced a paradox of such magnitude and clarity as it faces today in local and global markets. On a firm-consumer level, the focus on building relationships, deepening loyalty, and fostering consumer trust in the firm's commitment to serving customers has never been more intense or clear. Consider, for instance, the *Marketing Science Institute's* recognition of the five topics of top tier priority for 2002-2004. Each of these topics appears to relate one way or another to better understanding, and strengthening the relationship between the firm and its customers. Yet, at a collective level the general distrust of business motivations, open cynicism and widespread belief that business in general and marketing in particular will opportunistically exploit society's trust if given a chance has never been more palpable or real. Stories of this "crisis of confidence" abound in the popular press (Business Week, June 2002; Chain Store Age, May 2002). Additionally, polling data demonstrates the declining public trust in Corporate America (Golin/Harris Poll 2002; Booth-Harris Trust Monitor, 2001), general loss of public faith in institutions such as medicine (Schlesinger 2002), government (Chanley, Rudolph, and Rahn 2000), and business (Nye 1997). That collective distrust can coexist in an era when firms are redoubling their efforts to build relational trust is a paradox that has thus far remained below the radar screen of researchers and practitioners alike. As such, the collective-relational paradox of trust is little understood; even less recognized are its implications for consumers and firms in general, and individual firm-consumer relationships in particular.

The purpose of our study is to provide an initial exposition of the collective-relational trust paradox. We provide a conceptual foundation for the collective and relational trust concepts. We draw from sociology, psychology and management disciplines for a directed and meaningful analysis of the collective-relational paradox. We then propose a theoretical framework that attempts to capture the impact of collective trust/distrust on relational trust and their joint impact on customer loyalty in individual firm-consumer exchanges. Our study concludes by proposing future research directions within the collective-relational paradox and the pragmatic significance of the paradox in amplifying or attenuating a firm's efforts to build customer loyalty.

Our conceptual foundation for collective trust examines three elements: The definition of a collective, the substantive content of the collective trust construct, and the mechanisms underlying the antecedents and consequences of the collective trust construct. Following Zucker's (1986) historical analysis of the production of trust in society, the notion of collective refers to broad societal and economic institutions/groups that are perceived to be similar based on certain individual (e.g., society of accounting professionals) or firm-specific attributes (e.g., chemical industries association).

We specify the substantive content of the collective trust construct as consumer's willingness to invest resources, authority, and/or responsibility in a diffused or institutionalized collective entity to act on consumers' behalf to safeguard consumer interests in exchanges involving individual members of the collective (Shapiro, 1987). That is, a consumer with a high trust in a collective agency (e.g., airlines in general {diffused} or the FAA {institutionalized}) is more willing to entrust this agency with authority and

responsibility to regulate market exchanges involving its members to ensure that consumer interests are protected and disputes are adjudicated fairly.

There are three separate schools of thought that pertain to the mechanisms of collective trust. The first deals with the social-psychological theories of *generalized trust*—social exchanges based on general predisposition to trust others (Luhmann 1979). The second attributes the mechanisms of collective trust to the cultural environment of the individuals and the last proposes that collective trust is predicated on institutional performance alone (Newton and Norris 2000). We discuss each one of these perspectives and draw distinctions between the notion of a collective from a socio-psychological-political perspective and business perspective.

Unlike collective trust, relational trust has received significant attention in the marketing and management areas with emphasis on different aspects of this phenomenon. Organizational psychologists emphasize relational trust within firms, typically between employees and supervisors, and between firms, typically firms engaged in vertical or horizontal alliances (Gambetta 1988, McAllister 1995; Jones and George 1998; Brockner, Siegel, Daly, Tyler, and Martin 1997; Kramer 1999).

Marketing scholars emphasize relational trust at the interface of firms and consumers, typically between consumer and service provider/brand (Sirdeshmukh, Singh, and Sabol 2002; Singh and Sirdeshmukh, 2000; Iacobucci and Ostrom 1996; Fournier 1998), and of manufacturer and channel intermediaries typically involving vertical channel members or salespeople and a firm (Doney and Cannon 1997; Kumar 1996; Morgan and Hunt 1994; Gulati 1995; Moorman, Zaltman, and Deshpande 1992; Wicks, Herman, and Jones 1999; Lane and Bachmann 1996). In the tradition of academic research, these studies are founded on a theoretically based conceptualization of the relational trust construct, and important concerns regarding the substantive usefulness and validity of this construct have been addressed. Collectively, these studies represent a rich tradition of academic relational trust literature that can be employed to tackle the issues of collective trust, and the potential for a collective-relational trust paradox.

To promote research into this area, we follow the conceptualization of the collective trust construct with a framework of the asymmetric and monotonic effects of collective trust on relational trust and consumer loyalty. Several research propositions are drawn from the model. Future research directions and public policy implications conclude the study.

Cynics and Skeptics: Consumer Dispositional Trust

Amanda Helm, University of Missouri

ABSTRACT

This study investigated cynicism in a consumer context, using qualitative interviews in a grounded theory approach. Analysis revealed an underlying construct of consumer dispositional trust. Consumers generalize trust violations across various categories and see a generalized trust as part of their personality. Explorations of cynicism in the consumer context reflected a belief that companies lack integrity and a negative affect toward companies, with an emphasis on dishonesty or empty promises. Consumer cynicism is associated with disparaging and withdrawal behavior, precautions and retribution-seeking. Perhaps surprisingly, cynical consumers demonstrated very strong brand loyalty to the few companies they could trust.

Social commentators claim cynicism in America is reaching crisis proportions, and public opinion polls reflect decreasing faith in politics, media and education systems. Academic and popular literature about societal or political cynicism often point to Western consumer culture, especially advertising, as a major driver of this shift toward an increasing perception of a cultural hollowness (Goldman 1996; Stivers 1994). This pilot study investigated cynicism directed toward consumption itself, using qualitative interviews in a grounded theory approach. Analysis revealed an underlying construct of consumer dispositional trust, a relatively stable tendency to trust or distrust across multiple consumption situations. At the extreme distrust end of the continuum, consumer beliefs, affect and behaviors can be called consumer cynicism.

CONCEPTUAL FRAMEWORK AND LITERATURE REVIEW

Consumer Trust

At a macroconceptual level, conceptualizations of trust are fairly consistent in the vast trust literature, predominantly featuring two dimensions, competence (perceived ability to meet customer needs) and benevolence (perceived willingness to put the customer ahead of the self) (Doney 1997; Ganesan and Hess 1997; Singh and Sirdeshmukh 2000). Indeed these two dimensions of trust parallel communication work in source credibility and have remained relatively consistent since the days of Aristotle (McCroskey and Teven 1999; Wanzenried and Powell 1993). Most of the marketing literature on trust focuses on channels and business-to-business relationships. In addition, Sirdeshmukh et al. (2002) recently provided an in-depth analysis of the consumer trust concept, focusing on the trust concept itself rather than its consequences. They distinguish between trustworthiness (consumers' perceptions of company and frontline employee behavior) and trust (consumers' self-reported belief that the company and employees are dependable, competent, of high integrity and responsive to consumers).

In academic literature and common language use, trust is consistently represented as a relationship-specific construct. In contrast, this paper introduces the construct of consumer dispositional trust, an individual difference variable which impacts the way consumers interpret consumption interactions and their expectations for trustworthy behavior across multiple companies and situations. In terms of models of specific relationship trust, dispositional trust might be seen as an individual difference variable influencing trust, along with such factors as norms and perceptions of dependence and power.

Cynicism

Although cynicism has been a philosophical and literary construct for centuries, it has emerged as a social scientific construct only in about the last 50 years. In addition to general cynicism, social scientists have identified specific cynicisms targeted at specific institutions: work (occupational) cynicism, organizational or employee cynicism and organizational change cynicism (Abraham 2000; Dean et al. 1998). This paper proposes consumer cynicism as another specific cynicism worthy of investigation.

General or specific, cynicism is described as a learned attitude formed through the process Kanter and Mirvis describe: unrealistic expectations lead to disappointment, which leads to disillusion, a "sense of being let down or of letting oneself down, and more darkly, the sense of being deceived, betrayed or used by others" (1989, p.3). The first steps of this process correspond to widely accepted expectancy disconfirmation theory. Satisfaction is determined more by performance in relation to expectations than by performance in any objective sense. Scholars have portrayed negative disconfirmation of expectations as the primary mechanism for customer dissatisfaction (e.g. Oliver and Bearden 1985). Yet cynics are not merely dissatisfied—they are bitter, angry and resentful. They adopt the cynical attitude to ensure they will not be "taken for suckers" again (Kanter and Mirvis 1989, p.3). In academic terms, the cynicism attitude is characterized by "negative affect" (Dean et al. 1998).

The notion of empty promises or false appearances is a critical element common to all conceptualizations of cynicism. Although the deliberate creation of unrealistic expectations is not always included in formal definitions of cynicism, references to a fundamental disconnect between a publicly presented image and reality characterize all discussions of cynicism. The fundamental disconnect between the presented image and reality is necessary but not sufficient for cynicism. Cynicism also incorporates a feeling of manipulation or ethical violation, exploiting others for one's own interest (Chaloupka 1999). The pretense of unselfishness to mask selfish goals lies at the heart of the cynicism concept. It also lies at the heart of criticisms about advertising and other marketing messages.

Cynicism in the consumption context: Relevant consumer behavior research

Cynicism has not been studied in the consumption context *per se*, but research in other areas of consumer behavior suggests consumers may in fact be feeling cynical. The consumer alienation construct incorporates attitudes of distrust toward businesses and a feeling of being manipulated (Allison 1978; Durand and Lambert 1985), but also incorporates elements unrelated to cynicism, such as confidence in purchasing skills. Scholars have also found evidence of considerable consumer skepticism toward advertising claims (i.e. Koslow 2000), which relates to the disbelief component of cynicism but does not encompass the perception of deliberate manipulation or the negative affect of cynicism. A growing body of research on anti-consumption attitudes, exemplified by the 2002 Psychology and Marketing special issue on the topic and the Culture Jamming film presented at ACR 2002, suggests at least some consumers are feeling enough discontent to rebel through behaviors ranging from voluntary simplicity to defacing advertisements.

Thus, existing literature supports the notion that a cynicism-like construct has the potential to explain consumer attitudes and behavior, but the precise nature of this construct is not clear. The approach to this study was exploratory, with research questions in mind such as: Do consumers have attitudes resembling cynicism about the consumption process? What should a cynicism construct look like in the consumption context? How does it develop? What aspects or level of the consumption process is targeted—individual companies? Consumption culture?

METHODOLOGY

The conceptual framework outlined here is based on eight semi-structured interviews conducted February 28–March 7, 2003. These eight interviews are a pilot study for a larger interview project now in progress. Interview methodology is appropriate for the subject because cynicism is a conscious, even deliberate attitude. Cynicism is depicted in art and discussed in the public forum and everyday conversation. Although they may use other terms, people reflect on and attempt to manage their own cynicism. Thus, people are well qualified to report on their own cynicism, and their understanding and naïve theories are an essential part of the construct.

Sample and Procedure

The purpose of the study was initial conceptual groundwork on consumer cynicism construct, not to ascertain what proportion of the population is cynical about consumption, a question left for later research. Consumption-related cynicism could impact any consumer. For this pilot study, a convenience sample of members of the Hickman High School Music Boosters association (parents of high school students) was recruited. As a token of appreciation, the association was paid \$15 for each interview. For the full study, interviews will draw from a variety of community organizations selected to represent a broad spectrum of the population.

Volunteers from the boosters association scheduled individual appointments. After each subject had reviewed and signed a written consent form, interviews were conducted based loosely on an interview guide (McCracken 1988). Interviews typically lasted about an hour. The interviews were recorded on audio cassettes and professionally transcribed.

Questionnaire

Leading respondents was of particular concern because of possible social desirability and social contagion effects. Once cynical ideas are presented, participants may jump on the bandwagon in order not to appear naïve. Scholars refer to a culture of cynicism (Chaloupka 1999; Goldfarb 1991; Stivers 1994). To avoid leading respondents, interview questions began with positively valenced prompts such as asking about trust in a brand or company and used a balance of positive and negative prompts throughout. “Cynicism” or “cynical” are highly charged words laden with inconsistent but strong negative connotations of pessimism as well as the more positive connotations of sophistication. Therefore, the words “cynicism” and “skepticism” were not introduced by the interviewer until near the close of the session, unless subjects themselves spontaneously introduced those terms. Instead, the emphasis of the interview prompts was on terms associated with potential cynicism elements such as trust-mistrust, ethics, or overpromising.

Analysis

The transcripts were analyzed following the grounded theory procedures for open and axial coding outlined by Strauss and

Corbin (1998). Although the process was fluid, with multiple types of coding going on simultaneously, coding was loosely organized into phases focusing on increasingly high levels of analysis, similar to the process recommended by McCracken (1988). Initially, transcripts were read carefully line by line and labeled or categorized using open codes. Next, the transcript was read again, with a greater emphasis on code description and consistency. Third, the codes and associated quotations from the text were reviewed (moving up a level of abstraction from the whole text to just the coded quotations), and notes and comments were made on emergent conceptual issues. The concept of the dispositional trust continuum began to emerge about half-way through the coding process; after that point a profile memo was written for each interview subject addressing his or her trust/cynicism outlook. Finally, the analysis moved up yet another level of abstraction to focus primarily on clustering the codes, describing their properties and dimensions and defining relationships among them using axial coding. Throughout the process, the cynicism literature was used as a point of constant comparison (Strauss and Corbin 1998), drawing on not only the definitions specified in social scientific journals, but also the varying perspectives on cynicism in social commentary.

Although a formal audit was not completed, a researcher not involved in the project did conduct an independent open and axial coding analysis on a subset of three interviews. His conclusions were fairly similar, noting similar elements of the trust and cynicism definitions, a trust-cynicism continuum, and a dichotomy between a relationship-specific trust and a more general trust tendency.

EMERGENT CONSTRUCT: CONSUMER DISPOSITIONAL TRUST

The construct of consumer dispositional trust emerged from the data. As noted in the literature review, trust is typically described as partners’ attitudes and expectations in a specific relationship. Insight from the interviews suggests the existence of an additional type of trust, one that is generalized across multiple contexts. This paper proposes consumer dispositional trust as a relatively stable tendency to expect (un)trustworthy behavior across a variety of contexts.

In traditional models of relationship specific trust, dispositional trust would join the ranks of the many factors contributing to the development of trust in a specific relationship. Its influence would likely be particularly strong at the beginning of a relationship in the face of a lack of more specific information. Yet the influence of dispositional trust is not limited to trust in specific relationships. In the consumption context, dispositional trust appears to also influence consumer search and decision-making behavior and consumers’ interpretation of or response to myriad consumption interactions. Furthermore, distrustful consumers try to spread their distrust by socializing others.

Trust in the Consumer Context

As previously mentioned, the trust literature typically identifies two dimensions: competence and benevolence. Although consumers in this study mentioned product quality and skill of the company when talking about trust in particular companies or brands, the benevolence dimension seems to be much more salient when talking about generalized trust. When asked to define what the idea of trust in a company meant to them, interview participants emphasized fair treatment and living up to promises:

“In the sense of the company I think that they would treat me fairly, they would have a good product, a good service behind

that product... if I would have a problem that they would take care of it, they would try to resolve it, they would value me as a customer, and try to do their best to keep my business.” (I3)

“Trust that the product is going to do what it says it’s going to do” (I2)

“If they back up their product, I have full confidence that if there is ever a problem with this product that I will get full customer courtesy, I think that’s a part of it.” (I6)

“The break down for me probably occurs probably in some [support] service ... I have to sometimes really get right with people and make them do what they say they were going to do.” (I7)

Interview participants seemed fairly tolerant of problems with the actual products, but saw mishandling of their concerns as central to their concept of trusting in a company.

[Because so many of the components are not under the manufacturer’s control] “you’re going to have people and places and things and equipment that do not perform. Now, it’s how you handle its effect on your consumer, that is to me what speaks to ethics of doing business.” (I7)

Self-Characterization

Interview participants clearly perceived themselves to have some kind of generalized trusting/distrustful perspective and see this as a personality trait. Interview questions were phrased in terms of asking consumers to think of specific examples and then asking them to assess whether such an incident was typical of their experience. Other prompts asked their opinions of “most companies.” Instead of responding in terms of perceived frequency of company behavior, participants often responded with statements of self-characterization such as:

“I think I put trust into a company until it’s proven otherwise.”
I8

“I won’t use companies or I won’t work with people who I distrust and for me I’ve developed sort of a sense that I can’t know when you are putting me on, or when you are real flaky, and I don’t like to do business with people like that. ‘I’m just a sales call away from being your best friend,’ –No, I don’t like people like that.”

“Now I’m certainly not a naïve consumer, but I thought that was pretty interesting yesterday.” I1

Generalization

Generalization is critical in the formation of dispositional distrust. Interview participants saw negative incidents as learning experiences which changed their behavior in the future. One company’s failure was generalized to shape expectations for other companies’ behavior. Even trusting consumers generalized from an incident to a product category, and consumers in this study typically described negative incidents using category terms rather than specific brands.

For example, Interview 3 described an incident shopping with her sister for a computer in which the salesperson recommended a voice recognition package. Later they discovered “in the fine print” that the package did not include all the required hardware; the low price was not such a good deal after all.

I: So next time, later, if you are in the market to get voice recognition software...

R: I’m definitely not going to look for theirs. I mean—I would actually—I don’t remember the name myself because I’m not in the market for it but if I were I’d call up my sister and find out what it was. Because I definitely do remember the experience even though I didn’t associate the name with it.

I: What about other software?

R: I think it makes you more skeptical about any of it, I mean you want to read the boxes closer and be sure you are getting exactly what you think you are buying.

I: What about things other than software? Do you think it would carry over?

R: Probably not so much of one experience but I think the more experiences like that that you have with products as you buy—if I also bought panty hose and there was something funny about them and also about something else and you know, I mean, eventually, if you have enough of those experiences then I think it kind of makes you skeptical about everything, but as long as it more of an isolated thing I think it just kind of makes me more skeptical about software in general.

The literature also shows support for the idea of generalization. Research on the sleeper effect (Allen and Stiff 1989; Gruder and et al. 1978; Pratkanis, Greenwald, Leippe, and Baumgardner 1988), in which people remember information but disassociate it from the source, provides tangential support for the notion that distinctions among sources may erode over time. Is it likely that consumers would forget exactly which brand was responsible for violating their trust? Some studies do suggest that consumers are capable of becoming confused about brand names (Allen and Stiff 1989; Foxman, Berger, and Cote 1992; Kapferer 1995) and about which attributes belong to which brand (Kent and Allen 1994). In the example above, she has already forgotten the specific brand name, even though the incident was recent and her feelings were strong. Research on associative learning also supports the possibility that generalization can occur. Leippe, Greenwald and Baumgardner (1982) found that, when exposed to a series of advertisements including negative and neutral effects about different brands, consumers generalized the negative characteristics to the neutral brands when the brands were similar. This generalization has significant managerial implications—a competitor’s violation of trust can impact the whole product category.

Although interview participants had little difficulty in thinking of product categories that were particularly trustworthy (grocery stores, brand name foods, pharmaceuticals) or untrustworthy (hair regrowth products, used car dealers, pharmaceuticals), they also categorized in other unanticipated ways. One common categorization was of particular marketing practices. Not surprisingly, participants expressed skepticism of mail-order companies, ordering off a television commercial, and telemarketers. Several participants referred to “bait-and-switch” advertising (sometimes even using the term), in which promoted limited time sales did not live up to promises. Rebates and additional fees for maintenance contracts were also mentioned:

“I feel like they are trying to sell me this washer or dryer or they’re trying to sell me this TV set and then they say, oh but then for \$200.00 we’ll give you this extended warranty and so

forth and you're like, wait a second, back up your product, why do I have to pay for you to back up your product?" 16

"They are all doing the same thing, they are all issuing rebates. But you have to come home, fill out the paper work, mail the damn stuff off, and what if it gets there and 4 weeks later somebody opens it and says 'Oh, you didn't put the UPC code in it'? Does it die there? Will they give you a notice? Will you ever see your money? Well, I don't know, do you have a personal secretary that will keep track of all the rebates you've got coming in?... They hope that you will not send in the rebate so they'll get full price for it. They figure you are too stupid or too forgetful... I can't really say it is misleading but I think that they are banking on you either being too late or too stupid to do something that you shouldn't have to do. They should just give you the price." (17)

Another common categorization among interview participants was to trust small, local companies or stores over large, national "conglomerates." Participants almost all raised this issue themselves before reaching the planned prompts on the questionnaire. As one fairly cynical consumer put it, "The larger the company the more I distrust it" (11). Interview participants suggested several reasons for their trust in smaller companies: being more accountable because of being in the community, being more dependent on a small customer base (need for repeat business), and being less insulated in layers of hierarchy. Several participants felt strongly about this and made a deliberate effort to patronize local businesses even at higher prices.

COMPLEX CONTINUUM: TRUSTING, SKEPTICAL AND CYNICAL CONSUMERS

The consumer dispositional trust construct presented in this paper can be seen as a continuum, but it is a complex one. This pilot study suggests consumers with a predominantly distrustful outlook differ from consumers with a predominantly trusting outlook in more ways than simply degree of trust. Degree of generalization, salience, and affect are also relevant dimensions. During analysis, profiles were written for each interview participant summarizing the dispositional trust demonstrated, and these profiles were organized into clusters along the continuum, loosely categorized as trusting, skeptical and cynical. These were not intended to represent hard categories or formal classifications and the boundaries of each category are fluid.

Trusting Consumers

In this study, for consumers clustered at the most trusting end of the continuum, trust seemed to be less salient in the consumption context. Examples of companies or brands they particularly trusted or distrusted did not come to mind readily, and satisfaction issues, rather than trust issues, were mentioned more frequently when asked to explain brand and store preferences.

"I think for them [preferred stores] I look at it more as I like the selection they have, the prices they have and so, I don't know if I would say it was a trust sort of thing, I guess there's a certain amount of trust that kind of you know, you trust that they are going to kind of cater to your needs, but, not in the sense that we normally think of trust." (13)

"I don't know that I line up companies and say these are trustworthy and these aren't. As a whole, I just know that I've had good experiences with Toyota and most recently got a

Ford Explorer and that's been a real good vehicle for me." (15)

Interview participants in the "trusting" category made fewer self-characterization statements related to trust issues—they did not describe themselves as "skeptical" or "savvy" or "cautious" consumers as more skeptical consumers did.

Skeptical Consumers

Skeptical consumers represent the moderate cluster on the consumer dispositional trust continuum presented in this paper. Skepticism is defined as "an attitude of doubt or a disposition of incredulity either in general or toward a particular object" (Webster's 1990).

The advertising skepticism construct in the literature is closely related: "Skepticism implies that consumers recognize that advertisers have specific motives, such as persuading consumers, and therefore that advertisers' communications may be biased and varied in their truthfulness" (Mangleburg and Bristol 1998, p. 11). Although it is described as negatively valenced (Boush, Friestad, and Rose 1994), advertising skepticism is characterized as a needed consumer skill developed through socialization. In the context of this paper, consumer skepticism is not limited to advertising claims. All of the interview participants indicated some degree of skepticism toward advertising, sometimes to the point of discounting its claims completely. Even trusting consumers were skeptical of some advertising: "It may say that it can clean something and it would be really easy; you'd just squirt, let it rest, then take it off and it won't do that." (12)

Skeptical consumers in this study believe they need to be cautious and on guard against scams, but they don't indicate much negative affect or resentment. Associated behaviors seem to be limited to precautions—reading the fine print, checking the warranty, shopping around and researching major purchases. Their perception seems to be that there are a few truly untrustworthy or unethical companies, but that many companies can be trustworthy.

"I'm not like overly distrustful of companies I don't think, but not just you know automatic either... something had to happen to cause me to build a little more trust in one company than the other." (16)

Later, this participant characterized herself as "skeptical," which she defined as: "A little more cautious about thinking and checking things out before you just blindly trust." (16) Skeptical consumers saw themselves as becoming more skeptical overtime, but did not point to specific moments of disillusionment. Instead they referred to a gradual development and also mentioned media stories such as the tobacco companies, pharmaceuticals, and Firestone Tires.

Some skeptical consumers in this study see the trust as residing not in the companies themselves, but in external factors that would keep companies in line: competition/the marketplace, the legal system (fear of getting sued), licensing and certification, and government restrictions (FDA). For skeptical consumers, trust issues are salient. Compared to trusting consumers, they seem to be better able to recall specific incidents when trust was built or violated and are more likely to see preferred brands as something they trust.

Cynical Consumers

Two interview participants were clustered at the cynical end of the consumer dispositional trust continuum, and some consumers in

the skeptical group also made cynical statements about certain product categories. Cynical study participants are also skeptical, but, consistent with representations of the cynicism construct in social science literature, cynicism in the consumer context seems to be characterized by a belief in a pervasive lack of integrity among consumer companies and negative affect such as bitterness or resentment, as suggested by Interview 7's comment about the rebate process, "It's like I'm this little puppet and they are just manipulating me."

Cynics in this study perceive a pervasive dishonesty or sham and see companies as frequently manipulating consumers.

"[department store] has this big sale right now. All of a sudden everything in the store is just 'oh this is perfect for you', 'oh I'll be sure that I can find it for you,' 'I'll hold it for you.' It is just a motivation to move the merchandise out of the store ... Like yesterday, I tried on something that is really too small on me and it was really awful. And the clerk said, 'Oh this looks really great on you!' ... I felt very strongly that they have their meetings an hour before the store opens, and they have their motivational talks, and they have sales incentives. And that is the way the world works. Now I'm certainly not a naïve consumer, but I thought that was pretty interesting yesterday." (11)

All interview participants indicated that the underlying motive for most, if not all, companies was the bottom line profit. But cynics in this study expressed concern or irritation that businesses' over-eager pursuit of profit would trample other important considerations such as consumer safety, and that emphasis on short-term profits undermines company motivation to really build quality and customer satisfaction.

"I'm saying that profit means that I retain you over time as a customer that means I treat you good, I give you good service, I give you good products, I don't over-promise anything—and if I do make a mistake, I do apologize for it and I try to correct that. That's long term, that is profit. To me. And what I'm telling you is what I see today in the market place is that companies have a very short term approach to profit from the standpoint that they will not retain you because they will over-promise you and they will not deliver on service and they will treat you like you are not important. ... I know I keep going back to the same thing, which is a long term look but you don't get a customer today and then you blow them off tomorrow." (17)

For cynical consumers in this study, their dispositional trust was very salient. Descriptions of themselves as consumers emphasized beliefs that companies are untrustworthy and their own tendency to take extra precautions. In other contexts, two categories of behavior are typically associated with cynicism, disparaging and withdrawal behaviors. These categories can also be seen in the consumer context. Cynical participants described efforts to socialize others by bringing children up to be critical consumers, getting friends on board for boycotts, and spreading negative word-of-mouth. They also described, of course, avoiding buying from distrusted companies, but also mentioned trying to reduce consumption in general, avoiding impulse buys, avoiding negotiation and avoiding shopping. Two other types of behaviors were mentioned: precautions and retribution.

Like skeptical participants, they saw the risk of being "ripped off" as something they could minimize through caution, but to a greater degree. The following story from Interview 7 shows his inclination to take precautions. The quote also shows the salience

of the dispositional or generalized aspect of trust—he interrupts his own specific story to generalize to a perceived tendency of lower-level personnel to go back on verbal promises, a recurring theme for him:

"Somebody stole my credit card numbers so I had to cancel ... and in the course of handling it—or any kind of daily chores—you're going to have a conversation with somebody over the phone, some sort of personnel, and they'll tell you 'Sir, you're absolutely right somebody made those charges and we're going to take those off your card, blah, blah, blah.' Well who was it? When did they say it? What was ... you know what I'm saying? So if you don't record—and I have recorded conversations. I literally have recorded conversations."

The cynical participants also described efforts to gain retribution when unfairly treated, whereas, at least in this pilot study, more trusting consumers seemed to be more inclined not to bother. This contrasts with some implications of cynicism literature in other contexts, in which cynics withdraw, see themselves as powerless, and avoid futile efforts to change (Govier 1997). None of the participants were interested in doing business with companies they didn't trust, but for non-cynics, the motivation seemed to be primarily preventing their own dissatisfaction. For cynics, their avoidance of distrusted companies seemed to be motivated by an additional concern: punishing the company.

"It was totally unsatisfactory. I went to the Attorney General, I complained to somebody in Illinois where their office was, and I'll do whatever it takes to make sure that I get restitution but I'm fairly savvy but the average guy is going to give up." (17)

"I'm thinking about not shopping there any more even though I have a historical loyalty ... not that they would miss me but I think that you can only accomplish things if you start with one person at a time." (11)

Trust, Brand Loyalty and the Cynical Consumer

Initial expectations for the project were that a possible negative effect of cynicism might be a decreased capacity for brand loyalty. But as the dispositional trust construct emerged, it became clear that it influenced trust in specific relationships but it was not part of trust in specific relationships. Dispositional trust is not a capacity for trust; it is an inclination or predisposition to trust. If the predisposition not to trust (as in the case of cynicism) can be overcome, trust is still possible.

The cynical interview participants described themselves as brand loyal and talked more enthusiastically about the companies, brands, shops and salespeople they especially trusted more than any of the other interview participants. Against the background of so many distrusted companies, these exceptions stood out in sharp relief. For the cynical participants, trust built on previous experience was a primary reason for brand or store preference. They were more aware of specific brand names and seemed to see themselves as having a relationship or "doing business with" their preferred companies. The cynical consumers frequently mentioned being willing to pay more and go out of their way to buy from businesses they trusted and to rely on a trusted store or brand as a shortcut to purchase decision research. Interview 7 now limits his car shopping to one dealer—the only used car dealer he feels he can trust.

As with the punishing behavior, the motivation for the brand loyal behavior seemed to go beyond a desire to ensure their own satisfaction to a sense of rewarding the few trustworthy companies.

Cynical interview participants perceive a competitive business environment which discourages integrity in companies. They also saw consumers' own behavior as a major component of that business environment through consumer overemphasis on price (over quality), abuse of exchange and return policies, and failure to research. Perhaps the cynical consumers feel a need to try to counterbalance these other consumers, or perhaps they just feel a need to try to "help" their companies succeed in a competitive world; clearly they feel some responsibility to demonstrate their support of trustworthy companies.

Development of Cynicism

The cynicism literature describes a process of disillusionment leading to the development of the learned attitude of cynicism (e.g. Kanter and Mirvis 1989), but studies do not report individuals' accounts of their experience of this process. Cynical interview participants did point to specific personal incidents that caused them to increase their feelings of skepticism and could describe a generalization process.

"My dad died of cancer in 76; and I started reading all of the material about pollution of our food supply and I realized that chances were that our food supply was not as pure as it used to be because of the intensive farming, chemicals, pesticides, everything that was increasingly being used to produce more, better yields, and so up to that point I never gave any kind of thought to trusting the food but when that happened awareness finally that probably your foods are not as good as you thought. That was certainly a breakthrough, it was a different era for me." (11)

"I looked at a used vehicle and before I got home they were calling me and telling me they were taking that vehicle to the auction. 'We've got to sell it, we've got to make up the amount,' high pressure, high pressure, high pressure... [a few weeks later] I was talking to this friend of mine at [another dealer] and I told him the high pressure tactics used and he said, 'They didn't take it to the auction, that's just a technique.' I said, 'You think they actually lied to me face to face,' and he said, 'Yeah, I bet it is.' I went back over to the lot and it was still sitting on the lot. I caught them in that lie and that—it is buyer beware. I'm fully aware of that." (17)

CONCLUSIONS AND FUTURE RESEARCH DIRECTIONS

Using a grounded theory approach, this pilot study uncovers the concept of dispositional trust, and the meaning and structure of cynicism in the consumer context is explored.

Interview participants' comments clearly demonstrated that they perceived a trusting or distrustful outlook as a personality characteristic. Consumers in this study generalized violations of trust from one company across varying levels such as product category or promotion technique (i.e. rebates). This has significant implications for managers because the actions of a competitor clearly influence consumers' disposition to trust in the same product category—even for the most trusting consumers. Interview participants' observations in this study suggest that trust violations anywhere in the product category have implications for anyone in the product category, suggesting perceptions of industry standards as a possible area of future research.

Explorations of the meaning and structure of cynicism in the consumer context reflect the same elements characteristic of other types of cynicism: a belief that the target lacks integrity and a

negative affect, with an emphasis on dishonesty or empty promises. Behaviors typically associated with cynicism in other contexts fall into two major categories: disparaging behaviors and withdrawal behaviors. In the consumer context, the study suggests two other categories of behaviors are relevant: precautions and retribution. The cynical consumers' discussion of specific moments which shaped their cynical outlook offers a potential contribution to the cynicism literature as well as to consumer research and should be explored in future research. Perhaps the most interesting finding of this study is the committed, enthusiastic brand loyalty shown by cynical consumers.

Based on this pilot study, a full-scale interview study is in progress to further develop the theoretical constructs. Some of the research questions being pursued so far investigate the link between consumer dispositional trust and anti-consumption attitudes and consumer self-confidence and consumer notions of societal and economic forces behind their generalizations about companies. After further qualitative work to shape this construct, future research may include development of a quantitative measure.

Is it Still Worth to be Credible? A Meta-Analysis of Temporal Patterns of Source Credibility Effects in Marketing

Martin Eisend, Freie Universität Berlin

ABSTRACT

The purpose of this study is the examination of the development of the impact of source credibility in marketing communication over the years. A meta-analysis was applied to 167 relevant effect sizes. The results indicate that the effect of source credibility increased over the years. The rise was stronger especially for sources communicating personally with the consumers than for other sources, and for communication about services compared to communication about goods. Also, the rise of the effect sizes was stronger for cognitive and attitudinal effects than for other effects.

1 INTRODUCTION

Credibility is a concept rich in tradition. Scholarly examination of source credibility and its impact is as old as the discussion of rhetoric itself, having originated with the ancient Greeks. First empirical studies referring to the impact of source credibility can be backdated to research projects dealing with the concept of prestige in the 1930s (Arnett et al. 1931; Wegrocki 1934). Indeed, Hovland and his colleagues who worked on the *Attitude Change and Communication Research Project* at Yale University in the 1940s and 1950s are claimed to be the founders of modern source credibility research (Hovland et al. 1953; Hovland et al. 1949; Hovland and Weiss 1951). Their research interest in persuasion and in particular in the effects of source credibility rose from the worry about the efficiency of Nazi propaganda during World War II and the desire to find out means to improve the propaganda of the Allies. Since this time, a lot of research has been undertaken to examine the impact of source credibility. Also marketing researchers have detected the concept of source credibility as a powerful facility for influencing consumers. If a consumer perceives a source as having higher credibility than other sources, the consumer is more receptive to messages from the source and is more likely to be persuaded. However, whereas the idea and the concept of source credibility haven't changed in the course of time, consumers and consumption behavior have changed during the last decades. This has probably also led to a change of the impact of source credibility. The main research question of the study deals with the development of source credibility effects in marketing in the course of time. It will be answered by applying a meta-analysis of the effects of source credibility in marketing communication. Beforehand, a brief explanation of the concept of credibility and its effects in marketing communication as well as a rationale for the changes in consumer behavior over the years are required.

2 RESEARCH BACKGROUND AND RATIONALE FOR THE RESEARCH QUESTION

Credibility refers to a person's perception of the truth of a piece of information. It serves as a means for the receiver of the information to rate the source or transmitter of the communication in relation to the information. This rating correlates with the willingness of the receiver to attribute truth and substance to the information (Hovland et al. 1953, p. 21). Credibility is tied to information, and can thus be described as a communication phenomenon. Communication takes place between at least two parties. Any kind of communication between a supplier and a consumer that occurs with the intention of influencing economic transfers can be defined as marketing communication. A company or its representatives (e.g. salespersons) are the sources, whereas the consumer is the receiver of the message.

Research on the impact of source credibility belongs to the domain of persuasion research. Persuasion research deals with characteristics of the source, the message or the transmitter as independent variables whereas attitude formation or attitude change form the main dependent variables (see O'Keefe 1990; Perloff 1993). Beyond attitudes, other dependent variables are studied as well. The majority of the results indicate a positive effect of credibility on attitudes, cognitions, intentions and also subsequent behavior. However, some other variables (e.g. involvement, commitment) moderate the impact of source credibility, and some of those moderators can even reverse the effect so that a source having only moderate credibility can be more persuasive than a highly credible source (Sternthal et al. 1978).

Time can also be assumed to be such a moderating variable. Using a perspective of historical development (see Gronmo 1989), time represents a variety of occurrences and environmental changes and can be considered an all-embracing socio-temporal context variable. As this socio-temporal context has changed over the years, consumers and the way how they deal with communication from marketers will most likely have changed as well.

The assumption of changes over time is broadly supported by the idea of postmodernism. Postmodernism denotes and provides not only a philosophical framework or epistemological positions, but also marks an epochal phenomenon that is accompanied amongst other things by the rapid growth of new technologies, the rise of globalism and multiculturalism, and the waning of modern ideologies (Costa and Bamossy 1995; Firat and Venkatesh 1995, 1993). The transition from the modern to the postmodern period is a gradual shift and not a schism (van Raaij 1993). This transition has started in the 1960s and reaches different domains of society at a different pace. Main characteristics which describe conditions of postmodernism are pluralism and fragmentation which both lead to a liberalism of choices and a creation of insecurity in the context of consumption (Bouchet 1994; Firat and Venkatesh 1995). Pluralism leads to conditions where single ideologies have lost their dominance and consumers adopt a variety of values and lifestyles and at the same time refuse to obey authorities of modernity: skepticism is replacing dogmatism (van Raaij 1993). As a consequence, postmodern consumers seem to be more experienced as well as critical and skeptical about influences from marketers (Elliot et al. 1993). However, pluralism also leads to uncertainty since postmodern consumers now face a whole set of values, lifestyles, and symbols from which they have to choose (Bouchet 1994). In the context of communication, consumers also face an increasing information load.

These postulated changes attributed to the transition from modernism towards postmodernism can thus result in changes of attitudes and behavior towards influence techniques from marketers and particularly source credibility over the course of time. However, there are other reasons for expecting changes in source credibility effects over time. Kayande and Bhargava (1994) mention the improvement of data collection methods and analytical methods that may result in stronger relationships over time. Presumably also marketers have learned to use better credibility enhancers. These alternative explanations have to be considered when investigating the changes in source credibility effects over time. In the following section, we will formulate the hypotheses resulting from this delineation.

3 HYPOTHESES

Aforementioned postmodern consumers face a variety of small sets of ideologies, they increasingly refuse to obey any authorities and are claimed to be more experienced and critical. As a result, they have probably become more resistant to established influence techniques from marketers and are able to make out the usual credibility enhancing techniques used by marketers. Therefore, we suggest the following hypothesis:

H_{1a}: The impact of source credibility has decreased over the years.

However, another argumentation stands to reason. Pluralism of beliefs entails a challenge to the consumer who now has to choose from a huge variety of values, norms and lifestyles. As a consequence, consumers increasingly face uncertainty. Also in the context of communication, consumers face an increasing information load. Source credibility serves as a central factor in order to judge the veracity and quality of a message that can be easily and objectively assessed and trusted. It eases the evaluation of information, precludes extensive information research and thus reduces uncertainty. Therefore, consumers are likely to rely increasingly on source credibility. Therefore, we also assume the following hypothesis, which stands in contrast to the first:

H_{1b}: The impact of source credibility has increased over the years.

Both hypotheses suggest a significant correlation between time and source credibility effect sizes whereas the direction of the correlation pinpoints only one of both hypotheses. However, the magnitude of the correlation is supposed to differ with regard to various subsets which are important to marketers. Since personal communication is considered to be more persuasive than communication via media (Fill 2002), the credibility of sources with face-to-face contact to the consumer (e.g. salespersons) should increase or decrease more than the credibility of other sources (e.g. spokesperson in advertising).

H_{2a}: The magnitude of the correlation between time and source credibility effect sizes is greater for sources communicating face-to-face with the consumers than for other sources.

Another classification to be considered is the difference between services and goods. As services have a higher amount of experience and credence qualities than goods (Gabbott and Hogg 1994), the uncertainty of the consumer should be higher for services than for goods. Consequently, also the magnitude of the correlation between time and source credibility effect sizes should be higher for services than for goods. Again, the sign of the effect depends on an increasing resistance towards influencing strategies or an increasing use of source credibility as a reliable evaluation criterion by the consumers.

H_{2b}: The magnitude of the correlation between time and source credibility effect sizes is greater for services than for goods.

Furthermore, the strength of the effect patterns can also depend on the kind of variables affected by source credibility. Since credibility is often considered a cognitive phenomenon in information processing theories that influences mainly cognitions and attitudes (Perloff 1993), we expect a higher magnitude of the

correlation between time and source credibility effects for cognitions and attitudes compared to the magnitude of the correlation for all other dependent variables (e.g. behavior, emotions).

H_{2c}: The magnitude of the correlation between time and source credibility effect sizes is greater for cognitions and attitudes compared to other dependent variables.

4 METHODOLOGY

In order to synthesize the results of past studies, a meta-analysis was conducted. The methodological approach is described in this section.

4.1 Literature review

To identify relevant studies, a series of bibliographic searches was first carried out. A computerized bibliographic search using *Business Source Elite*, *ABI/Inform* (for business publications), *PsycINFO* and *PSYINDEX* (for psychology literature), the *Social Science Citation Index* and *Dissertation Abstracts* (for defended doctoral dissertations) was conducted. Additionally, an issue-by-issue examination of papers published in several important marketing journals since 1950 was conducted. Then, quotations of studies found were examined in order to identify further studies and unpublished manuscripts. The approach is consistent with recommendations made by several authors (e.g. Cooper 1982; Hunter and Schmidt 1990). However, the approach does not guarantee the constitution of a complete census of all relevant studies so that only a sample of relevant studies can be taken into account. All identified manuscripts were then inspected and selected in case they dealt with marketing communication as defined above and in case source credibility was explicitly under investigation as an independent variable and this independence was formulated in the hypotheses of the study. Results that dealt with separate dimensions of credibility were not considered if they couldn't be combined to credibility on the basis of theoretical assumptions of the study. As well, those results were excluded where credibility was used as an indicator for other constructs considered in the hypotheses. Based on these conditions and after excluding manuscripts using the same data as already included manuscripts, 46 manuscripts were found suitable for the purpose of the meta-analysis and provided enough data to calculate necessary effect sizes.

4.2 Analysis

The effect size metric selected for the analysis was the Pearson product-moment correlation coefficient r between credibility and the dependent variables. The coefficient was chosen because it is an easily interpretable and scale-free measure. For studies that did not report correlations but other measures (e.g. Student's t , F -Ratios), those measures were converted to correlation coefficients by means of formula given by Hunter and Schmidt (1990, p. 272). In order to examine the variability of the correlations, a homogeneity test statistic Q based on Fishers's Z -transformation was applied (see Hedges and Olkin 1985, p. 235). In case of heterogeneity, a grand mean of the correlation coefficient has to be considered as an average rather than a common correlation value and the variability in the correlations may be due to other moderating variables. As a result, we can proceed to apply the time variable as a possible explanation for the variability of the correlation coefficients. The following regression model was estimated: $|Z| = \beta_0 + \sum \beta_i X_i + u_i$, where β_0 is the intercept and β_i are the regression coefficients to be estimated. The Fisher's Z -transformations of the r 's serve as values of the dependent variable in the model. Absolute values for the Z 's are used since it is consistent with the focus on the strength of temporal dependence of credibility effects, regardless of the sign.

X_i are the predictor variables. The critical predictor is the year of publication of the study which is used as indicator for the year of the effect measured. However, the effect of year which serves as a proxy for a variety of socio-temporal variables may be confounded with other possible third variables that might also have changed over the years and therefore further moderators were included. In particular these variables are:

- type of survey: field study vs. experimental research
- kind of dependent variable: behavioral intention measures vs. other variables
- measurement of dependent variable: number of scale items
- stimulus presentation: text only vs. combination with picture or audio-visual

Since the sample sizes were unequal across studies, a variance weighted analysis was performed (see Hedges 1994). The overall fit of the regression model can be tested by the variability accounted by the regression model which follows a chi-square distribution with five degrees of freedom (for five predictor variables) and therefore should exceed a value of 11.07 in order to be significant for $p < .05$. The effect of each predictor variable is tested by the unstandardised regression coefficients (see Lipsey and Wilson 2001).

5 RESULTS

Altogether, $k=167$ effects from 53 independent studies with $n=12341$ subjects were collected from the 46 manuscripts. The grand mean of the absolute values of the correlation coefficients indicates the highly significant value .293 (unweighted average r 's) respectively .320 (unweighted average Z 's) and .267 (weighted average Z 's). The correlations range from .00 to .88 and indicate heterogeneity of the effects which is approved by the test statistic ($Q=1673.697$, $p < .001$). Heterogeneous effect sizes are consistent with the notion that moderating variables of the effect measured may lead to different findings and explain the variability of the effect sizes. The regression model specified above was estimated to uncover the influence of the moderator variables on the strength of the effect sizes (Table 1). The analysis was performed for all correlations as well as for the subsets resulting from the hypothesis. There were no serious indications for autocorrelation or multicollinearity.

All effects of time on credibility effects are significant and directionally consistent with hypothesis 1b. Also other moderating variables showed significant effects but not consistently for all subsets. In order to test the hypotheses for the subsets, the correlations between time and source credibility effects (displayed by the weighted average Z 's) were compared for the corresponding subsets and tested (see Table 2).

The differences found were also consistent with our expectations. The impact of time for personal communication, for services and for cognitions and attitudes was stronger than for impersonal communication, for goods and for other dependent variables under investigation. The results are discussed in the following section.

6 DISCUSSION AND CONCLUSIONS

The results provide evidence that the credibility of sources in marketing communication is an effective variable in order to influence consumers. Furthermore, the results support the assumption that the impact of source credibility has even increased over the years and lead us to conclude that it is still valuable for marketers to be credible. The results lead to a number of interesting contributions for marketing practice as well as for future research efforts.

The main advice for practitioners is to be aware of the powerful technique of source credibility. Above all, service providers can profit by source credibility when using highly credible sources for personal encounters with customers or by teaching their service employees credibility enhancing techniques. Also marketing researchers should be aware of the increasing impact of source credibility in marketing communication. Our results are consistent with the notion of the increasing uncertainty and skepticism of consumers caused by postmodern phenomena such as pluralism and fragmentation. This epochal phenomenon is likely to explain the increasing role of source credibility as a factor that can be easily assessed and trusted. However, the results do not prove this rationale as well as the accurate reasons for the differential rise of the impact of source credibility for the subsets under investigation. Time serves as a proxy variable for a variety of phenomena. Therefore, some other explications about changes in source credibility effects are conceivable. To a great extent, these alternative explanations were considered by including moderating variables extracted from the studies. However, further research is needed to filter out the reasons for the described patterns besides the rationale mentioned above. Nevertheless, the context of the transition from modernism to postmodernism can be a vantage point to elicit those factors. Another question is the importance shift caused by the increasing impact of source credibility for other factors of persuasion, e.g. the style of a message: did those factors lose their impact over the years or not?

The data of the meta-analysis are used to explain time effects. However, the meta-analytic data can not substitute a longitudinal study involving the same sets of respondents over an extended period of time. Longitudinal studies provide the potential for more accurate inferences about the development of source credibility effects. They can explore the temporal patterns in more detail and investigate concrete reasons for temporal changes by integrating additional variables (e.g. economic or political conditions). Additional cross-sectional studies can ensure variability of source credibility effects within subgroups that could not be examined in this meta-analysis (e.g. different countries). In this sense, this meta-analysis can only provide first hints for further studies and is not considered a substitute for new primary research. However, it can provide guidance to upcoming surveys and to researchers interested in the concept of credibility in marketing communication.

SPECIAL SESSION SUMMARY

Navigating Between Virtues and Vices: Moderators of Decisions Involving Hedonic versus Utilitarian Choices

Uzma Khan, Yale University
Oleg Urminsky, Columbia University

SESSION OVERVIEW

Everyday choices often reflect an ongoing conflict between the desire for hedonic vices on the one hand (e.g. buying a DVD player or designer jeans, watching television) and the presumably more rational need for utilitarian virtues on the other (e.g. buying an electronic organizer or vacuum cleaner, studying). Given limitations on resources, people regularly face difficult decisions to either indulge in a vice or to exercise self-control and be virtuous.

This conflict can be viewed from several different perspectives. In the traditional literature the difficulty of such tradeoffs is not directly addressed. Rather, consumer decisions are assumed to be based on stable evaluations of utility (e.g. Von Neumann and Morgenstern 1947) and conscious choices guide moment-to-moment behaviors (e.g. Deci and Ryan 1985, Mischel, Cantor and Feldman 1996). Vices and virtues are evaluated on a common utility scale and higher utility options are consciously chosen and acted upon.

One alternative stream of literature explores myopic, short-sighted behavior, in which the utility of long-term benefits is overly discounted relative to short-term desires (e.g. Ainsle 1975; Loewenstein 1996; Hoch and Loewenstein 1991). The myopic focus on short-term benefits can lead to over-consumption of hedonic vices and insufficient allocation of resources to longer-term virtues.

Another stream of research focuses on the role of guilt and self-control in decisions about hedonic and utilitarian consumption (e.g. Dhar and Wertenbroch 2003; Kivetz and Simonson 2002a, 2002b; Strahilevitz and Myers 1998). In this view, hedonic vices are difficult to justify and more painful to pay for (Prelec and Herrnstein 1991) and may induce guilt (Lascu 1991). Given the difficulty involved in such decisions, consumers may over-constrain their hedonic consumption (Kivetz 1999). Consumers who have difficulty choosing items that are perceived as indulgences may even pre-commit to luxuries in certain circumstances to avoid under-consumption due to self-control (Kivetz and Simonson 2002a).

This session explores the conditions under which people are more likely to act on their implicit desires for hedonic vices and under which they exercise greater restraint, favoring utilitarian virtues. The papers in this session raise important questions about contextual factors that may affect how the conflict between hedonic vices and utilitarian virtues is resolved. How are consumption timing decisions made for hedonic versus utilitarian options, and what is the effect of a salient cost? How do virtuous past actions affect relative preferences for hedonic versus utilitarian options? Are people more or less likely to act upon their implicit desires for vices after formulating behavioral intentions?

Taken together the papers attempt to uncover the processes which lead to choosing coveted but vice-full options in some conditions but not in others. Instead of considering these decisions in isolation, the papers in this session treat the decision process as context-dependent and often sequential, with current choices systematically connected to previous choices and behaviors. In the process of examining these issues, the papers extend beyond behavioral anomalies and provide insights into the underlying psychological mechanisms and moderators. The papers raise issues

of implicit versus explicit attitudes, conscious versus non-conscious processing, and personality-based differences in the susceptibility to guilt in the context of hedonic choices. This helps provide a framework for understanding how the conflict between the desire for hedonic experiences and the tendency for self-control is managed.

“Licensing Effect of Past Credentials on Sequential Choices”

Uzma Khan and Ravi Dhar

Consider two people who are similar in their wealth and lifestyle preferences. Both individuals perform community service on certain weeks and not on the others. Now assume that they are both at a mall to do some personal shopping. Who is more likely to buy something self-indulgent—the person who performed community service that week or the one who did not?

Most consumer choice literature focuses on decisions among a set of alternatives, independent of the manner in which consumer arrives at this choice. Recent research suggests that consumer choices across a sequence of decisions might be connected in systematic manner (Dhar & Novemsky 2003; Monin and Miller 2001; Dhar and Simonson 2000; Loewenstein & Prelec 1993). The current research examines how an initial choice involving a virtuous act (e.g., donating time or money to a charity) might reduce negative self-attributions associated with subsequent choices.

We illustrate the liberating effect of past actions in the context of choosing between options that are perceived as luxuries or necessities. While prior research in this area has used several labels somewhat interchangeably for the products (e.g., virtues and vices by Wertenbroch 1998, hedonic-utilitarian by Dhar and Wertenbroch 2000, luxury-necessity by Kivetz and Simonson 2002), a common assumption that underlies the distinction is that the purchase of luxury goods is associated with guilt and feelings of responsibility (Lascu 1991). Since consumers are often looking to justify their choices (Simonson 1989), these goods are at a disadvantage as they are often more difficult to justify than necessities. Generally speaking, the purchase of luxuries can be viewed as producing negative self-attribution since such consumptions are difficult to justify, induce greater guilt, and by definition, are not essential.

Three studies are conducted to demonstrate that the proportion of subjects choosing a more luxury item is higher after an unrelated charity involvement than in a control condition. An additional study is conducted to provide support for our theoretical explanation.

The first three studies use two between-subjects conditions in hypothetical choices to illustrate the proposed effect. In the control condition, subjects are asked to make a choice between two items. In the other condition, prior to making a choice between the same two items, subjects are asked to make a choice involving a virtuous act. Study 1 shows that the percentage of respondents who selected the luxury item (designer's jeans) over a necessity (vacuum cleaner) was greater in the condition where this choice was preceded by a choice on the type of community service to perform than in the control condition. Study 2 replicates this effect with two modifications: the initial virtuous act involved donating money (as opposed to time) and the items in the target set were from the same category but involved choosing between a high quality, high price and a low

quality, low price item. The third study extends the licensing effect to a buy/no-buy situation. Previous research (e.g. Prelec and Loewenstein 1998) suggests that purchase of hedonic/luxury goods often involve a pain of payment which increases the barrier to their purchase. Consistent with our main proposition that an initial virtuous decision reduces the negative self-attribution of making a luxury purchase, we demonstrate that percentage of respondents who purchase a concert ticket is higher after they make a decision about community service in comparison to the control condition.

We argue that engaging in altruistic acts give a boost in positive self-attributions. This reduces negative self-attributions associated with luxury items and make people more likely to choose such items. As a manipulation test, we measured participants self-rating on several personality traits. We find that as compared to the control condition, participants rated themselves significantly more compassionate, sympathetic, helpful, balanced, and warm after a choice on the type of community service to perform.

Finally, in the fourth study we provide evidence for the idea that the reduction in negative self-attribution due to a virtuous act is associated with a greater purchase of luxury items. Specifically, we show that the proposed licensing effect diminishes if the virtuous task can be attributed to some external motivation. In one condition we ask participants to imagine that they perform the community service as a result of a driving violation, while in the other condition they are told to imagine that *they* want to perform community service. We find that more people choose the luxury option over a necessity in the later condition. In conclusion, we discuss theoretical and managerial implications of our findings and suggest directions for future research.

"Reconciling Impulsiveness with Self-Control: Explaining Differential Impatience toward Hedonic and Utilitarian Consumption"

Oleg Urminsky and Ran Kivetz

Consumers often face purchase-timing decisions involving tradeoffs between when a good is received or consumed and the cost paid (e.g. prices that decrease over time, costs of expedited delivery, etc.). This paper addresses the question of which conditions motivate consumers to be more or less willing to accept monetary costs to receive goods sooner.

The notion that goods are discounted over time, with lower utility when deferred than in the present, is fundamental to modern economic theory (Strotz 1956). Therefore, given finite resources and implicit or explicit costs to receive goods sooner, timing preferences for different goods are often in conflict and inter-temporal choices may be made differently for hedonic versus utilitarian goods. One stream of research, centered on the notion of hyperbolic discounting, suggests that consumers discount benefits realized immediately ("vices") less than long-term benefits realized later ("virtues"), leading to a form of myopia in decision-making (Ainslie 1975; cf. Hoch and Loewenstein 1991). Relatedly, the notion of affect-dependent time discounting (Loewenstein 1996; Metcalfe & Mischel 1999; Mischel, Shoda and Rodriguez 1989; Vallacher 1993) suggests that goods higher in affective (i.e. hedonic) dimensions will be discounted more steeply over time than goods higher in cognitive (i.e. utilitarian) dimensions.

Another stream of research, however, focuses on the role of guilt and self-control in decisions about hedonic and utilitarian consumption (e.g. Dhar and Wertenbroch 2000; Kivetz and Simonson 2002a, 2002b; Prelec and Herrnstein 1991; Strahilevitz and Myers 1998; Thaler 1980). This research suggests that goods that provide the highest pleasure (i.e. desired hedonic items) inspire the most guilt (Lascu 1991) and, conversely, spending on utilitarian goods may be easier to justify and less painful (Kivetz 1999; Prelec and Loewenstein 1998). Indeed, consumers have been shown to utilize self-control mechanisms to resist the temptation of hedonic items or vices (e.g. Wertenbroch, 1998). In fact, research on mental accounting (e.g., Thaler 1985; Thaler and Johnson 1990) and mental budgeting (e.g., Heath and Soll 1996) suggests that consumers may not spend enough on hedonic items perceived as indulgence. Further, Kivetz and Simonson (2002a) argue that, for many consumers, a tendency to be overly far-sighted ("hyperopic") can lead to chronic underconsumption of hedonic luxuries. Such consumers are shown to employ deliberate self-control tactics, such as irreversible pre-commitments to hedonic consumption and experiences in low guilt situations.

This paper integrates both streams of research in the context of purchase-timing decisions for hedonic and utilitarian goods and provides a conceptual framework for when myopic, non-myopic, or even hyperopic choices are made. We argue that, while all goods are generally preferred sooner (cf. Loewenstein 1987; Loewenstein and Prelec 1993), there is a natural impulse to disproportionately desire hedonic goods earlier compared to more utilitarian goods. Thus, the baseline desire to expedite will be stronger for hedonic goods than utilitarian goods. Consumers' decisions, however, are typically not only affected by the desire to expedite hedonic goods, but also moderated by a higher-order process. Specifically, when choices involve salient costs and guilt-inducing hedonic luxuries, justifiability is assessed. When justifiability is perceived to be low, self-control behaviors are often triggered. The sensitivity of individuals to "luxury guilt" varies, and for those with high levels of such guilt, the self-control effect may be strong enough to lead to hyperopic choices (i.e. increased delay of hedonic consumption relative to utilitarian consumption of lower value).

These hypotheses were investigated in a series of studies using different goods and consumption activities as well as various delay mechanisms. Consumers were asked to make everyday choices involving a cost associated with more immediate consumption or ownership (e.g. deciding whether or not to wait for a cheaper price in the future, in a time period when prices were known to be falling). We found, in between subjects tests, that consumers delayed purchases of hedonic items (e.g. a DVD player) more than those of utilitarian items (e.g. a Palm Pilot organizer) that were equally or less desired. This finding is at odds with affective discounting, which indicates that hedonic goods should be discounted more steeply and customers should therefore place a greater value on receiving such items immediately, compared to otherwise equivalent utilitarian items.

We argue that the greater willingness to wait for hedonic goods is due to the exercise of self-control, particularly among consumers who tend to feel guilty about indulging themselves in the present and spending money on hedonic luxuries (i.e. high "luxury guilt" individuals). In fact, we find substantially more willingness to wait for the hedonic good among those with high luxury guilt (based on an individual difference scale) than among those with low luxury guilt. In contrast, we find no difference of luxury guilt, or even a small reverse effect, for the utilitarian goods. Thus, consistent with the notion that tempting items can give rise to self-control behavior in the presence of a monetary tradeoff, consumers with high luxury guilt defer hedonic goods but do not defer utilitarian goods, relative to consumers with low luxury guilt.

Additional experimental conditions demonstrate that reducing luxury guilt eliminates the tendency to delay purchases of hedonic compared to utilitarian goods. In these conditions, the choice options were the same, but a guilt-reducing manipulation was introduced (e.g. consumers chose when to use a gift certificate they had won in a raffle to buy a DVD player or a Palm Pilot). Across different studies, when such manipulations were employed, the difference in the timing of hedonic and utilitarian purchases was eliminated or even reversed, with consumers waiting longer for the utilitarian good than the hedonic good. Furthermore, in the alternative conditions designed to reduce the impact of guilt or when the tradeoff is non-monetary in nature (e.g. an extended warranty) and guilt is not induced, we found that consumers with low and high "luxury guilt" made similar choices and the pattern of differential timing for hedonic purchases-based on luxury guilt was eliminated.

The studies generalize these findings to other delay mechanisms (e.g., paying for expedited shipping; delayed availability of equivalent lower priced goods), different types of hedonic "vices" and utilitarian "virtues" (e.g., circus vs. planetarium tickets, office supplies vs. music CDs, even the same good framed as hedonic or utilitarian) and other guilt-reducing manipulations (bundled charity donations). Additional studies test boundary conditions of the effects, underlying mechanisms and alternative explanations.

"License to Sin: The Liberating Role of Reporting Expectations"

Gavan J. Fitzsimons, Joseph Nunes and Patti Williams

Asking consumers to respond to questions has long been known to lead to biased responses, and more recently, to lead to changes in the behavior being asked about. Asking intention questions leads to increases in behavior if the behavior is desirable, and decreases if the behavior is undesirable (Morwitz, Johnson and

Schmittlein 1993; Sherman 1980) asking satisfaction questions can similarly lead to changes in behavior (Dhalokia and Morwitz 2002). Simply notifying consumers in advance that they will later be asked to evaluate their satisfaction with a product or service substantially changes the consumer's experience (Ofir and Simonson 2001). In a recent study, Williams, Fitzsimons and Block (in press) found a curious anomaly however: when they asked respondents to report likelihood of performing a socially undesirable activity it actually led to an increase in the behavior. The current paper argues that this result may be much more robust than would be expected in a particular domain—that of vice behaviors.

Vice behaviors have an unusual property that most other behaviors do not—while the consumer may on one level wish they did not smoke, drink etc., on another level they clearly desire to engage in the behavior. In our research we examine behaviors in this category in which the consumer holds a conscious, explicit attitude towards the behavior that is in opposition to a non-conscious, implicit attitude. In a series of three studies we show that asking consumers to report their expectations about how often they will perform the behavior leads to significantly greater performance of the behaviors (than if they had not been asked their expectations). The reporting of expectations appears to serve as a liberating influence and permit the consumer to indulge his or her implicit desires more frequently than would otherwise be the case.

In a first study, half of a group of students were asked to estimate how many classes they would miss at the beginning of a semester. Actual classroom attendance was taken at every class. In this context, students reported a desire not to miss many classes, although they appeared realistic (none predicted that they would miss "0" classes). For the control group not asked to make a prediction, the average number of classes missed was 2.95. Those asked to predict how many classes they would miss estimated 2.98, suggesting they were very well calibrated on how many classes they would typically miss. Interestingly, this group ended up missing 3.78 classes, substantially greater than the control group ($p < .01$). Predicting (even accurately predicting) the number of classes they would miss appeared to "allow" the respondents to miss more classes than they otherwise would.

In a second study, we attempt to provide a means of defense to respondents so that the act of predicting performance of a "guilty pleasure" won't lead to increases in the behavior. For two behaviors (drinking more than two alcoholic beverages in a sitting, and watching television instead of studying) participants were asked to predict frequency of the behavior. As in study 1, making a prediction appeared to serve a liberating role. Alcohol consumption rose as a function of making a prediction (both number of days alcohol was consumed, and maximum consumed in a sitting), as did the number of times they watched television instead of studying (3.93 times versus a control rate of 2.61, $p < .01$). However, when respondents were given defensive tools that heightened their explicit attitudes that drinking and wasting time watching television were to be avoided, they were able to eliminate the increase in the behavior caused by the act of prediction. Both tools tested increased the salience of the explicit goal to avoid the sinful behavior—implementation intentions (Gollwitzer et al 2001) and a pre-committed self reward—and thus counteracted the question-driven activation of the implicit desire to indulge.

International Differences in Information Privacy Concern: Implications for the Globalization of Electronic Commerce

Steven Bellman, University of Western Australia
Eric J. Johnson, Columbia University
Stephen J. Kobrin, University of Pennsylvania
Gerald L. Lohse, Accenture

EXTENDED ABSTRACT

Differences in information privacy concern in relation to the Internet have been found in national probability samples of consumers from the U.S., the UK, and Germany (IBM 1999). International differences in regulation of information privacy (e.g., the European Data Privacy Directive: EU 1995) are supposed to reflect these concerns. In this study, we examine three possible explanations for these different forms of Internet regulation: (1) these differences reflect and are related to differences in cultural values (Hofstede 1980, 1991; Milberg, Burke, Smith, and Kallman 1995); (2) these differences reflect differences in Internet experience and/or familiarity with Web privacy practices; and (3) they reflect differences in the desires of political institutions without reflecting underlying differences in privacy preferences. We surveyed Internet-using consumers from 38 countries and controlled for differences in demographics (Poortinga and Malpass 1986) to isolate the effects of cultural values, government regulation, Internet experience and knowledge of Web privacy practices, on concern for information privacy on the Net. We find support for (1), that cultural values are associated with differences in privacy preferences, which in turn are reflected in government regulation.

Our study focuses on information privacy, which Westin (1967) defined as the amount of control that individuals can exert over the type of information, and the extent of that information, revealed to others. Government regulation of information privacy in many countries is based on four core fair information practices: *notice* of collection practices, *choice* at least in the use of collected data, *access* to collected data, and *security* and integrity of data (e.g., FTC 1998). Smith, Milberg, and Burke (1996) defined four similar dimensions of *Concern for Information Privacy* (CFIP). *Collection* reflects the growing impression that companies are collecting unreasonable amounts of personal data. *Unauthorized Secondary Use* refers to the utilisation of a consumer's information without permission. *Improper Access* reflects the disclosure of personal information to unauthorized individuals. Finally, the *Errors* dimension describes concerns about inaccurate information in databases, either by accident or design.

Milberg et al. (2000) found that CFIP increased with higher levels of three of Hofstede's (1980, 1991) cultural values dimensions, *Power Distance Index* (PDI), *Individualism* (IND), and *Masculinity* (MAS), but decreased with higher levels of *Uncertainty Avoidance Index* (UAI). Milberg et al. (2000) also found a significant and positive relationship between government involvement in the regulation of privacy, and CFIP, and a positive relationship between existing government involvement in regulation and preference for more government regulation. We intended to replicate these findings using a sample of consumers. We also hypothesized that familiarity with Web privacy practices may reduce CFIP. For example, Culnan (1995) found that consumers who were aware of name removal procedures for "opting out" of direct mailing lists were less concerned about information privacy. The need for more consumer education is a typical recommendation in the conclusion of academic studies (e.g., Culnan 1995; Whitman, Perez, and Beise 2001). Recently, industry groups in the U.S. such as TRUSTe (Benassi 1999) have been spending millions of dollars

on education programs to try to reduce consumers' privacy concerns and demands for increased government regulation.

We recruited 534 Internet-using consumers from 38 countries. Respondents completed an online survey in English consisting of the Smith et al. (1996) CFIP scale (adapted for CFIP at Web sites), two scenarios that elicited CFIP in a relatively lower-sensitivity context (purchases recorded on a bonus card at a physical store) versus a relatively higher-sensitivity context (medical and financial information collected by a Web site), an item that measured concern about the security of online transactions, and six items that formed an index of knowledge about Web privacy practices (e.g., TRUSTe, "cookies"). Cultural values were measured using Hofstede's (1980, 1991) country scores for the same four dimensions used by Milberg et al. (2000), for replication purposes, although we acknowledge concerns about Hofstede's imposition of a westernized scale on all cultures (e.g., Chinese Culture Connection 1987). Government involvement in regulation was classified into five categories developed by Milberg et al. (1995) using Privacy International's (1998) survey of international privacy laws. MANCOVA was used to test whether the hypothesized covariates—cultural values, government regulation, and Web privacy knowledge—significantly reduced differences in CFIP across six regions: the U.S., Canada, the United Kingdom and the Republic of Ireland, other countries from Continental Europe that were current members of the EU, Australia and New Zealand, and Other Countries. The MANCOVA also controlled for individual differences in demographics and Internet experience.

Respondents from countries with relatively higher overall cultural values scores indicated significantly lower CFIP. This effect was in the opposite direction to the finding of Milberg et al. (2000). Follow-up analyses showed that this effect was due mainly to the IND dimension of cultural values, and was consistent with previous findings that people from high IND countries (such as the U.S.) are less concerned about disclosing private information than people from low IND countries (e.g., Ting-Toomey 1991). Replicating Milberg et al. (2000) and Milberg et al. (1995), respondents from countries with higher levels of government regulation were more concerned about Errors, but less concerned about the security of transactions on the Net, which has generally been the focus of government regulation. Also, consumers from countries with already high levels of government regulation of information privacy were more likely to favor the introduction of even stronger regulation. The effect of Web privacy knowledge was not significant, which suggests that consumer education may not decrease CFIP, at least for Internet consumers with high levels of education, as our sample had. Internet experience reduced CFIP.

There were significant residual differences between the six regions. Respondents from every other region were more in favor of government regulation than U.S. consumers. Compared to respondents from the U.S., respondents from the UK and Ireland expressed significantly greater CFIP overall. These results suggest that managers should select a range of options, at the regional level if not the country level, from which customers could personalize their privacy preferences.

Impact of Culture on Cognition: An Evaluation of Judgment and Choice Processes Through a Collectivist Lens

Avinash Malshe, Univeristy of Nebraska–Lincoln
James W. Gentry, Univeristy of Nebraska–Lincoln

EXTENDED ABSTRACT

The marketing and psychology literatures identify a distinction between judgment and choice processes. However, Western (individualistic) perspectives dominate the discussion.

Judgment and choice processes, as studied to date, have always looked at likely outcomes in the context of the decision maker alone (the “I” perspective). The objectives in the decision tasks have always been assumed to be self-serving (such as maximizing personal utility; a notable exception to this argument is the study by Park (1982) that discussed the muddling through approach in decision-making in the context of husband–wife dyad. In this study, he showed that the members of the dyad rely on conflict avoiding strategies while making a decision. Thus, maximizing personal utility may not drive the decision task).

In the extant literature, judgment processes have been identified as optimizing procedures wherein the decision maker may use compensatory strategies. They are associated with extensive information search and critical evaluation of alternatives. Choice, on the other hand, has been shown to be a simplifying procedure wherein the decision maker utilizes non-compensatory strategies. Choice processes involve elimination of alternatives by utilizing attribute-based information processing, thus concentrating on the differences between various alternatives.

This paper argues that the judgment and choice processes will be different if they were examined across individualist and collectivist cultures. Based on current understanding about the individualist and collectivist cultures, this paper argues that cultural orientation would impact the decision objectives. This difference in decision objectives would change the criteria behind the judgment and choice processes, thus changing their structure.

The propositions, if supported, would add new insight to our current thinking about judgment and choice processes. They might show that these two cognitive processes are structurally opposite across individualist and collectivist cultures. We would understand that judgment processes in collectivist cultures are driven by simplifying objectives and involve non-compensatory, attribute-based comparisons. We would also understand that choice in collectivist cultures would be driven by optimizing objectives and would involve compensatory, alternative-based comparisons. Additionally, we would understand that choice processes in collectivist cultures involve extensive information search and are characterized by the addition of others’ perspectives to one’s own.

Culture's Influence on Consumer Behaviors: Differences Among Ethnic Groups in a Multiracial Asian Country

Kwon Jung, KDI School of Public Policy and Management
Ah Keng Kau, National University of Singapore

ABSTRACT

This study investigates the effects of culture on various aspects of consumer behavior in an integrative framework among the three ethnic groups in Singapore. Using the Hofstede's (1980) cultural framework, differences in their cultural orientation are hypothesized. Then, for each cultural dimension, related consumer behaviors are identified and differences in those behaviors are hypothesized according to the predicted differences in each related cultural dimension. Although the results seem to suggest that culture may be one of the major factors that influence the consumption behaviors, the strong evidence for the link between the Hofstede's framework and the related consumer behaviors is not observed in this study.

INTRODUCTION

As companies head towards a global market that deals with people from many different backgrounds and cultures, it has become essential for marketers to understand culture's influence on consumer behaviors. The recognition of the importance of culture on consumer behaviors has led to an increasing amount of research across cultures (Sojka and Tansuhaj 1995). More significantly, many studies have succeeded in establishing links between culture and consumer behaviors (McCracken 1986). According to Wallace (1965), culture is the all-encompassing force which forms personality, which in turn is the key determinant of consumer behaviors.

Numerous cultural studies on consumer behavior have been conducted, especially in western context. In those studies, differences were found in consumption patterns between people of various ethnic groups (e.g. Saegert, Hoover and Hilger 1985) and various geographic subgroups that hold differing cultural values (e.g. Gentry, Tansuhaj, Manzer and John 1988). For instance, researchers have found differences in various consumer behavior aspects such as brand loyalty (Saegert et al. 1985), decision making (Doran 1994), novelty seeking and perceived risk (Gentry et al. 1988) across subcultures. Although past research has identified differences in various consumer behaviors across cultures, most of the past studies dissected consumer behaviors and each study examined one or two specific aspects in a piecemeal-based way. There has been relatively little effort to examine the culture's influence on consumer behaviors in an integrated framework.

Therefore, the objective of this study is to investigate the effects of culture on various aspects of consumer behavior in an integrative framework. Using the Hofstede's (1980) cultural framework, various consumer behaviors that could be influenced by culture are identified and mapped to the Hofstede's cultural dimensions. Then, the influence of the cultural dimensions on the identified consumer behaviors is investigated in a multiracial Southeast Asian country.

SINGAPORE: A MULTIRACIAL SOCIETY

Although numerous subcultural studies were done in the past, most are done in the American or European context. Few have investigated ethnic effects in the Asian context. With major corporations seeking to move into Asia and sell to Asian consumers, it is surprising to note the lack of subcultural research in this region.

Singapore provides a good starting point for subcultural studies on Asian customers as it is a multiracial society of Chinese,

Malays and Indians. During the years when Singapore was under British rule, the three ethnic groups lived separately from each other. They were encouraged to maintain their own unique culture and customs, religious values and way of life. Although national harmony has been emphasized, it has been encouraged to maintain each ethnic group's own culture by the Singapore government since its independence.

The Chinese

The concept of 'face' or "public reputation" is a very important value in the Chinese culture in the context of interpersonal interaction and social exchange. A mirror reflection of the 'face' concept is the idea of gaining respect, or the concern for public reputation. The concept of 'face' points to an inner sense of worth which is experienced by the ego (Wong 1986; Wong and Ahuvia 1998). According to Hu (1944), the emotional impact of the loss of 'face' could constitute a real dread affecting the psyche of the ego more strongly than physical fear. Hence, the Chinese tend to place high importance on the protection of 'face'.

In addition, the granting of 'face' and the maintenance of cordial *guanxi* have been highly valued and widely practiced in the Chinese community, particularly in the business community (Tan 1986). According to Alston (1989), the term *guanxi* refers to the special relationship two persons have with each other. It is a relationship combined with reciprocity and connections. A practical consequence of *guanxi* is that personal loyalty is often more important than organizational affiliation or legal standards.

According to Bond (1987), loyalty is considered to be a virtue by the Chinese. The Chinese have been taught from young to place their loyalty to their family and kin. In the case of services, where there is interpersonal contact, Chinese consumers would tend to stay loyal to the same provider. This is because switching would render a loss of face to the provider, an unfavorable move that a Chinese customer would choose to avoid.

The Malays

Islam is regarded as an inseparable part of Malay ethnicity and is ingrained in its culture (Li 1989). It has been reported that 99.6% of Malays are Muslims (Singapore Census of population 2000). The *Qur'an*, the revealed word of God provides definite guidelines for people in all walks of life to follow. The guidance is comprehensive and includes the social, economic, political, moral and spiritual aspects of life. It states clearly the *halal* (lawful) and *haram* (forbidden). To the Muslims, there is no compartmentalization between religion and secular aspects of life, rather they see life as an integrated whole and they aim to live out Islam in all areas of their life. Indeed, the cumulative institutionalization of Islamic values and practices in Malay life is the single most important influence on the development of Malay culture in Singapore presently (Tham 1985).

According to Bedlington (1971; 1974), the Malay idea of *rezeki*, or belief in the predetermination of man's economic destiny, results in fatalism and a "lack of will to go on striving." As a result of placing their full trust in *Allah* to provide for them in times of need and distress, Malays are reported to avoid taking up insurance policies. To them, they only take it up if it is compulsory (e.g., car

insurance). This element of fatalism is also perceived to be the likely explanation behind the lack of achievement orientation among the Malays (Li 1989).

The Indians

Caste ideas or beliefs still operate among members of the Indian community in Singapore despite the fact that the structural props supporting the caste system are no more there in its entirety. The central religious tenet of orthodox Hinduism was that men were not equal and have never been (Tham 1985). The inequality of men was explained in terms of the merits and demerits accrued in previous incarnations. Therefore, each caste was required to live according to its ordained way of life (*dharma*). However, in the contemporary and meritocratic society of Singapore, the caste system has little functional value except when Indians themselves use it as a cultural marker to distinguish their members (Wu 1982).

As compared to the Chinese and Malays, there exists much lesser marketing literature on Indian consumers in Singapore. One speculation for this lack of research pertained to their size as well as the vast diversity within the Indian community itself. The official category of "Indian" is actually composed of its many linguistic groups, Pakistanis, and Ceylonese. Besides this, it is the group with the greatest heterogeneity in religion (please refer to Table 1). Religion, like ethnicity influences behaviors by the rules and taboos it inspires. There is also suggestion that the Indian orientation has disappeared among a vast majority of the population, persisting only among the most elderly Indians. Even so, it appears in a remote idealistic sense, in the form of "nostalgia and emotional attachment of the place where they came from" (Arasaratnam 1979).

CULTURAL DIFFERENCE AND ITS INFLUENCE ON CONSUMER BEHAVIORS

Having reviewed the key cultural tradition of the three ethnic groups, the differences in cultural values and associated consumer behaviors exhibited by the ethnic groups will be analyzed using Hofstede's (1980) cultural framework in this section.

Individualism-Collectivism

Family is important to all three ethnic groups, as is the case for most Asians. However, differing levels of collectivism could be detected among three ethnic groups in Singapore. The Malays see life as an integrated whole. According to Tham (1985), 53.8% of Malay respondents in his study listed loyalty to one's culture and way of life as an important value in their culture. This same value was listed by 40% of Indian respondents. However, it was not named at all by the Chinese respondents. The Malays believe that their religion holds them together as a community and it is from Islam that they derive their collective identity (Lai 1995). This is evidenced by the fact that 99.6% of all Malays in Singapore have Islam as their religion.

The Indians maintain that family solidarity should be shared by all relatives (Arasu 1975), and all members of the family should be integrated into the community. In Singapore, social and religious functions relating to marriage, birth and death are treated as important occasions among the Indians and this practice helps to maintain family and community solidarity among Indians.

The Chinese in Singapore tend to remain loyal only to their immediate family. For instance, they are concerned with propagating the family name (Wu 1975). However, in a recent study on Singaporean values by Kau, Tan and Wirtz (1998), it was found that the emphasis placed by the Chinese on family is rapidly diminishing. Only 67.4% of Chinese respondents agreed with the statement: "My family is the single most important thing to me", which was much lower than the percentages of Malays and Indians who agreed

(78.2% and 80.2% respectively). When presented with the statement: "Conforming to social norms is very important to me", 39.7% of Chinese respondents agreed with the statement as compared to 53.7% of Malays and 55.3% of Indians. This could be due to the influence of Western values, as well as an increase in affluence. Furthermore, many Chinese move out of their parents' home when they get married, so there is the loss of intergenerational family togetherness. Those trends could account for the lesser emphasis on collectivism on the part of the Chinese. Hence, the following hypothesis is proposed:

H1: The Chinese will exhibit higher levels of individualism, compared to the Indians and the Malays.

Individualism-collectivism pertains to the behavior of people in groups, their relationships with others around them, and how they perceive themselves in relation to others. We can identify several consumer behaviors that could be related to the relationships between individuals and their interaction with the people around them. They are reference group influence (Childers and Rao 1992; Webster and Faircloth III 1994), information sharing (Hirshman 1981; Webster 1992), opinion leadership (Ownbey and Horridge 1997) and ethnocentrism (Shimp and Sharma 1987). Based on the assumption that individualism-collectivism is one of the fundamental cultural dimensions that influences the related consumer behaviors, it could be said that people from cultures high in individualism would be less influenced by reference groups, less likely to engage in information sharing, less likely to be opinion leaders and are less ethnocentric. Hence, the following ethnic differences are hypothesized:

H2a: The Chinese are less likely to be influenced by reference groups compared to the Indians and the Malays.

H2b: The Chinese are less likely to engage in information sharing compared to the Indians and the Malays.

H2c: The Chinese are less likely to be opinion leaders compared to the Indians and the Malays.

H2d: The Malays and Indians are more likely to exhibit ethnocentric behaviors compared to the Chinese.

Uncertainty Avoidance

The Malays, with their fatalistic nature and their belief that everything is predestined and out of their control, may rank the lowest in terms of uncertainty avoidance. This is because their trust in their religion allows them greater tolerance for ambiguity and risk. A study by Yeo (1997) found that the Malays had the lowest levels of brand loyalty and perceived risk as compared to the Chinese and the Indians.

The Chinese also seem to show a tendency of uncertainty avoidance. This could be attributed to the need of the Chinese to adhere to group norms in order to protect one's 'face'. This may result in more image consciousness among the Chinese when they select socially visible products. In addition, Buddhists or Taoists also have inclinations towards seeking religious divinations when it comes to making decisions in difficult life situations (Khou 1996). This indicates that the Chinese may have a certain level of uncertainty avoidance inherent in the culture. However, the level of uncertainty avoidance, though expected to be lower than that of the Indians, is likely to be higher than that of the Malays. This is because only 64.4% of the Chinese are Buddhists or Taoists, compared to the 99.6% of Malay Muslims.

On the other hand, several studies have suggested that Asian Indians tend to have lower tolerance levels of ambiguity, risk and anxiety compared to subjects from America, Canada and Japan (Carament 1974; Orpan 1983). A study by Yeo (1997) confirmed this tendency by finding that Singaporean Indians placed an emphasis on product quality rather than brand when it came to making purchases. Hence, the following hypothesis is suggested:

- H3:* The Indians will exhibit the highest level of uncertainty avoidance, followed by the Chinese, then the Malays.

Uncertainty avoidance refers to how the unknown aspects of the future are dealt with. Extreme uncertainty causes anxiety and stress, and different people have different degrees of tolerance for such anxiety and stress. Different levels of uncertainty avoidance tendency could influence consumer behaviors that examine the ways people react in situations of uncertainty. Those behaviors could be perceived risk (Gentry et al. 1988), brand loyalty (Kanwar and Pagiavlas 1992; Hui et al. 1993), innovativeness (Hui et al. 1993; Tansuhaj et al. 1991), and information search (Garner and Thompson 1986; Hirshman 1983). These behaviors involve an element of risk, and therefore a culture that is high on uncertainty avoidance would exhibit consumption behaviors that may reduce this risk. Thus, people from such a culture would be likely to experience higher levels of perceived risk, more brand loyal, less likely to seek innovative products, and more likely to engage in information search. Thus, the following hypotheses are presented:

- H4a:* The Indians are likely to experience the highest levels of perceived risk in consumption, followed by the Chinese, then the Malays.
- H4b:* The Indians are most likely to remain brand loyal in their purchase of products and services, followed by the Chinese, then the Malays.
- H4c:* The Indians are least likely to seek out innovative products or services, followed by the Chinese, then the Malays.
- H4d:* The Indians are the most likely to engage in information search, followed by the Chinese, then the Malays.

Masculinity

It seems that there is evidence that sex role differentiation is still rather prominent in the Malay culture. Traditionally, Malay men want their wives to be submissive to the husband, and stay at home full-time to look after the children. This has not been changed much in modern Singapore. According to several studies, Muslim men still hold conservative socio-cultural attitudes regarding marriage. They feel that their authority in the house should not be challenged, and prefer their wives not to be graduates (The Straits Times 29/11/1995; 5/12/1995). Only 23.9% of Malay male graduates tied the knot with fellow graduates compared to the national average of 59.3% (The Straits Times 29/11/1995). Most of these men still prefer marriages arranged by their parents, and marrying down is the norm among them. These conservative attitudes are further evidenced by the fact that working wives make up only a third of all Malay couples, way below the figures of the Chinese and the Indians (The Straits Times 5/12/1995).

The Indians are becoming increasingly modernized compared to the Malays. Traditionally steeped in the notion that women belong in the house and should look after children full-time, this

view is changing with increased education and achievements by the Indian community in Singapore. 40% of all married Indian women work, second only to the 41% of Chinese women (The Straits Times 3/5/1994). Traditional Chinese women tended to stay at home to look after the household and the children. However, this has been changed in Singapore, as statistics have shown. Many Chinese women today are economically independent and perfectly capable of looking after themselves. Therefore, both the Chinese and the Indians would not be high on masculinity.

However, in a local lifestyle study conducted by Kau et al. (1998), it was found that the Indians had the most liberal views on feminism compared to the Chinese and the Malays. 78.5% of them felt that a woman should have her own career, while 63.4% of Chinese and 59.1% of Malays thought so. An even more interesting point to note was that 37.9% of the Indians agreed with the statement: "Women are smarter than men", while only 18% of Malays and 13.1% of Chinese felt so.

The above observations lead to the conclusion that the Malays have the most prevalent values regarding sex role differentiation, followed by the Chinese, while the Indians are the most profeminists. Therefore, the following hypothesis is developed:

- H5:* The Malays are likely to rate the highest on masculinity, followed by the Chinese, and then the Indians.

The cultural dimension of masculinity-femininity involves sex role differentiation and the dominance of either male or female values. This area of study is particularly of interest in the context of the cultural dimension of masculinity-femininity because sex role attitudes and perceptions are ascribed through cultural norms and these attitudes influence the household decision role structure and responsibility (Kim, Laroche and Zhou 1993; O'Connor, Sullivan and Pogorzelski 1985). Blood and Wolfe (1960) also stated that the degree of influence by either the husband or wife in a family decision is contingent upon the level of traditional marital values present in the family. It can be concluded that decision making in the family differs across cultures and is dependent upon the extent to which the couple's values belong to the traditional patriarchal system where the husband dominates, or the more modern view of joint decision-making. Thus, people from cultures higher in masculinity are more likely to engage in husband dominant decision making because they believe that men should be in charge of the household.

- H6:* The Malays are the most likely to engage in husband dominant decision making, followed by the Chinese, and then the Indians.

Power Distance

The Indian religion of Hinduism states that men are not equal and have never been. This resulted in caste differentiation which may still exist informally in Singapore today, though not in its entirety. Similarly, the Malays, because of their fatalistic nature, willingly accept concepts of inequality and they accept that being born unequal is part of each person's destiny in life and cannot be altered. The Chinese on the other hand, are not governed by any beliefs of this sort. Although all three ethnic groups share the values of respect for one's elders and filial piety, there is evidence that these traditional perceptions of inequality result in different degrees of power distance among the three ethnic groups. According to Kau et al. (1998), when presented with the statement: "Respect for authority is important in our society", 77.4% of Indian respondents agreed with the statement, followed by 72.2% of the Malays and 61.8% of the Chinese. Hence the following hypothesis is presented:

H7: The Malays and Indians will exhibit higher levels of power distance than the Chinese.

Opinion seeking could be one aspect that could be affected by the differing degrees of power distance. Opinion seekers are those who actively seek advice from others (Engel, Blackwell and Miniard 1990). Generally, there will be significant numbers of opinion seekers in cultures with high power distance. Therefore, people from cultures with a large power distance are more likely to be opinion seekers than those from cultures with a small power distance. Hence, the following hypothesis is suggested:

H8: The Malays and Indians are more likely to show opinion-seeking tendency than the Chinese.

METHODOLOGY

Samples

The research data was collected by means of a survey. The sampling unit was a married Singaporean individual, either Chinese, Malay or Indian because as one of the consumer behaviors involved is family decision making which looks at the interaction between husband and wife. A method of snowball sampling was employed in the distribution of the questionnaires in order to get respondents from each ethnic group.

A total of 300 questionnaires were distributed and 258 were returned, thus the response rate was 86%. Among them, 27 questionnaires were rejected either because the respondents were not from one of the three ethnic groups studied, were unmarried, or the questionnaires were not adequately completed, resulting in 231 valid samples. The sample comprised of 83 Chinese (35.9%), 75 Malays (32.5%) and 73 Indians (31.6%). The respondents did not appear to differ in terms of gender or age. As the requirement was for respondents to be married, there were also no significant differences in this aspect.

Measures

The cultural dimensions are measured using Hofstede's (1980) framework. However, the original values scales used by Hofstede (1980) contained work-organization related questions which cannot be directly applied in this study. Hence, an adapted version of survey questions was used from various sources (Triandis et al. 1986, 1988; Lao 1977; Scanzoni and Szinovacz 1980) which met more closely with the needs of this study. The scales were chosen based on the following criteria: (1) the scale should be generic in its nature, unlike Hofstede's values module survey which pertained to work; and (2) the scale should fit accurately to the descriptions of the four cultural dimensions outlined by Hofstede. Using this method, a list of statements was generated, screened individually for their face validity and a final list of twenty items obtained.

Measures for consumer behaviors were directly adapted from past studies (Park and Lessig 1977; Hirschman 1981; Hui et al. 1993; Shimp and Sharma 1987; Raju 1980; Oliver and Bearden 1985; Green et al. 1983; Wells and Tigert 1971). With the exception of information sharing and family decision making, all items were measured on a five-point Likert scale, ranging from "1" for "Strongly Disagree" to "5" for "Strongly Agree" including measures for the cultural dimensions. Information sharing was measured by asking the frequency of providing information to others on a five-point scale, ranging 1 for "Very low frequency" to 5 "Very high frequency." Family decision making was measured for grocery and major home appliances in four aspects such as when to buy, where to buy, what to buy, and how much to pay on a five-point scale, ranging from 1 for "Husband decide" to 5 for "Wife decide."

RESULTS

Differences in Cultural Dimensions

The results of ANOVA tests on the cultural dimensions show no difference among the three ethnic on individualism/collectivism ($F=1.11$, $p=.33$), uncertainty avoidance ($F=.91$, $p=.40$), and power distance ($F=.12$, $p=.88$), rejecting H1, H3, and H7. The three ethnic groups show significance differences on the masculinity dimension ($F=17.79$, $p=.00$). The pair-wise comparisons with Duncan test reveal significant differences among the three ethnic groups as predicted. Therefore, H5 is supported (Table 1).

Differences in Associated Consumer Behaviors

Although no significant difference is found on the relevant cultural dimensions, significant differences are found on the utilitarian reference group influence ($F=6.37$, $p=.00$), the information sharing ($F=4.88$, $p=.01$), the ethnocentric tendency ($F=8.11$, $p=.00$), and the brand loyalty ($F=4.37$, $p=.01$). As for the ethnic differences, the Malays tend to be more ethnocentric and to share information more than the Chinese and the Indians, whereas the Indians tend to be less brand loyal and less likely to be influenced by the utilitarian reference group information compared to other ethnic groups (Table 2).

It is found that the three ethnic groups differ in their family decision-makings. For grocery products, there is significant differences in means across the three groups for "when to buy" ($F=2.42$, $p=.09$) and "how much to pay" ($F=6.52$, $p=.00$). The pair-wise comparisons with Duncan test show that the Chinese and Indians wives dominate decisions of "when to buy" and "how much to pay" compared to the Malays. As for "where to buy", the Malays and Indians were significantly more husband dominated than the Chinese, while the Malays were more husband dominated than the Chinese for the aspect of "what to buy". It can be seen that the Malays were consistently more husband dominant in decision making than the Chinese. Thus hypothesis 6 was partially supported in grocery product category.

When it comes to major appliances, F-tests results again showed significant differences among the three groups for "when to buy" ($F=5.14$, $p=.01$) and "how much to pay" ($F=2.66$, $p=.07$). According to the pair-wise comparisons among the ethnic groups, the decisions of the Chinese and Indians were more wife dominated than the Malays for the aspects of "what to buy" and "where to buy". In addition, the Chinese wives took part in more decision making than the Malays when it came to "how much to pay". Again, the main differences found were those for the Chinese who were more influenced by the wife than the Malays. Therefore, hypothesis 6 was partially supported in major appliance category (Table 3).

DISCUSSIONS

Among the four cultural dimensions outlined by Hofstede (1980), the dimension of masculinity produces a significant difference among the three ethnic groups. The low masculinity rating for the Indians suggests that they have discarded traditional sex role ideas and are receptive to Western ideas of equality between sexes, and changes in gender roles. This can be seen from statistics which show that the percentage of working Indian women enjoyed the greatest increase of 12.6% among the three ethnic groups between 1980 and 1990 (Singapore Census of Population 1980; 1990). In addition, as the Indians become more affluent and enjoy greater achievements in their careers, the percentage of educated Indians also increases proportionately (The Straits Times 3/5/1994). Thus the Indians, especially the younger ones, find it easier to accept feminist ideas and values. On the other hand, the Chinese may still retain some of the traditional teachings that define

* Different letters (a, b, c) indicate significant differences between groups at 0.05 level with Duncan tests.
Scales are rated from 1-“ husband decided” to 5-“ wife decided”

strict gender roles and this could be the reason why they were rated higher than the Indians in terms of masculinity. This is especially evident in the socialization of children where girls will be clothed in pink, boys in blue, and the girls will play with dolls and the boys with guns. As for the Malays, they still hold traditional attitudes which state that the wife has to be submissive to the husband, and women should not be graduates and should not work (The Straits Times 29/11/1995; 5/12/1995). This resulted in them rating the highest on masculinity.

However, the differences are not as evident in the other three cultural aspects. This may be due to the ethnic integration efforts done by Singapore government. After Singapore became independent in 1965, the government began to promote ethnic integration. A situation of common national identity was constructed. All the communities were accorded equal status and rights, and given the fullest freedom to preserve their distinct ethnic culture, heritage and identity.

Among the 10 examined consumer behavior variables that were assumed to be influenced by the cultural dimensions, significant ethnic group differences are observed on utilitarian reference group influence, information sharing, ethnocentrism, brand loyalty, and family decision making behaviors. Although significant, the differences do not support the hypothesized cultural influence on consumer behaviors except for the family decision making behavior. A possible interpretation could be that the cultural dimensions developed by Hofstede (1980) may lack their validity in explaining consumer behaviors because they were not developed in the context of consumer behaviors and practices. If this is the case, their applicability to consumer behaviors is questionable and we may need other cultural frameworks to find better links between culture and consumer behaviors. However, the link between the masculinity and the family decision making behavior suggests that the Hofstede's cultural framework could be, at least in some aspects, a valid cultural framework within the Singaporean context of Chinese, Malays and Indians.

There are a few proposed directions for future research. Firstly, future studies should continue to investigate relationships between culture and consumer behaviors in order to come up with more specific relationships between them. To do this, future researchers should look into other cultural models than Hofstede's (1980), which could help us to find better links between culture and related consumer behaviors. Similarly, consumer behaviors other than the ones investigated in this study should also be examined in future research in order to develop a full picture of the way culture impacts behaviors. This study should also be extended to specific products or services, and to more demographically diverse samples of Chinese, Malays and Indians.

Examining Consumer Behavior in the Liberalized German Energy Market—The Influence of Customer Satisfaction on Customer Willingness to Switch Public Utility Companies

Gianfranco Walsh, University of Strathclyde

Klaus-Peter Wiedmann, University of Hanover

Markus Groth, The Australian Graduate School of Management, UNSW

EXTENDED ABSTRACT

In most European countries (e.g., Belgium, Denmark, Netherlands, Spain), the energy industry continues to undergo dramatic changes. Amidst a progressing liberalization of European energy markets, customer relationship management (CRM) concepts and their central goal—customer retention—are playing an increasingly significant role in the marketing considerations of energy supply companies. Yet, surprisingly little is known about the reasons why customers remain loyal to a particular energy supplier or why they switch suppliers. Energy suppliers need information on target group satisfaction and associated switching tendencies as well as customer willingness to switch utility providers. Most existing studies limit themselves to the quantitative determination of customers willing to switch.

In light of previous research that has demonstrated a link between customer satisfaction and outcome variables such as customer loyalty and recommendation behavior (e.g., Mooradian and Olver 1997), the purpose of this study was to investigate the relationship between customer satisfaction and switching intentions as well as to identify switching segments. In particular, the objectives of the paper were (a) to measure the satisfaction level of private energy customers with their current energy suppliers and customer intention to switch providers, (b) to analyze the strength of the satisfaction-switching relationship, (c) to analyze the motivation of customers to either switch energy suppliers or stay with their current supplier, (d) to identify various switching types that differ with regard to their motivation for switching energy suppliers, and (e) to discuss the marketing implications of the investigation.

We particularly focused on the German market for a number of reasons. Most importantly, German consumers have been reluctant to exercise choice and few private electricity customers wish to switch energy suppliers. But despite low switching rates, there is currently an enormous expenditure by German energy supply companies on CRM concepts, which aim at retaining existing and attracting new customers (Krafft et al. 2002). Furthermore, in comparison to companies in other sectors, German energy supply companies exhibit deficits with regard to customer satisfaction and corporate reputation (e.g., Kundenmonitor Deutschland 2001). Therefore, identifying and understanding the needs of loyal customers and switchers in the German market will be particularly useful in furthering our understanding of the relationships between customer satisfaction and switching behavior.

A total of 462 customers of a large German energy supplier were surveyed regarding their perceptions and future intentions in relation to their energy provider. The questionnaire included measures of customer satisfaction, switching intentions, motivation for switching/non-switching intentions, as well as demographic items. All items included in the current investigation were derived from theoretical considerations regarding possible switching motivation (e.g., Lin, Wu, and Wang 2000). The customer satisfaction scale was developed from a mix of original and adapted scale items derived from previous studies (e.g., Hennig-Thurau et al. 2002) and consisted of eight items. Switching and non-switching motives were measured with eight items each. Exploratory as well as confirmatory factor analyses were used to assess the reliability of

all measures. Factor analyses identified two motivational factors of non-switchers (*Satisfaction/Lack of trust in other providers* and *Wait and see*) as well as two motivational factors for switchers (*General dissatisfaction/Relationship fatigue* and *Monetary-motivated curiosity*). Depending on respondents' reported intentions to switch or not to switch, they only answered the questions relevant to their intentions. In particular, those customers who had definite switching intentions were examined more closely. In the analysis, the total sample was divided into subgroups of switchers (n=139) and non-switchers (n=323) and then motives were analyzed with regard to their switching tendency.

Results using regression analysis show that customer satisfaction had a significant effect on switching intentions. As expected, those customers who were more satisfied reported lower intentions to switch energy suppliers. In addition, cluster analysis was used to more closely examine switchers. Three unique clusters were identified. The first cluster, *Dissatisfied customers*, consists of primarily older, low-income customers who are particularly dissatisfied but who place little relevance on monetary incentives. The second cluster, *Relatively satisfied customers seeking change*, consists of customers who place relatively high value on monetary-oriented curiosity but less value on dissatisfaction/relationship fatigue. The third cluster, *Dissatisfied customers seeking change*, consists of primarily young, salaried employees and civil servants for whom both motives, dissatisfaction/relationship fatigue and monetary-oriented curiosity are equally important.

Results of this study are discussed in light of its theoretical as well as practical implications. In particular, we discuss the relevance of our findings regarding the relationship marketing literature as well as prior research on the customer satisfaction—customer loyalty relationship (e.g., Jones and Sasser 1995). Furthermore, directions for future research are identified.

Brand Extension Evaluations: Effects of Affective Commitment, Involvement, Price Consciousness and Preference for Bundling in the Extension Category

Håvard Hansen, Norwegian School of Management

Leif E. Hem, Norwegian School of Economics and Business Administration¹

ABSTRACT

Recent brand extension research has mainly focused on the judgmental effects of similarity between the established brand and the brand extension. This paper extends this research by investigating the effects of characteristics in the extension category. The results suggest that (a) affective commitment towards the incumbent brand in the extension category is negatively related to the intention to purchase the extension, and (b) involvement with the entry category increases purchase intention. Furthermore, price consciousness has a positive effect on preference for product bundling, while similarity and preference for bundling positively influences the intention to buy a brand extension. The results underscore the importance of extension category characteristics for consumer evaluation of extensions.

INTRODUCTION

As managers begin to more fully appreciate the advantages of introducing new products under existing brand names, the number of brand extensions has increased to a point where it now represents between 40% and 80% of all new products (Kanner 1989). In order to capitalize on a brand's equity, managers are likely to continue introducing new extensions into the market (Barone, Miniard and Romeo 2000). Although managers have a multitude of decisions to make regarding the appropriate marketing mix for their products brand extension managers have only two primary questions to consider: (1) which category to enter and (2) what characterizes the extension category.

Most research has concluded that increased perceived similarity between the parent brand and extension categories leads to more positive evaluations of the brand extensions (e.g., Aaker and Keller, 1990; Boush et al. 1987; Keller and Sood, 2003/4). Although the concept of similarity has been expanded to include the understanding of its antecedents and the role of brand characteristics such as breadth (Boush and Loken 1991), knowledge and particular associations (Broniarczyk and Alba 1994), the focus has remained on the attitude implications of brand-category similarity. Only a limited amount of research has gone beyond the brand-category similarity paradigm, and no more than a few studies have begun to explore the implications of consumer perception of the extension category (Kardes and Allen 1991; Jun, Mazumbar and Raj 1999; Smith and Park 1992). Smith and Park (1992) investigated the effects of the number of competitors present in the extension category, but no effect was found on the evaluation of the extensions. Furthermore, Kardes and Allen (1991) found that brand extensions tend to be rated as more favorable in low perceived quality variability conditions in the extension category than in high-perceived conditions. Finally, Jun et al. (1999) found that high tech brands are judged more positively if there is greater variation in quality among the current brands in the extension category.

The purpose of this research is to explore the effects of different characteristics of the extension category on the evaluation

of brand extensions. Based on the literature, it is suggested that at least five types of category characteristics influence the evaluation of brand extensions: (a) bundling, (b) price consciousness, (c) affective commitment, (d) involvement, and (e) perceived knowledge of the extension category. It is also hypothesized—as in past research—that similarity has a positive effect on brand extension evaluations. Data from a survey involving an established car brand extended to a service product-category was used to test the relationships. The paper closes with a discussion of the results, and insights on limitations and future research are offered.

RESEARCH HYPOTHESES

The primary purpose of this study is to determine empirically the extent to which the extension category characteristics affect the evaluation of brand extensions. The following discussion provides a rationale for the research hypotheses.

Perceived Similarity

Referent product–extension product similarity (hereafter referred to as similarity) is the degree to which consumers perceive the extensions as similar to other products affiliated with the brand (Smith and Park 1992). The most frequently considered antecedent of brand extensions is the level of perceived similarity between the original and extended brand. Several studies reported that the greater the similarity between the original and extended category, the greater the transfer of positive (or negative) affect to the extended brand (cf.; Aaker and Keller 1990; Boush et al. 1987; Keller and Sood 2003/4). This finding is based on the assumption that consumers will develop more favorable attitudes towards extensions if they perceive high congruence between the extension and the original brand (see Boush et al. 1987 for theoretical discussion). One important reason to include similarity in this study is to test the effects in a “real situation with real consumers”. Second, as similarity has been found to be a major determinant of brand extension evaluations, it is important to include this concept in the model to avoid spurious effects due to lack of an important variable. Therefore, the hypothesis that:

- H₁: The higher the perceived similarity between the brand extension and the parent brand, the higher the intention to purchase the extension.

Bundling

The bundling of products is a competitive instrument extensively used by marketers. For example, sport shops will often offer a package of both skis and ski boots at a single price, in addition to selling the items separately. Such a strategy, called *price bundling* (Soman and Gourville 2001), offers the customers a discount on both the skis and the boots when bought in a package compared to buying them separately. The advantage for the customer is a lower price; while the benefit for the shop is that the customers buy both products from the same shop instead of buying skis in one store and ski boots in another. While price bundling is valuable due to the discounted price, *product bundling* implies increased customer value due to the integral architecture of the bundle (Ulrich and Eppinger 1995). One important motive that makes product bundling appeal to consumers is the convenience of buying separate

¹The authors would like to thank Petter Moe, Andreas Nilsen and Niklas Sponheim for their invaluable help in collecting the data. The authors are listed at random and contributed equally to this paper.

products or services from one single supplier, thus limiting the number of interaction points. Stremersch and Tellis (2002), argue that the term “separate products” is important when defining the notion of bundling. According to their definition, *separate products* imply that the bundle consists of products for which *separate markets* exist, because at least some customers want to buy the products separately. According to Stremersch and Tellis’ (2002) framework of bundling strategies, price and product bundles can be divided into three categories—*unbundling*, *bundling* and *mixed bundling*. While an extensive elaboration of this 2x3 classification schema is outside the boundaries of this paper, the distinction between pure bundling and mixed bundling merits comment. A *pure* product bundle is a package of products that can be bought only in the bundle, and not separately. In contrast, *mixed* product bundling means that consumers can choose to buy the products separately or in a bundle. The latter kind of product bundling is the center of attention in this study, for several reasons. First, this is a study of a brand extension in which a firm that offers a physical, high involvement product extends into a lower involvement service category. This implies that the products/services bundled confirm to *separate products* for which *separate markets* exist. Second, while a pure bundling of products would imply that the products could only be bought in a package, this is a study of a situation where the parent brand can easily be bought without buying the extension, and vice versa. This is also the case for most brand extensions.

While the previous paragraphs illustrate the concept of mixed product bundling, the focal concept in this study is consumer preference for such bundling opportunities, more specifically the effect this has on the intention to purchase the brand extension (see Aaker and Keller 1990, p. 30). There should be several reasons why a preference for product bundling would increase the intention to purchase the brand extension. First, a major motivation to buy a product bundle is convenience (Stremersch and Tellis 2002). Second, bundling an existing product with a brand extension involves assembling a combination of products not previously offered in the market. As such, the bundle itself is new to the consumer. Recall that the success of brand extensions is largely based on the transfer of associations for a product in one category to a new product offered in a separate category. If the parent brand is one associated with affect and liking, the brand extension should benefit from being bundled with the parent brand due to the benefits of bundling alone, but also receive a benefit due to the transfer of affect from the parent brand to the bundle. Thus, the proposition that:

H_{2a}: The consumers’ preference for bundling will positively influence the intention to purchase the brand extension

The arguments outlining H_{2a} might be further advanced to advocate that the similarity between the parent brand and the extension would influence the consumers’ preference for product bundling. Again this study draws on the transfer of liking and affect from one category to another as a basis for brand extensions. Recall that this transfer is more likely to be found under conditions of high similarity (Aaker and Keller 1990). If the consumers evaluate the parent brand as being of high value, and have already developed positive feelings for this brand, the perceived value of a bundle consisting of two products carrying this particular brand is likely to be higher than a bundle consisting of the parent brand and another brand. Hence, due to a pure value perception argument based on the beliefs held about the parent brand, and the transfer of these beliefs to the bundle, consumers are more likely to prefer bundling under conditions of high similarity. Accordingly, the next hypothesis suggests that:

H_{2b}: The consumers’ preference for bundling will be positively influenced by the perceived similarity between the parent brand and the brand extension

Price Consciousness

The next research question suggests that the consumers’ inherent level of price consciousness will have an effect on the preference for bundling. In accordance with Lichtenstein, Ridgway and Netemeyer (1993), the conception of price consciousness is *the degree to which consumers focus exclusively on paying low prices*. Recall that a price reduction resulting from a bundling of products is defined as a *price bundle* (Stremersch and Tellis 2002), while the focus of this study is a mixed product bundle. Thus, there should intuitively not be any reason to believe that price consciousness would be related to a preference for this particular kind of bundle. However, for most consumers this theoretical distinction between price and product bundles is only an abstract phenomenon. More likely, consumers possess an experience-based assumption related to the bundling of products that suggests bundling is generally beneficial (Estelami 1999) due to reasons such as: 1) higher convenience, 2) reduced risk, e.g. through familiar brands, 3) lower prices, 4) fewer suppliers to visit and confront in case of product failure, etc. Previous research indicates that the economic savings from bundling is often really substantial, but cases of pure loss due to bundling also exist (see Estelami 1999). However, most consumers assume that bundling is a way of saving money. This implies that for consumers who are concerned about price, bundles should generally be fairly attractive. Hence, the posit that:

H₃: Price consciousness has a positive effect on the consumers’ preference for product bundling

Affective Commitment

The notion of commitment has been an important aspect of studies on customer relationships over the last decades (e.g., Gundlach, Achrol and Mentzer 1995). While the literature on commitment generally suggests that the phenomenon exists in different forms (Allen and Meyer 1990), most research has found the affective kind of commitment to be a major determinant of customer loyalty, while the effects of other types of commitment are more unclear (see Kumar, Hibbard and Stern (1994) for a marketing related study including all three forms discussed in the literature). Affective commitment is based on emotions and affective attachments to the commitment object (Porter et al. 1974), and thus, it is grounded on customer partiality and positive feelings for the relationship partner. If a customer’s affective commitment to a brand is high, this should bring about a wish and motivation to continue the relationship. Since this type of commitment does not include any instrumental cost-benefit evaluations, it is derived from the emotional pleasure associated with the relationship partner, and the feelings of fondness developed within the relationship. As such, affective committed parties are inclined to maintain the existing relationship, an assumption extensively supported by previous research (Kumar et al. 1994; Wieselquist et al. 1999). This study argues that consumers whose affective commitment to a supplier is high will be less receptive to a newly introduced product in this category. Regarding the brand extension, this implies that the intention to buy a new product will be lower the higher the level of commitment to an incumbent brand. Accordingly, the hypothesis that:

H₄: Affective commitment to a brand in the extension category will negatively influence the intention to purchase the brand extension.

Involvement

Research on consumer involvement goes back to Sherif and Cantril's (1947) early work. The current view in consumer behavior holds involvement to be a causal or motivating variable influencing the consumer's purchase and communication behavior. Involvement is defined as: "A person's perceived relevance of the object based on inherent needs, values, and interests" (Antil 1984, p. 204; Zaichkowsky 1985, p. 342). Involvement is considered an individual difference variable (Laurent and Kapferer 1985), and the comprehensiveness of both purchase decision processes and the processing of communications will vary significantly depending on consumer level of involvement.

The relationship between involvement with the extension category and brand extension evaluation is based on the fact that response differences between highly involved and less involved consumers reflect, to some extent, differences in risk-taking propensity. Highly involved consumers tend to be less risk averse than other consumers. Following from this, a common observation is that individuals high in perceived involvement are more venture-some and more willing to try new brands (e.g., Steenkamp and Baumgartner 1992). Moreover, the level of involvement enables the consumer to pick up news on additional brands in the category faster than less involved consumers. Hence, the familiarity argument and the risk prone argument are given as reasons to advocate that involved consumers will be more inclined to purchase a brand extension than less involved consumers. Thus, the fifth hypothesis suggests:

H₅: The consumers' involvement in the extension category will positively influence the intention to purchase the brand extension.

Knowledge

There has been a substantial amount of research on personal effects on decision-making in different contexts (see Brucks 1985; Hoch and Ha 1986). In this research, there is an introduction of consumer knowledge of the extension product class as an antecedent to intention to purchase. A rich amount of literature on knowledge in consumer research generally predicts that non-experts are more prone to be influenced by contextual variables than experts (e.g., Rao and Monroe 1988). It is often assumed that experts are more confident in their judgments and thus less susceptible to contextual cues. Drawing on differences in the amount of chronically accessible information as well as different cognitive processes, there would also be a prediction of smaller context effects for experts than for non-experts. Compared to non-experts, experts characteristically possess a rich and well-organized knowledge structure for the specific domain (e.g., Alba and Hutchinson 1987). This plentiful and orderly knowledge structure makes it easier for experts to find connections (matches) between different core brands and extensions. On the other hand for non-experts, only a small amount of information is chronically accessible. Based on these assumed differences in the amount of chronically accessible information, the prediction is that experts are more likely than novices to identify similarities between parent brands and brand extensions. Therefore:

H₆: Knowledge of the extension product category will positively influence the intention to buy the brand extension.

The conceptual model is presented in Figure 1 and portrays the hypotheses in this paper.

METHODOLOGY

The data used to test the theoretical model was collected by means of a survey mailed to 900 respondents. These were randomly drawn from the customer database of a national importer of cars produced by a global manufacturer. Stated differently, all customers throughout the country who had purchased a car of this brand from a brand dealer had the possibility of being included in the sample. The reason this car brand was chosen as the research context was the plan to introduce a brand specific insurance service directed at owners of this car brand (a brand extension). The insurance was intended to be sold only at the car dealers that sold the parent brand, and the insurance would also be labeled with the car brand (to exemplify: BMW Insurance only sold at BMW dealers). This was also found to be an adequate context, as the brand in question is generally perceived as a high quality brand (see Aaker and Keller, 1990, p. 31 for a discussion). Furthermore, the ability to study an original brand not previously extended broadly was positive since previous research has found that the breadth of an established brand has an influence on how brand information is processed, as well as on the evaluation of brand extensions (Kardes and Allen 1991; Keller and Aaker 1992). Of the sample of 900, a total of 255 respondents participated in the study, which corresponds to a response rate of 28.33%. Analyzing late response data did not indicate any non-response bias (Armstrong and Overton 1977).

Measures

The *dependent variable* was the intention to buy the brand extension. In the literature on brand extensions, consumer response to brand extensions has most frequently been operationalized using attitudinal measures, typically some form of overall evaluation of the proposed extensions (Fishbein and Ajzen 1975). For example, Keller and Aaker (1992) used the statement "Overall, I am very positive to extension 1" anchored by "totally disagree" and "totally agree" (see also Broniarczyk and Alba 1994; Keller and Sood 2003/04). This measurement practice was followed using a similar single item measure, although the focus was on purchase intentions.

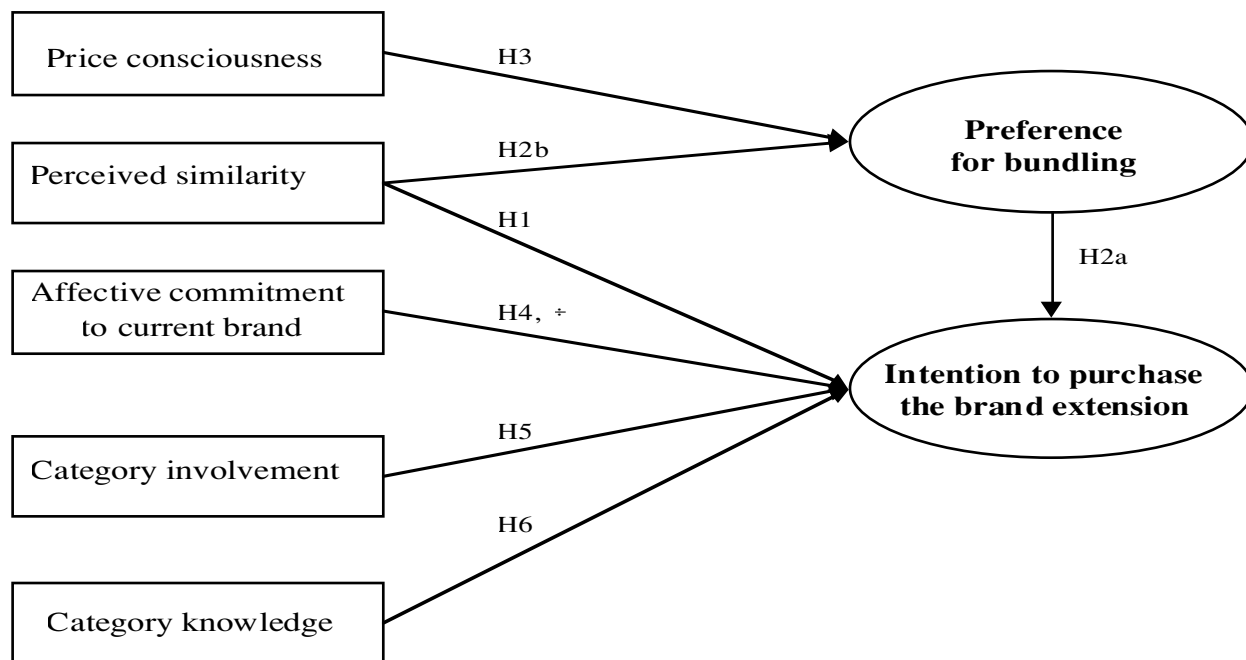

Among the *independent variables*, three items measured perceived similarity between the original brand and the extension. Two of the items were based on Smith and Park (1992), and the third item was based on Aaker and Keller (1990). The two items measuring preference for bundling were self-constructed based on definitions offered by extant literature (e.g., Estelami 1999; Stremersch and Tellis 2002), while the four items capturing the customer price consciousness were adapted from Lichtenstein et al. (1993). The three items capturing affective commitment to the incumbent brand in the extension category were adapted from Allen and Meyer (1990), while the category involvement construct was measured with four items adapted from Zaichkowsky (1985) and Laurent and Kapferer (1985). The three measures for category knowledge were based on Park et al. (1994). All constructs were measured with 7-point Likert type scales, anchored by "totally disagree" (1) and "totally agree" (7).

The quest for face validity was a two-stage process, with 3 marketing professors initially reviewing the items. After a revision based on their comments, 20 consumers were asked to answer the questionnaire and comment on anything that was felt to be ambiguous or in other ways not totally understandable. Some minor changes in the wording were made after this procedure.

Construct Measurement Model

The measurement model was tested by use of the structural equation modeling technique in LISREL 8.52. To test only the

FIGURE 1
Conceptual Model

specified relations between indicators and latent variables, all constructs was treated as exogenous (Andersen and Gerbing 1988). Throughout this procedure, the single item for intention to purchase the brand extension was given a fixed error term of 0.19. Single item scales are fixed in LISREL, and adding an error term ensures a stronger and more realistic model test (Bagozzi and Yi 1988). The initial tests suggested a total of 5 items for removal to meet the requirements of unidimensional measures. The re-specified model received a satisfactory fit with a Chi square value equal to 106,97 with 70 degrees of freedom ($p=0.00$). Other fit indices were a RMSEA of 0.045, a NNFI of 0.95 and a CFI equal to 0.97. These test measures all met the requirements of a well fitting model (e.g. Browne and Cudeck 1993).

The reliability of the scales was assessed using three measures proposed by Bagozzi and Yi (1988). First, item reliability was computed as $\rho_i = \frac{\sum \lambda_i^2 \text{var}T}{(\sum \lambda_i^2 \text{var}T + \theta_{ii})}$, where T is the construct reflected by the item. Second, the average variance extracted for each construct was defined as $\rho_v = \frac{\lambda_i^2 \text{var}T}{(\sum \lambda_i^2 \text{var}T + \theta_{ii})}$. Both the item reliability and average variance extracted scores should preferably exceed 0.5. Finally, the composite reliability was assessed by the formula $\rho_c = \frac{(\sum \lambda_i)^2 \text{var}T}{(\sum \lambda_i)^2 \text{var}T + \sum \theta_{ii}}$. Composite reliability should exceed 0.6 to be satisfactory (Bagozzi and Yi 1988). The reliability measures were generally satisfactory, although with exceptions on some scores. However, as an important aspect of measurement is to capture all facets of the construct (Bollen and Lennox 1991), all the measures were retained in the final measurement model to maintain the theoretical domain of the variables. This decision was also based on the fact that lack of reliability is accounted for in structural equation models (Jöreskog and Sörbom 1982).

The final test of the measurement model was directed at discriminant validity, which can be claimed to be present if no single pair of variables are perfectly correlated within the range of random error (Anderson and Gerbing 1988). According to the

correlation matrix, none of the correlations came close to 111 when adjusted for ± 2 standard deviations.

Structural Model

Test scores for the structural model are reported in Table 1. With a Chi-square of 110.94 (d.f.=74, $p=0.00$), a RMSEA of 0.044, a NNFI value of 0.95 and a CFI of 0.97, the statistics of fit indicated that the model satisfactorily reproduced the covariance matrix. As can be seen from Table 1, *perceived similarity* was found to positively influence both the *intention to purchase the brand extension* ($\gamma=0.30$, $t=3.55$), and the *preference for bundling* ($\gamma=0.38$, $t=4.67$), lending support to H_1 and H_{2a} , respectively. Furthermore, *preference for bundling* was assumed to positively influence *intention to purchase the brand extension* (H_{2b}). This hypothesis was supported, with test values equal to $\beta=0.36$ ($t=4.30$). In hypothesis 3 it was suggested that *price consciousness* has a positive effect on *preference for bundling*, and this hypothesis was supported ($\gamma=0.18$, $t=2.64$). Table 1 shows that H_4 , outlining the negative effect of *affective commitment to the current brand* on the *intention to purchase the brand extension*, was supported by the data ($\gamma=-0.26$, $t=-3.46$). Furthermore, it was proposed that the *intention to purchase the brand extension* would be positively influenced by *category involvement* (H_5). This hypothesis was supported, with test values equal to $\gamma=0.20$ ($t=2.34$). Finally, hypothesis 6 suggested that *category knowledge* would positively affect the *intention to purchase the brand extension*, but this hypothesis was not supported ($\gamma=0.11$, $t=1.41$). The squared multiple correlations showed that the model explains 17 % of the variance in the *preference for bundling*, and 48 % of the variance in the *intention to purchase the brand extension*.

DISCUSSION

Past research on brand extensions has traditionally focused on perceived similarities between parent brands and extensions and

TABLE 1
Parameter Estimates and Fit Measures for the Structural Model

<i>Hypothesis</i>	<i>Path</i>	<i>Estimate</i>
H ₁	Perceived similarity ⇒ Intention to purchase brand extension	0.30**
H _{2a}	Preference for bundling ⇒ Intention to purchase brand extension	0.36**
H _{2b}	Perceived similarity ⇒ Preference for bundling	0.38**
H ₃	Price consciousness ⇒ Preference for bundling	0.18**
H ₄	Affective commitment to current brand ⇒ Intention to purchase brand extension	-0.26**
H ₅	Category involvement ⇒ Intention to purchase brand extension	0.20*
H ₆	Category knowledge ⇒ Intention to purchase brand extension	n.s
<i>Squared Multiple Correlations</i>		
	Bundling	0.17
	Intention to purchase brand extension	0.48
$\chi^2(74)=110.94$ ($p=0.00$); RMSEA=0.044; NNFI=0.95; CFI=0.97		

* $p < 0.05$; ** $p < 0.01$; $n=255$

has examined the effects of these factors on evaluations of brand extensions. In this article the focus was on another important dimension, the effects of characteristics of the extension category on consumer evaluations of brand extensions.

The findings suggest that the degree to which consumers are emotionally attached to their currently chosen brand in the extension category might be a barrier to a competitor's successful entry. Several implications arise from this assertion. First, marketers who plan to extend their brand into a new category should *ex ante* analyze the level and diversity of incumbent brand commitment and loyalty held by target consumers. Second, the loyalty literature suggests that apparently loyal behavior might not be due to loyalty at all, but might instead be repurchase patterns stemming from habits, convenience, exit barriers and the like (Bloemer and Kasper 1995). Hence, repurchase pattern is not an adequate measure of how protected by consumer loyalty the existing brands are in the extension category, a fact the extending brand managers should take into account when designing an entry strategy for the brand extension. This conclusion might be drawn from the results of this study with regard to bundling.

As discussed earlier, bundling refers to two or more products sold in a package, and specifically the preference for a mixed bundle of products was studied. As expected, the consumers' preference for bundling increases the intention to buy the brand extension. It is probable that parent brands might use a bundling strategy to recruit customers who possess this preference, given that the parent brand and the extension make a logical bundle. The strength of the parameter estimates in this model suggests that the positive influence of preference for bundling is stronger than the negative effect of commitment to current brand, which further implies that bundling is a favorable strategy. This fact, combined with the strong impact of perceived similarity on the preference for bundling, suggests that the similarity route to extension success should not be underrated. Stated differently, the single most dominating success factor related to brand extensions has been found to be perceived similarity (e.g., Aaker and Keller 1990), and it can be argued that similarity has an additional positive effect through its impact on consumer preference for product bundles.

In accordance with the hypothesis, price consciousness seems to influence the consumers' preference for a mixed bundle of products. This implies that 1) there are some consumers who will find bundles very attractive due only to an inherent personality trait, and 2) firms might tailor their advertising campaigns in such a way that the economic virtue of the bundle would be signaled to these consumers. Stated differently, due to variation in this personality trait, marketers might gain extra sales by making sure that customers with high price consciousness are made aware of the bundling option.

It was found in this research that involvement in the extension category affects the intention to buy a brand extension in a positive way. Therefore, marketers should also consider the level of involvement held by consumers in the target segment for a brand extension. When planning to expand into a new product category the competent firm will do its utmost to assess and profile relevant target groups. Standard insight reveals that potential consumers who are involved in and who have a perceived need for the actual product are more likely to buy the extended brand.

Knowledgeable subjects did not have a higher intention to buy a brand extension compared to novices. This finding does not support the arguments that knowledgeable consumers with a rich and well-organized knowledge structure are better at finding similarity between core brands and extensions. Wänke, Bless and Schwartz (1998) argued that this rich and well-organized knowledge structure also makes it easier for experts to find mismatches between different core brands and extensions. The inconsistent results on this issue could imply that perceived knowledge could have both a positive and a negative effect on the intention to buy a brand extension, contingent on the context. Future research should address this issue.

Conclusions and Further Research

These findings not only contribute to the growing body of knowledge in the area of brand extension, but also suggest several specific issues that warrant further inquiry. First, the inclusion of the construct of commitment in further studies on brand extensions could produce interesting results. One basic assumption in the

literature is that extensions of well-known and well-liked original brands are advantageous due to transfer of positive affect to the extension. However, it has been pointed out in this study that even a very strong parent brand may find an extension difficult because consumers have an established relationship to a brand in the extension category. Hence, one possible avenue for further studies would be to investigate the different strategies the extending brand could apply to break consumers' relationships to incumbent brands.

Second, other characteristics of the extension category should be investigated in relation to the evaluation of brand extensions. One option would be to study the effects of dominance. This characteristic could be used to explore the effects of brand extensions on categories with stronger dominating brands versus weaker dominating brands (Laurent, Kapferer and Roussel 1995, p. G178). A third issue for future research would be how a brand extension affects the positions of the original brands in the categories? How do the original brands react to the new (extension) competitor? An interesting avenue for research would be to examine the dynamic processes that the extension undergoes within the extension category.

To conclude, this investigation has produced some interesting contributions to the literature on brand extensions. First, extending a brand into a category where consumers are highly committed to existing brands seems to be more challenging than expected. Thus, other options might prove more fruitful. Second, if the parent brand and the extension can form a natural bundle, a mixed bundle strategy seems to attract both customers with a general preference for such bundles, and also more price conscious consumers. Third, involvement in the extension category was found to effect the intention to buy a brand extension in a positive way, which implies that marketing activities might be successfully directed to the outlets where high involvement consumers are most easily found. Finally, in line with previous research, it was found that similarity had a positive effect on the intention to buy a brand extension. However, extending previous research, it was found that this similarity also increased the consumers' preference for a product bundle, which in turn was positively related to purchase intentions. As such a new basis has been established on which to advocate the importance of similarity. Accordingly, as some categories are more receptive to brand extensions than others, one should carefully consider which to choose. This article offers some guidelines.

A Consumer Preference Formation Perspective on Pioneering Advantage in Electronic Marketplace

Kuan-Pin Chiang, Long Island University

ABSTRACT

In physical markets, the pioneer or first-mover often enjoys large market share because of its early entry. This large share is often a result of high entry barriers for late entrants and high switching costs for consumers. In electronic markets, however, switching costs across online retailers are relatively lower and entry barriers are minimal. This paper extends the stream of competitive advantage research to e-commerce settings. Specifically, it conceptualizes and assesses the pioneering advantage of online retailers from the perspective of consumer preference formation. Several propositions were developed for future empirical testing.

INTRODUCTION

In recent years, e-commerce has reshaped the landscape of competitive advantage among companies (Evans and Wurster 1999). It transforms the way companies conduct their business and electronic merchants gradually grab a significant market share from competitors in the physical market. To gain an edge in this new economy, there is no time to analyze and plan. Given the speed of change, being first is often enough to create an advantage (Kardes and Gurumurthy 1992; Downes and Mui 1999). For example, Amazon.com was able to obtain first-mover advantage when it was established in 1995 with "a mission to use the Internet to transform book buying into the fastest, easiest and most enjoyable shopping experience possible" (Amazon.com). Its founder Jeff Bezos gave a great deal of thought in the selection of an initial category. He wanted a category for his e-tailing venture such that even the biggest, best-endowed physical competitor would be at a disadvantage. As the first commercial web site, the venture was novel, attracting attention of large number of Web surfers. In fact, its major rival—Barnes and Noble took a while to recognize the emerging threat of Amazon and to develop a strategy to combat the strength of its new competitor. BN.com is now counted as one of the top ten most visited sites in the U.S. in 1999 (Economist 1999).

Whether the success of Amazon was a result of pioneering advantage, or whether it was due to its technological innovation, is an important research question. The existence of inherent first-mover advantage and competitive advantage has been documented in the literature (Robinson 1988; Robinson and Fornell 1985). In physical markets, market pioneer or first-mover often enjoys enduring high market share advantage because of its early entry. This large share results from creation of high entry barriers for late entrants and high switching costs for consumers. In electronic markets, however, consumers' costs of switching among online retailers are relatively low and entry barriers for new players are minimal (Auger and Gallagher 1997; Klein 1998). The choice of being a first mover or an early follower is a critical one for managers, yet available research or practice-based evidence provides little guidance. It is not clear that a market characterized with lower switching costs and entry barriers will guarantee that first-to-market firms like Amazon will still be dominant as the market evolves (Coltman et. al 2000).

Given the lower entry barriers in electronic markets, pioneering efforts may ultimately prove to be of limited value. Provided high customer switching costs do not exist, the follower-entrants are often well positioned to exploit their existing strategic resources base and core competencies. Question such as how companies could retain competitive advantage becomes an important issue.

Does timing of entry in electronic market affect companies' competitive advantage? If first-mover advantage exists in electronic markets, how can it be explained and analyzed? What are the mechanisms affecting consumers' decision-making process in which companies could gain competitive advantage in e-commerce? These are only a few but important questions to be addressed.

In addition to radically transforming the business climate, e-commerce provides consumers more shopping and media options. It has been suggested that online consumers are empowered because the Internet allows them to compare prices, products, and services across a wide variety of stores in a matter of minutes (Abbott et. al 1999; Sheth and Sisodia 1997). In all markets, attracting and retaining customers has become an important issue. We argue that in electronic markets, customer attraction and retention are even more crucial than in physical markets. Online marketers will be able to sustain their competitive advantage by shifting consumers' preference, leading to a higher repeat visits and market share. In addressing these issues, previous literature in the stream of consumer preference formation assessing competitive advantage could provide some guidance (Carpenter and Nakamoto 1989; Senguta 1995; Hintzman 1986), provided it can be reinterpreted in the context of electronic marketplaces.

The objective of this paper is to extend the stream of competitive advantage research to e-commerce settings. Specifically, the goals of the paper are to conceptualize and assess the pioneering advantage construct in e-markets from the perspective of consumer preference formation. Rather than tackle the whole field of e-commerce strategy, the paper limits its focus to online retailers.

Before any further discussion, a few observations need to be made regarding the scope of this study. First, given the complex market structure of the retail sector, shifts in consumer preference among retailers could occur at various levels—(1) overall shift from physical market to online market, (2) shift from buying through physical retailers to online retailers to online market, (3) shift from physical retailers to a particular online retailer, (4) shift from competitive online retailer to another retailer (Dholakia et. al 2000). For example, consumers may prefer physical retailers on the whole over online retailers or vice versa. Similarly, they may choose online retailers over physical retailers for specific product categories. Since the focus of this paper is on electronic markets, the level will be on the overall preference of consumers for online retailers vs. physical retailers.

Second, as Carpenter and Nakamoto (1989) argue, the consumer learning process produces a competitive advantage apart from influencing consumer's ideal combination of attributes. In physical markets, the pioneer can thus become strongly associated with the product category as a whole and, consequently, become the "standard" against which later entrants are judged. The emergence of electronic markets, however, may blur the notion of pioneer in the category. For instance, it is possible in the book industry that Barnes and Noble is the "standard" in the category against which e-pioneer Amazon is judged in the consumer learning process. At the same time, Amazon could be the standard in electronic markets against which BN.com (the electronic unit of Barnes and Noble) is judged. To solve this problem, we argue that the use of such a referent standard depends on the length and depth of consumers' online shopping experience.

Third, as e-commerce enters a new phase, established firms—particularly branded goods suppliers and physical retailers—are slowly beginning to get involved (Evans and Wurster 1999). This will shift attention from growth strategies adopted by first movers (i.e., Amazon and E*Trade) to strategies that deliver sustainable competitive advantage for more traditional firms (Coltman et. al 2000). It is not clear, however, whether established brick-and-mortar retailers (e.g., Barnes and Noble and Wal-Mart) would automatically gain competitive advantages in the electronic markets. Therefore, two types of online retailers are considered in this paper—pure-play online retailers and brick-and-click retailers (online retailers with physical presence). Because physical presence is one of online store attributes influencing consumers' satisfaction with (Abbott et. al 1999) and preference for online retailers, it will serve as a marker of distinction among online retailers.

Lastly, as mentioned earlier, the focus of this paper is on the retailer level. The stream of past studies has assessed competitive advantage at a product level in the physical market. In electronic markets, however, it is the cyberbrands (e.g., Yahoo.com, Amazon.com) that are prominent. For example, Barwise (1997) suggests that in a busy, over-communicated, and untrustworthy world, consumers continue to gravitate towards brands as a way to simplify choices. In a recent survey on e-commerce, Ernst & Young found that 69 percent of respondents stated that brand name plays a significant role in their online buying decisions (Ernst & Young 1999). Thus, conceptually it seems justified to examine pioneering advantage at the level of online retailer brands.

The paper is organized as follows. First, we begin with a review of relevant literature of consumer preference formation in the domain of pioneering advantage. Based on this review, propositions are developed regarding consumer preference for pioneers and late entrants among online retailers. Finally, we conclude with potential implications of this research.

THEORETICAL FOUNDATIONS

In the literature, pioneering advantage can be analyzed within the framework of consumer learning mechanisms. Two streams of research are relevant. The first one is based on the idea of a "prototype model" (Schmalensee 1982; Carpenter and Nakamoto 1989; Kardes and Gurumurthy 1992), wherein pioneers are perceived as being "prototypical" of the schema in a product category, thus giving them a sustainable competitive advantage. The second stream is based on the notion of an "exemplar model" (Hintzman 1985; Sengupta 1995) which provides an alternate learning process of consumers. Rather than comparing with a single prototype, consumers categorize a new product by assessing whether it resembles many of the remembered exemplars from a category. Thus, according to this model, not one but a number of instances of a category can be highly salient perceptually and distinct in memory.

Prototype Model

Schmalensee (1982) has suggested that consumers are initially skeptical about the quality of any brand that enters the market. Yet, when consumers become convinced that the first entrant in the product category is satisfactory, the early entrant acts as the standard of comparison by which later entrants are judged. It is for this reason that it becomes difficult for followers to persuade consumers to learn about their late-entering alternative brands.

Kardes and Gurumurthy (1992) have described this order-of-entry effect as differential learning. For instance, consumers often find the pioneer to be novel and attention drawing while its followers appear to be redundant in comparison. The novelty of the pioneer promotes learning about its features, while the redundancy of the followers' attributes inhibits learning concerning their quali-

ties. Consequently, consumers tend to learn and remember more about the pioneer and will thus develop more favorable evaluations toward the pioneer.

Consistent with learning theory in general, Carpenter and Nakamoto (1986) argued that the process by which consumers learn about brands and form preferences for them has an important role in creating an advantage for pioneers, and that this process has two components. First, in the early stages of many markets, consumers may know little about the importance of the product attributes or their ideal combination. Thus, a successful early entrant can have a major influence on how attributes are valued and on the ideal attribute combination. Amazon, for example, may have had a significant impact in its early years on the formation and evolution of individuals' preferences for buying books online. This influence can shift individuals' preferences to favor the pioneer over later entrants, leading to a market share advantage for the pioneer. In essence, following successful experiences with a pioneering brand, buyers come to perceive the combination of attributes possessed by that brand as the ideal combination.

The second component of prototype model is based on the notion that consumers hold schemas for a product category (Sujan 1985). Pioneers are perceived as being "prototypical" of the schema, thus giving them a sustainable competitive advantage. A schema is defined as a memory representation of a particular stimulus domain (Fiske and Taylor 1991). A schema contains information about the category it represents and is often used to categorize a new stimulus. Thus a schema about the category "online bookseller" may contain attributes such as "one-click shopping", "search function" etc., as well as the interrelationship between these attributes. A new online bookseller possessing these typical attributes may be categorized as an "online bookseller", without much effort.

Exemplar Model

As a counterpoint to the prototype perspective, the exemplar approach (e.g. Brooks 1978; Hintzman 1986), suggests that one remembers separate instances (or exemplars) one has actually encountered, rather than some average prototype one has abstracted from experience. In this view, people categorize a new instance by seeing whether it resembles a lot of remembered exemplars from a category, rather than by comparing it with a single prototype. Thus, according to the exemplar view of schemas, a number of instances of a category (not just a single prototypical instance) can be highly salient perceptually and distinct in memory.

In a concise review, Fiske and Taylor (1991), note that the exemplar view has several advantages over the prototype view of schemas in being able to explain a number of schema-related issues with greater ease. The exemplar view most directly accounts for people's knowledge of specific examples that guide their understanding of a category. For example, to refute an assertion that all luxury cars come with power windows, one may retrieve a specific counter-example from the category "luxury cars." This illustration of reliance on concrete instances suggests the idea of exemplars and supports the thesis that an exemplar viewpoint allows for the salience of different category members.

Further, people often know a lot about the possible variation of members within a category. A prototype theory cannot represent information about variability. However, it is easy to describe people's knowledge of such variation by positing exemplars. Again, such knowledge of variability implies that the consumer is in a position to retrieve specific examples of a category.

In sum, a key difference between the prototype model and the exemplar model in the context of the pioneering problem is that the prototype model posits that the schema contains an abstract, global, generalized representation of the category, whereas the exemplar

model suggests that the schema contains differentiated, individual instances of the category. Based on the exemplar model, different members of a category could all be salient, and similarities and differences between these members can easily be perceived.

In explaining pioneering advantage, several moderating variables have been suggested to deepen the explanations regarding the use of prototype or exemplar among consumers. These moderating variables include amount of elaboration and heuristic processing.

Amount of Elaboration and Heuristic Processing

Development of heuristics based on category knowledge saves cognitive effort in decision-making (Alba and Hutchinson 1987; Sherman and Corty 1984). Within the product category, later entry is difficult because consumers tend to know and favor the pioneering brand. They have no reason to experiment with later entering brands. This suggests that consumers may use brand name of the pioneer as a heuristic in decision making under low elaboration conditions (Petty and Cacioppo 1986; Petty, Cacioppo and Schumann 1983), allowing them to make a sound choice with little cognitive effort. Thus, consumers may compare new brands to the pioneer using holistic or category-based processing, without exerting the effort necessary to process brand information at the attribute level. This argument is in line with prototype model. On the other hand, if consumers make attribute-level brand comparison which requires more cognitive effort, they may know that later entrants have the same attributes as the pioneer and evaluate them similarly. In such cases, the exemplar model may be at work.

This argument suggests that preference asymmetry may be enhanced by category-based processing in which prototype model would be used. On the other hand, if consumers tend to process information at the attribute level, thus employing the exemplar approach, then the pioneer's competitive advantage may be weakened even without differentiation.

PROPOSITIONS

In the electronic environment, consumers learn about the attributes of online retailers and form preferences for them. It has been proposed that online store attributes—which are extensions of physical store attributes—influence consumers' satisfaction and their loyalty to the online store (Abbott et. al 1999). Satisfaction is also likely to determine their preference toward a particular online retailer. Theoretically, the formation of preference could be derived from the two forms discussed—the prototype and the exemplar approach. These two approaches enable us to develop propositions about how the formation of preference could determine competitive advantage in electronic markets. Testing these propositions would reveal whether online retailers could gain competitive advantage by timing their entry to specific e-markets and by emulating specific types of retailers.

Pioneering Advantage in E-markets

Coltman et. al (2000) argue that in an industry dominated by rapid technological innovations, high-risk investments and market uncertainties, pioneering efforts may ultimately prove to be of limited value in a marketplace where barriers to entry are low and the rules of the market are still evolving. Based on this contention, it is worth investigating whether pioneering advantages exists in e-markets in which the pioneers can shift consumers' preferences to favor them over later entrants. Theoretically, the prototype model explains pioneering advantage by suggesting that the pioneer has a unique distinctiveness derived from its being the prototypical representative of the category. In such cases, consumers form a preference structure that favors the pioneer, making it difficult for later entrants to compete away the pioneer's market share. Thus,

along with the arguments made by Carpenter and Nakamoto, we propose that online shoppers will prefer pioneering online retailers than later entrants in the electronic marketplace.

P_1 : Online shoppers' preference is greater for pioneering online retailers than for late entrants.

Who is the Prototype?

The prototype model is based on the notion that consumers hold overall, aggregate schemas for a product category. Pioneers are perceived as being "prototypical" of such schemas, which gives them a sustainable competitive advantage. Since online shopping is a very recent development but many product categories for online shopping are well established, it is not clear which prototype consumers use to make their judgment in e-markets for a given category. For example, it is possible in the book industry that Barnes and Noble is the pioneer and standard in the category against which Amazon is judged in the consumer learning process. At the same time, Amazon could be the pioneer and standard in the e-market in which BN.com is judged. We argue that the use of which prototype (e.g., online vs. bricks-and-mortar) depends on consumers' online shopping experience in their learning process of online shopping.

When dealing with online shopping, most buyers require assurances that the goods are unused, properly identified, and legitimately obtained before they will source them from an unknown supplier (Coltman et. al 2000). It has also been found that security and quality of products are the two main factors preventing consumers from online shopping (Ernst & Young 2000). This suggests that consumers will tend to favor larger, incumbent and well-established retailers because consumers would feel more secure dealing with a known retailer in the new and alien setting of the electronic market. For novice online shoppers, it is likely that they know little about the store attributes or their ideal combination. They are likely to be concerned with security and quality of products. Online retailers with physical stores could provide more security and assurances regarding an easy merchandise return policy. Therefore, the pioneering brick-and-click retailer in the product category will influence novice shoppers' preference and serve as the prototype by which pure-play retailers are judged. In other words, for novice shoppers, the pioneer in the physical market (who has established a relatively early online presence) has more advantages than pure-play online retailers.

For consumers who are experienced with online shopping, satisfactory experiences are likely to reduce their skepticism of online retailers. For such experienced consumers, the pioneering pure-play online retailer will serve as the prototype. Thus, the following propositions are offered.

P_{2a} : For novice online shoppers in a product category, brick-and-click retailers (pioneer in physical market) are likely to serve as the prototype and preferred in the electronic market.

P_{2b} : For experienced online shoppers in a product category, pure-play (pioneer in electronic market) retailers are likely to serve as the prototype and preferred in the electronic market.

Exemplar versus Prototype

Depending on the level of elaboration, the literature suggests that two types of information processing would be used—category-based and attribute-based processing. When category-based processing is utilized, consumers tend to use heuristics—such as their

assessment of the pioneer—to make their decisions. Thus, the pioneer will become the prototype that would make it very difficult for later entrants to gain competitive advantage. On the other hand, attribute-based processing requires higher cognitive effort. In such instances, all brands would be compared. Consequently, pioneering advantage is weakened.

In e-markets, as the innovation of online shopping continues to diffuse, consumers' relative level of knowledge increases over time. Studies have found that increased knowledge regarding the product category produces greater elaboration (Petty and Cacioppo 1986), facilitating an attribute-based processing that would weaken pioneering advantage. As the level of online shopping experience increases, consumers are likely to adopt attribute-based processing rather than category-based processing. Therefore, for novice online shoppers, category-based processing will be employed in which pioneering retailers (in the market as a whole) will be the prototype. Such established retailers would, thus gain a pioneering advantage when novice shoppers turn to online buying. As their level of experience increases, the shoppers will be able to compare online retailers by store attributes. Similarly, for experienced online shoppers, their increased knowledge facilitates attribute-based processing across online retailers. Such processing would weaken any pioneering advantage. This leads us to the following proposition:

P₃: Online shoppers' preference for the pioneer diminishes as their level of online shopping experience increases.

Furthermore, the adoption of exemplar processing would enable consumers to compare a number of online retailers based on their attributes. When online shoppers decide to purchase a product in which they have already experienced online retailers in a product category, their choice will be based on a consideration set that contains either one online retailer (e.g., the pioneer) or more than one online retailer (i.e., the pioneer and later entrants). As their knowledge and experiences increase, it is likely that their consideration sets will include a number of online retailers to which both the pioneer and the late entrants will be compared. Thus, in addition to containing the pioneer, their consideration set may include the followers.

P₄: Online shoppers' consideration set is more likely to contain the followers as their level of online shopping experience increases.

IMPLICATIONS

The implications of the propositions presented here are three-fold. First, given the unique characteristics of e-commerce, researchers have questioned whether pioneering advantage exists. Theoretically, the prototype model (Carpenter and Nakamoto 1989) suggests that apart from influencing consumers' ideal combination of attributes, consumers' learning process produces a competitive advantage for the prototypical pioneer. The pioneer can become strongly associated with the product category as a whole and as a result become the standard against which all later entrants are judged. However, there is no empirical evidence suggesting that such formation will yield pioneering advantage in e-markets. Studies based on the first proposition would facilitate an understanding of whether or not online shoppers prefer pioneering online retailer to later entrants.

If the proposition is supported, it can contribute to the stream of research in which pioneer serves as the prototype and has a pioneering advantage. Additionally, support for the first proposition would indicate that the formation of preferences by online

shoppers is based on the existence of prototypes. On the other hand, if the proposition is not verified, key practical implications would ensure. In such a case, it is possible that in e-commerce markets with low entry barriers, fast-moving technology, and rapid and successive innovations, being a pioneer is not necessarily advantageous.

Second, since online shopping is still a relatively new phenomenon and many product categories are already well established in the physical market, it is not clear which prototype online shoppers would use for comparison. In our view, the use of prototype depends on consumers' experience in the length and depth of their learning process about online shopping. There is practical evidence that many established physical retailers are reluctant to enter or late in entering the e-commerce arena. Testing the second proposition could reveal whether brick-and-click retailers could enjoy competitive advantages with novice online shoppers by having established name recognition or tangible physical retail stores as references. For experienced online shoppers—since they are likely to assess online retailers based on online store attributes, simply having a physical presence or being the first in physical market does not provide competitive advantages for the online retailers.

Lastly, two types of information processing could occur as consumers' online shopping experience increases. The increasing knowledge of online shopping could influence consumers' decision and affect pioneering advantage. Specifically, online shoppers' expertise would eventually impact pioneering advantage because attribute-based processing would be adopted, leading to an enlargement of their consideration set for online retailers, including pioneer and later entrants. Therefore, pioneering advantage would be weakened.

CONCLUSION

The notion of pioneering advantage is an intriguing one that has sparked numerous research studies in the fields of marketing, business strategy, and economics. Within these ongoing research streams, the major point of departure of this study is the focus on the pioneering advantage in electronic markets and on online retailer settings. Such settings are different from the focus of the previous literature that has examined pioneering phenomena for branded products in physical markets. Understanding pioneering advantage in e-commerce is an important research area. This paper is only a beginning.

Normative Versus Comparative Fit: Prototype-based and Exemplar-based Brand Extension Evaluation

Huifang Mao, Indiana University
H. Shanker Krishnan, Indiana University

EXTENDED ABSTRACT

The purpose of this article is to enrich the conceptualization of “extension fit” in brand extension literature and to explore the information processing underlying extension evaluations. Well documented in brand extension research is the role of “fit” between the core brand and the new product in extension evaluations (e.g. Aaker and Keller 1990). This article questions the unidimensional conceptualization of the fit construct, and proposes two distinctive fits—normative fit (the typicality of the extension to the brand category) and comparative fit (the similarity between the existing product and the new product). Related with either normative or comparative fit, brand extension evaluation can occur as prototype-based (top-down process) or as exemplar-based (parallel process).

Differentiation of the two extension fits is especially crucial in a multiple-product brand scenario, where consumers may develop a brand schema in which they store not only each affiliated product as exemplar but also generalized higher-order brand knowledge as prototype. With prototype-based process, consumers infer the quality of extension products based on the abstracted brand prototype. The evaluation is a top-down deduction process where impression of the new product instance is made based on knowledge of the brand as a group. Normative fit, the typicality of the extension product to the brand category, determines the extent to which the attitude toward the brand be transferred to the new product. Extension evaluation can also occur in an exemplar-based parallel fashion. For extensions that are similar to some existing product, that is when the comparative fit is high, consumers may draw inference from the existing product to the new product, without retrieving any higher-order brand prototype information. While the prototype-based process requires some cognitive resource, the exemplar-based process is more effortless because its inference base and target are of the same level.

Brand extensions are evaluated in two stages: the first stage being exemplar-based and the second stage prototype-based. Comparative fit is necessary to activate the exemplar-based stage one, and normative fit becomes a better predictor for extension evaluation in the prototype-based stage two. Cognitive resource moderates the evaluation process: with little resource the evaluation is mainly exemplar-based; but with increasing resource the prototype-based stage is more thoroughly processed and determines extension evaluation to a larger degree. Hence:

- H1:* With high cognitive resource, high (versus low) normative fit will lead to favorable extension evaluations.
- H2:* With high cognitive resource, high (versus low) comparative fit will lead to favorable extension evaluations.
- H3:* With high cognitive resource, brand extensions with high normative fit but low comparative fit will receive more favorable evaluations than brand extensions with high comparative fit but low normative fit.
- H4:* With low cognitive resource, high (versus low) comparative fit will lead to favorable extension evaluations, regardless of normative fit.

Memory accessibility is predicted to moderate the process (Carlston and Smith 1996). Specifically, consumers who have

well-developed brand prototype are more likely to engage in prototype-based process while those who have direct experience with an existing affiliated product might involve in exemplar-based process. Hence:

- H5a:* Given high comparative fit, high (versus low) accessibility of a product exemplar will lead to favorable extension evaluation.
- H6a:* Given high normative fit, high (versus low) accessibility of brand prototype will lead to favorable extension evaluation.

The experiment was conducted with a 2 (normative fit: high vs. low) x 2 (comparative fit: high vs. low) x 2 (cognitive resource: high vs. low) x 2 (order of the two extension product replicates) between-subject design. Two dependent variables were examined—extension evaluation as an outcome measure and thought protocol as a process measure. Four covariates were included—brand familiarity, brand favorability, need for cognition, and gender.

With ANCOVA and cell mean difference comparisons, the results show general support to the hypotheses. First, consistent with hypotheses 1 and 2, both normative and comparative fit have main effects on extension evaluations (both $F(1, 272) > 114, p < .001$). Their significant interaction suggests that having both fits will further increase extension judgment but the improvement becomes incremental compared with having one fit ($F(1, 272) = 21.55, p < .001$). Second, consistent with hypothesis 3, subjects in the high-resource condition reported more favorable evaluation to extensions with only high normative fit than to those with only comparative fit ($t(74) = 1.98, p = .05$), indicating that normative fit be a better predictor than comparative fit when resource is sufficient. Third, although the effect of cognitive resource failed to reach statistical significance ($F(1, 272) < 1.46, p > .22$), the evaluation pattern is in the hypothesized direction. Extension products with high normative fit but low comparative fit were more favored by subjects with high (vs. low) cognitive resource, while products with high comparative fit but low normative fit were more positively evaluated by subjects with low (vs. high) resource. Fourth, as predicted in hypothesis 5 and 6, consumers who are familiar (vs. not familiar) with the brand gave more positive evaluations to the extensions with high normative fit; and consumers who have more (vs. less) direct experience with the product exemplar showed more favorable judgment to the extensions with high comparative fit.

Brand Name and Consumer Inference Making in Multigenerational Product Introduction Context

Seigyoung Auh, University of Melbourne
Chuan-Fong Shih, Wake Forest University

EXTENDED ABSTRACT

What is the significance of Microsoft using brand names that correspond to Windows 95, Windows 98, Windows 2000 and now Windows XP? What message does Intel convey to customers when they change their chip's brand name from 486 to the Pentium series? Although, research has confirmed that brand names associated with numbers and certain letters of the alphabet fit the description of high-tech and complex products (Boyd 1985; Pavia and Costa 1993), little is known as to why that is the case. A related research question that we address in this paper is the role of brand names in affecting upgrade likelihood decisions and the incremental willingness-to-pay for next generation products. Moreover, little is known as to what types of brand names would best summarize different levels of upgrades (normal vs. breakthrough) for next generation products.

According to cognitive representation of information, when these brand names are used in isolation or outside of any context that provides it any substantive meaning, they would be processed in a manner consistent with surface-level processing. However, multi-generational high-tech products are usually interpreted within a time progressive framework. In other words, the notion of time provides life and meaning to what otherwise would be nothing more than a group of numbers. A brand name such as MySoft 3.0 may convey a different meaning to consumers than its counterpart MySoft Elite (prone to meaning-level processing), which are both in the 3rd generation of its life cycle. In short, we expect that in the context of time progression, a brand name that is subject to surface-level processing (e.g., MySoft 3.0) can provide several advantages to firms compared to a brand name that is most likely subject to meaning-level processing (e.g., MySoft Elite). We test this general hypothesis in experiment 1.

In experiment 1, we found that brand name type had an effect on perceived technological improvement, product differentiation, and the degree to which one was willing to pay more for the current version compared to the previous version. Moreover, it was confirmed that the extent to which subjects are willing to pay more for the current version model compared to its predecessor is driven by technological improvement. These results bolster our belief that brand names operate as strong cues for enabling respondents to make inferences about how a current generation of a high tech product may be perceived to be different from its prior generation. Our empirical work is consistent with the results of Brucks, Zeithaml, and Naylor (2000).

In experiment 2, we examined how well different types of brand names can reflect respondent's perceptions of the degree of innovation of an attribute on some key dependent variables. In labeling brands in a sequential manner to reflect generational progression, a common procedure is to adopt progressive numeric labeling (version 1, 2, 3 etc). Such practices are inherently appealing because it is clearly understandable by the consumers as a continuation of prior generation. As such, brand equity and performance expectations can easily be transferred from one generation to the next. Alternatively, firms can pursue brand labeling strategies that signal to the consumer that the next generation product significantly deviates from its prior generation by abandoning sequential branding. A non-sequential brand labeling strategy (e.g., version 1, 2, 3, XT) can break the monotony of the brand signals and suggest

that the next generation product is significantly different from prior generations.

The two types of brand labeling (sequential vs. non-sequential) can be interpreted as either congruent or incongruent with the attribute improvement of the new generation product. That is, if we have a series of brand names in the order of MySoft 1.0, MySoft 2.0, MySoft 3.0 and a new introduction that corresponds to MySoft XT, this can be conceived as either a congruent or an incongruent brand label depending on the nature of the innovation type. Under a breakthrough innovation condition, MySoft XT would be considered congruent brand name because XT conveys non-continuous improvements. Conversely, when brand name MySoft 4.0 is used, it does not convey this information (breakthrough innovation) to consumers accordingly. When congruency exists between brand labeling and attribute improvement, both are used to evaluate products. When incongruency exists between brand labeling and attribute improvement, product information signaling is averaged to form an overall evaluation such that a breakthrough improvement may not be perceived as innovative as it could have been otherwise (i.e., sequential brand labeling attenuates the impact of a breakthrough innovation) or a non-sequential brand labeling can actually enhance the effect of a nominal innovation.

This is similar to the information integration theory such as cognitive algebra introduced in the impression formation literature by Anderson (1965, 1971). According to the cognitive algebra model, when conflicting and incongruent information is present, people tend to engage in an averaging mentality to arrive at a final decision. Our predictions for sequential brand labeling to diminish the effect of a breakthrough innovation and non-sequential brand labeling to improve the beliefs about a normal innovation are consistent with the anchoring and adjustment framework of Hogarth and Einhorn (1992). In simple terms, one information either pulls down or up the belief formed from the other piece of information.

Using a 2 (innovation type: normal vs. breakthrough) x 2 (brand name type: sequential vs. non-sequential) experiment, we found a significant interaction between innovation type and brand name type in that the effect of a breakthrough innovation was stronger for congruent brand names than for incongruent brand names. In particular, respondents expressed greater degree of upgrade, differentiation, willingness-to-pay, worthy of upgrade, and purchase likelihood for the next generation product compared to the current generation product in the breakthrough innovation condition as opposed to the normal innovation condition. The results underscore the importance of having brand names for high-tech products that are congruent with the level of attribute innovation, especially when the innovation is a breakthrough development. However, the effect of a normal innovation had similar effects on the dependent variables regardless of brand name type.

SPECIAL SESSION SUMMARY

A Deeper Look at Assortment

Susan M. Broniarczyk, University of Virginia and University of Texas

SESSION OVERVIEW

The construct of assortment has begun to attract attention in consumer behavior. Research has shown that consumer perception of assortment is not a one-to-one function of the number of products offered (Broniarczyk, Hoyer, and McAlister 1998). Consumer assortment perceptions are also affected by the organization of the assortment (Hoch, Bradlow, and Wansink 1999) and heuristic cues such as the size of the display (Broniarczyk et al. 1998). Recent research has moved from examining assortment as a dependent variable to examining the consequences of assortment on consumer decision-making (i.e., assortment as an independent variable). Large assortments have been found to result in consumer confusion (Huffman and Kahn 1998) and demotivate consumer choice (Iyengar and Lepper 2000). This session probes deeper into the effects that assortment may have on consumer decision-making in three important directions: (1) examines the composition of the assortment, (2) examines multiple stages of consumer decision making, examining both choice and consumption decision outcomes, and (3) examines the effect of marketing variables such as the structure of the assortment and retailer signage.

First, the session examined how the probability of purchase from a given assortment is contingent on the complementarity of the features used to differentiate its options. Chernev defined feature complementarity as the degree to which the utility of different product features is additive. He reported data from two experiments documenting that product lines differentiated on noncomplementary attributes tend to be associated with a greater probability of purchase compared to product lines differentiated on complementary attributes.

Second, the session examined the effect of assortment on multiple stages of consumer decision making, examining both choice and consumption decision outcomes. Broniarczyk, Goodman, Griffin, and McAlister reported research that examined both anticipated regret during the choice process as well as experienced regret after consuming the chosen alternative. Kahn and Wasnick reported six lab studies that examine how consumer's perception of variety affects consumption quantities. They showed that perceived variety may also serve as a "consumption rule" or benchmark that consumers use to gauge how many items should be consumed.

Third, the session examined the effect of marketing variables such as structure of the assortment and retailer signage. Kahn and Wasnick reported that structural aspects of an assortment moderate a consumer's perception of the actual variety. Specifically, this perception of assortment variety is influenced by the organization and relative symmetry of the frequencies of the items in the set (entropy) of the assortment. It is this perceived variety of the assortment that influences consumption utility and ultimately contributes to consumption quantity. Broniarczyk, Goodman, Griffin, and McAlister discussed the effect of retail display signage such as product descriptions and best seller tags on consumer processing of large assortments. They reported that these marketing interventions designed to assist consumers and reduce the regret associated with large assortments may instead exacerbate regret.

"Feature Complementarity and Assortment in Choice"

Alexander Chernev, Northwestern University

How does the relationship between product features influence the overall probability of purchase from a given brand's product line? This research argues that the choice share of a given product line is contingent on the complementarity of the features differentiating choice options. In this context, feature complementarity is associated with the additive properties of the utilities of choice alternatives (Lattin and McAlister 1985). Thus, complementary features, when combined, lead to a greater utility than each feature considered separately. For example, combining cavity prevention and tartar protection is likely to result in a combination that is superior to each feature considered separately. In contrast, combining noncomplementary features does not necessarily increase their overall utility: Blending banana and mint flavors does not necessarily create a superior combination.

This research argues that because complementary features are relatively independent from one another, they can be represented as levels of separate attribute dimensions rather than as levels of the same attribute. Furthermore, because complementary features can be represented as levels of discrete attribute dimensions, consumers are likely to opt for the best performance on *each* attribute; thus, the absence of a given feature will be viewed as a potential loss. This leads to the counterintuitive prediction that differentiating products using complementary features can actually decrease the attractiveness of an individual product.

Consider an offering differentiated on a single attribute (e.g., cavity prevention toothpaste). Adding complementary features to extend the product line (e.g., tartar control, whitening, breath freshening, etc.) highlights the attribute dimensions on which the original product is relatively inferior, thus decreasing its overall attractiveness. It could be argued that each new complementary feature used to extend the product line ultimately makes the extant products less attractive because they are dominated on the attribute made salient by the newly added feature. This research argues that increasing product assortment through complementary features could potentially lower the attractiveness of all alternatives in that assortment.

In contrast, because noncomplementary features tend to be mutually exclusive, they can be represented as different levels of the same attribute. Because the benefits offered by these features are often not additive, combining two or more features does not necessarily bring the feature closer to a consumer's ideal point.

The proposition that feature complementarity moderates the impact of assortment on choice is supported by the data from two experiments. The first experiment examines feature complementarity in a context where consumers are given a single product line and have the option to choose one of the available alternatives or make

no choice at all. The data show that, all else being equal, noncomplementary assortments are more likely to be associated with a greater probability of purchase than complementary assortments. The second experiment examines the impact of feature complementarity in a context where consumers are given a choice between two brands, one featuring a single option and the other featuring either a complementary or noncomplementary product line. The data from this experiment show that the choice share of the complementary product line is lower than the share of the noncomplementary line. Considered together, these findings extend prior product line and assortment research to account for the relationship among different features used to differentiate options in a brand's product line.

"Too Many Choices: The Effect of Assortment on Anticipated and Experienced Regret"

Susan Broniarczyk, Joseph Goodman, Jill Griffin, and Leigh McAlister, University of Texas at Austin

This research reports two studies that examine how enduring involvement and product information affect consumer reactions when choosing from large assortments. The Iyengar & Lepper (2000) paradox showed that consumers choosing from large assortments experience increased choice difficulty and experienced regret but also increased positive affect. Our Study 1 finds that this paradox is limited to high enduring involvement subjects choosing from a hedonic product category. The results of Study 2 show that marketing interventions to reduce the regret associated with large assortments may instead exacerbate regret. Specifically, we explore the effect of providing two types of information, product descriptions and "best seller" signs.

In Study 1, we extend Iyengar & Lepper's research by examining hedonic (chocolates) versus utilitarian (pens) product categories and consumers with high versus low enduring category involvement. Overall, we replicated Iyengar & Lepper's finding that subjects experience a higher level of choice difficulty and experienced regret when choosing from large relative to small assortments. However, we find that their result that decision fun is higher for large assortments only holds for high enduring involvement subjects in the hedonic category.

In Study 2, we examine two marketing interventions that retailers might introduce to reduce consumer regret when choosing from large hedonic assortments, product descriptions and "best seller" signs. We examine the effect of these interventions on both anticipated regret experienced during the choice process and experienced regret following consumption. Our results show that instead of reducing consumer regret when choosing from large assortments, display information may instead increase consumer regret.

We found that that the availability of product descriptions reduced subjects' anticipated regret relative to a control group. However, actual use of product descriptions was positively associated with higher anticipated and experienced regret. Consistent with Carmon, Wertenbroch, & Zeelenberg (2003), reading descriptions may have increased regret because subjects now knew more about foregone alternatives.

"Best seller" signs were placed on the display of the two top selling products. The presence of "best seller" signs did not increase the choice likelihood of the chocolate but did lead to negative

consumer decision consequences. Relative to the control, signs increased the anticipated regret and negative affect consumers experienced choosing from large assortments. Subjects apparently struggled with how to process the information from the signs and integrate it with their own preferences. Experienced regret was dependent on whether subjects chose a chocolate tagged with "best seller" signage.

"The Influence of Assortment Structure on Perceived Variety and Consumption Quantities"

Barbara E. Kahn, Wharton School, University of Pennsylvania
Brian Wansink, University of Illinois

If consumers are offered an assortment with three different flavors of yogurt, they are likely to consume an average of 23% more yogurt than if they are offered an assortment featuring only one flavor (Rolls et. al. 1981). This example is typical of many consumption situations where consumers must decide how much of a product to consume when there are no formal guidelines to help them (Drenowski, Henderson, Driscoll, and Rolls 1997). Previous research related to packaging has shown that package size (Folkes Martin, and Gupta 1993), shape (Piaget 1969), volume (Wansink 1996), and perceived volume (Raghubir and Krishna 1999) can all contribute to how much one consumes. In the yogurt example, however, it is not packaging but rather the assortment variety that seems to be influencing how much consumers are likely to consume. But how do consumers interpret or perceive the variety of an assortment, and why should this perception of variety affect consumption quantities?

In this research we show that structural aspects of an assortment moderate a consumer's perception of the actual variety. Specifically, this perception of assortment variety is influenced by the organization and symmetry of the frequencies of the items in the set (entropy) of the assortment (Young and Wasserman 2001). It is then this perceived variety of the assortment that influences consumption utility and ultimately contributes to consumption quantity. We show that perceived variety may also serve as a "consumption rule" or benchmark that consumers use to gauge how many items should be consumed.

We find support for our proposals in a series of six lab and field experiments involving adults and children with both food and hedonic non-food items. The first four studies clearly illustrate the robust phenomenon that assortment structure affects consumption quantities. The last two studies show that in addition to influencing perceived variety, assortment structures might also provide consumers with consumption norms that guide them in selecting consumption quantities. It appears that perceived variety and anticipated consumption utility influence consumption quantity up to a point and then the quantity decision appears to be influenced further by consumption rules.

These findings are of relevance to interdisciplinary researchers, yet the most immediate implications of this research are directed toward altering the structure of assortments so that they do not have unintended effects on consumption.

ROUNDTABLE

Mediation Analysis

Dawn Iacobucci, Northwestern University
Adam Duhachek, Northwestern University

Mediation is often of interest to social science researchers. A theoretical premise posits an intervening variable, an indicative measure of the process through which an independent variable is thought to impact a dependent variable. This roundtable provides the opportunity to clarify some misperceptions and confusions about how to test for mediation effects.

Without question, the most popular means of testing for mediation is the procedure offered by Baron and Kenny (1986). We'll begin by reviewing their classic approach. In their enormously influential paper, Baron and Kenny presented a series of tests to be conducted via regression models. We will review those techniques, and demonstrate that in a database of the *JCR* articles that contain mediation analyses, most analyses were not conducted properly. Oops. Even had they been, the state of the art has moved beyond Baron and Kenny's regression tests. That is, we absolutely agree that their approach has been hugely impactful, but the methodological literature also recognizes that the approach has shortcomings, and is no longer state-of-the-art. More contemporary methodology allows for superior tests of intervening variable effects. We will present some results of simulations to illustrate the conditions under which results obtained using the older methods might be particularly misleading. We provide a tutorial of how to test for mediation, presenting exactly those analytical steps to take and the precise results to report. Don't worry, it's easy!

We plan to raise issues regarding experimental vs. correlational data, cross-sectional vs. longitudinal data, the meaning of "causality" and the central need for strong theoretical defenses of mediation, issues of measurement error and complex inter-construct relationships, yep, a.k.a. "nomological nets." Of key importance, we will discuss the statistical issues regarding the proper assessments of mediation parameter estimates and indices to capture the phenomena.

We conclude by suggesting that mediation analyses are probably conducted more frequently than need be, but for those scholars who wish to do so, we offer clear prescriptions as to the steps to take to support or negate the premise of a mediator. In reviewing the logic of mediation as a concept, we suggest that many times a researcher should simply forgo a test of mediation.

SPECIAL SESSION SUMMARY

The World According to Garp: The Influence of Lay Theories About Others on Consumer Judgment and Behavior

Gita V. Johar, Columbia University
Anirban Mukhopadhyay, Columbia University

SESSION OVERVIEW

The entire field of attribution theory is dedicated to understanding how individuals make sense of the behavior of others. However, there has been far less study of how these inferences in turn affect the perceiver's own judgments and behavior (Furnham 1988). This special session presents ongoing research that examines this issue and provides a platform for a discussion of fruitful research directions.

Research in consumer behavior on the subject of lay theories can be broadly divided into three areas. One well-researched field is that of lay theories of statistical events, which encompasses decision-theoretic attempts to establish how, rather than being sophisticated statisticians, people use 'heuristics' and therefore suffer from 'biases' in their decision making (e.g., Tversky and Kahneman 1974). Another well-researched field is that of expectancy disconfirmation based satisfaction, where the lay theories under investigation are consumers' expectations about the services and products that they purchase (e.g., Oliver 1980). There is, however a third subset that concerns lay theories about people's motivations, abilities, and behavior. Research on the judgmental and behavioral effects of such lay theories about "people in general" is surprisingly scant.

The question of whether such generalized beliefs about others are accurate has generated much interest (Hoch 1988). A related question, that has only now become the focus of research attention, is how consumers' beliefs about others influence their own judgments and behavior. Recent work has shown that these beliefs can affect predictions of the correspondence bias (Van Boven, Kamada and Gilovich 2000), the endowment effect (Van Boven, Dunning and Loewenstein 1999), and hedonic contrast effects (Novemsky and Ratner 2003). The three papers in this session extend this work examining the accuracy, as well as the judgmental and behavioral impact, of beliefs in diverse domains such as others' preferences, motivations, and self-control.

Ratner and Kubowicz investigate people's beliefs about the extent to which others prefer monetary vs. non-monetary responses from firms in cases of service failure. They find that people overestimate others' desire for monetary rewards. This has interesting implications for managers, who may themselves hold such beliefs and therefore over-emphasize monetary means of service failure redressal. In the second paper, Nelson and Miller look at lay theories about approach and avoidance motivation, testing the hypothesis that observers tend to interpret others' actions as approach motivated even when they recognize that their own identical choices were motivated by avoidance. Their results demonstrate this asymmetry, which can have profound effects in several domains of public consumption. Finally, Mukhopadhyay and Johar examine the effects of lay theories of self-control on goal setting and achievement behavior. They find that people who believe that self-control is a limited resource tend to set fewer goals than those who believe that self-control is an unlimited resource. Limited self-control theorists are also less likely to succeed at keeping resolutions unless they are high in self-efficacy.

The topic of the accuracy and impact of lay theories is today at the cutting edge of psychology and consumer research. Taken

together, the three papers in this session constitute a significant step in the study of the effect of possibly inaccurate lay theories on consumers' judgments and behavior, across a variety of domains. This session addresses an important new area, and is relevant to the study of attributions, inference making, implicit theories, and behavioral effects. To this end, the reference in the session title to John Irving's classic novel serves as an ironic reminder about the multiplicity of possible viewpoints, and the pervasive sway of social influence.

"Apologies and Coupons to Resolve Consumer Complaints: How Appealing is Each to You Versus to Others?"

Rebecca K. Ratner and Claudia Kubowicz, University of North Carolina at-Chapel Hill

Research within the consumer complaint literature indicates that consumers care a lot about apologies (Tax, Brown, and Chandrashekar, 1998), especially after a service failure (Gilly and Gelb, 1982). However, apologies are not always forthcoming from firms (Tax et al.). How accurate are people's beliefs about the extent to which consumers care about apologies (i.e., non-monetary responses) relative to other types of actions (e.g., monetary compensation or a free gift) that a firm could take? Do decision-makers underestimate the extent to which others care about apologies?

Previous research demonstrated that individuals often overestimate the extent to which their peers' attitudes and behaviors are based on material self-interest (Miller and Ratner 1998). For example, people think that material stake as a function of group membership will have a larger impact than it actually does on others' attitudes toward social policies. Other studies provided evidence that people overestimate the impact of financial payment on their peers' willingness to engage in prosocial behaviors. In one study (Miller and Ratner 1996), participants overestimated the extent to which their peers' willingness to sign up for psychology experiments depends on the amount they would be paid. In another study, participants overestimated the impact of payment on their peers' willingness to participate as a donor in an upcoming blood drive (Miller and Ratner 1998, Study 1).

In the present research, we investigate whether individuals overestimate the extent to which their peers favor monetary responses from firms attempting to resolve a consumer complaint. Our key question is whether individuals understand the extent to which others care about apologies or whether they instead think that others favor more tangible/money-focused responses (e.g., a coupon for a free product). Based on the results reported by Miller and Ratner (1998), we predict that individuals will overestimate how attractive to others are the responses that enhance material self-interest (e.g., free products).

In a series of experiments, we asked individuals to rate the attractiveness of two possible responses from a firm to a consumer complaint. For example, participants read about a situation in which they have an unpleasant interaction with a rude cashier at a coffee shop. They were asked which of the following they would prefer from the coffee shop if they had registered their dissatisfaction: receiving something for free (a coupon for a free drink) or receiving an apology but no mention is made of a coupon. In several studies,

participants were asked which response they would prefer and which response they think that others would prefer, both in within-subjects and between-subjects designs. Across these studies, participants expected that others' preference for the apology would be weaker than their own.

We tested whether these results would extend to product failures as well as the service failure context described earlier. This is important to explore because previous research indicates that individuals' preferences for tangible rewards are greater in cases of product rather than service failure (Gilly and Gelb 1982). To test this, we made a slight revision to the earlier scenario: instead of describing an encounter with a rude cashier (a service failure), we described to some participants an experience at the coffee shop in which their drink contained spoiled milk (a product failure). As predicted, we found that participants' responses more strongly favored the apology response in the case of the service failure than the case of the product failure. Importantly, the self-other difference emerged again (and there was no interaction), indicating that for product as well as service failure, individuals thought that others' preference for the apology would be weaker than their own.

In additional studies, we find that individuals say they would be less inclined to choose the apology option on behalf of others than for themselves. We also find that people think others' preference for the apology is weaker than their own preference even if the product is a free gift to be sent to their home rather than a coupon; therefore, it appears that the self-other difference is not driven by a perceived differential willingness on their own versus others' part to return to the store (i.e., to redeem a coupon).

The results of these experiments suggest that people overestimate the extent to which others desire monetary responses rather than non-monetary, intangible responses (e.g., an apology) from a firm in cases of consumer dissatisfaction. As a result, managers may devote insufficient attention to providing non-monetary rewards to resolve consumer complaints. This pattern of results indicates how an erroneous lay belief can have important implications for the decisions made by marketers and managers.

“Seeing Choices in the Rejections of Others: Inferring Approach Motivation in Avoidance Motivated Decisions”

Leif D. Nelson, New York University and Dale T. Miller, Stanford University

In an unfortunately frequent circumstance, we are forced to decide between alternatives that offer no particular positives, but have differing degrees of negativity. Under these constraints, we pursue decisions that minimize the harm of the decision outcome, avoiding the most aversive of the possible options. These avoidance motivated decisions are even acknowledged in the pithy cliché of someone choosing the “lesser of two evils.” Nevertheless, despite the ubiquity of this understanding, the presence of avoidance motives runs against our lay theories about how people make decisions.

We hypothesize that when observing someone else make a decision, people infer that approach motives are operating, even when the decision is avoidance motivated. In many consumer decision circumstances, people sort through a number of possible options and select an option that they like most. For the observer, an approach-motivated account is both parsimonious and, in many cases, accurate. The approach-motivation assumption, which operates as a handy heuristic when interpreting preferences much of the time, becomes a liability when interpreting avoidance motivated decisions. In short, because people always seem to choose what they like, observers erroneously assume that people always like what they choose.

Across four studies we investigated the tendency for observers to assume that other people like what they choose. In Study 1, we investigated the asymmetry in motive ascription by looking at how people felt about the voting behavior of others. Prior to the 2000 presidential election, we asked people to identify which candidate they were planning to vote for, whether they were casting their vote principally because they liked their choice or because they disliked the alternative, and why they thought other voters were casting their vote. Consistent with our predictions, most people assumed that other voters were voting for the candidate that they liked, whereas most participants indicated that their own vote was cast out of dislike for the alternative. Despite being personally motivated by avoidance, people judged others in line with their lay theories of approach motivation.

In the second study, people were brought into the laboratory to taste soft-drink flavors and evaluate them. Participants tasted two pairs of sodas, each idiographically determined to have a positive and a neutral flavor or a neutral and a negative flavor. Participants were asked to decide which flavor they preferred and were subsequently told that most other people made the identical decision. Finally, everyone stated how much they would be willing to spend for a can of each of the four soda options, and how much they thought other people would be willing to spend. When making the avoidance-motivated decision between the neutral and the negative options, people thought that similar choosing others would be willing to spend more money for both options than they would themselves. Even when personally guided by avoidance motives, people inferred that others were acting out of approach motives, and therefore liked both of the alternatives more than they did themselves. As predicted, there was no difference for predicted willingness to pay when people were guided by approach motives.

One possible alternative account is that people assume underlying positive feelings for the stimuli (presidential candidates and soft drinks), and therefore assume that other people like the options even when they personally do not. We attempted to rule out this possibility by conducting a similar study in a domain that was explicitly negative: deciding between prison sentences. Participants read a description of someone facing a 10-year sentence in minimum-security prison. Some participants were further told that this same person chose the minimum-security prison sentence over an alternative of the same length at a maximum-security prison “where inmates were forced to do hard labor.” Despite the overwhelming negativity of the decision context, and explicit dominance relationship between the two options, observers inferred that the convict would be willing to spend less money and would be less likely to flee the country if he had chosen the prison sentence than if it had simply been assigned. Even when the context is negative, observers seem to infer a hint of approach motives in the choices of others.

In the final study we returned to a tasting paradigm, this time with a variety of jellybean flavors. Replicating the effects of Study 2, avoidance-motivated participants thought that someone else making the identical decision would be willing to spend more for the same options. We extended this finding by showing that participants selected a suboptimal flavor for the other person, consistent with perceived preferences but not with actual preferences. Finally, when told that they would have to share a single flavor with the other person, out of politeness for the other's apparent preference, participants selected a flavor that was suboptimal for themselves as well as for the other.

Across our four studies, observers tended to perceive approach motives in the avoidance motivated behavior of others. The strong lay belief that other people like what they choose belies personal

experience with numerous decisions guided by dislike for what is rejected. In each of the studies presented here, we examine the impact that these beliefs can have in our interpretation of others, but each of these effects can have consequences for personal decisions as well. Study 4 showed that an ill-conceived politeness can lead to suboptimal decisions, but a fundamental misunderstanding of underlying motives can have more pervasive consequences as well. Beliefs about normative preferences can have a direct impact on the decisions people make. The systematic misperceptions of these norms shown in these studies suggest that people may erroneously see others as liking their chosen options, and neglecting the real uniformity in what other people dislike.

“Where There Is a Will, Is There a Way? The Effect of Lay Theories of Self-Control on Goal Setting and Achievement”

Anirban Mukhopadhyay, *Columbia University* and Gita V. Johar, *Columbia University*

Goal directed behavior has often been modeled as a two-stage process, i.e., the setting of personal goals followed by the effort to achieve them (e.g. Thaler and Shefrin 1981). Research in this area also often recommends strategies with which to bolster self-control and achieve chosen goals. In this paper, we present a different look at the relationship between self-control and goal setting/achievement. Rather than assuming that success at achieving goals is a manifestation of effective self-control, we propose that lay theories or naïve beliefs about the nature of self-control affect the setting and achieving of goals.

Lay theories have been shown to affect judgments and behavior in a number of domains (Furnham 1988). For example, people’s beliefs about the role of individual differences in predicting behavior can influence their impressions of others. Dweck’s program of research demonstrates that theories about whether intelligence is a fixed quantity or an augmentable reserve can affect learning strategies and responses to failure (Dweck 1999). Similarly, we suggest that people’s beliefs about self-control can influence their goal-directed behavior. Specifically, the belief that self-control is a restricted resource (as per Muraven and Baumeister 2000) can determine the number of goals one sets for oneself. Success at attaining these goals will then also depend on an individual trait, self-efficacy, which determines persistence at challenging tasks.

We examine our propositions in the naturalistic but under-examined domain of New Years’ resolutions. It is interesting to note that this popular annual practice closely mimics prototypical goal-directed behavior. New Years’ resolutions are characterized first by people identifying favored outcomes (Thaler and Shefrin’s “planners”), and then by their working towards them (“doers”). Moreover, every resolution can be looked back on and evaluated as being a success or a failure.

Given this context, three studies were conducted to test these propositions in the domain of setting personal resolutions. The first two studies investigated the effects of lay theories that are manipulated or measured on setting resolutions, both general as well as consumption oriented. In Study 1, participants in a 2 x 2 between subjects design read passages that stated that self-control is a limited [or unlimited] resource that is also fixed [or malleable]. Following this “Reading Comprehension” survey was a “Motivation Assessment Questionnaire,” that looked completely different from the reading comprehension survey (e.g., a different font) to prevent participants from making any connections between the lay theory manipulation and this measure. Participants were presented with a blank table and asked to list all their current “personal, academic, or financial / consumption-related” goals, in as much detail as possible. It was found that “Unlimited-Malleable” theo-

rists set the highest number of resolutions; moreover, the resolutions were rated to be equally important across conditions.

Study 2 provided more direct evidence for the role of lay theories of self-control by showing that making people aware of their lay theory prior to setting goals can reverse the effect such that Limited-Malleable theorists set the highest number of resolutions. Participants’ lay theories were measured rather than manipulated, and the order of the lay theory measurement and goal-setting tasks was counterbalanced. As expected, the results of Study 1 held when the lay theories were measured afterwards, and were reversed (for malleable theorists) when the measurement preceded the goal setting.

The final field experiment extended the investigation to success or failure at goal achievement, manipulating respondents’ lay theories and assessing their impact on New Year’s resolutions in real time. This study was conducted in two phases, with respondents listing their planned resolutions in November, and then reporting on their success at keeping these resolutions the following March. Respondents’ lay theories were manipulated by making them read passages from credible sources that either stated that self-control is a limited resource (Muraven and Baumeister 2000) or that it is an unlimited resource (Descartes, quoted in Elster 1999). Consistent with the previous studies, unlimited theorists (respondents who read the Descartes passage) set more resolutions than limited theorists. Further, limited theorists who were low in self-efficacy reported significantly less success at keeping their resolutions than those in other conditions.

To summarize, we demonstrate that peoples’ lay beliefs about the nature of self-control can have a direct and tangible impact on their goal-directed behavior. Across the studies we measure or control for several factors including participants’ ratings of own self-control, goal difficulty, and number of goals. These non-intuitive findings are not only of relevance to the immediate theoretical study of naïve theories and self-control, but indeed to many other domains where planned action towards single and/or multiple goals is involved (e.g. savings, investment, health-related behaviors).

SPECIAL SESSION SUMMARY
Consuming Cyborgs: Researching Posthuman Consumer Culture
Markus Giesler, York University

SESSION OVERVIEW

Technological products and networks all around us dramatically change not only the electronic infrastructure of the markets, but also the social fabrics of consumers' lives. Yet despite its widely acknowledged significance, particularly in the context of consumption, technology has rarely been mentioned in the consumer behavior literature. As Glazer (1995) has pointed out, most of our understanding of consumer behavior is at best "technology neutral." To improve upon this impoverished view, the idea of posthuman consumer culture was explored and developed in this session as the symbiotic relationship between (1) the cultural frameworks that orient how consumers interact with commodities, (2) the economic priorities of the market and (3) the "heteroglossia of voices" on how, through the excessive consumption of high-technological products and networks, to alter our notions of what means to be human in the Cartesian sense.

First, Alladi Venkatesh illustrated the difference between traditional and posthuman epistemologies in marketing and explained why consumer researchers should attend with particular vigilance to posthuman thought on the epistemological level of analysis. Markus Giesler then presented ethnographic findings from Napster.com and proposed the cyborg as posthuman consumer and the prism of European (Luhmannian) social systems theory as one possible posthuman epistemology of consumption. Analyzing the consumption of popular Japanese Anime action figures, cultural critic and technoculture writer Erik Davis finally developed and explored steps to an ecology of virtual commodities.

The discussion leader Robert Kozinets commented on the ability of each presentation to provide novel insight into the cultural interplay between consumption and technology, to emphasize the import of a posthuman epistemology of consumption beyond the Cartesian legacy of the subject, and to explode posthuman dualisms such as materiality and information or mutation and hyperreality. Among other aspects, the discussion pointed to the conceptual groundwork laid by cyberneticist Norbert Wiener and phenomenologist Martin Heidegger and raised the importance to better understand the deep "technopolitical" consequences of posthuman consumer culture and society with respect to the posthuman incredulity towards the Cartesian subject.

"Posthumanism and the Sciences of the Artificial: Some New Directions for the Epistemologies of Consumption"

Alladi Venkatesh, University of California

The term, posthumanism has come to mean several things from non-aging bodies to grafting of silicon chips into the brain to probing into the deeper recesses of the mind. Recent writings on posthumanism suggest that we may be entering a new era concerning how we conceptualize human bodies and mental structures (Gray 2001, Halberstam and Livingstone 1995, Haraway 1991, Hayles 1999, Rutsky 1999). Some consumer scholars are also attempting to explore posthumanism and its implications to consumption and marketing practices (Venkatesh, Karababa, and Ger 2002). Although not strictly cast in terms of posthumanism, Zaltman's (2003) recent work on ZMET techniques contain some elements of posthumanism.

What is posthumanism? Katherine Hayles (1999) looks at it as the intersection of human mind and intelligence machines. Donna Haraway (1991) repeats a similar theme in her work on cyborgs.

Both Hayles and Haraway rather unwittingly capture the notion of the "artificial" as espoused in an earlier work by Herbert Simon (1982). Featherstone and Burrows (1995) view posthumanism as creating new cultures of technological embodiment. In this presentation, I will be concerned with the notion of the artificial and its connection to posthumanism. I will attempt to discuss the implications of these developments as we reconfigure our epistemologies of consumption.

I will begin the paper with Herbert Simon's seminal work, *The Sciences of the Artificial*. In his well-known book resulting from a lecture series, Simon has argued that many branches of human knowledge and practices—science, business, law, architecture etc, are concerned with the contingent, that is, not with how things are but how things might be—in short with "design."

For Simon all human ingenuity has been directed toward the creation of the artificial as opposed to what is already given, the nature. Nature is not a human creation, it already exists. But many entities we consider to be natural according to Simon are really man-made. Thus, the forest may be a phenomenon of nature; a farm is not, and the plowed field is no more part of nature than an asphalted street. However, what is remarkable about the world of the artificial is that all artificial entities are subject to the laws of nature and there can be no exception. An airplane is able to fly not because it defies the laws of gravity but because it obeys the laws to their last detail, otherwise the result can be quite disastrous.

It is in this context of the construction of the artificial that I place the whole discourse on posthumanism.

The human civilization is a march toward the creation of artifacts that are designed to adapt to natural systems. Associated with each artifact is a set of practices. When several artifacts are assembled together we create a system of practices. The basis of any system of practices is a system of knowledge. Systems of knowledge are known as epistemologies. As human beings, we try to adapt to the systems that we create. When the systems do not serve our purpose, we change the systems and the artifacts. It means that we also change our epistemologies. All these elements, artifacts, systems, and epistemologies are the artifacts of human ingenuity. However, in the Cartesian world, there has been one constant, the human mind, for it is sacrosanct and defines what it is to be human. In our march through history, we have been careful not to tamper with this human element. Only in science fiction we see attempts to change the human character with some serious consequences. Science fiction captures our imagination but sets limits to it. Thus the world of Frankenstein or Dracula excites our imagination but reminds us what can happen if we play with nature. In Simon's work, we do not deal with the artifacts of science fiction but objects of practical design that we create in the real world in order to experience them physically or phenomenologically. When this involves transgressing the world of the natural, we take risks. Another term for this risk taking is human progress.

To elaborate this point, Simon was careful to argue that none of the artifacts destroy the humanness of our lives. All systems are created so we preserve their human quality. The various artifacts we create are meant to enrich our lives. In the world of artifacts, Simon did envision the possibility of the merging of the human and the machine. He called this artificial intelligence. However, he was careful to note that what he is after is not to turn the human into machine, but to make machines more human. Thus computers are

computational machines of extraordinary capacity. It is in the same vein, that biological models have been injected into artifacts. The airplane was invented to mimic the flying bird. Similarly, the automobile was invented so it could run faster than a horse. In all these examples, the humanness did not change, only the world of artifacts did.

Where does posthumanism fit into this? Posthumanism seems to change the “humanness” of our existential condition rather radically. Simply put, it is an attempt to alter our notions of what is to be human in the Cartesian sense. According to Haraway (1995), Featherstone and Burrows (1995), Hayles (1999) and others, this can occur through cybernetic advancements. It is an attempt to extend the Simoinian world where machines can not only do routine computational tasks but can actually think logically and act linguistically. Posthumanism thus envisions changing the make-up what it is to be human. Thus, for example, electronic chips can be grafted into the human body and brain and all the primordial notions of what it is to be human can be altered in the process.

The consequences of posthumanistic advances to the world of consumption are quite substantial. Traditionally, our notions of what a consumer is whether he/she is an information processor or a cognitive subject or a cultural subject is derived from systems of humanistic epistemologies. The question is what kind of epistemologies can we envision in a posthuman world? My paper will address these issues.

“Consuming Cyborgs: Posthuman Consumer Culture and its Impact on the Conduct of Marketing”

Markus Giesler, Kellogg School of Management

In this presentation, I will discuss important findings from two years of extensive ethnographic case research on Napster.com and offer a variety of new insights into the praxis of posthuman consumption. In the consumption of Napster we find articulated some of the key facets of posthuman consumer culture that are interwoven in some of the most popular contemporary entertainment consumption practices (e.g. Giesler and Pohlmann 2003a, 2003b). I will show how Napster has promoted an emancipative space of choice enabled through infomedia technology, cultivated by interconnected cyborg consumers and operationalized through the code of the electronic gift. In doing so, my examination of Napster consumption provides both an excellent example of posthuman reality in consumer culture and an example of posthuman epistemology utilized in qualitative consumer research.

To best reveal the idea of posthuman consumer culture, I examine the phenomena that it structures: Napster consumer’s Internet music related consumption experiences. Interviews with Napster consumers and archival data were collected over the past three years to map micro consumption discourse and practices in order to build an understanding of the moderato and macro cultural processes constructing posthuman consumer culture. Two complementary methodological approaches that are oriented toward theory construction are used: the deductively-oriented approach of Burawoy’s (1991) extended-case method and the inductively-oriented approach of Sherry and Kozinets’ (2000) netnography.

This presentation (a) advances the theoretical notion of posthuman consumption; (b) searches for evidence of its existence in entertainment consumption situations; (c) discovers some of the manners, mechanisms, and particularities of posthuman consumption; and (d) situates these findings within the broader sociological and consumer literatures. My findings reveal that (1) Oscillation and paradox are hypothesized to have important effect as two basic cultural logics of posthuman consumption and (2) a systemic five-step schema is developed to illustrate the dynamics of posthuman consumption on the moderato level of analysis. (3) Information,

materiality, mutation and hyperreality are introduced as dimensions for (4) the semiotic square of posthuman consumption, a unifying framework that offers a macro perspective on posthuman consumption.

“Who Am We?” asks Sherry Turkle at the beginning of her seminal book *Life on the Screen—Identity in the Age of the Internet* (1995) alluding to her self as a multiple, distributed system and the paradigmatic move from modernist calculation toward postmodernist simulation. As we stand on the boundary between the real and the virtual, our experience recalls what Victor Turner (1985) termed a liminal moment, a moment of passage when new cultural symbols and meanings can emerge. Napster consumption uniquely inflects the complex ways in which these multiple viewpoints become enacted through positional “We(s)” that alter Napster participants’ consumption meanings through the exchange of songs on the screen. In an age where materiality tends towards ascendancy over information, what metaphor could be more fitting than that of the organism as an information system linked to prosthetic machines—the *cybernetic organism* also known as the *cyborg*?

“The Emergence of Virtual Commodities”

Erik Davis TechGnosis

Let us define “posthuman consumption” as the circulation of desire and commodities in environments that are so highly mediated and technological that it begins to generate behavior and situations that are quite foreign to existing thinking about what markets are and what consumers want. Then we can expect to find posthuman consumerism particularly advanced in the most virtual of environments today—the massive multiplayer online games like Ultimate Online or Everquest. And we do. These environments are not simply breeding their own increasingly complex economies (largely based on the scarcity of various objects, including land, as well as the man-hours logged improving characters). They are also giving us a glimpse into the sort of retail environments that may increasingly shape consumer experience—especially among the young and wired consumers who constitute the leading edge of posthuman consumption.

In these environments, I argue, the logic of brands is almost entirely severed from actual material commodities, becoming a kind of virtual animated style element—like the different avatar bodies that are bought off the shelf in Neil Stephenson’s (1992) *Snowcrash*. Here we see a space where the already rapidly oscillating movements of fashion can even more quickly sculpt the infinitely plastic material of virtual space. Nonetheless, the virtual environment also poses tremendous challenges to traditional models of consumption and intellectual property, and monetizing virtual reality will remain a pitched battle for some time.

Analyzing prominent science fiction literature such as William Gibson’s (1984) *Neuromancer* and Neil Stephenson’s (1992) *Snowcrash* in this presentation, I identify the ferocious cultural role of the “virtual,” defined as a sort of free play of the imagination that is captured and circulated through technological rather than psychological means. I suggest that posthuman consumers will and already do live inside of cartoons. Insights gained will help consumer researchers better understand the growing import of the virtual in every domain of everyday material life. The consumption of goods in the real world will be increasingly shaped by the fluid fantasies of the virtual, a process we can begin to understand by looking at the transformation of the styles associated with animation, especially Japanese anime comic consumption.

SPECIAL SESSION SUMMARY
Advances in the Study of Creative Cognition in Consumer Behavior

James E. Burroughs, University of Virginia
Page Moreau, University of Colorado

SESSION OVERVIEW

Since Guilford's (1950) landmark presidential address to the *American Psychological Association*, creativity has been an integral part of psychology, particularly in the domain of problem solving. A great deal of this work has focused on what is termed, "creative cognition" or how various thought processes and abilities impact creative outcomes (Finke, Ward and Smith 1991).

By contrast, research on creativity in consumer behavior is scant. Consumer researchers have focused almost exclusively on understanding the ways in which consumers learn about, construct preferences for, and choose among existing product alternatives. It is presumed that marketers identify and provide for consumer needs with limited regard for the possibility that consumers may meet needs creatively. Yet in many situations consumer needs are specific and unique, requiring the individual to play an integral part in manufacturing a novel solution to a given consumption problem. Examples include the need for an appropriate menu for a dinner party, for the "right" business casual wardrobe for a conference, for an updated room decor, or for a romantic week-long vacation. Across a variety of domains, consumers often act as their own agent of change, sourcing necessary components and assembling the parts to meet specific goals. More than 20 years ago, Hirschman (1980, p. 283) noted this deficiency in consumer research: "investigations of creativity have not focused on its potential applicability to everyday consumption activities." Unfortunately, this situation remains.

In the interest integrating creativity more fully into consumer research, we brought together three papers that examined theoretical, practical, and methodological aspects of creative cognition in a consumption context. The first paper presented by Darren Dahl and Page Moreau examines the role of constraints on generative and exploratory thinking by consumers in the context of new product ideation. This work also extends into the motivational and affective aspects of creative thought, considering not only the quality of consumers' creative thoughts but also their enjoyment for the task. The second paper presented by Tom Ward also used consumer product ideation as the platform of investigation, but focuses on the impact of abstract versus concrete thinking on creative outcomes. Finally, the third paper presented by Jim Burroughs and David Mick examines the role of metaphoric thinking ability in creative consumption. They reported on the development of a new instrument for assessing metaphoric thinking ability, including an initial test of the instrument in a consumer problem-solving context.

To date, understanding of the nature and role of creativity in consumer behavior is limited. The three papers presented are designed to address a different aspect of this deficit. Dahl and Moreau's work provides much needed theory on the role of environmental conditions (constraints in particular) in impacting creative consumption. Ward's research harbors practical implications for the types of thinking that should be engendered to optimize creative outcomes in areas such as new product design. Burroughs and Mick's work makes more of a methodological contribution, providing a tool for assessing an important construct within the realm of creativity. Combined, it is hoped that this research will stimulate greater appreciation for, and interest in, the study of an undeniably important aspect of human functioning.

"Manufacturing the Solution: The Role of Constraints in Consumer Creativity"

Darren Dahl, University of British Columbia
Page Moreau, University of Colorado

In this research, we examine the influence of constraints on the creative process and its outcomes. Three studies are undertaken to this end. Our first study examines the influence of input constraints on the type of information processing consumers undertake in a creative task. Specifically, we examine the effect of (1) restricting the parts available and (2) mandating the number of parts on the strategies used by consumers in creating a new toy. Using protocol data, we trace consumer's information processing strategies and show that both types of input constraints promote the use of more generative and exploratory thinking. A set of professional designers rated the creativity of the toys developed in the task, and we find a strong, positive relationship between the rated creativity and the degree of generative and exploratory thinking employed.

Using the same design as the first, the second study examines the influence of the same two input constraints on the consumers' subjective experience during the task. Specifically, we examine the influence of constraints on different forms of motivation, and we find that when the constraints are operating, consumers enjoy the task less and are less likely to have their motivational needs (i.e., autonomy and competence) met. Thus, while the constraints we employed improved the quality of the outcomes of the creative task, they reduced the quality of the consumer's experience. We know from the success of retailers who support consumers' creative endeavors (e.g., Michaels, Lowe's, Martha Stewart), however, that offering constrained creative opportunities is rewarded in the marketplace.

To better understand this apparent contradiction, it's important to take a closer look at the types of constraints operating. In the first two studies, the constraints employed involved the inputs used by participants when constructing their new idea. But there were no constraints on how these inputs were used or combined to form the outcome. Hence, an almost infinite number of solutions could still be constructed. Would constraining the process or the outcome influence perceptions of autonomy and competence differently than constraining the inputs? To answer this question, we ran a third study in a more realistic consumer situation, and we manipulated whether or not the outcome and the process were constrained. Specifically, we had participants bake cookies under a variety of task conditions. Half of the participants were required to make a specific cookie and to decorate it in a specific way; the other half were simply required to make a cookie. To manipulate constraints on the process, we varied the amount of instruction provided. Finally, we measured baking experience, hypothesizing it as a moderator of the effects of the constraints. All three factors interacted to influence consumers' subjective experience.

"Strategic Approach and the Degree of Novelty in New Idea Generation"

Thomas B. Ward, University of Alabama

In this research I examine the role of alternative idea generation strategies in consumer creativity and new product ideation. In particular, I focus on the influence of abstract versus concrete

thought on the originality and acceptability of ideas people develop for new sports and new forms of entertainment. Previous research has shown that the majority of individuals who are asked to develop new ideas for a given domain (e.g., novel fruit or tools) begin by retrieving highly accessible, specific domain instances, whereas a minority begin by considering more abstract forms of information. The latter produce ideas that are rated as more original, suggesting that more product innovation might be obtained through abstract as opposed to concrete strategies. In the present studies I asked whether the additional originality afforded by abstract approaches might be obtained at a cost to the acceptability of the ideas. Can too much originality negatively impact acceptability?

For the domain of sports, participants performed one of two separate tasks. Fifty-eight participants listed known instances of sports and 87 used their imagination to develop ideas for new sports and then reported on the factors that had influenced their creations. The lists of known instances were used to determine the most accessible instances in the domain (e.g., baseball was highly accessible as indicated by the fact that it was listed by 56 of 58 participants, whereas shot put was listed by only 2). The new sport designs and reports of influential factors were used to determine which participants had relied on known instances in designing their novel sport and which sport instances were used most often. Consistent with previous research, the majority of participants (69%) in the imagination task reported retrieving specific known instances of sports (e.g., baseball), whereas the minority reported thinking about more abstract considerations (e.g., the purpose of competition in sport). Accessibility of known instances was influential in that there was a strong positive correlation between the number of participants who listed a given sport as a known instance and the number who used that sport as the basis for their novel creation, $r=.78$. Also consistent with previous research, the novel sports designed by those who retrieved specific known sport instances, were rated as significantly less original than those developed by participants who accessed more abstract forms of knowledge. However, they also received higher acceptability scores, in particular, ratings of how likely it is that people would want to play the new sport. In addition, there was a significant negative correlation between ratings of originality and ratings of the likelihood people would play the sport, $r=-.23$. Similar results were obtained in a study that used forms of entertainment as the knowledge domain.

The results suggest that there is a balance between the originality of new product ideas and their likelihood of their being deemed acceptable, and this balance is directly influenced by the strategy used in developing the ideas. Abstraction increases originality, but can decrease acceptability. When more novelty is desirable in a new product, accessing abstract principles could be most appropriate; when more familiarity is the goal, retrieval and modification of specific known exemplars may be more effective.

“Development of a Test of Metaphoric Thinking Ability and Initial Validation through a Creativity Experiment”

James E. Burroughs, University of Virginia

David Glen Mick, University of Virginia

In this research we develop and test an instrument for assessing metaphoric thinking ability (the MTA—SC; see Appendix). Metaphors are fundamental in human thought (Lakoff and Johnson 1980). Because they take abstract, remote and unfamiliar concepts and relate them through the concrete and familiar, they are also indispensable in the creative process. Cognitively speaking, they help connect solutions from previously disparate domains to new problem contexts (Runco 1991). Unfortunately, empirical research on the relation between creativity and metaphor has been hampered

by a lack of valid methods for assessing metaphoric thinking ability. Moreover, the few instruments that do exist are beset by a number of limitations. They are either applicable to a limited population (i.e. children; Polio and Polio 1979), cumbersome to administer and/or score (see e.g., Barron 1988), or they explicitly call for the use of metaphors in completing the task (see e.g., Helstrup 1988). This latter situation is problematic for creativity research because it is essential that individuals be allowed to freely access metaphors in structuring thought. Given these limitations, we sought to develop a new instrument that would be useful for adults, easy to administer and score, and would allow metaphor to naturally represent itself in thought.

We followed standard scale development procedures (i.e. generation of multiple items, analysis and paring of items, etc.) and discovered a sentence completion task worked best. Respondents are provided with sentence stems that can then be completed either literally or metaphorically. For example, one truncate is, “Helping someone is...” Responses are then independently scored on three levels. The lowest score is assigned for literal completions, such as, “Helping someone is the right thing to do.” Intermediate scores are assigned for statements which are metaphorical in content, but represent “dead” metaphors (i.e. they have become integrated into common use in the language). An example is, “Helping someone is to lend a hand.” Finally, the highest score is assigned for statements that are metaphorical and generative in content. For example, one of our respondents said, “Helping someone is to make a deposit in the bank of Karma”.

Two validity checks were undertaken on the new instrument. First, a known-groups validity check was conducted using copywriters at Grey advertising in New York. Confirming our expectations, these copywriters scored significantly higher on the MTA—SC than respondents drawn from the general population. Second, the nomological validity of the test was assessed. Respondents in an experiment were given a basic consumption problem to solve (facing a social situation of being late for a dinner when they discover their shoes are scuffed and they are out of polish). The results indicate that individuals higher in metaphoric thinking ability produced more creative solutions to this problem. We hope that this new instrument opens the way for new research on metaphor and creativity.

Examining the Mediating Relationship of “Play” on Ritual Enduring Involvement

Lee Phillip McGinnis, Washburn University

James W. Gentry, University of Nebraska

ABSTRACT

The focus of this study is the examination of the effects of perceived sacredness of a particular consumer ritual on consumers' level of “play” and enduring involvement. In this study, the sociological concept of “play” is operationalized as flow, *communitas*, and ecstasy. We also examine the relationship between the components of play and enduring involvement and how play can serve as a mediator. In a study of experienced golfers, play is found to mediate the relationship between the perception of golf as being sacred and one's enduring involvement in the game.

INTRODUCTION

Belk, Walendorf, and Sherry (1989) examined sacredness as consumption that exceeds everyday needs. They contended that sacred consumption has the potential to become a vehicle of transcendent experience. In this study, we examine the consumption of a male-dominated ritual—golf—that we believe has the potential to be considered sacred. We contend that the more people consider a ritual domain to be sacred, the more likely they will gain the positive outcomes of a ritual, which, in this case, are operationalized as ecstasy, flow, and *communitas*. We also contend that those who consider golf to be sacred will also experience higher levels of enduring involvement, but such an effect will be mediated by our conceptualization of “play” and the individual components of play (*communitas*, flow, and ecstasy). In order to achieve enduring involvement, we contend that perceptions of sacredness are not enough; people need to experience the “fruits” of a ritual first before they can establish enduring involvement (see Figure 1). More specifically, we hypothesize that seeing golf as “sacred” will have a direct effect on one's enduring involvement, but also that one's experience of “play” will serve to enhance that relationship.

Golf may be considered a ritual because it satisfies the conditions noted by Rook (1985), who asserts that ritual behavior can include both everyday and extraordinary human experiences. More specifically, ritual behaviors are positive and meaningful aspects of life that occur in fixed, episodic sequences. These behaviors have a tendency to be repeated over time in a dramatic and serious fashion with inner intensity. Our background interviews and research indicate that golf is definitely an activity that can be dramatically scripted, treated with inner intensity, and repeated over time.

We begin this paper with an investigation into sacredness. We then examine our conceptualization of play and discuss the individual components (*communitas*, flow, and ecstasy) that comprise play. Next, we explore the hypothesized relationships involving sacredness, play, and enduring involvement. The results of these relationships will be analyzed and discussed.

BACKGROUND AND HYPOTHESES

Sacred versus Profane

According to Durkheim (1915), sacred items are special things, protected, isolated, separated, prohibited, and inaccessible. Durkheim, as interpreted by Belk et al. (1989), saw sacred things being beyond individual creation. He also contended that the sacred could emerge collectively when society removes things from ordinary human usage. Belk et al. (1989) contend that sacred does not necessarily have to mean religious; some elements of life can have no connection to religion and yet be revered, feared, and treated with respect by consumers.

Belk et al. (1989) explain that sacredness can best be defined in terms of contrasting it with the profane (i.e., the ordinary parts of life). In determining sacredness then, it is important to consider its opposition to the profane. Belk et al. (1989) came up with eleven other properties of sacredness other than opposition to the profane that make something sacred, including ritual, myth, *kratophany*, *hierophany*, ecstasy and flow, and *communitas*. Belk et al. describe *communitas* and myth as primarily social concepts, and ecstasy and flow as primarily psychological. Sacred consumer domains potentially fall under six categories: places, times, tangible things, intangibles, persons, and experiences (Belk et al. 1989). We argue that golf is especially susceptible to being considered sacred due to its long, rich tradition, adherence to strict conduct and etiquette, and how seriously people treat the game.

Play: *Communitas*, Flow, and Ecstasy

In this section, we examine the concept of “play” and demonstrate how the game of golf is capable of providing a playful experience. The term play or playfulness has been used in a variety of contexts, but all definitions appear to describe play as a sense of self-determined freedom without constraints. For example, Deegan (1989, 1998) describes play as anti-structure in nature where one is truly liberated from the underlying manipulative structures of modern society. Holt (1995) describes play in a consumption context as capturing the autotelic dimension, in which the consumer-object-consumer interaction has no ulterior end. Play that is not truly liberating is what Deegan (1989) calls “fun.” Fun has the appearance of play, but it is not. Fun, or “good times,” is the outcome of rituals generated in such contexts as discrimination, capitalism, bureaucracy, and technological control. Thus, Deegan labels fun as a flawed *communitas* experience.

Based upon the definitions listed above, however, we contend that play in the context of a sacred ritual experience can be defined in terms of *communitas*, flow, and ecstasy. Even though more constructs could be added in the context play, we restrict our use to these in order to capture what we think are the most common experiences gained from leisure activities such as golf. These experiences, for the most part, closely coincide with Deegan's (1998) use of “play” and “playfulness,” which are key components in the ritual framework.

Communitas: With *communitas*, social categories and status disappear, and people of the same condition develop intense but fleeting feelings of comradeship and egalitarianism. Authentic *communitas* can be established as a result of play, “wherein each member's essential humanity is recognized and shared” (Deegan 1998, p. 7).

Flow: Flow is described as exceptional moments that stand out as being the most memorable yet effortless in people's lives. It is akin to the concept of “being in the zone,” whereby a person loses track of self-consciousness and time. During flow, “a person loses contact with ordinary reality and experiences heightened sensory appreciation and flow of time and space” (Deegan 1989, p. 26). Flow is the serenity a person feels when the heart, will, and mind are all on the same page (Csikzentmihalyi 1997).

Activities likely to produce flow include those that have clear-cut yet challenging goals. “Conflicting desires, intentions, and thoughts jostle each other in consciousness, and we are helpless to keep them in line” (Csikzentmihalyi 1997, p. 28). Flow, or peak experience, occurs when a person's skills are fully engaged in

FIGURE 1
The Mediating relationship of play

accomplishing a challenging goal. It is evident that golf is capable of producing a flow experience because it does provide clear-cut goals as well as other attributes for its participants. Golf may be particularly suited to such experiences due to its serene settings and challenging nature.

Ecstasy: Ecstasy, for the purpose of this study, is the third operationalized component of play. Belk et al. (1989) describe the sacred as being capable of producing ecstatic experiences whereby a person stands outside of one's self. It has also been described as a joy that arises from the transcendental reality of sacred things. In addition, ecstasy is a momentary experience, which marks the extraordinary character of sacred experiences (see Belk et al. 1989). Ecstasy should be present in golf, as it is in settings such as baseball spectating (albeit rare), due to its ability to create dramatic situations (e.g., the unexpected spectacular shot) and outstanding performances (see Holt 1992). However, like flow and *communitas*, it is unlikely that a person who feels alienated from a domain will experience ecstasy due to the fact that the mind is not free from disturbance. Alienation blocks the needed mental capacity to experience positive, if not transcendental, emotions.

Belk et al. (1989) describe *communitas*, flow, and ecstasy as properties of sacredness. While perhaps a property of sacredness, it appears from Belk et al.'s (1989) description that *communitas* could also be an outcome of a sacred ritual experience. Belk et al. (1989) describe ecstasy and flow in similar fashions, writing that “the sacred is capable of producing ecstatic experiences” (p. 8), while flow refers to the psychological “effect of participation in the sacred” (p. 9). Deegan (1989) alludes to *communitas* as an outcome of the ritual experience as well. In describing baseball spectating as sacred ritual, Holt (1992) uses a passage from Turner (1969) that suggests transcendent experience, or ecstasy, is an outcome of sacred ritual. Overall, it is quite clear that all three components of “play” (*communitas*, flow and ecstasy) are likely outcomes of a sacred ritual experience; those who report higher levels of perceived sacredness are likely to report higher levels of *communitas*, flow, and ecstasy.

H_{1a} : The greater one perceives golf to possess sacredness, the greater the level of *communitas*.

H_{1b} : The greater one perceives golf to possess sacredness, the greater the level of flow.

H_{1c} : The greater one perceives golf to possess sacredness, the greater the level of ecstasy.

Sacredness and Enduring Involvement

Richins and Bloch (1986) suggest that enduring involvement is the degree to which the product relates to the self or the pleasure one receives from the product. Higie and Feick (1989) suggest that enduring involvement is “an individual difference variable representing an arousal potential of a product or activity that causes personal relevance” (p. 690). They found that enduring involvement has two distinct components: hedonism and self-expression. Based upon Belk et al.'s (1989) analysis of the sacred and what emerges from things that are considered sacred (i.e., heightened commitment), we argue that those who consider golf to be sacred will also display higher levels of enduring involvement.

H_2 : The greater one perceives golf to possess sacredness, the greater the level of enduring involvement.

We also contend that play reinforces the personal importance of a ritual, which ultimately leads to one establishing enduring involvement. When people experience salient aspects of play, such as flow, they are likely to attempt to re-experience that state (Celsi et al. 1993). Further, one can argue that having the desire to repeat an activity can ultimately result in that activity becoming more serious and central to that person, therefore helping that person establish enduring involvement. In sum, we contend that experiencing higher levels of play will lead to higher levels of enduring involvement.

H_3 : The greater the level of play experienced while playing golf, the greater the level of enduring involvement.

The Mediating Effect of Play in the Sacredness—Enduring Involvement Relationship

Even though it is expected that higher levels of sacredness will have a positive influence on enduring involvement, we also expect that play and the components of play will mediate a relationship between sacredness and enduring involvement. A variable is said to serve as a mediator to the extent it explains the relationship between a predictor and criterion (Baron and Kenny 1986). We contend that when people experience the positive effects (*communitas*, flow,

TABLE 1
Scale Reliabilities for Domain Sacredness, Play and Enduring Involvement (After Purification)

Scale	Pretest 1	Pretest 2	Pretest 3	Final Survey
Domain Sacredness				.84* (6 items)
Places	.92	.85	.74	.78
Times	.94	.93	.91	.73
Tangibles	.86	.88	.90	.90
Intangibles	.86	.78	.90	.83
Persons	.74	.88	.81	.84
Experiences	.81	.83	.87	.82
Play				.90*
Communitas	NA	.86	.86	.79
Flow	.85	.89	.89	.81
Ecstasy	NA	.94	.90	.84
Enduring Involvement	.96	.93	.93	.86 (2 factors)

NOTE—Some scale items may have been altered or added from one pretest to the next.

and ecstasy) of something they consider to be sacred, they are likely to experience higher levels of enduring involvement than they would without experiencing these effects. Play is that part of a ritual that leads to ongoing pleasure and makes a person want to continue in that activity and establish what is known as enduring involvement. Play is also that part of ritual that helps a person make sense of everyday life, makes a person feel alive, part of a community, and re-energized (Deegan 1989). In short, we contend that play is that part of a ritual that makes the meaning of an activity more salient and more memorable. Thus, while sacredness is seen to lead to enduring involvement in the game of golf, that relationship is enhanced through the experience of play in the game's rituals.

H₄: The relationship between sacredness and enduring involvement is mediated by the linear combination of "play" and each of its individual components.

METHODOLOGY

Scale Development

The scales for this study were taken from the literature and adapted to the context of golf or were created from conceptual definitions. Enduring involvement and flow fall under the previous category while domain sacredness, communitas, and ecstasy fall under the latter. Each scale was tested on three different occasions (not including the final survey) with undergraduate college students. All scales were purified going through an iterative process involving the analyses of item-to-total correlations and the exploratory factor analyses (see Gerbing and Anderson 1988).

For sacredness, we used conceptual definitions from Belk et al. (1989) to create our items. Items were created from each of the six domains of places, times, tangible things, intangibles, persons, and experiences. We obtained a one-factor solution with six items and an ending alpha of .84.

For the concept of play, which was operationalized through communitas, flow, and ecstasy, scale purification was more simplified and straightforward. Using conceptual definitions from Belk et al. (1989), Deegan (1989, 1998), Holt (1995), and Turner (1969),

we formulated a six-item scale, one-factor scale for communitas that had a final alpha of .79. Flow, in our study, is a seven-item one-factor scale developed largely from the conceptual definitions of Belk et al. (1989), Csikzentmihalyi (1990, 1997), and Deegan (1989, 1998) and from a scale from Stein et al. (1995). Flow had a final alpha of .81. Ecstasy was also developed from conceptual definitions taken from Belk et al. (1989). Ecstasy is a six-item, one-factor scale with a final alpha of .84. The three constructs, which were highly correlated, were combined to get an overall measure of play, with an aggregate alpha of .90.

For the enduring involvement scale, items from both McIntrye (1989) and Higie and Feick (1989) were adapted into a golf context for this study. We also added some items that combined the use of pleasure with one's intent to play golf for the long run. Even though it might be possible to argue that one's long run intent bordered on a behavioral outcome, we felt that such a component only added to our understanding of the depth of one's involvement in golf by focusing on the time aspect of enduring involvement. Enduring involvement in this study is a nine-item, two-factor scale with an ending alpha of .86 (see Table 1).

Sample

In all, 2,000 questionnaires were sent to golfers belonging to a midwestern state golf association, with 1,200 going to women. The total list had over 17,000 names, with 14,683 men and 3,068 women. The list was cleaned of all names that had either incomplete addresses or addresses of the participant's home golf course. Once all names were alphabetized, approximately every 18th name on the men's list was selected while every third name on the women's list was selected. A total of 165 surveys were returned due to insufficient or outdated addresses. The overall response rate for the mailed questionnaires was 41.8 percent. The response rate for women (43.5 percent) was slightly higher than that for men (39.3 percent). A total of 767 surveys were entered.

RESULTS

We begin this section with a look at the construct means. Enduring involvement had the highest mean (5.32) followed by

TABLE 2
Means for Model Variables

Scale	Grand Mean (N=767)	5 years or less (N=56)	5 – 20 years (N=362)	Over 20 years (N=349)	F (sig.)
Play	4.59	4.34	4.60	4.62	3.43 (.03)
Comm.	4.98	4.65	4.92	5.08	8.51 (.00)
Flow	5.12	4.94	5.12	5.14	1.35 (.26)
Ecstasy	3.68	3.42	3.76	3.63	3.48 (.03)
Enduring Inv.	5.32	4.93	5.27	5.43	10.76 (.00)

Note—Scales ranged from strongly disagree (1) to strongly agree (7).

FIGURE 2
The Mediating relationship of play

flow (5.12) and *communitas* (4.98). Only the mean for ecstasy came under the scale’s midpoint at 3.68, indicating that golfers experience few moments of ecstasy on the golf course (see Table 2).

In terms of our hypothesized relationships, results generally went in the predicted direction. H_{1a} through H_{1c} tested whether a positive relationship exists between sacredness and the components of play: *communitas*, flow, and ecstasy. Each path was significant at an alpha of .05. The standardized coefficient between sacredness and *communitas* was .45 ($p < .001$), the path between sacredness and flow was .53 ($p < .001$), and the path between sacredness and ecstasy was .65 ($p < .001$). When run by years playing golf, all of these paths were significant for both men and women. The path between sacredness and the linear combination of the play dimensions was also significant at .65 ($p < .001$). When this latter path was run by sex, the value for men was .68 ($p < .001$) and for women it was .63 ($p < .001$). Hypotheses H_{1a} - H_{1c} were supported. See Appendix 1 for the reported results.

With H_2 we examined the relationship between sacredness and enduring involvement. The direct effect of sacredness on enduring involvement using a single predictor model was significant ($b = .56$, $p < .001$). When run by sex, the effects were significant for both men ($b = .54$, $p < .001$) and women ($b = .57$, $p < .001$). H_2 was supported (see Appendix 1).

With H_3 we examined the relationship between play and enduring involvement using both the linear combination of play and each of its individual components. This relationship was significant ($b = .72$, $p < .001$). It was also significant for men ($b = .67$, $p < .001$) and women ($b = .75$, $p < .001$) separately. When each of the components of play (*communitas*, flow, and ecstasy) was regressed individually with enduring involvement, each path was significant (see Appendix 1). Support for H_3 was provided.

With H_4 , we examined the mediating relationship of play. The mediating relationship of play between sacredness and enduring involvement was partially supported, suggesting only partial mediation. We used a four-step process in which we first demonstrated that the initial variable (domain sacredness) is correlated with the criterion variable (enduring involvement). This value is called path c . Secondly, we showed that the initial variable is correlated with the mediator (play) (see Baron and Kenny 1986). This value is called path a (see Figure 2). For the first path (c), the value was .56 ($p < .001$), while for the second path (a) the value was .65 ($p < .001$) with a standard error of .02.

The third step involved setting up the initial variable (sacredness) and the mediator (play) as predictors of enduring involvement with both predictors entered at the same time. This step is used to obtain values b and c' . For path b , or the relationship between play

*p < .001

**p < .05

and enduring involvement, we obtained a value of .61 with a standard error of .04. For *c'* we obtained a value of .17.

In terms of our hypothesized relationships, results generally went in the predicted direction. H_{1a} through H_{1c} tested whether a positive relationship exists between sacredness to play is *a* and its standard error is *s_a*, and the path from play to enduring involvement is *b* and its standard error *s_b*. The goal is to divide the difference between *c* (.56) and *c'* (.17), or the product of *a* (.65) and *b* (.62), by the value obtained from this formula. If this figure exceeds the critical value of 1.96, there is a mediating effect. To achieve complete mediation between sacredness and enduring involvement, the effect of sacredness on enduring involvement must be equal to zero. In our case, this value equaled .40 (p<.001), indicating only partial mediation. Using the value of .026 ($\sqrt{b^2s_a^2 + a^2s_b^2 + s_a^2s_b^2}$) obtained via the modified test of significance (see Baron and Kenny 1986), the z-value of 15.38 for the mediated effect was significant at the 1.96 critical value.

When the results were run by sex, the z-value for men was 8.10 while for women it was 13.60. Partial mediating effects were also obtained for the components of play, whereby communitas, flow,

and ecstasy were individually tested as mediators. The mediating role was the same for men and women. H₄ was supported (see Appendix 1).

DISCUSSION

The mediating relationship of play between sacredness and enduring involvement is perhaps the most important finding in this study. The significance of this partial mediator indicates that people are more likely to establish enduring involvement in an activity, especially one that might be considered a ritual, if they can experience the positive results of that ritual. While perhaps commonsensical, this indicates to practitioners that although people might hold an activity or product in the utmost or sacred esteem, marketers would be better served if they fostered environments conducive to establishing flow and communitas. Exploring such environments in future studies would add more to our understanding of “playful” situations.

The study investigated experienced golfers’ perspectives; these golfers had joined a state golf association, had played the game for several years, and have established handicaps. Experience

APPENDIX 2

Values for the Mediating Effect of Play and Its Components on the Domain Sacredness-Enduring Involvement Relationship

Mediator	a (X,M)	b (M,Y)	a * b (c- c')	SE of Mediating Effect	Significance of a * b (z value)

in the game leads to the perception of its sacred elements, and the experience of "play" enhances the relationship between sacredness and enduring involvement. These findings represent the goal of the golf industry in terms of the "love of the game."

However, the study does not shed great light on the lived experience of the beginning golfer. The golf industry as a whole is experiencing a "churning effect," as participants leave nearly at the same rate that others enter. Given that the perception of sacredness appears to grow with experience, beginners are unlikely to become enduringly involved in the game because of the perception of golf as being sacred. Thus, we expect that the role of play in establishing enduring involvement is even more important for this segment. While all participants "play" golf, clearly many do not experience play. The golf industry needs to focus more attention to how it can enhance flow, communitas, and ecstasy for this segment.

A contribution of this study is the effort to operationalize "sacredness" and the components of "play." While further work is needed, at least we provide starting points.

CONCLUSION

Establishing enduring involvement is important in any consumer domain because it leads to ongoing product-related information search and transmission (Bloch 1981). In addition, people with enduring involvement are likely to be opinion leaders, who influence others' opinions in a particular product category or activity (see Higie and Feick 1989).

As indicated by Holt (1992), baseball spectating may indeed exist as a sacred ritual, but only to some of its participants. In this study, golf may indeed exist as a sacred ritual to some participants, but it must be ferreted out in a systematic way through demographic, behavioral, or other segmentation variables to determine who in particular exhibits these characteristics. There appears to be a difference in how many years a person plays golf and whether they consider golf to be sacred. Future studies should not only consider this variable, but others such as frequency of play, average golf score, whether people play private versus public courses, and age of golfer to determine different levels of perceived sacredness.

Sex-Typing of Leisure Activities: A Test of Two Theories

George M. Zinkhan, University of Georgia

Penelope J. Prenshaw, Millsaps College

Angeline Grace Close, University of Georgia/North Georgia College and State University

ABSTRACT

Leisure activities are considered here as a subset of consumption, and we are interested in the relationship between gender schema and leisure activities. In order to test rival predictions about gender schema, sex-typing of leisure activities is related to two individual difference measures: gender personality (Bem 1981) and gender-role attitudes (Spence 1984). 271 subjects were given a list of 75 leisure activities and asked to indicate whether they felt the activity was masculine, feminine, or somewhere in between. We do not find support for Bem's (1981) theory, but do find partial support for Spence's (1984) theory. The findings indicate that males sex-type leisure activities to a greater extent than females. Both sex and gender-role attitudes are found to be significant ($p < .05$) predictors of sex-typing.

INTRODUCTION

All cultures have developed a network of associations that surround the concepts of masculinity and femininity. Thus, in addition to male and female role assignments, individuals are also expected to acquire sex-specific personality attributes. In other words, to be masculine or feminine is defined within specific cultures. This process, whereby a society transforms male and female into masculine and feminine is known as the process of sex typing (Bem 1981). However, individuals within a culture may differ from one another in the degree to which they adopt or subscribe to cultural definitions of masculinity and femininity.

In recent decades, "appropriate" roles for men and women have undergone major changes; and such changes are manifest in changing patterns of behavior (Scanzoni 1978). For example, it is not uncommon to find women who hunt or go to football games. Nor is it especially rare to find men who knit or enjoy the ballet. The evolution of traditional sex-role patterns may be sufficient impetus for researchers to become less interested in the male-female dichotomy and more interested in the self-perceptions that are presumed to go along with being male or female.

To date, it has been well established that there are differences in leisure behavior between men and women (Gentry and Doering 1979; Hawes 1978; Ragheb 1980; Kleiber and Hemmer 1981 and Hirschman 1984; White and Gruber 1985). Among these different studies, however, one finds little evidence to indicate whether the bases of differences are biological and/or the result of socialization experiences. In addition, these studies have concentrated on only a small number of leisure activities for comparison and therefore cannot be used to draw conclusions about leisure behavior in general, but only conclusions about the few activities examined.

Gender ideologies structure perceptions of leisure. That is, leisure activities, as a category of experience, are gendered and shaped by social context (Green, Hebron and Woodard 1990). In order to explain differences among women and men in their sex-typing of leisure activities, one must first analyze these differences on the basis of sex-typed socialization (Deem 1986).

Gender Related Theory and Concepts

Gender is a sociological concept, referring to a social category scheme such that these categories are mutually exclusive (Sherif 1982). Gender refers to the cultural definitions of what appropriate male or female behavior involves (Henderson 1989). As

Constantinople (1973) observed in her analysis of masculinity-femininity tests, conventional theories have implicitly assumed that these various categories of masculine and feminine personality attributes and behaviors flow together to form a single bipolar continuum. It is presumed that individuals can be assigned a single place along this hypothetical masculinity-femininity dimension, with most men falling toward the masculine pole and most women falling toward the feminine pole.

Bem's (1981) Unifactorial Gender Schema Theory

Bem (1974) made an important addition to this conceptualization. The essential difference between her approach and that of earlier investigators lies in the attention paid in her theory to the men and women who fall at the center of the hypothetical masculinity-femininity continuum. These individuals are described as non-sex-typed, in contrast to masculine men and feminine women (who are described as sex-typed individuals). Non-sex-typed individuals exhibit a mixture of stereotypically masculine and feminine qualities or fail to exhibit many of either.

Bem (1981) has linked these notions about sex typing to the concept of gender schemata. Gender schema theory proposes that sex-typed individuals have a greater readiness than non-sex-typed individuals do to engage in gender-schematic processing. That is, sex-typed individuals have a generalized readiness to process information in terms of a gender schema (i.e., a network of sex-linked associations that organizes and guides an individual's perceptions). In contrast, non-sex-typed individuals are characterized as aschematic individuals who are relatively unresponsive to stereotypically masculine and feminine cues when processing information.

Operationally, BEM assesses sex-typing by means of the Bem Sex Role Inventory (BSRI), a self-report measure in which individuals can be classified into one of three categories: (a) masculine sex-typed; (b) feminine sex-typed (both are high on one sexual dimension, low on the other); and (c) non-sex-typed. The last category is divided into two possibilities: (c1) androgynous-high on both sexual dimensions, or (c2) undifferentiated-low on both sexual dimensions. Bem's theory predicts that masculine men and feminine women should engage in gender-schematic processing, consistently organizing information on the basis of gender-linked associations, and that androgynous and undifferentiated men and women should not engage in such gender-schematic processing.

There are mixed opinions about the core properties of femininity and masculinity and their relationship with other gender-related phenomena. Bem (1974) predicts a strong relationship between gender identity (masculinity, femininity and androgynous) and gender-related phenomena. She states that knowledge of an individual's typological status permits generalizations about the degree of sex-typing or gender schematization and other gender-related behaviors preferred or adopted by that individual.

Spence's (1984) Multi-Factorial Theory of Gender Identity

Spence criticizes this view; she proposes a weak relationship between an individual's masculine and feminine personality attributes and adopted gender-stereotyped behaviors and beliefs. The theory is based on the view that children's emerging sense of gender identity initially stimulates a child to adopt gender-stereotyped behaviors and beliefs. However, once gender identity is firmly established, other factors (i.e., gender role attitudes) take over to

protect and confirm one's sense of gender identity. Thus, variables leading to individual differences in the enactment of gender roles include not only situational factors, but also such internal dispositions as attitudes toward the appropriateness of maintaining traditional gender role distinctions, personal preferences for certain kinds of activities, and perceptions (realistic or unrealistic) of the positive or negative consequences of acting in certain ways.

Study Purpose and Objectives

With past gender theory in mind, we now discuss the purpose of the current study. It is generally accepted that perceptions of the suitability of particular leisure activities for males and females exist, and are based on sex-related stereotypes. Colley (1987) cites two sources from which these sex-related perceptions may emanate. First, they may be based on views of what is appropriate for the roles men and women enact at work and in the home. Second, perceptions may reflect stereotypes of male and female physical and psychological traits (particularly in relation to sport participation).

The appropriateness of particular leisure activities for males or females is often used as a predictor for participation. However, research has only investigated the sex-appropriateness of sports and physical activities within the leisure domain (Colley, Nash, O'Donnell and Restorick 1987). Therefore, the first research objective is to create and validate a comprehensive list of leisure activities and to classify these activities as "masculine," "feminine," or "neutral".

The second objective is to investigate the determinants of sex-typing of leisure activities. The theories of Bem (1981) and Spence (1984) purport to explain the phenomenon of sex-typing; the former takes a personality approach, while the latter takes an attitudinal approach toward understanding sex-typing. A central issue in testing Bem and Spence's theories, concerns whether a personality approach or an attitude approach is more appropriate. Although personality research has contributed much to our understanding of psychological phenomena, some researchers are disenchanted with the sometimes weak relationships, which appear to exist between personality and behavior (Kassarjian and Sheffet 1991). Spence's attitude approach, within the domain of sex-typing, represents one possible alternative. Thus, this study investigates the effect of gender personality and gender-role attitudes upon sex-typing of leisure activities, and seeks to determine the individual and combined effects of these gender-related phenomena upon sex-typing of leisure activities.

Previous Research

Despite the practical and social interest associated with the sex-typing of leisure activities, only one study in recent literature has examined whether leisure activities are perceived as masculine, feminine or neutral. Gruber (1980) surveyed interests, knowledge and sex-typing of leisure activities and found that of twenty-nine activities, seven were sex-typed as masculine and six were sex-typed as feminine by both males and females. However, his analysis involved only sports and skilled activities. In addition, only one predictor was considered as a determinant of sex-typing: sex of the respondent.

A more comprehensive study by Colley, Nash, O'Donnell and Restorick (1987) investigated the effect of sex, gender personality attributes, gender-role attitude and participation on the number of sports sex-typed as male and the number of sports sex-typed as female. They found that these predictors explained 37.5% of the variance in the number of male sex-typed sports and 14% of the variance in the number of sports sex-typed for females. Here again,

the research focus concentrated not on leisure activities per se, but on the narrower realm of sports and physical activities.

Research Hypotheses

Thus, based upon prior literature, a clear distinction can be made between gender-role attitudes and gender identity (masculine and feminine personality attributes). In order to test the implications of Bem's (1981) and Spence's (1984) theories regarding the determinants of sex-typing, support for and statement of three hypotheses follow.

Studies have found that, from early childhood onwards, males are under greater pressure than females to conform to sex-appropriate behavior (Maccoby and Jacklin 1974). Thus, men may be more likely than women to sex-type leisure activities, as specified by H1:

H1: Men will be more likely to sex-type leisure activities than will women.

Hypothesis two is proposed to test Bem's theory, which predicts sex-typed men and women (those exhibiting masculine or feminine personality traits) are more likely to label leisure activities as being more masculine or more feminine, thus engaging in gender-schematic processing. Whereas, non-sex-typed men and women (those exhibiting androgynous or undifferentiated personality traits) will not engage in gender-schematic processing, and so are more likely to label leisure activities as being either masculine or feminine. Thus,

H2: "Masculine" men and "feminine" women, as defined by the Bem Sex Role Inventory, will be more likely to sex-type leisure activities than will men and women with nontraditional gender-role attitudes.

Finally, hypothesis three is proposed to test Spence's theory, which predicts a strong relationship between gender-role attitudes and adopted gender-stereotyped beliefs. From this prediction, it is reasoned that men and women with traditional gender-role attitudes will label leisure activities as more masculine or more feminine. Conversely, those individuals having nontraditional gender-role attitudes, are less likely to make such assignments, and will view leisure activities as either masculine or feminine.

H3: Men and women with traditional gender-role attitudes will label leisure activities as either "more masculine" or "more feminine".

METHODS

Pretest

A sample of 120 business students at a large southwestern university was utilized. Each was given a pre-test of a written, multi-part instrument. Section I of the questionnaire required the respondent to indicate on an 11-point scale whether seventy-five leisure activities are either extremely masculine, extremely feminine or gender neutral. This inventory of leisure activities was generated by combining previously developed taxonomies of participation (cf. Ragheb 1980 and Hawes; Talarzyk and Blackwell 1975). Additional activities were added to this list based on input from experts on leisure behavior. One purpose of the pretest was to ascertain whether using such a large number of leisure activities presented too tedious and fatiguing a task. The results indicated that not only was the task not fatiguing, but that, in fact, respondents felt it was "fun." The instrument was reduced to a 7-point scale.

Shading was added to every other activity, for it was found that respondents lost their place within the questionnaire.

Sample

Two samples of respondents were asked to complete the revised multi-part questionnaire. The first sample consisted of 218 business students at the same university, but not including those who participated in the pre-test. A secondary sample consisted of the adult membership of a Girl Scout Council representing a southern region.

It was felt that these two samples were diverse, thus allowing for more varied and generalizable results. The questionnaire was mailed to one hundred male members and one hundred female members of the Girl Scout Council with an enclosed self-addressed, stamped envelope. Of the 200 mailed, 53 were returned (resulting in a 26.5% response rate). The questionnaire was also administered in a classroom setting to students enrolled in introductory business courses as part of an extra credit assignment.

Measures

Sex-Typing. Using the same inventory of leisure activities, respondents were asked to rate on a seven-point scale whether each of the 75 activities are: extremely masculine (3), extremely feminine (-3), either masculine or feminine (0), or somewhat in between 0 and 3 or 0 and -3. Based on these scores, a classification system was devised to categorize the activities as masculine, feminine, or neutral. For each respondent, activities were categorized as masculine if any degree of masculinity was perceived (3, 2, or 1), feminine if any degree of femininity was perceived (1, 2, or 3) or neutral (0). We report the total number of males and females endorsing the activities as masculine or feminine by greater than 50% of the sample as sex-typed. This separation is further noted in tables 1 through 3.

Gender Role Attitudes. Gender-role attitudes were measured using the Attitudes toward Women Scale (Spence and Helmreich 1978), a fifteen-item instrument that contains statements describing the rights, roles, and privileges women ought to have or be permitted to have. Respondents indicated their agreement with each statement on a four-point scale ranging from "agree strongly" to "disagree strongly." Low scores indicate a more traditional, conservative attitude toward gender roles.

Masculinity-Femininity. The masculine and feminine personality scores were measured using the Personal attribute questionnaire (Spence and Helmreich and Stapp 1975), which consists of two major scales. The M-Scale contains eight items describing characteristics that are descriptive of masculine personality traits. Similarly, the F-Scale contains eight items describing qualities more characteristic of feminine personality traits. Respondents indicated on a horizontal, 5-point scale the extent to which each phrase describes him or her, with items summed to yield a total M score and a total F score for each respondent. Sex-typed individuals are those scoring high on one sexual dimension, low on the other.

Demographic Items. Finally, a designation of the sex of the respondent was requested. This was coded as a zero-one dummy variable.

Regression

A regression using ordinary least squares is used to determine the degree of sex-typing. The dependent variable, degree of sex-typing, relates to the number of leisure activities an individual labels as either masculine or feminine. Three independent variables are investigated to determine their effect upon sex-typing: biological sex, gender-role attitudes, and gender identity (sex-typed vs. non-sex-typed). Thus, the regression equation can be expressed as:

$$\text{Sex Typing} = f(\text{Biological Sex, Gender-Role Attitudes, Gender Identity})$$

RESULTS

Sex-Typing of Sports

Having developed a comprehensive list of leisure activities, the results of this study indicate that many leisure activities are not sex-typed. In fact, of the 75 leisure activities surveyed, 33 were identified as neutral (greater than 50% of the sample). Many of these leisure activities can be categorized as media-related: watching TV, listening to the music (e.g., radio, tapes, CDs), going to movies, renting movies and reading magazines. Also identified as appropriate for either male or female, were a variety of outdoor activities such as jogging, bicycling, playing tennis and swimming. Several activities, described as individual activities, were not sex-typed by more than half of the sample. These included reading a book for pleasure, taking a nap, and doing crossword puzzles.

More leisure activities were sex-typed for females (33) than for males (28) (see Tables 1 and 2). Leisure activities sex-typed as masculine included those requiring physical activity (e.g., playing football, playing basketball, working out at a gym), outdoor activities (e.g., hunting, fishing, canoeing), and other more passive activities (reading newspapers and taking a nap).

Those leisure activities sex-typed as feminine included activities such as: sewing, aerobics, shopping, cooking, and talking on the phone. Many of the feminine-typed activities were related to cultural activities (e.g., attendance at the ballet, opera and theater plays, visiting art museums, playing the piano, and painting or drawing).

A higher proportion of males than females, sex-typed leisure activities for both sexes—providing support for hypothesis 1. Chi-square tests indicated that for most of the masculine-typed activities (23 of 28) this sex difference was statistically significant ($p < .05$, see Table 1). This sex difference tended to be most marked for activities, which require physical strength or relate to sports or outdoor activities. Some interesting exceptions included playing cards and taking a nap. However, both women and men were in agreement concerning the masculine identity of hunting, playing checkers or chess, playing backgammon and collecting (i.e., stamps or coins).

A greater consensus was exhibited between the sexes for the feminine-typed leisure activities. Out of the 33 leisure activities sex-typed as feminine, chi-square tests indicated only 11 activities in which this sex difference was statistically significant ($p < .05$, see Table 2). For example, this sex difference was most marked for such leisure activities as visiting with friends, dancing, playing badminton, and nature study (e.g., bird watching).

Finally, Table 3 shows those leisure activities not sex-typed by greater than 20% of the sample. In other words, these activities were perceived as gender neutral by at least 20% of our sample. We use the 20% cut-off, since so many of the activities in our sample are sex-typed. Out of these 66 leisure activities categorized as "either", 53 were identified as neutral by a greater percentage of females than males. Thus, more females identified more leisure activities as gender neutral than the males did. Chi-square tests indicated that this sex difference was statistically significant ($p < .05$, see Table 3) for 48 of the activities sex-typed as "either".

Correlation Analyses

Table 4 shows a correlation matrix of the three predictors and one criterion variable (number of sex-typed leisure activities=NLA). As shown in Table 4, both sex and gender-role attitudes were significantly ($p < .01$) related to NLA. As predicted by H1, males sex-typed more than females and, as predicted by H3 (using the

TABLE 1
Leisure Activities Sex-Typed As Masculine

	Total %	Males %	Females%
Playing football	97.42	99.16	96.05*
Hunting	97.42	97.48	97.37

*Difference between male and female perceptions are significant at .05, using a chi-square with 1 degree of freedom.

gender role attitude scale) traditional scores were associated with greater sex-typing.

Regression Analyses

Regression results using ordinary least squares are shown in Table 5. Recall, the dependent variable, degree of sex-typing, relates to the number of leisure activities an individual labels as either masculine or feminine. As shown in Table 5, the estimated regression equation is:

$$\text{Degree of Sex-Typing} = 40.99 - 3.54 (\text{Biological Sex}) - 0.09 (\text{Gender-Role Attitudes}) - 1.27 (\text{Gender Identity})$$

As a group, the independent variables explain about 4% of the variance in the number of leisure activities sex-typed ($R^2 = .039$). In the multiple regression setting, only sex contributed significantly ($p < .05$) to the prediction of the sex-typing scores, thus providing further support for H1. However, neither Bem's (H2) nor Spence's (H3) theory were supported by the multiple regression results.

DISCUSSION

One striking find is the significantly higher proportion of males than females who sex-typed leisure activities (as predicted by H1). Males are especially likely to type leisure activities as masculine. In contrast, there is agreement among subjects as to the sex-typing of feminine leisure activities. It appears that men are much more certain as to what leisure activities constitute "their turf." These results parallel the research on sex-role development, which predicts that, starting with early childhood; males are under greater pressure than females to conform to sex-appropriate behavior (Maccoby and Jacklin 1974). Therefore, male conceptions about the sex-appropriateness of leisure activities are more rigid than those of females.

Previous research has found rather consistently that both men and women rate masculine attributes, activities, and occupations as more desirable, important and prestigious than feminine rated attributes, activities and occupations. If women continue to show interest and participation in "masculine" activities, how might this affect the prestige and status of those activities? For example, Fisher (1972) suggests that an increase of women in certain occu-

pations might serve to reduce the status of those occupations. Further, activities emphasizing achievement, (i.e., games and sports, which are shown here to be identified with the masculine sex) are essential to the development of the masculine role and thus may remain as one of the few areas left to develop masculine identification.

The results of our study do not support Bem's theory, as specified in hypothesis two. The personality measures of masculinity and femininity were not significant predictors of sex-typing. This finding supports those who are disillusioned with a personality approach for predicting behavior. One reason, which has been offered to account for this weak relationship, is based on the validity of the particular personality-measuring instrument (Kassarjian and Sheffet 1991). For example, the instrument employed here (the Personal Attribute Questionnaire-PAQ) does not measure the entire range of dimensions associated with the constructs of masculinity and femininity. Instead, the PAQ focuses on specific aspects; these are highlighted, as aspects of femininity are nurturance and

warmth (which are termed expressive or communal traits). Thus, one possibility for future research is to investigate alternative measures of masculinity-femininity.

Although biological sex explained more of the variance in the respondent's sex-typing of leisure activities, there is some support for Spence's theory. H2 (derived from Spence's theory) is supported by the correlation results (as shown in Table 4). In addition, as specified by Spence's theory, the relationship between personality and leisure behavior is weak. Therefore, for understanding the sex-appropriateness of leisure activities, an attitude approach may offer a better framework than a personality approach.

It may be possible to improve the explanatory power of Spence's theory by refining the measurement procedure. In this vein, Orlofsky, Ramsden and Cohen (1982) have devised a sex-role behavior scale, comprised of male-valued, female-valued and sex-specific items in four interest/behavior areas: recreational and leisure activities, vocational preferences, social interaction and marital behavior. This measure may provide a more accurate

assessment of attitudes, especially with regard to leisure behavior. The strength of biological sex over the gender-related concepts in predicting the sex-typing of leisure activities is apparent. However, one should not interpret from these findings that gender-related concepts are unimportant to the study of leisure behavior. As a caution, it should be noted that our response rate in the secondary sample is rather low (53/200, or 26.5%). This fact may limit the generalizability of our findings.

However, the dynamic changes occurring in traditional sex-role patterns may only now be emerging (Stern 1988); and similarly, such changes in perceptions of leisure activities may only now be appearing. One perception of leisure is based on consumption, which we will further discuss.

Leisure as Consumption

In his winter 2002 column of *ACR News*, Stephen Hoch discusses how "consumption behavior is a more salient aspect of

touristical [sic] pursuits than it is of everyday life" (p. 1). Of course, leisure activities are a part of "everyday life." Yet, they also are emphasized considerably when a consumer is "on vacation" or engaged in "touristical pursuits." Correspondingly, there is a long history in consumer behavior research of trying to understand the nature and meanings of leisure activities. We continue that tradition here by concentrating on the sex-typing of such consumption-laden leisure activities.

When traveling to unknown territory, both men and women find that their activities break out of a ritualistic routine (Hoch 2002). That is, "when we travel to exotic locales, that routine is no longer in place and just getting through the day involves many discrete consumption acts in very unfamiliar territory and we are true amateurs." (Hoch 2002 p.1) As described by Hoch (2002), "consumption behavior is a salient aspect of touristical pursuits." (p. 1) It is important to note that the leisure consumption by tourists is distinct from consumption habits (and other patterns) of natives.

Consumers, when traveling (e.g., on vacation) to an unknown territory with a distinct setting, have unique experiences. For instance, there are differences in preparation (e.g., agenda planning). In many circumstances, natives do not prepare for their leisurely activities (e.g., reading magazines, playing volleyball, bicycling for pleasure). Secondly, tourists often seek out “hotspots” or meaningful experiences on a trip. This may result in differences in how the activity is experienced. Whereas the ESPN Zone may provide an ultimate experimental experience (Sherry 2001) for tourists, Chicago natives nonchalantly accept the consumption center as routine (e.g., as part of everyday life).

After the trip is completed, tourists may treasure the resulting records and artifacts (e.g., scrapbooks, travel journals). In contrast, natives may not feel compelled to record an environment that is frequently encountered. In Hoch’s (2002) travel journal to India, he reports on activities such as purchasing souvenirs, bargaining, visiting temples, learning from natives, and bodysurfing. We report on similar experiences here, including sightseeing, visiting with friends, and water skiing.

Conclusion

In conclusion, the relationship between gender schema and sex-typing of leisure (consumption) activities brings competing psychological (e.g., Bem) and sociological (e.g., Spence) theories into a consumer behavior perspective. We find that leisure activities, as a subset of consumption experiences, may be sex-typed—especially by males. As gender roles change in society, these patterns may change.

Assessing Motivations for Sports Volunteerism

Paul Z. Wang, University of Technology, Sydney

ABSTRACT

Drawing on recent conceptual models on volunteer motivations developed mainly in social psychology, this study proposes that motivation for sports volunteerism is a multidimensional construct that comprises five distinct components, namely (1) Altruistic Value, (2) Personal Development, (3) Community Concern, (4) Ego Enhancement, and (5) Social Adjustment. A 20-item scale measuring motivations for sports volunteerism was developed using survey data from 935 qualified respondents. Results of confirmatory factor analysis via LISREL software provided reasonably adequate support for the five-factor dimensionality, reliability, convergent validity, and discriminant validity of the measurement scale.

INTRODUCTION

Every year, millions of volunteers donate substantial amounts of their time and effort to a cause that they care about. The most recent survey on giving and volunteering in the United States shows that 83.9 million Americans, accounting for 44 percent of American adults, engaged in some form of volunteer activities with a formal organization in 2000, with the total number of hours volunteered reached 15.5 billion hours (Independent Sector 2001). According to the latest survey of voluntary work by the Australian Bureau of Statistics (2001), about 4.4 million Australians, representing 32 percent of the total adult population, provided volunteer services through an organization in 2000. Moreover, there is ample evidence that volunteerism is a global phenomenon that can be found in many other parts of the world (Curtis, Grabb and Baer 1992).

The opportunities for volunteer service are now as broad as the spectrum of human needs. Volunteers can be found in such wide-ranging areas as the arts, youth service, education, health care, welfare, environmental protection, sports and recreation. As a growing and widespread social phenomenon, volunteerism is obviously a topic worthy of researchers' attention. Yet surprisingly, a review of the literature indicates that many prior studies on volunteerism have been primarily descriptive in nature (e.g., Brudney 1993; Perkins 1989; Spacapan and Oskamp 1992). Lack of reliable and valid measures appears to be one major reason for the relative paucity of rigorous empirical research on volunteerism. For example, Cronbach's alpha associated with measures used in one empirical study ranged just from 0.25 to 0.37 (Unger 1991). Among the limited number of empirical studies found in the literature, there were many studies using either just single-item scales to measure volunteer motivations or exploratory factor analysis to assess the motivational dimensionality underlying volunteerism (e.g., Andrew 1996; Farrell, Johnston, & Twynam 1998; Lysack and Krefling 1993; Phillips 1982).

However, exploratory factor analysis without a sound conceptual foundation and the use of single-item measures have long been shown to be inadequate in construct validation and theory testing (e.g., Churchill 1979; Gerbing and Anderson 1988; Nunnally and Bernstein 1994). The development of any scientific theory is virtually impossible without accurate and reliable measurement of theoretical constructs. Using confirmatory factor analysis via LISREL (Jöreskog and Sörbom 1993), the present research attempts to develop a psychometrically sound multi-item scale to measure motivations for sports volunteerism. Data for the main study were collected from prospective volunteers for the Sydney

2000 Olympic Games. As little research has been done in the area of volunteer activity for sporting events, this study draws on the conceptual models on volunteer motivations developed mainly in social psychology.

The remainder of this paper is organized into five sections. The first section reviews the relevant literature on volunteer motivations. The second section discusses the proposed five motivations for sports volunteerism. The third section outlines the research methodology, while the fourth section reports study results. The paper concludes with a discussion of research findings and suggestions for future research.

LITERATURE REVIEW

Despite recent advances in research on volunteer motivations, there is still considerable debate about the underlying structure or dimensionality of volunteer motivations. Cnaan and Goldberg-Glen (1991) argue that motivation to volunteer is a unidimensional construct. Smith (1981) proposes a two-dimensional structure consisting of altruistic and egoistic motives (see also Phillips 1982).

Using content analysis, Morrow-Howell and Mui (1989) identified three major categories of volunteer motivations: (1) Altruistic, (2) Material, and (3) Social. As the name implies, altruistic motives pertain to intangible rewards that are intrinsic to the volunteering act itself, namely satisfactions resulted from feeling that one has helped someone else. Material motives, in contrast, are concerned with tangible rewards such as collecting memorabilia, strengthening one's résumé, and developing one's career. Finally, social motives refer to individual satisfactions with rewards of interpersonal interactions. In a study of motivations for participating in a recreation-related voluntary association, Caldwell and Andereck (1994) described three categories of motivations for volunteering: (1) Purposive, (2) Material, and (3) Solidary. Their scheme bears a strong resemblance to that of Morrow-Howell and Mui (1989). Purposive motives relate to doing something useful to society. Material motives pertain to tangible rewards such as learning job-related skills. Solidary motives are concerned with social interaction, group identification, and networking.

In their program of research on AIDS volunteers, Omoto and Snyder (1995) found that five specific motivations for volunteer work could be consistently identified. They defined these motivations as (1) Values, (2) Understanding, (3) Personal Development, (4) Community Concern, and (5) Esteem Enhancement. Values pertain to the underlying beliefs held by a person that one should make altruistic and humanitarian contributions to society. Understanding reflects the fact that volunteering may serve to satisfy a person's intellectual curiosity about other people and the problems that they face. Personal development focuses on issues of personal growth and the opportunity to make friends and gain new skills. Community concern reflects people's sense of obligation to or concern about their community (see also Omoto and Snyder 2002). Finally, Esteem enhancement encompasses motivations that deal with finding ways to cope with guilt over being more fortunate than others.

Similarly, Clary and her associates (1994) identified five motivation factors that may affect intention to volunteer. They include (1) Knowledge, (2) Social Adjustment, (3) Value Expression, (4) Ego Protection, and (5) Utilitarian Concern. Four of the above five motivations, namely Knowledge, Value Expression,

Ego Protection, and Utilitarian Concern, correspond to Omoto and Snyder's (1995) Understanding, Values, Esteem Enhancement, and Personal Development motivations respectively. More recently, Clary and her associates (1998) identified a set of six motivations, which they claim to be of generic relevance to volunteerism. The set of six generic motivations includes (1) Values, (2) Understanding, (3) Social, (4) Career, (5) Protective, and (6) Enhancement.

FIVE MOTIVATIONS FOR SPORTS VOLUNTEERISM

Drawing on the various conceptual models on volunteer motivations reviewed in the preceding section, this section examines five salient motivations considered most relevant to sports volunteers: (1) Altruistic Value, (2) Personal Development, (3) Community Concern, (4) Ego Enhancement, and (5) Social Adjustment. There are two major reasons for adopting this multi-dimensional structure or conceptualization of volunteer motivations. First, previous evidence to support the unidimensional structure was rather weak. Although acknowledging the existence of multiple motives for volunteering, Cnaan and Goldberg-Glen (1991) decided on the unidimensional structure based primarily on the results of an exploratory factor analysis. In their factor analysis of 28 potential motivation items culled from extant literature, only the first factor, made up of 22 items, turned out to have acceptable level of reliability. No follow-up confirmatory factor analysis was conducted. Such an exploratory and data-driven approach is widely considered inadequate in construct validation (e.g., Churchill 1979; Nunnally and Bernstein 1994). This is evidenced by the low factor loadings (ranged from 0.309 to 0.650) and the apparent lack of face validity with some of the scale items. For instance, items measuring social motivation, such as "opportunity for relationships," were lumped together with altruistic motives, such as "it creates a better society," and egoistic motives, such as "excellent educational experience."

Second, the overwhelming majority of prior studies have suggested that motivation to volunteer is a multidimensional construct (see Cnaan and Goldberg-Glen 1991 for a comprehensive review of various motives for volunteerism). Recent studies on volunteerism (e.g., Clary et al. 1998; Omoto and Snyder 1995, 2002) have provided not only convincing arguments for developing conceptually distinct motivation dimensions, but also compelling empirical evidence in support of the multidimensional structure. Unlike most of earlier studies that relied on just content analysis and exploratory factor analysis (e.g., Morrow-Howell and Mui 1989), recent studies have incorporated new developments in structural equation modeling (Jöreskog and Sörbom 1993) and employed the state-of-the-art techniques for scale development and construct validation (Nunnally and Bernstein 1994). From the methodological point of view, recent studies are much more rigorous than most earlier studies on volunteerism. Therefore, the present research used these recent empirical studies as the point of departure to study motivations for sports volunteerism.

Altruistic Value

Volunteerism, by its very nature, is prosocial and altruistic. Altruistic value represents a person's intrinsic beliefs in helping others and contributing to society. A person with altruistic value tends to think about the welfare of other people, to feel empathy for them, and to act in a way that benefits them. Volunteering for a worthy cause provides people with an opportunity to express their humanitarian concerns and translate their deeply held values into actions. Prior research on volunteerism suggests that intention to volunteer is positively related to altruistic value and volunteers

often choose their voluntary acts without expecting a complete *quid pro quo* (Piliavin and Charng 1990; Unger 1991).

Personal Development

Personal development refers to a volunteer's desire to receive self-oriented benefits pertaining to personal growth and learning of new skills. Volunteers seeking personal development value not only the chance to gain new knowledge and experience but also the opportunity to challenge themselves and test their existing skills and abilities. The review of literature on volunteerism indicates that there are egoistic as well as altruistic motivations for volunteering (e.g., Phillips 1982; Smith 1981). Personal development represents one important aspect of egoistic motivations. Volunteerism provides people with the opportunity to learn job-related skills and allows those who are not participating in the job market to acquire or maintain employment skills. This is consistent with Becker's (1964) theory of human capital investment. Human capital investments are those activities that enhance labor market value. Such activities improve a person's skills, knowledge, and mental health.

Community Concern

Community concern reflects people's sense of obligation to and/or involvement with their communities (Omoto and Snyder 2002). At a time of shrinking government funding and rising public demand, more and more social service organizations rely on volunteers to help feed the hungry, house the homeless, and put the unemployed back to work. Community leaders are urging their members to pitch in to strengthen and improve their communities. As a community service, volunteerism is regarded as an integral part of civil society. Bonjean, Markham, and Macken (1994) found community involvement to be an important dimension of self-expression in volunteer organizations.

Ego Enhancement

Ego enhancement encompasses motivations that deal with positive strivings of the ego (Clary et al. 1998). Research on mood and helping behavior suggests that people use helping as a means of maintaining or enhancing positive feelings about themselves (e.g., Carlson, Charlin, and Miller 1988). Feeling good about oneself can be a powerful motivator of volunteerism. For example, Clary and her colleagues (1998) found ego enhancement to be significantly related to satisfaction with volunteering and intentions to volunteer. To help with the staging of the Olympic Games is a once in a lifetime experience for most people. Volunteering for an international sporting event such as the Olympic Games can thus be very exciting and would instill pride and self-esteem in sports volunteers.

Social Adjustment

Social adjustment reflects motivations regarding relationships with other people. Volunteer work is an activity in which a person can participate with his or her friends and engage in activities viewed favorably by important others (Clary et al. 1994, 1998). Past research has provided consistent evidence that people consider perceived social expectations when they form behavior intentions. Harrison (1995) found subjective norm to be positively related to intention to volunteer in a homeless shelter. Fisher and Ackerman (1998) used a social norm perspective to examine the effects of recognition and group need on volunteerism. Their experimental results showed that group members would volunteer when the group need is high and recognition is promised. Clary and her colleagues (1998) found social adjustment to be significantly related to satisfaction with volunteering and intentions to volunteer.

TABLE 1
Results of Exploratory Factor and Reliability Analyses

Measurement Item (<i>m</i> =scale mean; <i>sd</i> =standard deviation; α =Cronbach's alpha)	Rotated Factor Loading	Item to Total Correlation
(1). Altruistic Value (<i>m</i>=4.52; <i>sd</i>=1.33; α=0.82)		
I have an obligation to help others.	0.749	0.53
I volunteer because of my personal values and beliefs.	0.722	0.66
I volunteer because I enjoy helping other people.	0.686	0.68
Because I consider myself to be a person who gets involved.	0.684	0.67
(2). Personal Development (<i>m</i>=4.57; <i>sd</i>=1.46; α=0.86)		
To challenge myself and test my skills.	0.813	0.73
To learn more about other people and cultures.	0.764	0.66
To get to know people interested in the same things as I am.	0.749	0.68
To gain experience.	0.712	0.66
To share my knowledge and skills with others.	0.659	0.69
(3). Community Concern (<i>m</i>=5.63; <i>sd</i>=1.07; α=0.79)		
Volunteering does something good for the community.	0.770	0.61
Volunteers make a valuable contribution to the community.	0.732	0.58
Volunteering is a community service.	0.701	0.50
We should promote volunteerism for the good of society.	0.692	0.60
People should be willing to donate time to help others.	0.665	0.57
(4). Ego Enhancement (<i>m</i>=4.89; <i>sd</i>=1.50; α=0.79)		
I would enjoy being part of the occasion.	0.769	0.69
It would just be fun.	0.731	0.62
It would make me feel good.	0.613	0.58
(5). Social Adjustment (<i>m</i>=4.90; <i>sd</i>=1.32; α=0.80)		
People at my job/school would approve of my volunteering.	0.856	0.78
People who are close to me would support me to volunteer.	0.776	0.57
My family members would encourage me to volunteer.	0.761	0.58

METHOD

Data Collection

Data for the study were collected from people aged 18 or over who were living in the metropolitan area of Sydney, Australia. A quota sampling technique was adopted to obtain a reasonably representative sample from both males and females and across four age brackets: 18 to 34, 35 to 49, 50 to 64, and 65 or over. The data collection method involved the use of personal interviews with a self-administered questionnaire. The fieldwork was undertaken by 170 undergraduate students from a major university in Sydney as part of their course work for a marketing research subject. The questionnaire used in the survey had previously been pretested using a convenience sample of 82 Sydney residents. Several items were removed because of low reliability. A number of minor wording and layout changes were also made as a result of this process. Of the total number of 1020 questionnaires distributed for completion, 935 usable ones were obtained. The sample is balanced across gender with 49% males and 51% females.

Measure Development

All constructs of interest were measured with multiple items. These multi-item measures were developed following the recommended psychometric scale development procedures (e.g., Churchill 1979; Gerbing and Anderson 1988; Nunnally and Bernstein 1994). Based on the definitions of the constructs, items were generated from previous measures found in the relevant literature (e.g., Clary et al. 1994; Cnaan and Goldberg-Glen 1991; Harrison 1995; Omoto

and Snyder 1995) and from interviews with past volunteers. In addition to traditional assessment methods such as exploratory factor analysis, Cronbach's coefficient alpha, and item-to-total correlation, the present study assessed psychometric properties of the final measures by means of confirmatory factor analysis procedures using LISREL (Jöreskog and Sörbom 1993).

Respondents were asked to indicate their agreement on a 7-point Likert type scale (ranging from 1 being "strongly disagree" to 7 being "strongly agree") with statements regarding the five dimensions of motivations for sports volunteerism: (1) Altruistic Value, (2) Personal Development, (3) Community Concern, (4) Ego Enhancement, and (5) Social Adjustment.

RESULTS

As described in the preceding section, items derived from conceptualizations of the five proposed dimensions were first analyzed with traditional scale assessment methods. They included exploratory factor analysis (principal components with varimax rotation), Cronbach's coefficient alpha, and item-to-total correlation analyses. Through these exploratory analyses, unreliable and ambiguous items (i.e., items that loaded on multiple constructs or had low item-to-total correlations) were identified and removed during the pretest. As shown in Table 1, this process resulted in a 20-item instrument measuring the five motivational dimensions for sports volunteerism.

To help assess the dimensionality and internal consistency of the measure, the 20-item motivation scale for sports volunteerism was subjected to exploratory factor analysis and reliability analysis

TABLE 2
Results of Five-Factor Confirmatory Factor Analysis

Model Fit Statistics	
Chi-square: χ^2	773.26
Degree of freedom	160
p-value	0.000
GFI (goodness-of-fit index)	0.92
AGFI (adjusted goodness-of-fit index)	0.90
TLI (Tucker and Lewis index)	0.91
CFI (comparative fit index)	0.93
RMSEA (root mean square error of approximation)	0.06
Construct Reliability	
CR for Altruistic Value	0.82
CR for Personal Development	0.86
CR for Community Concern	0.79
CR for Ego Enhancement	0.79
CR for Social Adjustment	0.82
Average Variance Extracted	
AVE for Altruistic Value	0.53
AVE for Personal Development	0.56
AVE for Community Concern	0.45
AVE for Ego Enhancement	0.56
AVE for Social Adjustment	0.62
Maximum ϕ^2	0.49

using the data of the main study. Kaiser's rule (eigenvalue larger than one) was used to determine the number of factors to extract. The results are summarized in Table 1. Examination of the exploratory factor analysis results in Table 1 indicates that the 20-item motivation scale yielded five factors. All the items were loaded on hypothesized factors with very low cross-loadings and the factor loadings were all above 0.60. The Kaiser-Meyer-Olkin Measure of Sampling Adequacy value was high (0.90), indicating that all the items in the motivation scale appear to be well developed. Examination of the reliability analysis results in Table 1 shows that Cronbach's coefficient alpha values ranged from 0.79 to 0.86 and the item-to-total correlations were all above the recommended value of 0.5 (Nunnally and Bernstein 1994). These results suggest that the five motivation subscales for sports volunteerism were reliable measures.

To further examine the measurement model of the motivations for sports volunteerism, the 20 motivational items were subjected to confirmatory factor analysis via LISREL (Jöreskog and Sörbom 1993). The five-factor model representing the hypothesized correlated five-dimension structure was estimated for purposes of assessing overall model fit, construct reliability, convergent validity, and discriminant validity (Gerbing and Anderson 1988). Table 2 summarizes the confirmatory factor analysis results.

As shown in Table 2, the hypothesized five-factor measurement model representing the five motivations for sports volunteerism appears to fit the data reasonably well ($\chi^2(160)=773.26$; $p<0.01$, $GFI=0.92$, $AGFI=0.90$, $TLI=0.91$, $CFI=0.93$, and $RMSEA=0.06$). Although the chi-square statistic was statistically significant ($\chi^2(160)=773.26$; $p<.01$), this is not unusual given the large sample size in this study and the large number of items needed to measure

the five motivations for sports volunteerism (Bollen 1989). Under these circumstances, absolute fit measures such as the chi-square statistic are less useful than incremental fit measures such as the Tucker and Lewis index (TLI) and Bentler's comparative fit index (CFI). The high values of TLI and CFI as well as GFI and AGFI (0.90 or greater) and the low value of the root mean square error of approximation (RMSEA, less than 0.08) all indicate a reasonably good level of overall model fit.

To further assess the dimensionality of the 20-item scale measuring the five motivations for sports volunteerism, a series of tests of the nested models were conducted, which comprised the null model, one-factor model, two-factor model, three-factor model, four-factor model, and five-factor model. The factor loading matrix specification in LISREL for one- to five-factor models comes from the results of exploratory factor analysis using principal components extraction method and varimax rotation. Instead of using Kaiser's rule (eigenvalue larger than one) to determine the number of factors to extract, the program was told to extract one, two, three, four, and five factors, respectively. Table 3 provides the test results of the nested models.

As can be seen from Table 3, model fit improves from the null model to the five-factor model (All chi-square changes are significant, $p<0.01$). And more important, among the six measurement models tested, the five-factor model exhibits the best fit in terms of GFI, AGFI, TLI, CFI, and RMSEA. These findings thus lend further support to the five-factor structure of the 20-item motivation scale for sports volunteerism.

Evidence of internal consistency or scale reliability in confirmatory factor analysis is provided by construct reliability (CR). As shown in Table 2, CR estimates for the five motivations ranged

TABLE 3
Tests of Nested Measurement Models

Model	χ^2	df	$\Delta\chi^2$	p-value	GFI	AGFI	TLI	CFI	RMSEA
Null model	8459.45	190	n/a	N/a	0.32	0.25	n/a	n/a	0.22
1-factor	3211.69	170	5247.76	0.000	0.68	0.61	0.59	0.63	0.14
2-factor	2191.96	169	1019.73	0.000	0.78	0.72	0.73	0.76	0.11
3-factor	1482.40	167	709.56	0.000	0.84	0.79	0.82	0.84	0.09
4-factor	1097.54	164	384.86	0.000	0.89	0.86	0.87	0.89	0.08
5-factor	773.26	160	324.28	0.000	0.92	0.90	0.91	0.93	0.06

from 0.79 to 0.86. Consistent with those of Cronbach's coefficient alpha reported earlier, these results suggest that the five motivation subscales for sports volunteerism possess adequate reliabilities.

After assessing dimensionality and reliability, convergent validity and discriminant validity are examined. Two approaches were used to assess convergent validity. The first one recommended by Anderson and Gerbing (1988) is to examine whether factor loading for each indicator is statistically significant. Since t-test shows that factor loadings for all the indicators were highly significant ($p < 0.001$), the motivation scale for sports volunteerism appear to have convergent validity. Fornell and Larcker (1981) proposed a more stringent test of convergent validity. Their approach calls for the calculation of a statistic known as average variance extracted (AVE). AVE estimates of 0.5 or above indicate convergent validity. As shown in Table 2, AVE estimates for all the dimensions were above 0.5, with the exception of community concern, whose AVE estimate was 0.45, slightly lower than the recommended cut-off value of 0.5. These results indicate that the motivation scale for sports volunteerism exhibited reasonably adequate convergent validity.

There are also two approaches that can be used to assess discriminant validity. The first approach was proposed by Anderson and Gerbing (1988). They suggested that discriminant validity should be assessed by chi-square differences test through putting equality constraints, one at a time, in the factor variance-covariance matrix. In the current study, discriminant validity is established if the chi-square fit of the five-factor model is better than the fit of all possible combinations of four-factor models. In all of the ten necessary comparisons, the overall fit of the model was significantly diminished by constraining the factor correlation to unity. The chi-square difference values ranged from 312.91 to 1100.94, far above the critical value of 18.47 ($df=4$) at the significance level of 0.001. These results thus indicate discriminant validity for the five-factor measurement model.

Fornell and Larcker (1981) described an alternative approach to the assessment of discriminant validity. According to them, for any pair of constructs to demonstrate discriminant validity, the average variance extracted (AVE) for each construct should be greater than the squared factor structural coefficient (ϕ^2 derived from LISREL) between the pair. The squared structural coefficients ranged from 0.09 to 0.49. As shown in Table 2, all the AVE estimates were greater than the squared structural coefficients, indicating again that the motivation scale for sports volunteerism seemed to have adequate discriminant validity.

Overall, the findings reported so far have provided reasonably strong evidence in support of the five-dimension structure, reliability, convergent validity, and discriminant validity associated with the 20-item motivation scale for sports volunteerism.

DISCUSSION AND CONCLUSIONS

Every day around the world, countless volunteers from all walks of life share their time, skill, and energy to help those in need. Given the growing emphasis on volunteerism in both nonprofit and business organizations, it is important to understand and assess the motivations underlying volunteerism. By identifying such motivations, volunteer organizations can design effective programs to recruit prospective volunteers and retain their existing volunteer labor force. However, a review of the extant literature indicates that very few studies have systematically evaluated the factors that motivate people to participate in volunteer programs. Lack of reliable and valid scales to measure motivations for volunteerism appears to be one major reason for the relative paucity of rigorous empirical research on volunteerism.

This research represents one of only a few empirical examinations of the motivational dimensionality underlying sports volunteerism. It offers a conceptualization and a multi-item measure of motivations for sports volunteerism. Drawing mainly on recent conceptual models on volunteer motivations (e.g., Clary et al. 1998; Omoto and Snyder 1995, 2002), the present research proposes that motivation to volunteer in major sporting events is a multidimensional construct that comprises five distinct components, namely (1) Altruistic Value, (2) Personal Development, (3) Community Concern, (4) Ego Enhancement, and (5) Social Adjustment. Results of confirmatory factor analysis via LISREL provided support for the overall measurement model, reliability, convergent validity, and discriminant validity associated with the scale for sports volunteerism.

Results of the study highlight the need for researchers to examine measures of motivations for volunteerism in a more rigorous manner. Structural equation modeling, as demonstrated in the current research, provides an appropriate way of assessing multi-item measurement scales. This research offers a point of departure for future research on sports volunteerism. Further refinements in both conceptualization and measurement are both possible and desirable. Although the current research has developed a multidimensional scale to measure motivations for sports volunteering, many of the items are general in nature and could be adapted to measure motivations for volunteering in other domains. Researchers in the future could also examine the structural relationships among motivations for volunteerism, their antecedents, and outcomes in various research settings.

SPECIAL SESSION SUMMARY

It Could Happen to Me: Risk Estimates and the Positivity/Negativity Bias

Nicholas Lurie, University of North Carolina at Chapel Hill

SESSION OVERVIEW

Much of consumer behavior involves implicit or explicit risk estimates. For example, the decision to drive instead of fly may involve estimates of relative safety, and getting a mammogram may involve estimates about the probability of developing breast cancer. In an effort to change consumers' risk estimates and behavior marketers often provide consumers with base-rate information. For example, sellers of credit card reports often cite the number of victims of credit card fraud and sellers of disability insurance cite the number of people who are temporarily disabled during their lives.

At the same time, research suggests that consumers are often poor estimators of risk (Slovic, Fischhoff and Lichtenstein 1980) and generally overestimate the probability of good things and underestimate the probability of bad things happening to them (Weinstein 1980). Other research has shown that consumers often fail to incorporate base-rate information in making estimates (Tversky and Kahneman 1998) and that framing can lead to dramatic differences in how base-rates are incorporated into preferences (Tversky and Kahneman 1981). This special session addressed these issues by 1) examining factors that lead consumers to under or overestimate risk for themselves and others in the population, 2) examining how actual frequencies are incorporated in new estimates, 3) examining the link between estimates, preferences and behavior.

In the first paper of the session, Ying-Ching (Michelle) Lin presented her work with Priya Raghurir and Chien-Huang Lin that seeks to explain the "self-positivity" (self-negativity) bias in risk estimates that leads to the under- (over-) estimation of risk relative to others. By looking at risk estimates for oneself versus others, for positive versus negative, and for controllable versus uncontrollable events, the authors are able to demonstrate that self-positivity is a strategic device to maintain or enhance self esteem, rather than a self-serving bias.

In the second paper, Punam Keller presented work with Isaac Lipkus that studies how providing absolute versus relative risk information affects women's estimates for developing breast cancer as well as their intentions to undergo early-detection screening (mammograms). The authors find that women who are provided only data on their own risk of breast cancer give more accurate self-estimates than those who are provided with data for themselves and women who are at lowest risk. Contrary to many theories of health behavior, lowering risk estimates does not lower intentions to get mammograms.

In the third paper, Nicholas Lurie and Michael Ranney presented a series of studies that show that asking consumers to make estimates before indicating preferences can lead to preferences that are in some cases closer to, and other cases farther away from, preferences based on actual data, or preferences elicited before estimates. Importantly, making estimates can limit preference change in the face of actual data. Feedback on the mortality rates of one disease can improve estimates for other diseases and bring consumers closer to what seem to be their true preferences.

After the three papers were presented, Geeta Menon moderated a discussion between the participants and audience that explored connections between the papers, the accuracy of risk estimates, ways to improve estimates and the link between estimates and behavior.

"Feeling Better or Staying Miserable: Why Self-Positivity?"

Chien-Huang Lin, National Central University, Taiwan

Ying-Ching Lin, National Chi Nan University, Taiwan

Priya Raghurir, University of California at Berkeley

Consumers' decisions to purchase products or services are frequently a function of the perceived risks of the product or service's performance. For example, the likelihood of purchasing a specific brand of car, appliance, software or service is a function of the perceived risk of the product or service being able to perform satisfactorily and not break down. In other domains, purchase probabilities may be contingent on perceptions of the likelihood of an event occurring (e.g., purchasing a lottery ticket, a product with a sweepstake promotion etc.). In yet other contexts, consumers' health-related behaviors are contingent on their perceptions of the risk of contracting a specific disease, in absolute terms or relative to the average person. However, a fairly robust finding is that individuals' believe that they are less at risk than an "average" other person for a negative event, (i.e., the "self-positivity" bias; Perloff and Fetzer 1986), and more likely to experience a positive one (i.e., show "unrealistic optimism," Weinstein 1980). This systematic bias can lead to non-optimal purchases, decisions, and behaviors. Consumer researchers are increasingly examining this issue in contexts ranging from AIDS (Raghurir and Menon 1998) and Hepatitis C (Menon, Block and Ramanathan 2002) to depression (Keller, Lipkus, and Rimer 2002) and breast cancer (Luce and Kahn 1999), and have implicated reducing self-positivity as a route to encourage preventative behavior. Accordingly, an important consumer welfare goal is to reduce the self-positivity bias.

This paper examines the underlying reasons behind self-positivity to better understand how to reduce and eliminate the bias. We propose that self-positivity may be due to three different reasons: maintaining or enhancing self-esteem, reducing anxiety associated with the uncertainty about future life outcomes, or an overall desire to feel happy using a denial mechanism. We suggest that examining the moderating effect of perceived controllability of an event, the use of base-rates in self-estimates, and the manner in which optimists and pessimists estimate likelihood can assist in disentangling which of these three routes lead to self-positivity. These variables can also explain inconsistent effects regarding the presence of self-positivity across a range of events, the direction and presence of self-positivity for different populations (e.g., depressives), and the differential resilience of the bias to base-rate information.

If the underlying mechanism for self-positivity is to feel happy, then beliefs should always reflect optimism, irrespective of the perceived controllability of the behavior. If it is an anxiety-reduction mechanism, then self-positivity should be greater when events are more uncertain or less controllable. However, if self-positivity is due to self-esteem maintenance, then it should be lower for controllable events. This is because people can attribute a lower risk of a negative event to their own actions, so the strategic belief that they are less at risk than others should improve their self-esteem.

Examining the manner in which base-rate information is used to update self-estimates also illuminates the reason behind self-positivity. If it is due to uncertainty reduction, then base-rates should always be used. If self-positivity is due to a wish to feel happy, then pessimists should use base-rates to update their self-

estimates, while optimists should not update. However, if it is due to self-esteem maintenance, optimists and pessimists may react differently to base-rate information. Optimists, who have high self-esteem and demonstrate self-positivity, should be less likely to update their self-estimates overall. When they do, they should be more likely to update their estimates for more (versus less) controllable events. However, pessimists, with a pattern of self-negativity and low self-esteem, should update their estimates for events irrespective of the perceived controllability of the event.

We argue that self-judgments are constructed so as to maintain self-esteem. To test this, we examine the attenuating effects of: (i) providing reference points to act as “base-rates” and (ii) decreasing the perceived event’s controllability on the self-positivity bias. Three studies programmatically examine this idea.

Study 1 shows the attenuating effect of controllability perceptions and the presence of base-rate information in the domain of the disease: cancer. Although there are a number of ways an individual can reduce the risk of cancer, the relationship of the disease to individual behaviors, is not entirely within individual control—many individuals who do not engage in “high risk” activity, are still diagnosed with cancer. We show that increasing perceptions of the lack of control over contracting cancer, along with base-rate information about the incidence of cancer eliminates the self-positivity bias.

Studies 2 and 3 extend the investigation beyond the domain of cancer. We argue that self-positivity will be exacerbated (i) for conditions where it is easier to, and (ii) for individuals who would like to, maintain or enhance self-esteem. Study 2 replicates the results of Study 1, using different manipulations: measuring controllability of different behaviors rather than manipulating it, and extending the domain to include positive events. Results show that when events are perceived to be within an individual’s control, they perceive themselves as less at risk for a negative event and more likely to enjoy a positive event. When events are perceived to be outside of the individual’s control, base-rate information attenuates the self-positivity effect. However, when events are perceived to be controllable, then the presence of base-rates exacerbates the self-positivity bias: self-estimates contrast away from the provided base-rate.

Study 3 examines why self-estimates reflect a contrast away from base-rate information for controllable events. It shows that the above effects are contingent on individuals’ level of optimism: optimists are more likely to update self-estimates when events are less controllable. Pessimists demonstrate self-negativity irrespective of the perceived controllability of the event. They assimilate base-rate information into self-estimates irrespective of the perceived controllability of the event. However, this assimilation is not always adequate, leading to a reduction, but not an elimination of a self-negativity effect. The combination of a reduction of self-negativity for pessimists and no change in self-positivity for optimists for controllable behaviors, leads in aggregate to self-estimates showing a contrast away from base-rates, as found in Study 2.

“Risk Information: Truth and Consequences”

Punam Anand Keller, Dartmouth College

Isaac M. Lipkus, Duke University Medical Center

In general, people tend to think that bad things happen to other people and not to themselves. This has been referred to as the optimistic bias (Weinstein 1980). However, the situation seems to be quite different for breast cancer. Women consistently and quite dramatically overestimate their chances of getting breast cancer (Lerman et al. 1995). It is possible that this tendency to overestimate

risk has led to excessive worries, may deter breast cancer screening or, conversely, lead to excessive screening (Epstein et al. 1997; McCaul et al. 1996).

So how are medical professionals to communicate breast cancer risk information in a way that increases the accuracy of risk perceptions? Giving women relative risk information (i.e., self vs. others), in addition to their absolute risk, might help them understand their own risks. Indeed, adding a reference point to help people judge whether a risk is considered low, average, or high, has been shown to affect risk perceptions (Smith, Desvovages and Payne 1995).

The literature is mixed on whether people will rely on objective or social comparison information when both are available. According to Festinger’s (1954) classic article on social comparison processes, people prefer to use objective information to evaluate their opinions and abilities and only rely on others when objective information is not available. By contrast, Klein (1997) indicates that social comparison information is more important than objective information. Across three studies, comparative risk information had more impact on self-evaluation and emotional judgments than objective risk information.

How should the addition of relative risk to absolute risk information affect women’s perceived risk of breast cancer? Given that most women overestimate their risk of breast cancer, they should lower their risk estimates if they are only given their absolute risk of breast cancer. However, assuming that people are sensitive to relative risk information, in addition to absolute risk information, having women compare their risk with the risk of others should affect both perceived risk and accuracy. Specifically, if women are constrained to compare their risk with a woman at lowest risk, they should be less inclined to lower their perceived risk, leading to diminished accuracy. This format, as other studies have suggested (Klein and Kunda 1993), curtails women’s tendencies to sustain self-serving social comparisons.

The primary goals of our study were to (a) examine the impact of absolute and relative risk information not only on perceived risk and mammogram screening intentions, but also on emotional responses to getting breast cancer, and (b) assess participants’ evaluations of risk information and attributional accounts for under- or overestimation of risk.

We tested our hypotheses in a sample of women aged 40 and older. In a pre- to post-test design, 121 women were given their 10-year risk of getting breast cancer with or without being given comparative data for women their age and race at lowest risk. Participants were more accurate when they received their own risk without comparison data for women at lowest risk. Women who received only their own risk estimate reported being at lower risk than other women. The majority of women who overestimated their risk after receiving the objective risk information did so because they did not understand the meaning of the numbers and/or because they felt the objective risk information failed to incorporate important factors such as level of exercise. Overall women reported that obtaining their 10-year risk estimate either did not affect or increase their intentions to get a mammogram. These results suggest that giving women their individual risk of getting breast cancer improves accuracy while also enhancing feelings that they are at lower risk than other women. Counter to many theories of health behavior, reducing women’s perceived risk of breast cancer did not lower their intentions to get mammograms. Implications for the communication of breast cancer risk are discussed.

“The Effect of Making Risk Estimates on Consumer Preferences”

Nicholas Lurie, *University of North Carolina at Chapel Hill*

Michael Ranney, *University of California at Berkeley*

Although much of consumer behavior *implicitly* involves risk estimates (for instance, getting a mammogram implies a certain level of perceived risk of developing breast cancer), it is important to examine the effect of making estimates explicit. Making risk estimates explicit (i.e., by asking consumers to estimate the frequency of death from heart disease), may have important implications for behavior. For example, making estimates may lead consumers to be more likely to use data in developing preferences, making choices, or making them think more globally about risk. If consumers' risk estimates are accurate, they may lead to preferences that are closer to those consumers provide when given actual risk data (e.g., the number of women that die from heart disease). On the other hand, if consumers' estimates are inaccurate, asking for estimates prior to preferences may bias preferences away from those provided under full information. Another important issue regards how making estimates affects the integration of data. Making estimates may serve to anchor consumers' initial preferences and therefore make them less likely to change their preferences later in the presence of actual data. If estimates are an important determinant of preferences, then to what extent can providing consumers with risk data for related topics (information seeds) improve consumers' risk estimates and bring consumers closer to what seem to be their true preferences?

This paper presents the results of a series of studies that examine the effect of making estimates on preferences and vice versa. Using several variations of the EPIC method (Ranney et al., 2001), in which participants are asked to estimate (E), form preferences (P), integrate (I) actual data, and change (C) their preferences, we examine the relationship between estimates and preferences for allocating funds to research on pairs of various leading causes of death. Disease pairs included lung cancer versus skin cancer, breast cancer versus heart disease, stroke versus diabetes, and Alzheimer's disease versus Parkinson's disease. In addition to estimating frequencies of death, participants were asked to provide non-surprise intervals and confidence ratings for these intervals. Feedback consisted of actual mortality data from the Centers for Disease Control and Prevention (CDC).

We find that estimated frequencies are often far from actual frequencies and that the accuracy of estimates and non-surprise intervals are not reflective of self-reported familiarity with a disease, whether a friend or family member has the disease, or confidence in non-surprise intervals. More importantly, we find that, relative to eliciting preferences before estimates, or eliciting preferences only in the presence of actual mortality data, eliciting estimates before preferences can bring consumers closer to their post-feedback preferences for research support for some diseases (e.g., lung cancer) but farther away for other diseases (e.g., breast cancer). Those for whom actual frequencies fall outside non-surprise intervals are more likely to change their preferences after receiving feedback. At the same time, we find that initial preferences serve as anchors that limit the updating of preferences in the face of actual data and that making estimates can change the locations of these anchors. Interestingly, although there is high variance in the extent to which people who have a disease are seen as responsible for having their condition (e.g., lung cancer versus Alzheimer's) perceived “culpability” only occasionally seems to affect preferences.

In a second study, we find that providing information “seeds” (cf., Friedman and Brown 2000), in which participants are asked to

make estimates and then receive feedback for a different pair of diseases, improves estimates and moderates the biasing effects of making estimates found in the first study. These results have important public policy implications, since risk estimates often drive resource allocations (e.g., charitable contributions to different organizations). Although consumers seem willing to dramatically change their preferences in the face of actual data, they are still rather unwilling to discard their initial (pre-feedback) preferences. Information seeding is one way to improve estimates and enhance preference useful malleability. Examining other ways to improve consumers' numerical reasoning represents an important step for future research.

Do The Ones We Love Sometimes Hurt Us The Most: The Role of Relationship Norms on Consumers' Perception of Fairness and Brand Evaluations

Pankaj Aggarwal, University of Toronto

EXTENDED ABSTRACT

Prior work on fairness perceptions has found that in order to assess overall fairness of an event, people sometimes focus on distribution of the final outcome while at other times they focus on how they are treated by others in their interaction. This distinction between *distributive* fairness and *interactional* fairness can be of particular importance in a brand context since a better understanding of what influences a consumer's perceptions of fairness would go a long way in not just managing consumer complaints but also improving the long-term health of the brand.

Prior work has found that there is a two-way interaction between distributive and interactional fairness (Blodgett, Hill and Tax 1997). In other words, it has been found that issues of interactional fairness become especially relevant when the outcome is perceived to be distributively unfair. Thus, prior work suggests that when faced with a failure of product performance or service delivery, marketers need to take special care about how the consumers are treated by them. This research explores the question of whether the type of relationship that consumers have with a brand, in fact, influences the degree to which this attention to interactional fairness might be relevant. Thus, the primary goal of this work is to use a relationship framework to study differences in consumers' sensitivity to different aspects of fairness, which in turn influences their responses in the face of a negative brand experience.

Two types of consumer-brand relationships are examined—*exchange* relationships in which people provide benefits to others in order to get something back in return; and *communal* relationships in which benefits are given to take care of others' needs and to demonstrate concern for their well being (Clark and Mills 1993). It is hypothesized that, since, consumers in an exchange relationship attend to what they get and what they give, they would be influenced more by issues of distributive fairness. On the other hand, since, communal consumers attend to whether or not they are cared for in the relationship, they would be influenced more by issues of interactional fairness. Thus, a three-way interaction is hypothesized between relationship type, distributive (un)fairness and interactional (un)fairness. In other words, it is expected that consumers would be more sensitive to issues of interactional fairness when facing low rather than high level of distributive fairness, and this effect would be stronger for communal rather than exchange consumers. Further, this research explores the differences in the behavior of communal and exchange consumers as the level of interactional fairness changes.

Experiment 1 uses a scenario-based stimuli to test for a three-way interaction between relationship type, distributive fairness and interactional fairness. The relationship norms were first manipulated by getting the participants to read a description of their interaction with a hypothetical takeaway restaurant. Participants then read a description of a specific interaction—which resulted in different outcomes that were either distributively fair or unfair, and either interactionally fair or unfair. Participants then gave rating on different items that tapped into brand evaluation, quality of relationship and future intentions. Results supported the hypothesis for all three dependent variables. It was found that negative effect of distributive unfairness was mitigated as a result of the interactional fairness and that this effect was stronger for communal relative to exchange consumers. Results of the experiment highlight that communal consumers evaluate the brand better than exchange

consumers when faced with interactional fairness and evaluated the brand much worse than exchange consumers when faced with interactional unfairness. This suggested that the two relationships lead to some different processes that might be insightful to investigate.

Some recent work in organizational behavior suggests that there is threshold number of violations of fairness that must take place before a decision maker rejects a given alternative (Gilliland, Benson, and Schepers 1998). These authors suggest that beyond a threshold number of violations, the situation is judged to be unfair regardless of the number of violations. Given the evidence on the existence of a threshold of rejection, it is reasonable to expect participants to show a threshold of rejection to changes in the level (intensity) of interactional unfairness rather than only to the number of violations. Additionally, given that communal consumers are more sensitive to issues of interactional fairness, one would expect communal consumers to be more likely to have such a threshold of rejection more than exchange-oriented consumers. Experiment 2 tested this hypothesis.

Experiment 2 used a similar manipulation of relationship norms as was used in the first experiment. In this experiment, it was also decided to have four different levels of interactional fairness (poor, low, medium, and high). Thus, it was a 2x4 between subjects design. As before, participants read a description about an interaction with a brand (in this case an audio store), and then gave their response to items that tapped into their perception of brand evaluation, quality of relationship, and future intentions. Results suggest that communal consumers are more likely to show a threshold of rejection (somewhere between high and medium levels of interactional fairness) than exchange consumers. Specifically, results showed that exchange consumers lower their brand evaluations in a more linear fashion with each lower level of interactional fairness. In contrast, communal consumers lower their brand assessment dramatically between high and medium levels, beyond which their response too follows a more linear function.

In addition to being theoretically interesting this research outlines some important implications for marketers who sometimes struggle with handling consumer complaints.

Group Dynamics of Impulse Buying: An Extended Social Facilitation Perspective

Xueming Luo, State University of New York at Fredonia

EXTENDED ABSTRACT

While impulsive buying has attracted researchers' attention for more than one and a half centuries (e.g., Mill 1848; Baumeister 2002), most existing theory and research are limited to investigate it at the intrapersonal level. Although the individual level conceptualization of impulse buying is definitely not incorrect, it may be incomplete in that it excludes the potential interpersonal influence at the group level. Given the fact that most consumers shop not alone but with a group of people such as family members or friends, and that a large amount of impulse purchases are decided and made in the presence of friend and/or family groups, it seems rather logic to conceive the potential influence of group situations on one's impulse behavior. More important, according to social facilitation theory in social psychology (Triplett 1897; Zajonc 1965), an individual consumer's learning, motivation, and behavior may be facilitated by the presence of a group of people. In particular, consumers may engage in impulsive buying in a group situation that others are buying for five different reasons; (1) they are facilitated simply due to the mere presence of others, (2) they think others' opinions and behaviors are credible under the informative influence, (3) they may use others' behavior and their purchase as socially approved and desirable in general under the normative influence, (4) they want to compete when others are buying, not missing out on having products that others have, and (5) they may have released the inhibition in buying products they don't need but want to do so, taking others' buying behavior as a reasonable justification. Therefore, this research theorizes that the social presence and interactions with a group of people in shopping may influence the individual's felt impulse and resulting impulsive behavior.

Surprisingly, the academic and trade press has paid less attention to the existence and potential of the group influences on impulse buying beyond the individual level perspective. This research attempts to alleviate this deficiency in this research. An examination of impulse buying at the social group level is desired and important because Rook (1987, p.196) calls for future research on investigating impulse purchase from "a social environment (group versus solo buying) context", after a classical and comprehensive review of impulsive buying concepts. In addition, such an investigation at the group level may in general contribute to the consumer literature in that the existing literature is unbalanced and lacking studies of "groups of consumers such as two-person dyads, families, peer or friendship groups" at the interpersonal level (Bagozzi 2000, p388). Accordingly, this paper is to mainly explore group influences and their implications for individual impulse buying behavior.

Two experiments were conducted to test the influences of group type and group cohesiveness on impulse buying. The results of study 1 with a 2 (group shopping vs. solo shopping) x 2 (family members vs. peer friends) x 2 (high cohesive group vs. low cohesive group) mixed-factorial design support the ideal that group influence may induce more or less impulse buying than solo shopping without group influence. In particular, the more cohesive is the shopping group of peer friends, the more buying impulsiveness and impulsive purchase behavior would be reported. In contrast, the more cohesive is the shopping group of family members, the less buying impulsiveness and impulsive purchase behavior would be recorded. Study 2 used a 2 (high vs. low susceptibility to group influence) x 2 (group shopping vs. solo shopping) x 2 (family

members vs. peer friends) x 2 (high cohesive group vs. low cohesive group) mixed-factorial design. The results support the premise that the interpersonal antecedents' influences on consumer impulsive behaviors are moderated by susceptibility to group influence.

Three potential contributions of this paper are noteworthy. First, it extends the impulse buying literature from the *intrapersonal* trait perspective to *interpersonal* group dynamics perspective. It theorizes that group influence may induce more or less (than solo shopping) impulse buying depending on the cohesiveness of the shopping group and the member type of group (friends or family members). Second, it tests and finds initial evidence of the potential interpersonal antecedents of impulsive buying such as group type and group cohesiveness. Third, it lends some support that the interpersonal antecedent influences may be contingent upon individual traits such as susceptibility to group influence. Thus, both interpersonal antecedents and individual traits are important determinants of impulse buying and, thus, ought to be considered simultaneously in future research on impulse buying behavior.

When Research Participants Don't Tell It Like It Is: Pinpointing the Effects of Social Desirability Bias Using Self vs. Indirect-Questioning

Sabrina M. Neeley, Miami University
Maria L. Cronley, Miami University

EXTENDED ABSTRACT

Social desirability bias reflects the basic human nature to present oneself in a positive manner to others. Typically, this tendency takes the form of over-reporting opinions and behaviors that are congruent with values deemed socially acceptable and under-reporting those deemed socially undesirable. This bias concerns many behavioral researchers because of its threat to construct validity in measurement construction. However, social desirability bias is not just a problem for scale construction, but it can also present problems as a moderating variable or confounding factor when examining behavior. Since so much consumer behavior research examines the influences of others on attitudes and behaviors, as well as social/symbolic presentation, we would expect consumer research to potentially suffer from the compromising effects of social desirability bias. King and Bruner's (2000) investigation of papers published in top marketing journals from 1980-1997 revealed that only thirteen papers tested social desirability bias as a potential source of error.

Research designs that use a self-report format and measure constructs that have high social influence appear to foster problems with social-desirability bias (Fisher 1993; Fisher and Tellis 1998; Jo 2000; King and Bruner 2000). The use of indirect questioning is believed to lower social desirability bias by asking participants to report from the perspective of another person (Fisher 1993; Fisher and Tellis 1998). The assumption is that participants will project their own opinions and behaviors onto the referent person (Calder and Burnkrant 1977; Grubb and Stern 1971; Haire 1950). Self-report questioning methods, on the other hand, may increase the potential for social desirability bias as the participant seeks to manage the researcher's impression of him or her.

Recently, consumer behavior researchers were called to increase attention to social-desirability bias in design, measure construction, and analysis (Fisher 2000; King and Bruner 2000; Mick 1996). This research contributes to the discussion of the effects of social desirability bias in consumer research by examining the differences in responses between a self-report and an indirect-questioning method in split samples for two different studies of consumer behavior. These studies show the differences in reports that can be attributed to this bias.

The first study examines the influence of other people's opinions in a consumer's post-purchase evaluation and determination of satisfaction and looks at the use of this comparison standard for both expressive and private products. A 2 (questioning method) x 2 (product) between subjects experiment was performed. Each participant received a scenario about a recent purchase of either an expressive or private product and were asked to report on comparison standards used during post-purchase evaluation and satisfaction determination for either "you" (self-report) or "Jordan, a typical college student" (indirect-question). Results indicated significantly higher reporting of the use of other people's opinions by the indirect-question group during both post-purchase evaluation and satisfaction determination. Additionally, participants using an indirect question format rated other people's opinions as a more important comparison standard than did those using a self-report. Third, the difference in reported use of other people's opinions between participants using indirect vs self-report formats showed

strong significance for expressive products, but not for private products.

The second study is an exploratory survey of the effects of social desirability bias in a particular situation, health communication. It examines the ways in which physicians and patients discuss advertised prescription medications, motivations and attitudes behind those discussions, and outcomes of the conversations. It is qualitative in nature, and observes the potential moderating impact of social desirability bias on reported attitudes and behaviors related to patient-physician communication. Social norms typically encourage cooperativeness with those in authority and perceived power, but patients may feel intimidated by their physician. Given the nature of the communication relationship between patient and physician, social desirability may moderate the reported willingness to discuss medications, since patients want to appear cooperative and informed, and thus may self-report a high willingness to interact with their physician, but they may actually be intimidated or anxious.

Additionally, social desirability may play a role in reported attitudes towards persuasive communications (prescription advertising in this study). Research has found that when thinking about prescription drug ads in general, self-reported attitudes towards the ads tend to be rated lower than when a specific advertisement is being evaluated. In terms of social desirability influence, a person rating prescription advertisements in general may feel less compelled to please the researcher with positive evaluations than when evaluating a specific brand ad and may even unconsciously desire to appear unaffected by and unimpressed by this type of advertising (i.e., "I'm not persuaded by these ads, but others are."). Thus, while general attitude measures toward prescription drug ads would seem socially neutral, we might expect that with indirect-questioning, more favorable attitudes towards the ads to be reported.

Like the first study, a split sample was employed in order to observe potential between subjects moderating effects of social desirability bias. Study results supported the hypotheses about the effects of social desirability bias on the reporting of communication about, and attitudes toward, advertising. Participants evaluated themselves as more willing to discuss medications than typical others. Additionally, participants self-reported more moderate attitudes towards prescription drug advertisements than typical others.

The goal of this research was to examine the effects of social desirability bias in consumer research. While most consumer behavior studies examine social desirability bias as a threat to construct validity during measurement development, this research differs in that it considers social desirability bias as a moderator, or confound, in an empirical study explaining attitudes and behaviors. While the information goals of the two studies presented differ, results of both studies exemplify the potential sources of error from social desirability bias in consumer research. Results support that indirect-questioning methods evoke higher responses of socially undesirable behavior (e.g., influence from other persons and advertising) than a self-report. Additionally, the second study illustrated that a self-report question format would show higher reports of socially desirable behavior (e.g., discussions with physicians) than an indirect-question format.

What is the Relation between Culture and Desirable Responding?

Ashok K. Lalwani, University of Illinois, Urbana-Champaign

Sharon Shavitt, University of Illinois, Urbana-Champaign

Timothy Johnson, University of Illinois, Chicago

Jing Zhang, University of Illinois, Urbana-Champaign

EXTENDED ABSTRACT

The literature in cross-cultural psychology suggests that collectivists are more likely to engage in deception in order to save face and maintain harmonious relationships with others. In contrast, individualists are portrayed as candid and sincere because individualism encourages people to "be yourself." For example, Trilling (1972) argues that people in individualist cultures are more likely to seek sincerity and authenticity, whereas people in collectivist cultures de-emphasize authenticity. Similarly, Triandis (1995) proposes that honesty in interactions with strangers is a characteristic that is more highly valued by individualists than collectivists.

We argue that people with both types of cultural orientations engage in desirable responding, albeit in distinct ways. Given that individualists exhibit considerable biases in the form of possessing overly positive and unrealistic views of the self, enhancing the positivity of the self-view, and actively seeking information that maintains that inflated self-view (Diener, Diener and Diener, 1996; Heine and Lehman, 1995; Heine, Lehman, Markus and Kitayama, 1999; Taylor and Brown, 1988), we argue that individualists are likely to exhibit self-deceptive enhancement, the tendency to see oneself in a positive light and to give inflated assessment of one's skills and abilities.

On the other hand, given that collectivists are more likely to engage in deception (e.g., Triandis and Suh 2002; Trilling 1972), which in turn has been linked to impression-management motives (e.g., Jacobson, Berger & Millham, 1970; Kashy & DePaulo, 1996; Sengupta, Dahl & Gorn, 2002), we argue that collectivists are more likely than individualists to answer dishonestly in order to present themselves in a socially desirable manner.

Data were collected by administering questionnaires to an ethnically diverse sample of adults residing outside the campus of a major metropolitan area (study 1), and students attending a large Midwestern University (studies 2 and 3). In general, the results supported the above propositions. Findings also indicated that the horizontal dimension of both individualism and collectivism accounts for these relationships. Furthermore, the tendency of collectivists to engage in impression management was mediated by scores measuring their tendency to lie.

Our findings have important implications for researchers using surveys as a method of data collection. As is well known, desirable responding is one of the major causes of response bias and is a major threat to the validity of research findings (Johnson & Van de Vijver, 2002). Our findings suggest that researchers need to account for response bias in data collected across different cultures.

Further, the results of this study likely have important implications for various domains of consumer behavior. For example, our findings suggest that people with collectivistic cultural orientations would be more prone to overstating consumption of goods that help them maintain face or enhance their social standing, such as branded or expensive products. Collectivists may also understate their consumption of undesirable products like cigarettes and alcohol. Similarly, our findings suggest that people with an individualistic orientation and more particularly with a horizontal individualistic orientation may be more likely to exaggerate their skills and prowess in various matters (e.g., financial decision making, consumer judgments, and the like).

Image Congruence and Attitudes toward Private Brands

Dongdae Lee, Tongmyung University of Information Technology

ABSTRACT

Focusing on three types of image congruence surrounding private brands, this study explores their relationships with and effects on attitudes toward private brands. According to results; (1) private brands' images need to be created and maintained as target customers want, (2) product categories similar in image to their stores should be included in private brands, (3) retailers have to improve consumer attitudes toward stores by making their store images similar to consumers' self images, and (4) retailers need to change value-oriented strategies for their private brands with quality-oriented strategies.

Private brands have accounted for a sizable fraction of sales in retailing. For example, private brands have accounted for 13% of US supermarket sales in 1991 and 20% of Canada supermarket sales in 1990 (Hoch and Banerji 1993). There is also a report that private brands are top sellers in 77 categories among 250 product categories sold in the US supermarket (Quelch and Harding 1996).

Popularity of private brands is expected to grow among retailers due to several reasons. First, private brands have a higher gross margin opportunity than national brands (Lewison 1994; Raju, Sethuraman, and Dhar 1995). Although private brands are typically priced 15–30% lower than national brands (Ailawadi, Neslin, and Gedenk 2001; Mason, Mayer, and Ezell 1994), lower marketing costs compensate for the lower prices and allow private brands to enjoy higher overall gross margins than national brands. Second, private brands help retailers to gain control in the channel power struggle between retailers and manufacturers. With private brands as a bargaining tool, retailers can ask national brand manufacturers for better trading terms such as cheaper prices, quicker deliveries, more promotional items, and others. (Ailawadi, Borin, and Farris 1995; Chintagunta, Bonfrer, and Song 2002; Narasimhan and Wilcox 1998). Third, retailers can build distinctive store image with their private brands (Grewal et al. 1998; Richardson, Dick, and Jane 1994; Sayman, Hoch, and Raju 2002). Kenmore and Craftsman are good examples. These two private brands help shape Sears' image of economy and practicality. Fourth, private brands with strong and exclusive image can develop store traffic and loyalty (Corstjens and Lal 2000; Levy and Weitz 2001). Forenza and Hunters Run sold exclusively by The Limited store are powerful magnets for customers of the Limited.

Since the Frank and Boyd's (1965) seminal paper, research on private brands has been performed on various issues. Earlier research on private brands explored socio-psychological and demographic characteristics private brand users have (Coe 1971; Frank and Boyd 1965; Myers 1967) or studied differences between national brands and private brands (Swan 1974). Research on private brands in the 80's turned its focus on behavioral aspects of private brand users (Bellizzi et al. 1981; Cunningham, Hardy, and Imperia 1982). Studies on private brands in more recent years are mostly about factors and conditions related to market performances (Batra and Sinha 2000; Corstjens and Lal 2000; Dhar and Hoch 1997; Hoch and Banerji 1993; Raju, Sethuraman, and Dhar 1995; Richardson, Dick, and Jain 1994), positioning strategies (Ailawadi, Neslin, and Gedenk 2001; Sayman, Hoch, and Raju 2002), channel conflicts (Ailawadi, Borin, and Farris 1995; Narashimhan and Wilcox 1998), effects on retailers' pricing strategy (Chintagunta, Bonfrer, and Song 2002), and so on.

Various images are related with forming attitudes toward brands. For example, symbolic qualities of brands or brand

personalities are major determinants of brand evaluation and purchase. (Hirshman and Holbrook 1982; Solomon 1983). A consumer's self image also has a certain effect on brand evaluation (Grubb and Hupp 1968). Consumers prefer brands identifying with themselves, and their perception of a brand is organized along with their self images. Store image is another important factor in consumer brand evaluation. The image of a brand can be damaged if the brand is associated with a retailer having a less favorable image. For example, if Benetton apparel were sold in K-mart, Benetton would have difficulty in maintaining its high fashion image. Despite such importance, researchers did not have paid due attention to images related with private brands. Images or positioning problems of private brands are generally ignored by marketing literature (Sayman, Hoch, and Raju 2002).

Three types of image congruence particularly draw our attentions in relation with attitudes toward private brands. They are image congruence between a private brand and a consumer's self, image congruence between a store and a product category, and image congruence between a store and a consumer's self. These three types of image congruence are derived from three essential components determining attitudes toward private brands: brands, stores, and consumers. Between brands and consumers, image congruence between a private brand and a consumer's self is derived. Between stores and brands, image congruence between a store and a product category is derived. Between stores and consumers, image congruence between a store and a consumer's self is derived. Focusing on these three types of image congruence, this study tries to find their relationships with and effects on attitudes toward private brands. Along with image congruence, this study also explores roles of attitudes toward stores which are closely related with attitudes toward private brands. Although effects of image congruence have been explored by many researchers (Bellenger, Steinberg, and Stanton 1976; Hirshman and Holbrook 1982; Solomon 1983), they have never been studied under an integrated framework nor the perspective of private brands.

LITERATURE REVIEW

Importance of image in consumer behavior has been well documented (Bellenger, Steinberg, and Stanton 1976; Dobni and Zinkhan 1990). Image provides a critical cue for customer perceptions of products, brands, salespeople, and stores. Through image, consumers perceive a brand as a symbol and form quick summary information about the brand's quality and other related characteristics.

Image Congruence between a Private Brand and a Consumer's Self

Consumers purchase a specific brand not only for functional utility but also for social meaning and images the brand is associated with (Solomon 1983). Consumers prefer a brand when its characteristics match their perceptions of themselves. Because consumers compare a brand's personality and themselves, consumers' preference of a brand might be due to image differences between brands (Grubb and Stern 1971). It's quite natural for consumers to prefer brands that fulfill or enhance their self image. They try to maintain and affirm their worthiness as an individual. Through self-enhancing brands, they expect to heighten the value of themselves and to acquire social recognition (Kunda 2000). In fact, consumers tend to identify themselves with the brand they own. In a study employing two competing automobile brands,

Grubb and Hupp (1968) found that self concept and brand concept are closely related.

As in the case of national brands, there is a strong possibility that consumers' attitudes toward a private brand are closely related to their self images. If consumers believe that a private brand is similar to themselves, they will evaluate the private brand more favorably. On the contrary, if consumers believe a private brand is unfit for their self images, the private brand would be evaluated less favorably. Theoretical supports for a positive effect on the evaluation of private brands by image congruence between private brands and consumer themselves could be found in categorization theory. According to categorization theory, category similarity has a positive effect on consumer evaluation of a new category (Rosch 1973). That is, if a new category matches an existing category, consumers' attitudes toward the new category would be similar to their attitudes toward the existing category. Thus, if a consumer feels a private brand, a new category, similar to his/her self, an existing category, s/he would evaluate the private brand positively because s/he would normally have a positive attitude toward her/his self. Based on this reasoning:

H1: As image congruence between a private brand and a consumer's self becomes higher, a consumer's attitudes toward the private brand will be more favorable.

Image Congruence between a Store and a Product Category

Store image has considerable impact on the shopping decisions of the consumers (Zimmer and Golden 1988). Retailers maintain consistent store image to appeal to target segments. Store image consistent with the needs of the target market segment can lead to increased store loyalty, sales, and profit (Corstjens and Lal 2000). When they determine the merchandise mix of a store, retailers have to consider their store images. For example, a retail store trying to build high tech image should be equipped with high tech products. As an important element consisting of store image, merchandise mix should represent appropriate combinations of products fit for store image and customer needs. Because private brands are a part of store image, product categories associated with private brands are expected to reflect store image quite well. When they decide to include a new product category into its private brand, retailers need to carefully examine its effect lest it diminish the image consistency of the store.

A product category having similar characteristics to a store will make a good member for a private brand. For example, economic and utilitarian products are suitable for a discount store's private brands. Because these products offer a close conceptual fit for the store, consumers would have favorable attitudes toward private brands associated with these products. In the same vein, luxurious or high fashion items are more appropriate for a department store or a specialty store's private brands. If a new product category included into a private brand is unfit for store image, image incongruity between a store and a private brand will occur. For example, if Wal-Mart sells high fashion mufflers at very expensive prices under its own brand, Kathy Lee, consumers will be confused at the contradictory images the product brings in. In short, congruence between product image and store image will have a positive effect on a consumer's attitudes toward a private brand. While consumers evaluate private brands containing product categories fit for store image favorably, they evaluate private brands containing product categories unfit for store image unfavorably. Based on this reasoning:

H2: As image congruence between a store and a product category becomes higher, a consumer's attitudes toward

a private brand associated with the product category will be more favorable.

Store Attitudes and Attitudes toward Private Brands

As a part of a retail store, private brands are significantly affected by the evaluation of the store (Dodds, Monroe, and Grewal 1991). Because private brands generally do not engage in extensive out-of-store marketing activities, consumers commonly depend on their attitudes toward the store or store image when they evaluate a store's private brands. That is probably why consumers think sporty and urban images from 'Hunters Run' of the Limited and frugal and reliable images from Sam's Choice of Wal Mart (Levy and Weitz 2001). To receive more positive evaluation for their private brands, retailers have to improve consumers' attitudes toward stores through the development of specific store images that target customers want and prefer. Of course, consumers will not automatically evaluate private brands favorably even if they have favorable store attitudes. If, as mentioned in the previous section, inappropriate product categories are used for private brands, or if images of private brands do not fit well for store image, consumer evaluation of the private brands could remain unfavorable. Nonetheless, if all other conditions are equal, consumers with more favorable store attitudes would evaluate private brands more positively than consumers with less favorable store attitudes. Based on this reasoning:

H3: As a consumer's attitudes toward a store becomes higher, his or her attitudes toward the store's private brand will be more favorable.

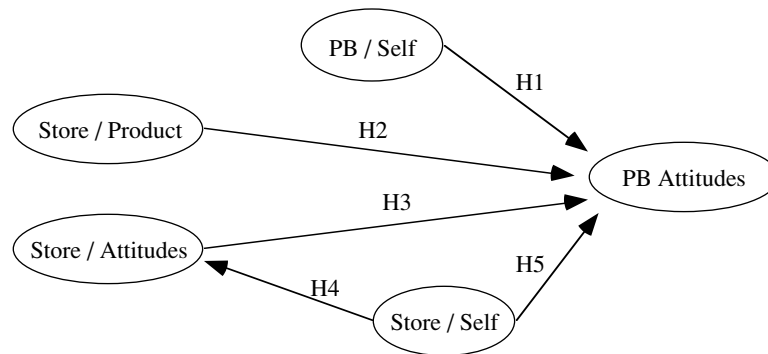

Image Congruence between a Store and a Consumer's Self

Effects on Attitudes toward Stores: Store image has a significant effect on consumers' store loyalty (Martineau 1958). Many studies support that store image has positive effects on consumers' purchasing in the store (Grewal et al. 1998; Zimmer and Golden 1988). Like a brand, consumers tend to select a store that has a personality consistent with their self images. Consumers prefer a store that provides self-enhancing opportunities (Kunda 2000). According to Bellenger et al. (1976), consumers' store loyalty is related to congruence between store image and self image. Therefore, developing store images consistent with self image of target consumers can lead to more positive attitudes toward the store. As in the case of image congruence between a private brand and a consumer's self, categorization theory again can be borrowed to explain the effect of image congruence between a store and a consumer's self on attitudes toward a store. If a store matches well with themselves, consumers will evaluate the store more positively. If a store does not match well with themselves, consumers will evaluate the store less positively. Based on this reasoning:

H4: As image congruence between a store and a consumer's self becomes higher, a consumer's attitudes toward the store will be more favorable.

Effects on Attitudes toward Private Brands: While image congruence between a store and a consumer's self has a direct positive effect on attitudes toward a store, it also seems to have a direct positive effect on attitudes toward private brands. As mentioned in the previous section, private brands are a part of store image. Therefore, if consumers believe a store fits themselves well, they will feel private brands of the store fit themselves well and evaluate private brands of the store more favorably. On the contrary, if they regard the store as not their type, they may evaluate private brands of the store less favorably. Based on this reasoning:

FIGURE 1
Hypothesized Relationships

H5: As image congruence between a store and a consumer's self becomes higher, a consumer's attitudes toward the store's private brand will be more favorable.

Figure 1 summarizes all the hypothesized relationships.

METHOD

Study Design

Two types of image are utilized for the current study: functional image and hedonic image. Two Korean retail stores are employed for the manipulation of store image. One is a department store (Lotte) and the other is a discount store (Mega Mart). Department stores represent hedonic image and discount stores represent functional image. Both stores are top contenders in each category. Perfumes and detergents are employed for the manipulation of product image. Perfumes are for hedonic image and detergents are for functional image. These two product categories were selected after a pretest. They had the most distinguishing image, either hedonic or functional, among eight product categories tested—earrings, crystals, perfumes, bracelets, cooking foils, detergents, toothpastes, shampoos. This manipulation of store image and product image resulted in a total of 4 different experimental cells: Lotte Perfumes, Lotte Detergents, Mega Mart Perfumes, and Mega Mart Detergents. For the current study, two real private brands—Charlotte from Lotte, Basquia from Mega-Market—are employed. They are utilized along with the assumption of new brand extensions into two product categories (i.e., perfumes and detergents). Details are explained in the following section. Consumer's self image was not manipulated but simply measured.

Data Collection

A total of 283 Korean consumers participated in the study. Subjects were conveniently sampled from residential areas near each store. They were randomly assigned to each of 4 experimental conditions. Only subjects who are familiar with the store in the questionnaire were allowed to fill out the questionnaire. Eight trained research associates conducted the field survey. They received about \$1 per response. Questionnaire items were arranged in the following order: 4 items measuring image congruence between store and product, 4 items measuring image congruence between store and self, 3 items measuring attitudes toward store, 3 items measuring product image, 4 items measuring image congruence

between private brand and self, 3 items measuring store image, 3 items measuring attitudes toward private brand, and a couple of demographic items in the end. Among the above mentioned measures, both product image measure and store image measure were for the purpose of manipulation checks. Before measuring image congruence between private brand and self, following sentence was mentioned: "Recently, many big retailers sell their own store brands. Lotte (or Mega Mart) has Charlotte (or Basquia) as one of their store brands. Assume that Lotte (or Mega Mart) sells perfumes (or detergents) under their own store brand, Charlotte (or Basquia). Please indicate your opinion on an appropriate number below in relation with Charlotte (or Basquia) perfumes (or detergents)." Subjects spent 5-10 minutes to finish the questionnaire. Among 283 responses, 10 were deleted due to omission and other reasons, resulting in a total of 273 completed questionnaires.

Measures

Image congruence: Traditionally image congruence was measured indirectly using discrepancy scores (Sirgy 1982; Sirgy et al. 1991; Sirgy et al. 1997). Examples of traditional congruence measure models include simple difference model, weighted simple difference model, Euclidian distance model, absolute difference model, difference squared model, and so on. In this study, however, congruence was measured with a new direct method suggested by Sirgy et al (1997). Based on Sirgy et al's (1997) self image congruence measures, items measuring a consumer's holistic, gestalt-like perception about the image congruence were developed for each of three image congruence. For the measurement of each of three image congruence, four 1-5 strongly agree-strongly disagree Likert type scales were developed respectively. Measuring items for the case of Lotte perfumes are summarized in Table-1. The same sentences were applied for the cases of detergents and Mega Mart.

Attitudes: Three 5-1 bipolar scales with endpoints labeled "good-bad", "like-dislike", and "favorable-unfavorable" were developed for the measurement of attitudes. The same scales were used for the measurement of attitudes toward store and attitudes toward private brands.

Image: Two identical sets of 5-1 bipolar scales with end points labeled "functional-hedonic", "rational-emotional", and "problem solving-autotellic" were developed to measure hedonic and functional dimensions of store image and product image. They were developed based on previous studies (Hirshman and Holbrook 1982), and used for the manipulation checks.

TABLE 1
Measuring Items for the Image Congruence
(Lotte Perfume Case)

Image Congruence	Items	
store vs. product	SP1	Lotte and perfumes fit well each other.
	SP2*	It's appropriate for perfumes to be sold at Lotte,
	SP3	Perfumes and Lotte make senses each other,
	SP4	Image of perfumes and image of Lotte are very similar.
store vs. self=	SS1*	Seeing Lotte users is very much like as if I see myself.
	SS2	Image of Lotte and my self-image are very similar.
	SS3	Lotte users are very much like me.
	SS4	People like me are the typical Lotte users.
private brand vs. self	PS1	I will be the typical user of Charlotte perfume.
	PS2*	Charlotte perfume will reflect well who I am.
	PS3	Charlotte and I will fit well each other.
	PS4	Image of Charlotte perfume and my self-image will be quite similar.

* items removed from the final analysis

RESULTS

Preliminary Data Analysis

Prior testing the proposed model, measurement models for exogenous variables(x) and endogenous variables(h) were tested with confirmatory factor analysis (Anderson and Gerbing 1988). Test results showed that while model fit for endogenous variables(h) was good ($c^2=13.27$ (d.f.=6, $p=.039$), NFI=.99, CFI=1.0, RMR=.041, GFI=.98, AGFI=.94), model fit for exogenous variables(?) was not very good. Using modification index, one observed variable from each of three exogenous variables(x_1, x_2, x_3) was removed. The new measurement model for x variables with three observed variables each produced a good model fit ($c^2=110.48$ (d.f.=47, $p=.00$), NFI=.96, CFI=.98, RMR=.037, GFI=.94, AGFI=.91).

Descriptive statistics for product images and store images were calculated. Perfumes (i.e., hedonic products) were rated more hedonic than functional in both stores ($m=2.57$ for Lotte; $m=2.43$ for Mega Mart), and detergents (i.e., functional products) were rated more functional than hedonic in both stores ($m=3.88$ for Lotte; $m=3.58$ for Mega Mart). Lotte (i.e., a hedonic store) was rated more hedonic than functional in both product categories ($m=2.98$ for perfumes; $m=2.71$ for detergents), and Mega Mart (i.e., a functional store) was rated more functional than hedonic in both product categories ($m=3.75$ for perfumes; $m=3.33$ for detergents). To find no difference in mean image values between experimental manipulations mentioned above, t-tests were performed. Contrary to expectation, t-tests identified significant differences in three cases except the case of perfumes. That is, no difference was found only in mean perfume images between Lotte (2.57) and Mega Mart (2.43). Because mean image values appeared as expected (i.e., functional when it should be, and hedonic when it should be), however, appropriateness of manipulations was checked again with

aggregate data based on product images and store images (Table 2). T-tests were performed to confirm differences in both product and store image manipulations. Test results showed that manipulations were successful. Table 2 summarizes t-test results for both product and store images

Hypothesis Tests

Hypotheses were tested through structural equation model using LISREL 8.30. The structural equation model is depicted in Figure 2. The structural equation model was estimated with Maximum Likelihood method after fixing the loading of one of the observed variables of each construct to 1. An acceptable model fit was generated ($X^2=257.14$ (d.f.=77, $p=0.0$), NFI=.94, CFI=.95, GFI=.90, AGFI=.84, RMR=.068), and hypotheses were tested with the analysis results (Table 3).

H1 is about the positive effect of PS(image congruence between a private brand and a consumer's self) on PA(attitudes toward private brands). The gamma coefficient between PS and PA was negative and significant ($g_{21}=-.73$, $t=-11.25$, $p<.000$). Because smaller values in the image congruence measure mean higher congruity, a direct positive effect of PS(image congruence between a private brand and a consumer's self) on PA(attitudes toward private brands) was observed. As the image congruence between a private brand and a consumer's self becomes higher, a consumer's attitudes toward a private brand become more positive. H1 was strongly supported.

H2 proposes that SP(image congruence between a store and a product) would have a positive effect on PA(attitudes toward private brands). The gamma coefficient between SP and PA was negative and significant ($g_{22}=.12$, $t=2.24$, $p<.05$). As images between a store and a product become more similar, a consumer's attitudes toward private brands become more positive. SP(image congruence

TABLE 2
Mean Ratings of Product and Store Images and t-test Results

Image Type	classification	mean (n)	s.d.	T	p-value
Product Image	Perfumes	2.4934 (152)	.7768	-12.923	.000
	Detergents	3.7245 (121)	.7884		
Store Image	Lotte	2.8611 (132)	.6408	-8.136	.000
	Mega Mart	3.5626 (141)	.7809		

(1: hedonic, emotional, autotellic 5: functional, rational, problem solving)

FIGURE 2
Tested Structural Equation Model

between store and product) has a direct effect on PA(attitudes toward a private brand). H2 was supported.

H3 is about the effect of SA(attitudes toward a store) on PA(attitudes toward a private brand). The beta coefficient between SA and PA was positive and significant ($\beta_{21}=.10, t=1.91, p<.05$). Attitudes toward a store have a direct positive effect on attitudes toward a private brand. In other words, consumer with more positive attitudes toward a store would have more positive attitudes toward a private brand. H3 was supported.

H4 suggests that SS(image congruence between a store and a consumer's self) has a positive effect on SA(attitudes toward a store). The gamma coefficient between SS and SA was significant ($\gamma_{13}=.44, t=-5.75, p<.00$). With the increase of similarity between a store's image and consumers' self images, consumers' attitudes toward the store become more positive. H4 was strongly supported.

H5 is about the relationship between SS(image congruence between a store and a consumer's self) and PA(attitudes toward a private brand). The gamma coefficient from SS to PA was significant ($\gamma_{23}=.19, t=2.78, p<.05$) but opposite to the hypothesized direction. Image congruence between a store and a consumer's self has a direct negative effect on attitudes toward a private brand. As

consumers feel themselves more similar to a store, their attitudes toward a private brand of the store become less positive. H5 was not supported.

DISCUSSION AND CONCLUSIONS

This study shows that image congruence between private brands and a consumer's self has a positive effect on attitudes toward private brands. In other words, as in the case of national brands, consumers compare private brands with their self-image when they form attitudes toward private brands. Therefore, retailers need to make their private brands deliver images that target customers want to attain. Reading customers' minds more carefully and developing their private brands' images in accordance with are what retailers need to do.

This study also confirms that image congruence between a store and a product category has a positive effect on attitudes toward a private brand associated with the product category. Consumers facing image incongruence in a store due to a wrong product category may be confused about intentions of the store. Confusion in image by consumers will not only interrupt retailer's store image fortification strategy but also have a detrimental effect on consumer's

preference of a store. Before including a new product category into their private brands, therefore, retailers need to find product categories similar in image to their stores.

Attitudes toward a store, as expected, have a positive effect on attitudes toward a private brand. In other words, if consumer attitudes toward a store become favorable, consumer attitudes toward a private brand become favorable too. One precaution, however, is interpretation of the positive effect by attitudes toward a store on attitudes toward a private brand should be limited because the effect is not highly significant ($t=1.91$, $p < .05$). Of course, if all other things are equal, stores with better image or more positive attitudes will have higher chances to receive more favorable attitudes toward private brands.

Positive effects of image congruence between a store and a consumer's self on attitudes toward a store were also confirmed. Because store attitudes have positive effects on attitudes toward a private brand, image congruence between a store and a consumer's self also has positive effects on attitudes toward a private brand, though indirectly. Therefore, retailers are recommended to plan and develop store images appealing to and wanted by target customers, and to maintain the established store images the same.

Contrary to the hypothesis, image congruence between a store and a consumer's self has negative effects on attitudes toward a private brand. That is, as consumers believe a store becomes more similar to their selves, they develop more unfavorable attitudes toward a private brand of the store. Although this result is somewhat unexpected, it could be understandable when we consider the negative perception many consumers have against private brands (Dunne and Narasimhan 1999; Richardson, Dick, and Jain 1994). If components of store image are grouped into two dimensions—positive and negative—and if consumers perceive private brands negatively, private brands, a component of store image, may belong to the negative dimension. If this is the case, even though consumers have positive attitudes toward the store, they may not have positive attitudes toward private brands that constitute the lowest class of merchandise in the store. As consumers feel the store more similar to themselves, their attitudes toward private brands could be all the more negative because private brands reflect negative aspects of the store. If this explanation is appropriate, this result means retailers to turn their value-oriented strategies into quality-oriented strategies to overcome consumers' negative perceptions toward private brands in general. According to many recent studies (Corstjens and Lal 2000; Dhar and Hock 1997; Hoch and Banerji 1993; Sayman, Hoch, and Raju 2002), quality-oriented strategies are more viable than value-oriented strategies for the success of private brands in the long run. Consumers' negative perceptions toward private brands

seem to have been a barrier rather than a catalyst for the development and success of private brands in the market.

Limitations and Future Studies

This study has some limitations. First, this study lacks unique characteristics in its theoretical framework for a study of private brands. To overcome this weakness, future studies need to either develop a more unique theoretical framework or compare private brands with national brands simultaneously. Second, besides three types of image congruence, other types of image congruence can be considered in the model. For example, image congruence between a private brand and a store or image congruence between a store and a divided consumer's self such as ideal self can be dealt with. Third, although this study explains the opposite test result of H5 with negative perceptions many consumers have against private brands, the explanation may not be enough. To solve this problem, more sophisticated studies are essential. Finally, this study was performed in Korean context. To verify and generalize the finding of current study, cross-cultural replications on this subject are required.

Category Induction and Nonmonotonicity: Application to Branded Products and Their Competitors

Christopher Joiner, George Mason University
Barbara Loken, University of Minnesota

EXTENDED ABSTRACT

In this research we examine the use of categories in reasoning, or more specifically, how individuals use information about one set of categories to make inferences about (or generalize to) another category. In particular we focus on the nonmonotonicity phenomenon (Osherson et al. 1990), examining how information about a competitor's product can weaken inferences about a brand's products under different conditions. We examine this category-based induction phenomenon in a pair of studies that investigated some of the factors, including the similarity of the competitor's product and the type of attribute information, that might mediate the effect.

Few studies have directly sought to examine the role of category relationships in inference making about brand categories, even though an important function of categories in information processing is to support these inferences (Ross and Murphy 1999). If consumers believe that two products belong to the same category, they may perceive them as sharing category attributes (Barsalou 1992). If a consumer believes that Nike cross trainers are durable, she may infer that another Nike product, or perhaps all Nike products, are durable. Osherson et al. (1990) developed an influential similarity-based model of category induction that we use as the conceptual basis for an investigation of consumer inference making.

Two studies examined the nonmonotonicity phenomenon in the context of brand categories. Presentation of the information as arguments followed the technique commonly used in research examining category-based induction (e.g., Choi et al. 1997; Osherson et al. 1990):

Argument A:	<u>Nike cross trainers are durable</u>	(premise)
	Therefore, all Nike products are durable	(conclusion)
Argument B:	Nike cross trainers are durable	(premise #1)
	<u>Reebok cross trainers are durable</u>	(premise #2)
	Therefore, all Nike products are durable	(conclusion)

Respondents were asked to rate the strength of each argument and then to select which one was strongest in a forced choice question. The nonmonotonicity effect was demonstrated when the single-premise argument (A) was rated as stronger than the two-premise argument (B).

The Osherson et al. (1990) model suggests that this inference from one branded product to others can be weakened by introducing seemingly irrelevant information. If the consumer knows that not only Nike, but also Reebok, cross-trainers are durable, she may be less likely to generalize this characteristic to the overall Nike brand category than without this competitor information. In other words this information may weaken inferences that all Nike products are durable. In a sense, the addition of information about Reebok sneakers (being durable) should not be relevant to whether the consumer infers that all Nike products are durable. So why should irrelevant information have an impact on inferences about branded products?

One explanation derives from theories, like the Osherson model, that analyze how people use category membership to determine how far they can generalize an attribute from one object to another (cf. Barsalou 1992; Osherson et al. 1990). Building on previous research, we examine how similarity judgments between

branded products and categories affect consumers' willingness to generalize about product attributes. According to Osherson's model, individuals are thought to generate an "inclusive category" that includes all of the brands, products, and categories being considered and which serves as an information processing, or inference-making, context. When competitor information is introduced along with the focal brand, this inclusive category/context broadens to include the competitor information. This broadening can create changes in perceptions about the similarities between the brands, products, and categories being considered. We look at how differences in these similarity perceptions impact the inference process.

We expect that adding a premise about a dissimilar competitor/product, as compared to a more similar competitor, will cause individuals to generate a broader, more variable inclusive category. As a result, the similarity relationships that drive consumers' inferences will be lessened, increasing the likelihood of the nonmonotonicity effect. The addition of the dissimilar competitor should have a significant impact on individuals' willingness to generalize the attribute. We also address a criticism of the Osherson model by directly investigating how the nature of the attribute (meaningless/blank vs. meaningful/nonsalient vs. meaningful/salient) plays a role in this form of reasoning. We suggest that when individuals reason about meaningful product attributes (vs. meaningless, hypothetical attributes), they are more likely to rely on existing category knowledge and to use heuristic, similarity-based processes increasing the incidence of the nonmonotonicity effect. Blank attributes are more likely to elicit more formal, analytic strategies that rely on non-similarity-based modes of making judgments decreasing the incidence of the effect.

Our data reveals that the nonmonotonicity effect does exist with consumer stimuli. Consumers reduced their willingness to generalize about a brand attribute from a specific branded product (Nike cross trainers) to the general category (all Nike products) as a result of the simple addition of information about a competitor's product that possesses the same attribute. Our data provided support for the Osherson et al. (1990) similarity-based coverage hypothesis. The introduction of the competitor information changed the category that provides a context for the information and the resulting similarity judgments that support the attribute inferences. Our data suggest that the nonmonotonicity effect is moderated by the two factors we considered. First, the nature of the attributes appears to play a significant role in similarity-based reasoning. Meaningful, and especially salient, attributes increased the incidence of the effect. Second, the addition of information about a dissimilar competitor increases the likelihood of the effect relative to information about a similar competitor.

When Categorization is Ambiguous: Factors that Facilitate and Inhibit the Use of a Multiple (Versus Single) Category Inference Strategy

Jennifer Gregan-Paxton, University of Delaware

Steve Hoeffler, University of North Carolina

Min Zhao, University of North Carolina

EXTENDED ABSTRACT

Prior research has established that categorization plays a central role in new product learning (Sujan, 1985). Very little is known, however, about the operation of this commonly studied category-based learning process under conditions of categorization ambiguity. Categorization ambiguity exists when information about a new product makes it difficult or impossible to place the novel offering in a single, existing category. Many of the new technological innovations hitting the market today fit this profile, as they often combine the features and functionality of existing products to create a single hybrid product. For example, there are personal digital assistants (PDAs) with cell phone functions and cell phones with PDA functions. The categorization of these products is highly ambiguous because, in both cases, the hybrid could logically be considered either a PDA or a cell phone.

It is currently unclear how consumers use existing category knowledge when faced with ambiguity of this nature. Of particular interest is whether and under what circumstances consumers employ a multiple (versus single) category strategy to generate inferences about ambiguous products. When faced with a PDA-cell phone, for instance, the question is whether consumers will base their expectations about the product on knowledge associated with multiple categories (*both* the PDA category *and* the cell phone category) or a single category (the PDA category *or* the cell phone category). Existing consumer research is all but mute on this issue. The focus of prior studies has been almost exclusively on inference generation from a single category (for a notable exception, see Moreau, Markman, and Lehmann 2001), leaving all but the most basic questions pertaining to multiple category use unanswered. Addressing this void, the purpose of this paper is to examine the factors that determine whether consumers will rely primarily on a multiple or single category inference strategy under conditions of categorization ambiguity.

Generating Inferences When Categorization Is Ambiguous

Existing research suggests that individuals are able to use information from multiple categories to draw inferences about ambiguous stimuli, but that they are typically unwilling to do so unless significant contextual support is provided. These findings are valuable for establishing that individuals can employ a multiple category strategy, but they give us little insight into the general factors that facilitate and hinder the use of a multiple (versus single) category strategy. In addition, it is difficult to predict which category consumers would select as the source of inferences in the event that a single category strategy is implemented. Absent this information, it is difficult to make specific predictions about consumers' use of existing category knowledge to generate inferences about ambiguous products.

With this in mind, in the next section, we identify two factors—category familiarity and the nature of the category cue—that we believe are responsible for regulating the incidence of multiple (versus single) category inference processes.

Category Familiarity

In order to generate inferences via a multiple category strategy, it is often necessary to change or update at least one of the

categories involved in making the prediction. To see why, consider the case of the PDA-cell phone mentioned earlier. When consumers confront an ambiguous product like the PDA-cell phone, and attempt to use both the PDA and cell phone categories to make predictions, they are likely to generate inferences that entail discrepant attribute values. As an example, if consumers are asked if the PDA-cell phone will be good at *scheduling*, their PDA category will indicate a positive response, while their cell phone category will indicate a negative or “not applicable” response. In contrast, if consumers are asked if the new product will be good at *making phone calls*, their PDA category will indicate a negative or “not applicable” response, while their cell phone category will indicate a positive response. In general, thinking about an ambiguous product as an instance of one category will lead to the generation of very different expectations than thinking about the product as an instance of a second distinct category.

This suggests that a category updating process is likely to be initiated as a result of multiple category inferencing. That is, consumers are likely to either (a) update the PDA category to accommodate the new value for making phone calls or (b) update the cell phone category to accommodate the new value for scheduling.

The Nature of the Category Cue

Category membership information can be delivered either *perceptually*, via visual depiction of a category member, or *conceptually*, via a category label. Research on the relative diagnosticity of conceptual versus perceptual information in the inference generation process has yielded mixed results. In one study, subjects were presented with pictures of exemplars that were physically similar to members of one category, but possessed the label of another category, and were asked to predict a missing feature. The results suggested that subjects placed significantly more weight on the (conceptual) category label information than the (perceptual) category similarity information when generating their inferences (Yamauchi & Markman, 2000). Other research has reported just the opposite. Pitting category label information against category similarity, Florian (1994) found strong evidence that subjects based their attribute inferences entirely on similarity.

This divergence in findings may be explained, at least in part, by variance in the relative diagnosticity of perceptual versus conceptual information across stimuli and situations (Feldman & Lynch, 1988). Supporting this interpretation, Yamauchi and Markman (2000) found that not all category labels were equal in their ability to override category similarity in the inference process. Specifically, category labels designed to convey class inclusion information (e.g., labels indicating two types of bug) had more power to sway inferences than those lacking this highly diagnostic information (e.g., labels indicating two shapes of wing).

Hypotheses

H1: When an ambiguous product is represented perceptually by a high familiarity category and conceptually by a low familiarity category, a single category inference strategy will be used where inferences will be based on the high familiarity category.

H2: When an ambiguous product is represented perceptually by a low familiarity category and conceptually by a high familiarity category, a multiple category inference strategy will be used where inferences will be based on both the conceptually and the perceptually cued categories.

Results and Implications

While it has been possible in prior research to prompt individuals to draw on multiple categories to generate inferences about an ambiguous item, rather extreme measures were required to achieve this outcome. Indeed, this body of work leaves one with the impression that people are unlikely to rely on a multiple category inference strategy unless they are placed in highly contrived conditions. The results of our studies suggest otherwise. Respondents in study 1 employed a multiple category inference strategy in response to an ad that represented an ambiguous product perceptually as a member of a low familiarity category (PDA) and conceptually as a member of a high familiarity category (cell phone). Attempts to focus respondents' attention on a single category in study 2 by strengthening the activation of the low familiarity perceptually cued category failed to dissuade them from relying on multiple categories to generate inferences. Likewise, attempts to weaken the conceptual cue in study 3 by replacing it with a low (versus high) familiarity category failed to derail the use of multiple categories.

Is Being Good Better Than Being Cheap, or is Being Cheap Better Than Being Good?

ABSTRACT

An assumption in the literature on defensive customer retention strategies is that customers who receive poor service quality from their current supplier are more inclined to switch to an attacking supplier. However, what to communicate to trigger switching from existing supplier to a new, previously unknown supplier is less known in this literature. This paper investigates how attacking firms can design persuasive advertising messages aiming to capture competitors' customers. In a 2 x 2 factorial experiment we find that economic advertising appeals are more persuasive than appeals stressing service quality for subjects currently receiving poor service quality. For customers who perceived service quality to be satisfactory, there was no difference in persuasiveness between the different appeals.

INTRODUCTION

In a wide range of contemporary textbooks, journal publications and popular press discussions on service marketing, firms have been advised to focus on service quality, customer satisfaction, and customer loyalty. In other words, maintaining long-term relationships with customers has been a catchphrase over the last decades, and this defensive strategy towards improved economic performance (Anderson, Fornell, and Lehmann 1994; Fornell 1992) has proved significant merits to its credit. However, while firms strive to keep their current customers satisfied and loyal, this strategy has usually been accompanied by attempts to recruit new customers. For example, introducing services of enhanced sophistication to members of their frequent flyer programs has not necessarily reduced airline companies' quest for recruiting new customers by means of price reductions, new product developments (e.g. new destinations) and the like. Hence, service firm managers are often confronted with the riddle of combining defensive strategies aimed at keeping current customers satisfied and loyal, and offensive strategies directed at "stealing" customers from competitors. We acknowledge both these strategies as equally important, and as such, this paper attempts to delve into how a service firm can use basic knowledge about defensive strategies when initiating offensive marketing strategies in target markets. Stated differently, how can knowledge on the mechanisms working within the basic quality, satisfaction and loyalty models be used by attacking companies in designing advertising appeals to capture the customers of incumbent service providers? This is the center of attention in this research, and the subsequent paragraphs will outline our specific research questions.

When trying to retain customers, the quality of the service delivery has proved to be a major determinant of customer loyalty (Zeithaml, Berry and Parasuraman 1996). Hence, the dominant thinking is that customers who perceive the service to be of high quality, will be more inclined to stay with the service provider than customers who experience the opposite (Oliver 1997). However, due to the intangible nature of most services, two different customers might have completely different quality perceptions of the same service provider. To further complicate the issue, the same intangible nature of services might result in different objective quality levels because service quality differ among employees who provide the service, at different points in time, and the like. Accordingly,

variation in customers' perception of service quality might result from either an objective quality difference or from a subjectively perceived difference based on expectation diversity (Boulding et al. 1993). These basic assumptions explain why perceptions of service quality often vary within the customer group of one specific company. Customers who assess the quality of received services to be unsatisfactory should be more inclined to switch to another supplier, which is an assumption supported extensively in the literature (Fornell et al. 1996; Ping 1993; Selnes 1993; Yi 1990). Frequently, a motive needs to be triggered to affect behavior. In this case the question pertains to which appeals could trigger the motive to switch?

Firms who are initiating an offensive strategy aimed at recruiting customers presently served by competitors should intuitively aim for the dissatisfied customers. The assumption from the loyalty literature is that these are more prone to switch than the satisfied customers. The question, then, is what kind of message to send these customers? Drawing on a customer value perspective (Newman 1988), although in a simplified version, we argue that customers can either be told that higher service quality can be acquired at a price equal to the one paid today, or that the same level of quality might be received at a lower price. Stated differently, a persuasion attempt can draw on two fundamentally different kinds of arguments; being better or being cheaper.

Being Better...

First, one might argue that if the reason some customers are dissatisfied is because of quality absence, then the message should focus on the quality dimensions of the service offered. So doing, several effects might be achieved. If the customer compares the quality he has received from the current supplier with the quality arguments communicated by the attacking firm, any gap in favor of the attacking firm may produce a situation of perceived inequity, thereby decreasing satisfaction even more and in so doing boost the intention to switch to the attacking supplier (Yi 1990). Moreover, if an attacking firm plays the service quality card, the message will hit the displeased consumer right in the heart of his source of dissatisfaction with the current supplier. In a relationship between a service provider and a customer, the customer's satisfaction level is based on an attitude-like post purchase evaluation (Mano and Oliver 1993). An important detail in this respect is that for a wide range of services the core offering is more or less standardized (e.g. hotel beds, airline seats, travel agent services), leading competition to be more or less centered around the extended offering (Zikmund and d'Amico 1996). Stated differently, competition places the additions in the spotlight, while the core offering is often more or less equal across firms. This implies that the quality of the core offering itself might often be viewed as a hygiene factor, while the extended (service) offering is what makes up motivation factors (Herzberg, Mausner and Snyderman 1959). Drawing on a multi-attribute attitude model (Lutz 1991), being informed about an alternative supplier's quality on important (extended product) attributes might alter the customer's attitudes in favor of this new supplier. Likewise, from a decision theory perspective (Bettman, Johnson and Payne 1991), arguments focusing on the attacking supplier's quality on attributes where the current relationship partner performs

poorly might result in the attacking firm being the one that stands out in a firm-by-firm comparison. Now the incumbent firm is not just facing a dissatisfied customer, but a dissatisfied customer aware of a better alternative. And probably worse—a customer with an increased intention to switch.

Being Cheaper...

Second, a persuasive message can be rooted in purely economic arguments, thus trying to position one's own services as cheaper than those of the competitors. Economic arguments like low price is a competitive strategy that draws on the varying price consciousness, price sensitivity and economic well being of consumers (e.g. Lichtenstein, Ridgway and Netemeyer 1993). While the economic success for a low price strategy is contingent on a variety of issues like the firm's ability to develop a cost leadership (Porter 1985), the inherent consumer benefits related to low price is more straightforward. For example, given that service products hold equal quality levels, the less expensive one should generally be chosen over the more expensive ones (Edwards 1954). Hence, economic arguments should intuitively be tempting to a number of consumers. In addition to the attractiveness of economic arguments *pr se*, the intangible nature of services also gives reasons to expect that customers will be influenced by price arguments. Services are an experience kind of product, and their quality can thus first be properly evaluated at the time of consumption (Lovell 1983). The smoothness of a hotel bed, the taste of a restaurant meal, or the social character of a bank employee–customer interaction cannot be appraised until the customer actually tries or purchases the service. This implies that up front evaluations to a large extent has to be based on beliefs and evaluations of more tangible facets of the service, of which price is the most explicit one. From a decision theory perspective we might argue that one of the few real diagnostic pieces of information a customer can receive about a formerly untried service is its price (Feldman and Lynch 1988). As such, the alternative supplier does not necessarily have to convince the consumer that the quality of the services offered is better than the ones currently received, as long as the price is lower.

Summing up, the preceding paragraphs have shown that the service quality literature gives little advice when it comes to how an attacking service brand should target the customers of incumbent service brands with advertising appeals. However, we have argued that judgments of service quality received from current supplier, might affect the extent to which appeals from attacking brands trigger motivation to switch or not. We have presented arguments suggesting that the two main appeal strategies of being better or being cheaper draw on different explanatory assumptions. The service quality appeal might be effective because it positions itself as better than the service experience received from the current supplier, and thereby facilitates comparison. In other words, the appeal attempts to juxtapose itself on attributes of the extended service offering, a challenging task considering the customer's reduced ability to assess these attributes prior to experience (Zeithaml 1988). However, the economic appeal's effectiveness rests on the assumption that price is a more diagnostic piece of information in service delivery settings where the quality of the delivery is impossible to assess prior to switching. The following paragraphs presents an experiment undertaken to test these two options.

METHODOLOGY

The purpose of the current study was to test the extent to which customers with different service quality judgments were differently motivated to switch from their current service supplier based on quality vs. economic advertising appeals from an attacking brand. Basically, this represented a 2 (ad-appeal; economic vs. service

quality) x 2 (service quality: high vs. low) between subjects factorial design. Subjects were 113 undergraduate business school students who participated as part of a course requirement. The use of this subject-pool enabled us to efficiently assess their judgments of received service quality and expose them to advertising messages at different points in time. Setting and subjects were considered in conjunction. The context chosen was retail banking, and the attacking service firm was a hypothetical bank with a brand name set up for this study only. The group of students receives student loans from an official government office, a fixed amount at a regulated interest rate. As such, they are consumers with money to spend, and importantly, money to place in a bank. Additionally, all students would have bank accounts already, and they would all have some experience with a current bank-service provider. During the past decade a number of new actors have entered the retail bank market in question, and a several of these have targeted their services especially towards students. This implies that we could credibly announce that a new bank aiming directly at students was to be launched, thus providing a good cover for our manipulation.

Manipulation and Measurement

The first key independent variable, *advertising appeal*, was manipulated through two advertisements. The service quality oriented appeal offered "your own personal adviser to assist you in everything related to personal finance", "We will work hard to adapt to your personal needs", "Membership with Gold-card status in our Key-Customer Program", etc. The focus was intentionally service-relation oriented, and nothing was said about economic benefits. In the economic appeal version, statements included "The student's first choice, and the first bank in the market with price-guarantee", "PC-purchase financing with 0% APR, two year down payment", etc. Besides from argument type, the two ads were completely identical in all other respects (i.e. colors, fonts, pictures, size, etc) and they were both in the format of a full screen sized Internet advertisement.

Service quality was measured with reference to the subjects' current bank-relationship. A total of 6 Likert-type items adapted from the Servqual-instrument were used to tap this construct (Zeithaml and Bitner 2003). Examples on items are "Employees in your bank understand your specific needs" and "Employees in your bank are consistently courteous with you". A confirmatory factor analysis was employed to test the unidimensionality of the service quality scale. A one-factor solution was attained, with factor loadings varying from 0.735 to 0.872. The eigenvalue for the first factor was 4.25, and 70.8 % percent of the variance was explained. The 6 items were collapsed into a summated rating scale with Chronbach's Alpha=0.9. We thus believe the validity and reliability of the service quality measure is quite satisfactory. Next, the summated rating scale was dichotomized based on a median split (median=3,67), thus forming one high and one low service quality group.

The measure on Intention to switch to the attacking retail bank was adapted from the behavioral intentions measures offered by Zeithaml, Berry and Parasuraman (1996), and read "When you get the opportunity to switch from your current retail bank and to this new bank, how likely do you think it is that you will switch to this new bank?" Both the service quality scale and the behavioral intention item were 5-point measures, with anchors "Totally agree/Totally disagree" and "Not likely at all/Extremely likely", respectively.

Experimental Procedure

The study was completed in two sessions. First, students were randomly assigned to two groups, shown the cover story, and the

TABLE 1
Service Quality x Ad Type Interaction

		Ad type	
		Economical	Serv.qual
Service quality	High	4.19 (1.77) n=26	4.37 (1.82) n=27
	Low	5.75 (1.64) n=32	4.42 (2.13) n=28

note: std.deviation in parentheses

advertising message (either the economic appeal or the service quality appeal). Subjects were exposed to the ad for 15 seconds. Pretests had proved this to be sufficient to read all message arguments at a moderate pace. Subjects then filled out a booklet consisting of a variety of demographic questions, advertisement ratings, and also indicated to what extent they intended to switch to the new bank, once launched. Finally, they answered questions pertaining to the perceived relevance of the messages, the cogency of the presented arguments, and evaluated the extent to which the theme of the advertisement was economical or service oriented, measures intended to serve as manipulation checks.

The second round of the study commenced two days later. As a part of another study, the students answered a standardized customer satisfaction index questionnaire (e.g. Johnson et al. 2001). The subjects were told to answer the survey with the currently used retail bank in mind. Items for service quality assessment were embedded in this questionnaire.

Results

To assess the extent to which the advertisements were perceived as economical or service quality oriented, a one-way ANOVA was run on the item asking subjects to rate on a nine point scale the extent to which the theme of the ad was 1=economical, to 9=service quality. Subjects in the economical treatment condition rated the advertisement as significantly more economical ($M=3.96$) than subjects in the service quality condition ($M=5.8$), ($F(1,110)=20.904$, $p<.000$). A similar analysis was also run to assess the extent to which the two advertisements were perceived as equally cogent. Subjects in the economical treatment condition perceived their advertisement to be more cogent ($M=5.38$) than those in the service quality condition ($M=4.75$), ($F(1,110)=3.47$, $p=.065$), indicating that there could be a chance that the economically oriented advertisement by nature was more convincing. Finally, it could also be the case that the two ads were seen as unequally relevant to the subjects. A one-way ANOVA indicated that subjects in the economical treatment condition perceived the advertisement slightly more relevant ($M=5.81$) than those in the service quality condition ($M=5.13$), ($F(1,110)=3.014$, $p=.085$).

Intention to Switch to the Attacking Brand

The crucial test in this study is the extent to which subjects are motivated to switch to the attacking brand dependent on the service quality level of their current brand, and the advertising appeal of the attacking brand. A 2(service quality) x 2(ad type) between-subjects ANOVA on intention to switch yielded the results presented in

Table 1 and Figure 1. First, a main-effect of service quality was obtained as subjects in the low service quality condition was significantly more inclined to switch than subjects in the high service quality condition ($M_{low\ serv.\ qual}=5.09$, vs $M_{high\ serv.\ qual}=4.28$, $F(1,109)=5.38$, $p=.022$). This a result that corresponds to our expectations, as the basic assumption is that low service quality leads to behavioral consequences unfavorable to the company (Zeithaml et al. 1996). There was no main-effect of ad-type, indicating that the small difference found in the manipulation check did not appear in the motivational capacity of the different advertisements.

Additionally, there is a significant interaction effect between service quality and ad-type ($F(1,109)=4.635$, $p=.034$). As indicated in Table 1 and Figure 1, the service quality argument scores equally regardless of the subjects' level of perceived service quality from their current supplier.

In contrast, the economical appeal scores significantly better among the customers who are dissatisfied with the service quality received from their current supplier. These subjects are not receptive to claims about improved service quality from the attacking supplier. In other words, the results indicated that addressing the causes of consumers' unhappiness when trying to seize them from a competitor is not a feasible strategy.

Related to subjects who rates the services received from the incumbent service supplier to be of high quality, the two ad-themes are equally (in)effective. Accordingly, the effect of ad-type on customers' intention to switch is dependent on the quality received from current supplier. Our results have shown that economically oriented advertising themes are not unequivocally more effective in an assumingly economically oriented business like retail banking.

DISCUSSION AND IMPLICATIONS

The results of our experimental study hold some important implications for marketing theory and practice. In outlining the background for the study, we drew on extant satisfaction literature when advocating that persuasion attempts towards dissatisfied customer should aim at the basis for this displeasure (e.g. Oliver 1997; Newman 1988). In contrast, based on a rational decision making perspective (e.g Edwards 1954) we also argued that price arguments would be a viable strategy due to the intangible nature of experience goods (Alba et al. 1997). Stated differently, information on tangibles will be most diagnostic, and information on aspects like price will therefore influence the decision outcome the most. The empirical findings supports this line of arguments. The idea that customers are unable to evaluate quality dimensions of services

FIGURE 1
Ad Type x Service Quality Interaction

up front is supported by the interaction effect, which shows that economic arguments are the most persuasive ones when the target customers are dissatisfied.

The results of our study also have managerial implications for both offensive and defensive marketing strategies. First, independent of argument type, attacking firms will have an easier job in increasing their number of customers if they first and foremost concentrate on the competitors' less satisfied customers. Furthermore, for the attacking firm our results clearly indicate that recruiting competitors' customers will most successfully be achieved by persuading them by means of economic arguments. However, there are both pros and cons related to such a strategy. As for the pros, a newly introduced brand might find itself with a fast growing market share if competing on price. In this light, price arguments will be very efficient if market share is the firm's primary objective. However, the cons of such a strategy is that firms applying this strategy might both be viewed as a low price actor in the market, while also facing the challenge of keeping low prices on a long-term basis. While the practical examples on price strategies aimed at customer recruitment exists in vast numbers, the examples on how such strategies have constrained firms from reaching the economic performance yearned for is also substantial. Generally speaking, the major drawback of being tempted by price cuts in order to attract new customers is that competitors can easily copy this strategy. As such it does not help firms achieving a sustained competitive advantage (Barney 1991). Hence, we suggest that firms should take the results found in our study into consideration when designing offensive strategies, and contemplate what argument type to use in relation to the overall ambition of the firm, both in terms of market share, brand positioning and future performance.

Second, also for firms applying defensive strategies aimed at retaining their customers our results are of importance. Due to the aforementioned inherent intangibility of services, the level of service satisfaction held by customers will always vary to some degree within a customer group. When trying to improve the satisfaction, loyalty and thus persistence to persuasion among currently dissatisfied customers, our results might be viewed in favor of playing a price, or economic argument, card. We do not necessarily see this as a fruitful path to increased performance. While price arguments might be the most efficient strategy when trying to recruit customers, recall that the reason customers leave due to low service quality is not related to price, but to quality (Zeithaml et al. 1996). Hence, we suggest that firms facing such challenges should focus on improving the facets of service that are the direct antecedents to service failure, and have a long-term orientation on this course of action. Only through focus on customer needs and preferences will the firm be able to increase satisfaction among customers, and adhering to such a focus will be a more successful route to competitive advantage than being tempted by short-term price cuts (Barney 1991).

Limitations and directions for future research

This research presents some initial results indicating that a company that aims to sway customers from an incumbent brand should be attentive to the service quality perceived by the incumbent's customer when designing persuasive advertisements. Especially, it seems that customers receiving poor service quality, are not necessarily looking for alternative suppliers promising better service quality, but rather, a better deal in more economic terms. However, additional studies are needed to address methodological and

theoretical concerns. First, this study only used undergraduate students as sample. It might be argued that based on their relatively lower income-level, they should by nature be more receptive to economically oriented claims. Then again, we should expect so regardless of their level of perceived service quality. In the high service quality group, no differences in claims' persuasiveness were found, thereby questioning the extent to which an "economical bias" influenced our results. Additional studies could test our assumption in another sample, or vary the sample according to this potential biasing factor. Second, evaluations of service quality can be made with varying levels of confidence, depending on the extent to which consumers evaluate search, experience or credence services (e.g., Zeithaml 1988). Banking services are for many purposes search (you can seek out prices prior to adoption), experience (you will experience service level as the relationship develops), and credence (due to lack of expertise, you will have to trust that the bank does its best for you). However, our study did not allow analysis to check the extent to which these sources of performance information were differentially affecting the customers' evaluations or responses. Future research could address this within a bank setting, or utilize different service categories to provide a more explicit test. Third, we utilized a cumulative approach to the measurement of service quality (see e.g., Anderson, Fornell and Lehman 1994), as this cumulative approach has been argued to be more indicative for behavioural intentions. This did not allow us to manipulate service quality judgments. Conversely, service quality could be manipulated in future studies utilizing different service categories. Finally, we measured intention to switch two days prior to assessing level of service quality. Although our service quality measures were embedded as part of a large survey, covering other areas as well, it could be the case that students remembered their previous responses, and tuned their subsequent quality evaluations accordingly. We would assume that the same tuning-problem could surface if the experiment followed the opposite order, but this could also be explicitly manipulated in future studies. A final venue for future research could be to include measures of personality traits, customer expertise, and other situational variables to assess the robustness of our results.

SPECIAL SESSION SUMMARY

The Influence of Cultural Thinking Style on Evaluative Processes

Kyoungmi Lee, University of Illinois at Urbana-Champaign
Sharon Shavitt, University of Illinois at Urbana-Champaign

SESSION OVERVIEW

Many current theoretical frameworks pertaining to consumer evaluation have been validated only within the U.S. culture. Maheswaran and Shavitt (2000) proposed that the lack of robust frameworks across cultures has severely limited the development of theory-based empirical work. The three papers in this session suggest that culturally linked thinking styles are important mechanisms underlying consumers' evaluative processes for a variety of products and services.

Although cultural thinking styles have been studied intensively in social psychology, they are only starting to attract attention in consumer research. Social psychologists have characterized the reasoning of Western cultures such as the U.S. as analytic, context-independent, and characterized by formal logic, whereas that of Eastern cultures is characterized as holistic, context-dependent, and dialectical (Nisbett et. al. 2001).

In the first paper, Priester, Park, Petty, Wang, and Lee examine whether members of different cultures have different cognitive tendencies toward acceptance of the feelings of conflict toward a target, which pertains to the tendency of *dialectical thinking*, and further different levels of evaluative tension. Specifically, from the standpoint of Western cultural reasoning, the coexistence of positive and negative feelings about the same target is viewed as a contradiction. Hence, those in Western cultures perceive such feelings of "intrapersonal" conflict as less acceptable—accordingly, evaluative tension increases. East Asian dialectical reasoning, however, is more tolerant of such "intrapersonal" conflicts, accepting contradiction and the need for multiple perspectives.

In the second paper, Lee and Shavitt investigate the role of *context-dependent* thinking styles and salient self-construal in pre-purchase quality evaluation. Previous research has concluded that the effect of store name on quality evaluation of a product is minimal compared to price and brand name. They suggest that consumers with salient interdependent (vs. independent) self-construal use store name more, because they are more concerned about the social image implied by store name.

In the third paper, Fedorikhin and Cole suggest that members of different cultures may appraise a service failure differently. Accordingly, a wait for 20 minutes at a McDonald's could evoke more anger in a person from one culture than from another. Such difference in appraisal of service failure and subsequent emotional response may stem from different expectations of consistency of service quality based on cultural cognition. For example, members of holistic cultures are more likely to tolerate an environment that is less controlled and more contradictory to their expectations than are those in analytic cultures (Peng and Nisbett 1999). Notably, the authors found that consumers high in vertical individualism are the most susceptible (i.e., generate more anger) to service failures such as long wait times, which subsequently affects their purchase intentions. It implies that in analytic cultures involving more vertical individualism, people have lower thresholds of tolerance when their expectations conflict with perceived service failure.

"Culture Moderators to Feelings of Ambivalence: When Intra- versus Inter-Personal Conflict Leads to Feelings of Evaluative Tension"

Joseph R. Priester, University of Michigan
Kiwon Park, University of Michigan
Richard E. Petty, Ohio State University
Yu-Peng Wang, Shih Chien University, Taiwan
Kyu-Hyun Lee, Hannam University, South Korea

In both marketing and psychology, there has recently been a surge of interest in better understanding the construct of ambivalence (e.g., Larson, McGraw, and Cacioppo 2001; Newby-Clark, McGregor, and Zanna 2002; Nowlis, Kahn, and Dhar 2002; Sengupta and Johar 2002). Attitudes are typically conceptualized as lying along a bipolar continuum, ranging from negative/unfavorable/dislike on one end of the continuum to positive/favorable/like on the other end. Such a conceptualization obscures the possibility that certain attitudes may contain both positive and negative reactions. For example, Otnes, Lowrey, and Shrum (1997) found that individuals, rather than feeling differing degrees of positivity, often felt both positive and negative reactions to wedding planning.

Recent research by Priester and Petty (2001) has demonstrated that feelings of evaluative tension (i.e., ambivalence) can be the result of not only an individual's own positive and negative feelings (intrapersonal conflict), but can also be the result of holding an attitude that is inconsistent with an important other, such as a best friend of a parent (i.e., interpersonal conflict). Of particular interest with the Priester and Petty (2001) findings was that intrapersonal conflict influenced feelings of evaluative tension approximately three times greater than interpersonal conflict. That is, an individual's own feelings were more influential in causing feelings of evaluative tension than interpersonal attitudinal conflict. It should be noted that these findings were based upon individuals from an independent (i.e., USA) culture, in which the self is largely construed as an individual's own traits, abilities, thoughts, and feelings (Markus and Kitayama 1991). This finding for individuals from an independent culture raises the intriguing question of whether the antecedent of ambivalence varies as a function of culture. Such is the question that drives this research program.

In order to address this question, 1) measures of individuals' own positive and negative reactions to attitudes (i.e., intrapersonal conflict), 2) measures of the extent to which individuals' attitudes were consistent or in conflict with important others (i.e., interpersonal conflict), and 3) indicators of the extent of feelings of evaluative tension were collected. From these measures we could examine the relative influence of intra- versus inter-personal conflict on feelings of evaluative tension.

We adopted two approaches to addressing the conceptual issue of culture. First, measures of individual differences in independence and interdependence were collected. Second, individuals were recruited from either interdependent (Korea, Taiwan) or independent (USA) cultures. As such, we were able to ask whether 1) individual differences, regardless of the country of the participant, and 2) whether country of the participant, influenced the relationship of the source of conflict (inter- versus intra-) on feeling of evaluative tension. That is, we were able to assess how cultural differences potentially moderate the antecedent of ambivalence

using two different operationalizations of interdependence and independence.

The results are consistent with the hypotheses. Specifically, for individuals who are high in interdependence and low in independence (as assessed by individual differences) interpersonal conflict has a greater influence of feelings on evaluative tension than intrapersonal conflict, whereas for individuals who are high in independence and low in interdependence, intrapersonal conflict has a greater influence on feelings of evaluative tension than interpersonal conflict. Similarly, for individuals from interdependent countries, interpersonal conflict has a greater influence of feelings on evaluative tension than intrapersonal conflict, whereas for individuals from independent countries, intrapersonal conflict has a greater influence on feelings of evaluative tension than interpersonal conflict.

The value of this research has to do with broadening the conceptualization of ambivalence from a definition of conflicting positive and negative reactions to one of understanding ambivalence as the result of conflict with beliefs and norms consistent with cultural differences.

“The Role of Cultural Cognition in the Use of Contextual Cues in Product Quality Judgments”

*Kyoungmi Lee, University of Illinois at Urbana-Champaign
Sharon Shavitt, University of Illinois at Urbana-Champaign*

Quality evaluation drawn from extrinsic cues such as price, brand name, and store name play an important role in consumers' prepurchase evaluations of a product. Generally speaking, high price, good brand name, or positive store name connote better quality products to consumers. When consumers consider all three cues together, however, the findings of previous research suggest that the effect of store name on a product's perceived quality is statistically insignificant, whereas those of price and brand name are substantial (Rao and Monroe 1989).

These findings must be disappointing for retailers who have grappled with the task of maintaining a positive store name and image in a highly competitive retail environment. Still, the findings suggesting a minimal impact of store name have been verified only within Western cultures. We suggest that the impact of store name on product evaluation actually depends on consumers' self-construal.

For example, in an interdependent cultural context, people might be more prone to using cues such as store name to make their decisions. One reason might be that when an interdependent self-construal is salient, people tend to use contextual cues (Kuehnen, Hannover and Schubert 2001). Another might be that, to the extent that one's relations with others are salient due to an interdependent self-construal, consumers tend to be interested in socially visible information that will reflect favorably on their public image. Our research was not designed to distinguish these possibilities, only to assess the role of store cues in product evaluation in independent vs. interdependent cultural contexts.

In Study 1, we examined the effect of a store cue on product evaluation by choosing two cultures in which independent and interdependent self-construal are dominant. Specifically, we measured consumers' evaluations of running shoes using a 2 X 2 X 2 (i.e., high-low price, brand name, and store name) between-subjects design in both the U.S. and Korea. Supporting the hypotheses, the results revealed that the favorability of a store's name affected quality evaluation in the Korean sample but not the US sample. Further an interaction showed that when store image is low, even a good brand name could not enhance quality perceptions in the Korean sample. This is contrary to previous findings suggesting that the effect of brand name is the strongest among the three cues

and does not diminish under various cue conditions (Dodds, Monroe, and Grewal 1991). Our results suggest that previous findings regarding the insignificant effect of store name on brand perceptions may actually be culturally bounded.

In Study 2, we sought to replicate these effects by priming independent and interdependent self-construals among U.S. participants. Microwaves were the stimulus product and participants were presented with price and brand name along with either store name or a *Consumer Reports* type rating along a 5-star quality scale. Both price and brand name were fixed at a middling point, whereas the valence of store name and consumer 5-star-scale rating were varied. A statistically significant 2-way interaction emerged between self-construal prime and the use of store name ($F(1, 59)=3.11, p<.05$). That is, participants in the interdependent prime condition were more influenced by store name ($M=-.13$ vs. $.47$) than were those in the independent prime condition ($M=-.73$ vs. $.60$). However, as expected, there was no significant difference in the use of 5-star quality ratings information ($F(1,59)=.02, n.s.$) between independent ($M=.31$ vs. $.82$) and interdependent ($M=.27$ vs. $.60$) prime conditions. Thus, participants in the interdependent-priming condition were influenced by store name more than were those in the independent-priming condition, but this was not a general tendency to give greater consideration to any information.

We argue that an interdependent self-construal leads consumers to use store name as a cue because it enhances interest in socially visible information that will reflect favorably on one's public image. If this is correct, then one would expect store name also to be used as a cue under other circumstances that enhance interest in socially visible information. For products that convey symbolic information, for instance, store name may be used as a cue even when an independent self-construal is salient. In Study 3, therefore, we compared the use of store name with utilitarian vs. symbolic products. Between-subject factors were self-construal priming (independent vs. interdependent) and product types (utilitarian vs. symbolic). Microwaves and running shoes were determined as utilitarian and symbolic products respectively based on pretests. High versus low store name was a within-subject factor. For microwaves, a significant difference emerged across prime conditions in the use of store name ($F(1, 38)=2.9, p<.05$). Specifically, replicating Study 2, participants with interdependent priming were more influenced by store name ($M=-.05$ vs. $.58$) than those with independent priming ($M=.33$ vs. $.53$). For running shoes, however, the effect of store name did not depend on prime condition ($F(1, 35)<1, n.s.$); i.e., there was no difference in the effect of store name between interdependent ($M=.00$ vs. $.42$) and independent-primed participants ($M=-.22$ vs. $.50$). In short, when store name was considered relevant to consumers with an independent self-construal because the product carries symbolic meaning, differences across priming condition disappeared and consumers overall used store name in their product evaluation. Therefore, it appears that store name is used as a significant cue in product evaluation for consumers with salient interdependent self-construal because of their increased concern about social image.

“Service Encounters and Emotions across Individuals and across Cultures”

*Alexander Fedorikhin, University of Southern California
Catherine A. Cole, University of Iowa*

The US economy has not only become more service oriented, but increasingly dependent on exporting these services. According to Starbucks' Chief Executive Orin Smith, the company's overseas outlets will eventually outnumber domestic stores. A company like Starbucks sells more than just a cup of coffee; it also sells a friendly

ambiance and positive emotional experience. However, just like many other CEO's nowadays, Mr. Smith realizes that what constitutes friendly ambiance and positive experiences varies from country to country because consumers are not the same in other countries, even if they speak the same language. Managers therefore recognize that it is important to study how cultural differences influence consumer emotional reactions to service experiences.

There also appears to be an increase in academics' interest in studying international differences in consumer behavior recently including recent calls for researchers to "break out of the North American box" (Gorn 1997). One area that has not received much attention of marketing academics is cross-cultural differences in consumer emotional experiences.

This research project is the first one to investigate the interactions of consumer emotions with cultural orientation variables in their impact on behavioral intentions variables, such as intentions to spread word of mouth, purchase intentions, and willingness to complain, all crucial variables in consumer behavior from both theoretical and managerial perspective.

Background

Individualism/collectivism, perhaps the most central dimension of cultural variables, has been used in marketing to understand how cultural differences affect various aspects of consumer behavior. Several recent analyses report that these constructs can be further differentiated in terms of horizontal (emphasizing equality) or vertical (emphasizing hierarchy) dimensions (Singelis et al. 1995, Triandis and Gelfand 1998). Literature in this area indicates that a person can score high or low on all four dimensions (Triandis and Gelfand 1998).

Methodology

To conduct our research, we constructed 8 scenarios about a trip to a local cafe, varying length of wait (longer or shorter than expected), responsibility for wait (service provider versus client), and equality of treatment (equal versus unequal treatment). We then randomly distributed the scenarios and written translated questionnaires to consumers in the US, Russia, and Argentina. The countries were selected because they vary widely on the collectivism/individualism dimensions.

Results

We predicted and found that the effects of length of wait on negative emotions (anger and guilt) and positive emotions (joyfulness) are moderated by consumers' cultural orientation. For example, the length of wait had a stronger effect on those who scored high on the vertical individualism dimension than those who scored low (more anger and less joyfulness). Most importantly, as hypothesized, we found that the effect of emotions on behavioral intentions is moderated by cultural orientation variables. For example, the collectivism dimensions moderated the negative effect of anger on the intention to keep patronizing the service provider, such that those who scored high on the collectivism dimensions were less likely to stop patronizing the service provider even when they were angry compared to those low on collectivism.

SPECIAL SESSION SUMMARY

Effects of Framing on Magnitude Perceptions of Prices

Manoj Thomas, New York University

Vicki Morwitz, New York University

SESSION OVERVIEW:

It is widely accepted that the perceived magnitude of price plays an important role in product choice and consumer decisions. A question that is of interest to researchers in pricing is whether the perceived magnitude of the price is the same as the nominal magnitude of the price. In this session, we present and discuss research that addresses this question. The three papers presented in this session address the basic research question: What factors cause consumers' perceived price magnitude to differ from the nominal magnitude of the price? The first paper by Nunes and Drèze examines the effect of the currencies used to frame the price on consumers' reactions to that price. More specifically, this paper examines how firms can strategically use prices issued in combinations of currencies (e.g., dollars and miles or points), and how the firm can alter the distribution of these points as well as the reward levels to maximize loyalty and willingness to pay. The second paper by Redden, Williams and Fitzimons examines whether prices are framed as a partitioned price (e.g., base price plus separate charge for shipping and handling) or as one aggregate price (e.g., total price including shipping) affects consumers' perceptions of the price magnitude. Specifically, this paper focuses on the circumstances and the mediating variables that determine when partitioned prices lead to underestimation of the total product price. This paper suggests that consumers' expectations with regard to whether the price will be offered as a partitioned price, will moderate the effect of this framing on magnitude perceptions and choice. The third paper by Thomas and Morwitz examines how the left digit in a price exerts an undue effect on consumers' magnitude perceptions. Specifically, this paper examines whether changing the price of a product by one cent (which in turn changes the left digit of the price) can significantly alter the perceived magnitude of the price. This paper shows that even a one-cent change in price can impact perceived magnitude of the price under certain circumstances.

LONG ABSTRACTS

"The Pseudo-Sunk Cost Effect: How Varying Reward Levels Affects Prices in Alternative Currencies"

Joseph C. Nunes and Xavier Drèze

The immense popularity of loyalty programs has resulted in a variety of new "currencies" that people budget, save and spend much like money. For example, 100 million people worldwide collect frequent flier miles. After comparing the relevant figures with all of the notes and coins in circulation around the globe, the *Economist* (May 4, 2002, p. 62) proclaimed miles the "world's second biggest currency" after the dollar. American Express is in the midst of a marketing blitz touting how points earned in its *Membership Rewards* program have no expiration and offer the greatest selection of "must-have rewards." Yet, it is unclear how consumers value alternative currencies, or more specifically how reward redemption levels impact their valuations. As consumers are increasingly able to pay for goods and services such as airline travel, hotel stays and groceries in various combinations of currencies, understanding how shoppers respond to prices utilizing alternative currencies is becoming increasingly important to marketers.

Traditionally, consumers must accumulate enough of a particular currency (e.g., American Express Reward Points, Frequent Flier miles) to "earn" a reward. Previous research (Drèze and Nunes 2004) has outlined the conditions under which a combined-currency price, or a price issued in multiple currencies (e.g., \$39 plus 16,000 miles) is preferred to a price issued in one currency. This research explores how the firm can manipulate reward levels and the distribution of currencies in order to increase customer loyalty and steer preferences between combined-currency prices and prices assessed in a single currency.

We conducted a series of studies and presented three experiments. Study 1 tests the effect of increasing versus decreasing fungibility (i.e., the ability to spend various increments) on a consumer's drive to accumulate a currency (i.e., customer loyalty or retention) and choices regarding when and how to spend increments of that currency. Heath, Larrick and Wu (1999) have shown that people are willing to exert more effort as they approach their goal and less effort as they move away from a goal. Just as someone whose goal is to do 40 sit-ups would be expected to exert more effort to do their 39th sit-up than their 35th, 4,000 miles would mean more to someone with 20,000 miles than to someone with 10,000 miles, when the amount needed for a free ticket is 25,000 miles. We hypothesize that reward levels act as goals and that the marginal value of alternative currencies increases as consumers draw nearer to their goals. The result shows how the strategic setting of reward levels can affect the valuation of alternative currencies, and hence both (a) loyalty, and (b) the choice of pricing schedules when various options are issued in combinations of currencies.

Study 2 illustrates how bequeathing consumers with an endowment in an alternative currency can increase their propensity to make future purchases (loyalty) and the amount that they are willing to spend (willingness to pay). We find that endowing consumers with assets in a particular currency, while elevating the goal (the quantity of that currency that they must accumulate to earn a reward) commensurately, increases the marginal value of each unit of the currency. A sunk cost (Arkes and Blumer 1985) is traditionally associated with decision-makers reluctance to "waste" what they have allocated to a purpose, or to see progress (i.e., effort) towards a goal that they do not wish to discard. We demonstrate a similar effect when consumers are given assets in an alternative currency—they see these points or miles as progress, despite the fact that they are not truly earned and no effort was expended. Therefore someone given 500 points will work harder (spend more, or steer purchases) to reach 1,500 points than someone with 0 points will work to reach 1,000. The effect is mediated by the type of medium (purchases versus points) and the presence of an explanation for the endowment. The result is that the firm can strategically use endowments to boost loyalty (i.e., customer retention) while holding the revenue objective (goal in the alternative currency) constant.

In Study 3, we explore some traditional mental accounting phenomena that are robust with regard to dollars, and how consumers respond when analogous choices are presented in alternative currencies. The results reveal mixed support for the expected results given previous findings in mental accounting.

“Price Partitioning: No One Likes Surprises”

Joe Redden, Gavan Fitzsimons and Patti Williams

Marketers frequently break a product's price into two required components, such as \$70 plus \$10 shipping and handling. This practice has been referred to as partitioned pricing (Morwitz, Greenleaf, and Johnson 1998). The assumption is that product demand will increase when the price is presented as two separate components, as people will not accurately calculate the total cost and will make decisions based upon a lower perceived price. Since every firm does not present their prices this way in practice, there are likely conditions under which partitioning is not beneficial. While past research has investigated the phenomenon (e.g., Morwitz, et. al. 1998), questions remain regarding how consumers process this information and circumstances under which partitioned prices may be more or less beneficial to marketers. This research uses consumer expectations to explain when price partitioning can provide an advantage, and when partitioning can be detrimental.

Morwitz, Greenleaf, and Johnson (1998) have shown that consumers will increase product choice under a partitioned pricing regime. They attribute this to a lowered perceived cost due to either under-adjustments from the base price anchor, or the absence of any adjustment due to the cognitive effort required. Chakravarti, et. al. (2002) recently found that mental accounting helps explain different partitioning behaviors. By partitioning a specific attribute, marketers encourage a mental accounting comparison for that attribute and can position a product more favorably.

Although these results focus on the positive benefits of partitioning, a number of theories suggest that partitioning could have potential costs. First, people may view the additional surcharge as a loss, in which case prospect theory (Kahneman & Tversky, 1979) would suggest decreased product demand due to a segregation of losses. Second, marketers may trigger reactance (Brehm 1981) in consumers who feel their options have been reducing by forcing them to pay for an attribute they thought they were already getting. Third, an additional fee that is not typical for that product could increase the attention paid to the task (Goodstein 1993) and cause consumers to focus more on the price and exert the mental effort to perform the necessary addition.

When a customer expects the surcharge item to already be included in the base price, these potential costs will become more salient. Most of the existing partitioning studies have involved attributes which are customarily priced in a partitioned fashion (e.g., shipping, warranties). However, consumers will expect some attributes to be included with the base price, such as a fee for speaking with a bank teller or flying standby on a flight (*NY Times* Dec. 28, 2002). These expectations will be based upon previous experience with the category, the array of choices in a consideration set, etc. We have used this idea of expectations to explain existing results, as well as suggest moderating conditions and new effects.

A first study has found several key results supporting the expectation story. The study chose an ambiguous attribute (web features) to partition for the price of a cell phone. The expectations about whether this attribute should be in the base price were measured, rather than manipulated. Subjects always saw a control phone with a single lump-sum price and were randomly given a second phone that either had partitioning or a single lump-sum price of the same amount. The dependent variables were product choice likelihood and recall of total cost. Product choice was significantly lower than a combined price when price partitioning was not expected. Cost recalls suggest a reactance or attention mechanism at work as most recalled prices were near the base price or near the accurate total price (i.e., very few recalled prices were in between the base and total price). Further, a number of subjects appeared to mistake the partitioned price for an optional fee. If this misinterpre-

tation helps drive the partitioning effect, this suggests that partitioning may be particularly effective when the subject is not involved.

Two additional studies examine the mediating constructs of the partitioning-expectation interaction. Both of these studies retain product choice and cost recall as the dependent variables. The second study replicates the findings in our first study and explores the constructs mediating the results of the first study. The design is similar to the first study with additional emphasis on the required nature of the surcharge, as well as measures to determine the mediation of reactance and/or confusion. The third study manipulates consumer expectations by making partitioning in the choice set either the norm or the exception. This design provides some insight into the temporal and contextual nature of the partitioning expectations.

“Penny Wise and Pound Foolish: The Left Digit Effect in Perceptual Responses to Multi-Digit Numbers”

Manoj Thomas and Vicki Morwitz

The popularity of nine-ending price points amongst retailers has attracted researchers' attention as early as 1930. Past research suggests that using a nine ending price (e.g., \$1.99 instead of \$2.00) can have a significant impact on firms' profits (Schindler and Kibarian 1996, Blattberg and Neslin 1990, Stiving and Winer 1997). However, the cognitive process that leads to price ending effects remains enigmatic (Monroe and Lee 1999).

We conducted four experiments to examine how price endings affect numerical cognition processes. Results of study 1 suggest that nine endings in a product price reduce the perceived magnitude of the price relative to a reference price only when the left-most dollar digit changes. Study 2 shows that effects of nine endings in a price are moderated by the difference between the nine-ending price and reference price; nine-endings effects are *more likely* to manifest when the prices being compared are close to each other. Study 3 measures response times to confirm that the moderating effect of distance was mediated by cognitive load. Study 4 replicates this effect in a non-price domain, namely consumers' perception of quality ratings. Based on these four studies, we propose three properties of nine ending price cognition: the left digit effect, the distance effect and domain invariance.

The Left Digit Effect. The left digit effect refers to the property that underestimation of a nine ending price is more likely when the left-most digit of the nine ending price changes. Using a nine ending instead of a zero ending, for example \$2.99 instead of \$3.00, changes the dollar digit (from three to two) and it is this change in the left digit rather than the one cent drop that affects the magnitude perception of the price. The analog model of numerical cognition (Dehaene 1997) states that multi-digit number comparison entails two processes; first the different digits in the numbers are converted into holistic mental quantities represented on an internal analog scale and then these analog representations are compared. However, despite the fact that perceivers take into account all the digits in encoding the magnitude of a multi-digit number, due to left-to-right processing, at least in some situations, the left-most digit is likely to exert a greater influence on the encoded magnitude.

Distance Effect. The left-digit effect does not manifest always. Perceivers tend to anchor magnitudes of multi-digit numbers on the left digit only when the internal discriminability between the two numbers being compared is poor. Research in marketing suggests that price evaluation often, if not always, involves a comparison of two prices, a target price and a comparison standard (Adaval and Monroe 2002, Janiszewski and Lichtenstein 1999, Niedrich, Sharma and Wedell 2001, Winer 1988). However, before two numbers can be compared the numerical symbols have to be mapped on to the internal analog scale. This process of mapping from numerical

symbol to mental magnitudes imposes a cost on the speed of mental calculations when the numbers being compared are close to each other. The closer the numbers being compared, the greater is the difficulty in discriminating the numbers on the internal analog scale. Consequently, the closer the numbers being compared, the greater is the likelihood of the left digit effect.

Domain Invariance. Domain invariance refers to the property that the underestimation of nine-ending numbers is not restricted to the domain of prices; it manifests with other multi-digit numbers also. Past research has often attributed the popularity of nine ending prices to perpetuated retailing practices (Gabor 1977, Gabor and Granger 1964, Schindler 1991). Based on a survey of published material and informal conversations with consumers and retailers, Schindler (1991) proposed a list of fourteen meanings that price endings are likely to communicate to consumers. These meanings can be broadly classified into two groups: price-related meanings (such as “low price,” “discount price”), or meanings concerning non-price attributes of the product or retailer (such as “low quality”). However, if consumers’ favorable response to nine ending prices is solely on account of the images of ‘discount’, ‘low price’ etc. evoked by these prices, then these effects should be confined to the domain of prices. On the contrary, if these effects are, at least partly, due to the influence of left-to-right processing during the magnitude encoding of multi-digit numbers, then these effects should remain invariant to changes in domain. Drawing on the premise that left to right processing is a fundamental characteristic of multi-digit encoding, we predict that left digit effect and its interaction with distance effect will manifest in all nine ending numbers and not just prices. (It may be noted that we are not ruling out the image effects phenomenon in price cognition; rather, our suggestion is that nine ending numbers can be underestimated even when these numbers are not associated with images of low magnitudes.)

The question whether consumers respond differently to a price that is a cent lower than the nearest round figure is interesting from a theoretical as well as managerial perspective. From a theoretical perspective, the answer to this question will contribute to the literature on cognitive responses to numerical stimuli. The answer will be germane to researchers debating whether numbers are processed analogically or digitally (Dehaene, Dupoux and Mehler, 1990; Hinrichs, Yurko and Hu, 1981).

SPECIAL SESSION SUMMARY
Memory Accessibility and Product Judgment

Stijn M. J. van Osselaer, Erasmus University

SESSION OVERVIEW

Three papers were presented that investigate the effects of accessibility of information in memory on product judgment.

The first paper, by Tybout, Sternthal, Malaviya, Bakamitson, and Park, addresses a paradoxical set of results. Prior research suggests that asking consumers to generate multiple reasons to buy a product can have both positive and negative effects on product judgments. The authors investigate the conditions under which these effects occur. Their results show that the effects of generating reasons are moderated by the accessibility of the reasons in memory. When the reasons are highly accessible or inaccessible, asking for more reasons prompts more favorable judgments. Between these extremes in accessibility, asking for more reasons prompts less favorable judgments. The authors argue that these results are driven by the independent operation of two memory processes—one involves using the content of the retrieved information as a basis for judgment (i.e., evaluation is based on the diagnosticity of the accessible information), while the other involves monitoring of the retrieval process and then making a judgment based on how easy it is to retrieve the information (i.e., evaluation is based on the accessibility of the information). When accessibility of reasons in memory is very low, consumers do not perceive ease of retrieval to be diagnostic of their feelings about a product. In such a situation, product judgments are based on the content of the information available (with more positive information being retrieved when asked to generate more rather than fewer reasons). When accessibility of reasons in memory is very high, retrieval ease is again not perceived as diagnostic and product judgments are again based on the content of the information considered. Between these levels of accessibility, ease of retrieval is perceived as diagnostic and the difficulty of retrieving many reasons has a negative effect on product judgments. Four experiments support these hypotheses.

In the second paper, Vanhouche and van Osselaer report four experiments showing that attributes that often bias product judgments can also enhance the accuracy of product judgments by making individual consumption experiences more accessible in memory. Specifically, the authors show that adding product information (e.g., irrelevant attribute information) that initially biases product evaluations because consumers expect it to be correlated with product quality even when it is not, can actually make those evaluations more accurate over time. This happens because the added information does not merely function as a general heuristic cue that biases judgment. It can also help consumers access specific product experiences in memory. The authors find that this is not only the case when the biasing cue and actual quality are completely uncorrelated. For example, when price and quality were positively correlated across products but one product featured a high price and low quality, post-experience quality judgments for the latter product were more accurate than when no price cue was added. Finally, the authors also find that potentially-biasing cues, such as price, may have an even stronger exemplar-memory-enhancing effect than cues that consumers do not expect to be related to product quality. This might be the case because violations of quality expectations lead to better encoding of experiences in memory.

In the third paper, four experiments by Lee and Labroo examine the role of memory accessibility in yet a different way. The authors investigate how accessibility of the target product may serve as the basis of product judgment. Specifically, the authors

suggest that accessibility of a product in memory may be defined in terms of how easy it can be recognized (i.e., perceptual fluency) or how quickly it comes to mind (i.e., conceptual fluency). They further propose that consumers may develop a more favorable attitude toward a product when the product becomes more accessible in memory, either perceptually or conceptually. Their results across three experiments show that enhancing perceptual or conceptual fluency of the target increases liking for the target. In addition, the experiments provide evidence that conceptual and perceptual fluency effects on affective responses are additive. Finally, the authors present results suggesting that whereas perceptual fluency always has a positive effect on consumer attitudes, conceptual fluency may lead to less favourable attitudes when negatively valenced associations are being primed.

Wyer provided an overview of research on accessibility and judgment and pointed out the papers' contributions and outstanding questions within this context. Specifically, he explored how the direct effect of ease of retrieval and the content effect in the paper by Tybout et al. might combine to influence judgment. Do they jointly influence judgments, with more influence of the process that is stronger in the particular context, or do the processes combine according to a race model in which the winning process "takes all"? Wyer pointed out that Vanhouche and van Osselaer's results may be dependent on the type of goal participants had during processing and on dependent measures—recall of the quality of previously-encountered products versus judgments of those products' current desirability. In addition, he asked whether the added cue (e.g., price, irrelevant attribute) had a direct effect on memory or made participants encode other product information better. Finally, Wyer related Lee and Labroo's research on conceptual fluency to the activation of narratives in episodic memory, pointing out that narrative representations of information can often have stronger effects on judgment than information presented in other forms. If conceptual fluency is based in narrative episodic memory, perceptual fluency effects seems to be based in semantic memory processes, explaining the additivity of the two types of fluency effects.

SPECIAL SESSION SUMMARY

Diagnosing Identity: Exploring the Complex Relationship between Consumer Identities, Motivation, and Health-Related Behaviors

Sonya A. Grier, Stanford University

H. Rika Houston, California State University, Los Angeles

SESSION OVERVIEW

Consumer research has demonstrated the link between identities and consumer behavior, and we have long known that people use products for self-expressive reasons (e.g. Gardner and Levy 1959). However, less attention has focused on *how* people's identities motivate identity consistent behavior. The papers in this session examined the motivational forces that underlie different kinds of identities and how these forces motivate the consumer towards identity consistent behavior or drive them away from identity inconsistent behavior. Further, all three papers focused on the relationship between identity and behavior in the *health domain*, an economically important and socially relevant domain that receives limited theoretical attention. The three papers in the session took different approaches to considering identity, the significance of the source of the identity, and how these identity "meanings" may influence consumer attitudes and practices related to their health and well-being.

Rika Houston examined the macro identity of "motherhood." Motherhood is an identity that reflects an aspirational, role transitional, "desired self" that many women adopt in North American culture. Her presentation described the emotional, financial, and medical health of consumers facing the cultural dilemma of involuntary infertility during their quest to attain the desired social identity of "mother." By integrating the analysis of historical and cultural text, secondary data, and ethnographic fieldwork, she presented a conceptual framework for understanding how the cultural-determined identity of motherhood affects consumers' identity consistent behaviors in the infertility marketplace.

Michael Basil and Edward Maibach examined how people's behaviors reflect an avoidance of a particular identity through an examination of consumer obesity. Being "obese" represents a "feared self" that is antithetical to the proliferation of popular culture driven idealized self-imagery. Their research created attitudinal and behavioral profiles of people who are obese in order to identify cognitive prototypes that underlie an avoidance-type of motivational force. Their nationally representative results suggest significant behavioral differences among those who are objectively vs. self-identified as overweight, and pose significant implications for interventions to curb the nation's obesity epidemic.

Sonya Grier described her research with Amy Marks that investigated how multiple identities influence women's smoking behavior. Their research utilized both qualitative and quantitative research to identify the key determinants of smoking behavior among women in South Africa, and the role of culture as a protective factor. Their results illustrated the process consumers use to manage the motivations generated by multiple, sometimes conflicting identities on behavior. The discussion leader for the session, Americus Reed II, made integrating comments and promoted discussion between the participants and the audience in order to allow a larger understanding of the topic to emerge.

Overall, the three presentations and the discussion that followed provided insight into how the motivations inherent in attaining, avoiding or managing identities influence health-related behaviors. The session's methodological pluralism, incorporation of prior research, the social relevance of the topic, and the provocative Q&A session contributed to a more holistic understanding and

provided a conceptual platform for those in attendance to truthfully address the complex relationship between health, identity and consumer behavior.

ABSTRACTS

"The Motherhood Mandate: Gender, Identity, and Consumption in the Infertility Marketplace"

H. Rika Houston, California State University, Los Angeles

This paper explores the emotional, financial, and medical health of consumers facing the dilemma of involuntary infertility. The significance of this dilemma cannot be understated since motherhood has been viewed as the primary vehicle through which women have formed their identities and found their "place" in contemporary North American culture since the beginning of the 19th century (Arendell 2000, Bassin 1994). Indeed, the intensity of this cultural mandate is so strong that the state of involuntary non-motherhood has now become medicalized through the birth and proliferation of a multi-billion dollar infertility industry since the 1970s.

After making the life-altering decision to become a parent in the first place, the inability to do so after repeated attempts seems to contribute to a slow downward spiral of emotions exacerbated by high price tags, low success rates, and a growing list of real and potential medical complications. From an emotional perspective, the 'infertile' are described as sharing the typically negative characteristic of 'desperation.' For example, ethnographic interviews of in-vitro fertilization consumers conducted by Franklin (1997) and ethnographic field work conducted by this author clearly reveal the overwhelming desperation and uncertainty experienced by female consumers of infertility products and services. Involuntarily infertile women, already burdened by self-doubts and desperation, often express further resentment at the public expectation of friends and family members who repeatedly ask them to explain the details of their personal dilemma or to justify their relentless quest to become a 'biological' mother when other alternatives such as adoption or non-motherhood exist (Franklin 1997, Kirkman 2001, Wischmann et. al 2001). With such a heavy emotional burden, it is easy to understand the psychological motivation for such consumers to pay large sums of money in the infertility marketplace.

From a financial perspective, accurate cost estimates for infertility procedures are difficult to obtain due to limited regulation and wide variations in cost associated with factors such as the age of the consumer and the complexity and duration of the required treatments. However, 'standard' in-vitro fertilization (IVF) treatments alone can average around \$8,000 to \$10,000 for the first cycle of treatment to a total of \$50,000 to \$150,000 for a series of cycles that result in a successful pregnancy and a live birth (American Society for Reproductive Medicine 2002, Kershner 1996, Moore 1996, Stephen 1999). Additional procedures, usually necessary when the infertile consumer is a woman over the age of 35, often add thousands of dollars to these average costs. Needless to say, the price tags are considerably high even though some infertility clinics offer 'money-back' guarantees if treatment does not result in a live birth (Schmittlein and Morrison 1999). A financial cost versus benefit analysis of the assisted reproductive procedure price tag

presents a perplexing question that can only be explained by the deeply embedded psychological motivation that potentially drives such consumers to conform to the cultural mandate of 'motherhood'.

Even after the emotional and financial challenges are confronted, the growing list of potential medical complications associated with infertility products and services is formidable. First and foremost, pregnancies facilitated by the consumption of assisted reproductive technologies are more likely to result in multiple births and multiple births are at considerably greater risk for medical complications (Schieve et al. 1999, Seifer et al. 2001). The Centers for Disease Control and Prevention (2000) and The National Center for Health Statistics (1999) reported that from 1980 through 1997, the annual number of twin births rose 52% while the annual number of triplet or higher-order multiple births rose over 400%. Compared to singleton births, a twin is seven times more likely and a triplet is over 20 times more likely to die in the first month of life. Premature birth, which occurs in 50% of twin pregnancies and 90% of triplet pregnancies, is associated with an increased risk of respiratory distress syndrome (RDS), intra-cranial hemorrhage, cerebral palsy, blindness, deafness, low birth weight, and neonatal morbidity and mortality. Maternal complications of multiple gestations only complicate the matter. They include premature labor, placental abnormalities, maternal hemorrhage, pre-eclampsia, gestational diabetes, anemia, and other complications resulting from the cesarean birth that is standard practice with multiple gestation (American Society for Reproductive Medicine 2001). The most troubling unanswered question, however, is whether or not the ovulation drugs used by millions of infertile female consumers will increase their risk of developing ovarian cancer later in life (Hesselberth 2000, Kershner 1996). Although there still has not been any conclusive cancer research related to the hyper-stimulation of ovaries with ovulation drugs, the Food and Drug Administration now requires many fertility drugs to carry a warning that they may increase the risk of ovarian cancer. In summary, the multi-faceted combination of emotional, financial, and medical challenges involved with the consumption of products and services in the infertility marketplace bear witness to the strong impact that the culturally fostered identity of 'mother' has upon the health behaviors of women who find themselves caught in the quandary of this complex dynamic.

Through the use of secondary data, a comprehensive analysis of historical and cultural texts on the history of assisted reproductive technologies, and ongoing ethnographic field work, the author proposes a conceptual framework for understanding this timely gaze into the social and technological construction of consumer identity and their related health behaviors. Results point to existing public policy to address the needs and rights of consumers in the infertility marketplace, as well as possible avenues for future public policy.

"Obesity: Government Definitions Versus Self-Identity on Consumer Attitudes, Perceptions, and Behaviors"

*Michael Basil, University of Lethbridge
Edward W. Maibach, Porter Novelli*

The prevalence of obesity has increased dramatically in the United States recently (Flegal, Carroll, Kuczmarski & Johnson, 1998; Galuska, Serdula, Pamuk, Siegel & Byers, 1996; Kuczmarski, Flegal, Campbell & Johnson, 1994; NHLBI, 1998). Being overweight increases the risk of hypertension, lipid disorders, type 2 diabetes, coronary heart disease, stroke, gallbladder disease, osteoarthritis, sleep apnea, respiratory problems, and certain cancers (NHLBI, 1998). The total costs approaches \$100 billion annually

(Wolf & Colditz, 1998). From a marketing perspective, the most important questions to answer about obesity revolve around people's current beliefs, attitudes, and behaviors. Do people perceive themselves to be overweight or obese? Do people see themselves to be at risk as a result of their weight? Do they feel self confident in their ability to do something about their weight? Only to the extent that people feel efficacious should we expect them to act. If people do not feel confident regarding things they can do to control their weight, the starting point should be an effort to build efficacy. This research explores these questions by examining the attitudes and behaviors of those who are objectively overweight with those who are not objectively overweight but self-identify that way.

The majority of the data for this study are from Porter Novelli's *Healthstyles* survey, which is administered annually. For each of the focal years (1995, 1996 and 1996) the survey received a response rate of at least 70%, and sample sizes included approximately 3000 individuals. In addition, data from Porter Novelli's 2002 *ConsumerStyles* was also used. The mean reported weight was 172 pounds (188 for men, 160 for women, $F [1,8602]=842$, $p<.001$). The calculated body mass index (BMI) was 27.3 (27.3 for men, 27.2 for women, $F [1, 8602]=0.49$, $p>.10$). This compares closely to NHANES-III and BRFSS data (Flegal et al., 1998; Kuczmarski et al., 1994, 1997; Galuska et al., 1996). Key analyses compared objective and subjective evaluations of obesity on a variety of psychological and behavioral differences.

First, people who are obese by government standards tend to perceive themselves as overweight. However, there are a considerable number of people who are overweight by government standards but do not describe themselves as being at least 20 pounds overweight. In addition, 12 percent of people who are not overweight estimated themselves to be at least 20 pounds overweight. With regard to attitudinal differences, the results show that objective obesity level shows a strong positive relationship with perceptions of health risk and weaker negative relationships with the importance of life satisfaction and perceptions of physical fitness as attractive. The results show that objective obesity level shows a weak negative relationship with confidence in maintaining a low-fat diet and with exercising regularly, but a strong negative relationship with confidence in staying thin or losing weight. With regard to questions of actual behaviors, the results show a weak negative relationship between the objective level of obesity and peoples' fruit and vegetable consumption and moderate relationships with days per week of moderate and strenuous physical activity. This relationship gets stronger, however, using people's self-identification of being overweight. In this case the behaviors are more strongly related to identification as overweight than the government categories.

Addressing again the issue of self-confidence, is the determinant of confidence a person's objective obesity level, their subjective identification as overweight, or from people's behavior? In this case the results show that the largest predictor of people's confidence in being able to maintain a low-fat diet show is their previous experience with low fat eating. The second largest predictor of confidence is a person's age, such that older people are more confident in these abilities. The analysis of people's confidence in being able to exercise regularly shows that experience with moderate exercise is the largest predictor of confidence. The second largest predictor of confidence is their current level of strenuous exercise. The analysis of people's confidence in being able to stay thin or lose weight shows that current obesity level is the largest predictor of their current level of confidence. The second largest predictor of confidence is their current level of strenuous exercise. The third largest predictor is their current level of moderate activity.

In sum, all of the analyses demonstrate that the largest predictor of self-confidence in being able to maintain a low fat diet, exercise, or lose weight is their current status on that behavior. These data appear to closely follow trends observed elsewhere. In general, almost 60% of the sample can be categorized as overweight. Although overweight people generally know they are overweight, suggesting that the message of what constitutes overweight has reached this population. With increasing obesity, people's life satisfaction declines, they see physical activity as less important and less attractive, they have slightly less confidence in being able to maintain a low fat diet, slightly less confidence in being able to exercise regularly, but much less confidence in being able to lose weight or keep it off. And while objective obesity was related to feeling at physical risk as a result of their weight, the subjective evaluation of being overweight was more important. Obese people express an interest in low fat foods, but appear skeptical that it will help them lose or keep off weight, especially as their level of obesity increases. With regard to eating habits, increased levels of obesity do not appear to relate to a higher level of consumption of fruits and vegetables, perhaps even a slight decrease in fruit and vegetable consumption. Finally, increasing levels of obesity relate to lower levels of moderate and strenuous physical activity. Initial results suggest that in most cases the self-identification as overweight has a stronger relationship with attitudes and behaviors than the government BMI categories. Additional analysis is in progress to compare the identification as being overweight with eating and exercise behaviors.

“Identity as Motivation For A Non-Smoking Lifestyle: The Role of Cultural and Health Identity in Women’s Smoking Behavior”

Sonya Grier, Stanford University
Amy Marks, University of Cape Town

Consumer behavior has long argued that people use products as a form of self-expression (Gardner and Levy, 1955; Levy 1959), highlighting the relationship of identity to behavior. Smoking, for example, is one behavior that is typically marketed as a way to influence one's identity. Tobacco companies have spent billions in the last century to make their products social icons that people use to communicate who they are or want to be. Much of advertising content tries to link different “identities” or lifestyles to different brands of cigarettes, so people can find one that expresses just what they want to be and say. Thus, a smoking lifestyle has embedded within it a deeper level usage of the cigarette and its smoking to express personal meanings publicly (Marks, 1997).

Identity has been posited to provide implicit rules for actions that influence identity consistent behavior (Terry, Hogg, and White, 1999). Recent work on the Theory of Reasoned Action (TRA) and Theory of Planned Behavior (TPB) provides growing empirical evidence for the predictive effects of identity on understanding consumer intentions and behavior (Terry, Hogg, and White, 1999; Sparks and Guthrie, 1998; Conner and McMillan, 1998). Our research uses TRA and TPB constructs as an organizing framework and integrates literatures on social identity, gender and culture, to examine the link between identity, norms, attitudes and smoking behavior with a focus on understanding the underlying process(es) that drive effects. Since people have multiple identities that may differentially affect a given domain, the research examines two types of identities: a) *cultural identity* (an individual's perception of membership in a cultural group and the value placed on that membership), and b) *health conscious identity* (an individual's perception of self as one concerned about health-related practices). The research also takes advantage of the research context to focus

on group level cultural norms, in contrast to the TRA/TPB focus on more individualized subjective norms (Terry et al, 1999). Two forms of cultural norms are examined (Cialdini, Reno and Kallgren, 1990; Povey, et al, 2000): perceived ‘injunctive norms’ concerning cultural approval or disapproval of smoking and ‘descriptive norms’ entailing perceptions of relevant others’ smoking.

Our basic premise is that identity should be a significant predictor of smoking attitudes and behavior to the extent that a particular self-definition is an important part of a woman's self-concept. We develop specific hypotheses regarding the relationship of multiple identities, multiple norms, attitudes and behavior with a focus on understanding the mechanisms underlying the influence of identity on behavior. These issues are examined in a context where identities are in flux—black women living in townships ringing a metropolitan center in South Africa. Although black females in South Africa comprise 40.5% of the population (Leholhla, 2002), they have one of the lowest rates of tobacco consumption in South Africa (Yach, Saloojee, and MacIntyre, 1992; Reddy, et al, 1996; Steyn et al., 1997). In particular, we focus on tobacco manufacturers' increased targeted marketing efforts that are aimed at exploiting black women's changing identities to alter their traditional non-smoking lifestyle.

As suggested by prior research (e.g. Montano, Kasprk and Taplin (1997), our quantitative investigation was built upon prior qualitative research (Marks and Ratheb 1998) which employed in-depth, open-ended elicitation interviews as well as focus group interviews to identify the behavioral outcomes, referents, facilitators and constraints relevant to smoking behavior. The rich phenomenological understanding of the targets and their relationship to smoking/non-smoking gained from the qualitative work was used to design a comprehensive survey to identify the key determinants of women's orientation toward and use of cigarettes. The questionnaire was designed taking into account variations in respondents' education levels. Key constructs included cultural beliefs and personal attitudes about smoking, cultural identity, health conscious identity, perceptions of cultural injunctive and descriptive norms, and exposure to marketing activities. After a pretest, the survey was administered in the local language, Xhosa, to a stratified cluster sample of black women from Cape Town area townships, resulting in a respondent sample of 1314, with 959 non-smokers and 355 smokers.

Two stage logistical regression analysis indicates that both cultural and health conscious identities serve as significant predictors of behavior independently of other TRA/TPB variables and that they significantly improve the model's ability to classify respondents as smokers versus non-smokers. The first model using TRA/TPB variables classified 86.7% of the respondents into smoking versus non-smoking [-2LL=768.428, $X^2=643.140$, 4 df, $p<.000$], with the odds ratios showing attitude to contribute the most to the model (1.517), followed by injunctive cultural norms (1.133) and descriptive norms about friends' smoking (.353). Adding the cultural and health identity variables significantly improved the model's ability to classify smoking behavior to 92.1% [-2LL=638.580, $X^2=772.987$, 6 df, $p<.000$, change in -2LL of 129.848, 2 df, $p<.000$], with the odds ratios showing attitude to still contribute the most to the model (1.596), followed by health identity (.802), cultural identity (.54) and then descriptive norms about friends' smoking (.415). The addition of the identity measures rendered cultural norms insignificant, and since the identity and norms variables are correlated, further analyses of the interactions will investigate their joint effect on smoking, with particular interest in the relative effect of individual level identity (health) versus social level identity (cultural).

Clean and Dirty: Playing with Boundaries of Consumer's Safe Havens

Güliz Ger, Bilkent University
Baskın Yenicioğlu, Bilkent University

ABSTRACT

The marketplace, with its continuously increasing symbolic nature and infinitely many alternative consumption choices, poses a disorderly and threatening environment for consumers. This conceptual paper discusses the ways in which consumers magically create, eliminate, or shift many boundaries surrounding them through rituals and practices related with cleanliness in order to construct a safe 'home' in an otherwise threatening environment.

Rituals and practices related with cleanliness can be observed in many spheres of everyday social life. We buy products and services to clean our bodies, clothes, and homes. Cleaning products industry continuously introduces "new and improved" products. These products range from basic consumer goods like Colgate toothpastes, Procter and Gamble cleaning agents, and Johnson and Johnson shampoos and bath products, to more high-end designer products like Nilfik's Advance Hip Vacuum Cleaner, Caldrea's Green Tea Patchouli Linen Spray or pure silk cheesecloth dusters, to all natural 'green' products by companies like The Body Shop or Lush. Global detergent producers such as Unilever spend huge amounts of money and time on marketing research to determine the preferred and perceived degree of whiteness and cleanliness in different cultures. Removing dirt is not only an important concern for home and personal care but also for the environment—such as chemical and industrial pollutants. Food products advertise the absence of impure additives and preservatives. Yet, dirt can also become a medium of play for consumers wishing to become part of nature (Belk and Ger forthcoming). These are among the examples that indicate the daily significance of cleanliness in consumption. Yet, to our knowledge, consumer researchers have not studied this topic.

Cleaning practices and rituals are deeply and closely linked with cultural categories and their significations (Ger 1999). Cultural categories, invisible to the social actors, are constantly substantiated so that the world is constructed to conform to the imagined world (McCracken 1999). This substantiation of the social world can be through commodities or practices and rituals of consumption. For example, grooming rituals are not only performed for hygienic reasons, but also as part of a body language and a social communicative action (Rook and Levy 1983). In the market place, where human relationships come to be represented more and more through meanings embedded in goods produced for sale there is massive overproduction of commodity signs. The meanings governing the social world do not only reside in the commodities per se, but are also a matter of practices that make use of the symbolic (Denzin 2001; Firat and Venkatesh 1995; Schor and Holt 2000). McCracken (1999) refers to these practices and rituals as social actions aimed at the manipulation of the cultural meanings for the purposes of communication and categorization.

We argue that rituals and practices related to the concepts of clean and dirty have an underlying role in this process of communication and categorization as they obliterate, create, or shift the boundaries of the geo-social maps of individuals. We define the geo-social map as a map of the imagined location of the consumer in the social. Social life is established around boundaries. Through categorization and communication, the consumer places him/herself and others in the geo-social map with respect to the boundaries depicting his/her social life world. The point of departure of our

paper is the work of Douglas (1991). Douglas maintains that the social world has a structure made up of borders and social actors perceive everything according to these schemata. Within this contention dirt is essentially disorder and eliminating it helps organize the environment. Social actors, who have been alienated (Miller 1987) or even deterritorialized (Deleuze and Guattari 1983) through capitalist marketplace dynamics, try to objectify (Miller) or re-territorialize (Deleuze and Guattari) their social relationships through magical rituals and practices. In that process, consumers' practices engage with the meanings of cleanliness in order to locate themselves and others on their geo-social maps, defining a safe haven, whether at home, work or play, in a threatening environment.

Cleanliness and dirt have been argued to be of great historical importance in setting up, obliterating, or shifting boundaries between the savage and the civilized, peasant and bourgeois, and the lower and the upper classes in the Western world during the civilization and industrialization process (Davidoff 1995; Elias 1995; Hoy 1995; Huxley 1986; Ross 1996; Vigarello 1985). The notions of clean and dirty have also been of great importance in Eastern societies. For example, cleanliness plays a key role in Hindu caste relations. The upper castes have been distinguished by an unconditional recognition that they are ritually clean. These distinctions are so radical that sometimes even touching or being seen together is forbidden as the dirty lower caste may contaminate the upper clean castes (e.g., Bergel 1962). Notions of cleanliness also have significance in Islam, which specifies how and when people should clean themselves as well as the rituals of cleaning the deceased before the burial.

In the contemporary disorderly world of cultural meanings, the notions of clean and dirty play an important role in determining the daily consumption practices of the social actor who tries to order his/her social world. Order-making practices and rituals establish consumers' locations in their social maps by making statements about boundaries. Eliminating dirt is a creative effort to re-organize or re-order the social life world to make it conform to an imagined geo-social map.

After providing a brief historical background and clarifying what we mean by "clean" and "dirty", we conceptually explore how consumption practices of clean and dirty negotiate this elusive map and its boundaries. We suggest that boundaries between inside and outside, upper and lower classes, familiar and unfamiliar, and culture and nature appear, disappear and shift through the everyday rituals and practices of 'clean' and 'dirty,' defining a safe haven.

MEANINGS OF CLEAN AND DIRTY

The first entry in the Webster Dictionary for the word clean is 'free from dirt or pollution' and 'free from contamination or disease.' Other definitions are 'unadulterated, pure' and 'free from flaws;' 'free from moral corruption or sinister connections of any kind' and 'free from offensive treatment of sexual subjects and from the use of obscenity;' and 'free from error or blemish.' Webster defines 'clean' with respect to its antonym. The entries for 'dirty' also follow the same style: 'not clean or pure;' that which 'containing impurities;' 'morally unclean or corrupt;' 'indecent, vulgar;' and 'not clear and bright.' Consistent with the Saussurian notion that language is a system of differences, Webster defines clean and dirty in relation to each other, whereby 'clean' gains meaning only with respect to 'dirty'.

In a pilot study in Turkey we find that when people think about 'clean' and 'dirty' they draw their understandings from two realms: conceptual and material. Conceptual understandings are about abstract and ideological issues such as purity, sacredness, soul, nature, beauty, feelings, love, mind, and the world at large. For example, the notions of the purity of a newborn baby or unconditional love are regarded as 'clean', whereas disturbing the balance of the world and the lack of sensitivity to world issues are interpreted as being 'dirty'. Material understandings, on the other hand, take on a more immediate, every day perspective, such as cleanliness and dirtiness of the body, clothing, food, house, and the environment.

This conceptual/material relationship is also evident in Delaney's (1991) ethnography on family, kinship, and social relations in a Turkish village. Villagers give much greater importance to cleanliness in a conceptual sense (e.g. purity, sacredness) than the cleanliness of their material surroundings, except inside their homes. For example, they consider the road that links their village to the big city to be 'bula?ık' (not clean/pure) as it opens the village up to the dirtiness of the city, while the dusty village roads covered with mud, animal defecation, and garbage are not a concern for cleanliness.

Hence, not only the conceptual and material meanings and experiences of clean and dirty differ with respect to the borders existing in the social realm, they also locate, establish, and obliterate these borders according to different social realms.

HISTORICAL ROLE OF CLEANLINESS AND DIRTINESS IN SOCIAL STRUCTURES

Cleanliness has been conceptualized as a reflection of the civilization process (Elias 1995; Vigarello 1985). Analyses of the changing attitudes towards cleanliness since the Middle Ages indicate that, as the means of distinction of nobility and the proof of ancestry played a diminishing role, manners became the differentiating element among social classes in modernizing France. Cleanliness, as part of these behaviors and manners, became synonymous with *civilisé*, by which "civil" people wished to designate "the specific quality of their own behavior, and by which they contrasted the refinement of their own social manners, their "standard," to the manners of simpler and socially inferior people" (Elias 1995, p. 32). Therefore, being visible, and expressed as a refinement of behavior, personal space, and of self-discipline, cleanliness became a norm not only of the individual but also of the social, depicting the history of cleanliness as the history of the pressure of civilization on the world of personal space. The authority figures in the perception of cleanliness in the seventeenth century France were not scholars or hygienists, but rather the authors of manuals of etiquette and experts in manners. This displacement of the basis of authority highlights the social communicative function of cleanliness, rather than its individual hygienic functions. The history of cleanliness is thus seen not as a history concerning hygienic practices, but rather as a social history from aristocracy to bourgeoisie, a history of changing structures in social life during the civilization era in France (Vigarello 1985).

Davidoff (1995) who studied the pursuit of and meanings given to cleanliness throughout the 19th and 20th centuries in Western Europe maintains that it was not cleanliness per se but the meanings ascribed to cleanliness that were vital, for they realized as well as symbolized the need to establish status through deference, order and ritual. The function of the pursuit of cleanliness, she argues, is to impose order on disorder, to transform the anarchy of raw material into acceptable cultural artifacts, to maintain the boundaries between nature and civilization. During this process of boundary definition and maintenance, patterns of consumption had

been one of the most common markers of status definition (Davidoff 1995).

In the USA, from the pre-Civil War era to the 1950s, the society transformed from 'dreadfully dirty' to 'cleaner than clean'—an obsession with cleanliness (Hoy 1995). Hoy argues that this transformation is based on an assimilation process, the attempts to persuade the masses to become American, rather than a simple care for hygiene. America, in the course of this transition, came to link being clean with being respectable, socially responsible, and healthy. This view also emphasizes the symbolic nature of acts of cleanliness. Taking Vigarello's (1985) accounts on the transition from aristocracy to bourgeoisie a step further, Hoy (1995) suggests that the pursuit of cleanliness was critical in the development of a middle class during the industrialization and urbanization process in the United States. She argues that clean and classy went together in this process and middle-classes differentiated themselves from the lower classes through cleanliness.

Huxley's (1986) essay "Hyperion To A Satyr" illustrates the symbolic importance of cleanliness for class differentiation. Focusing on dirt in the history of human existence and analyzing dirt's effect on creating class barriers, Huxley talks about the need to segregate oneself from others deemed pathetic, smelly, and filthy. Reflecting on a time when, while at the beach, he came across thousands of condoms scattered on the sand, probably coming from a sewer not far away, he flashes back to the times when dirt was a normal and intended part of society. He asserts that the segregation between those who felt they were less stinky and others intensified over time as dirt and stink started to be considered bad and the rich began to wash themselves. This distancing, according to Huxley, started with one substance, dirt; the largest cause of discrimination is argued to be based on the connection in the human mind between dirt and people of a lower social class (Wilson 2001).

As cleanliness became a visible sign of social structures, around 1915, Dadaism emerged as a critical and revolutionary avant-garde movement, trying to destroy these structures. Frankl (1992) argues that the Dadaist cult climaxes in the undoing of "the separation between the clean and the dirty, between those who have freed themselves from anal fixations and avoid contact with dirty matter—the clean and superior people—and those who make themselves dirty, soil themselves in the course of their labors" (p. 172). Dadaists provide a social criticism and seek to obliterate the distinction between the upper and lower classes by breaking down the distinction between the clean and the dirty. As art is often considered 'cleaner' and 'higher' than the rest of the world, Dadaists try to show that art can be just as dirty as, or even dirtier than, the world. In their effort to sweep all divisions away Dadaists blur the boundary between cleanliness and dirtiness (Kuspit 2001). This resembles the medieval rituals of folk carnival which Bakhtin (1965) argues are intentionally grotesque and based on the vulgar body to create a world oppositional to the official one, liberating individuals from the structures of social life.

Practices and meanings of cleanliness are linked not only to social structures within a society but also to international structural relations. Analyzing the modernization process from the point of view of hygiene, Ross (1996) argues that the new cult of cleanliness that the French culture faced after the Second World War is a part of an ideology of consumption that is at work within the process of turning to American-style mass-consumption habits. Similarly, Barthes (1972) maintains that what the French children of the war yearn for—*fringale*—is cleanliness, and what they need is purity. Observations on the symbolic rather than functional cleanliness in decolonializing France suggest that cleanliness also symbolizes being washed of all the stains left behind from colonial times (Ross 1996).

These accounts of academic, literary, and art works indicate that cleanliness and dirtiness are important factors in identity formation, class differentiation, and international social structures—in both bringing people together and dividing them apart. However, the contemporary social structures are very fluid and fuzzy. The unstructured, disorderly social life worlds based on the ever-changing cultural categories demand a way for the consumers to make a clean exit out of this mess.

MAGICAL RITUALS AND PRACTICES OF CLEAN AND DIRTY IN CONSUMER SOCIETY

Contemporary life consists of discontinuities, pluralities, chaos, instabilities, constant changes, fluidities, and paradoxes in which both symbolic production and consumption are major areas of societal participation (e.g. Firat and Venkatesh 1995). Culture, language, aesthetics, symbolic representations, and literary expressions that are central to the current market dynamics contribute to this fluid disorder. In the contemporary consumer society, “in place of a secure order of values and social positions, there is a bewildering variety and fluidity of values, roles, authorities, symbolic resources, and social encounters” (Slater 1997, p. 83). In this rather disorderly marketplace consumers try to build an orderly and “clean” habitus (Bourdieu 1986) with boundaries and borders establishing their place and the others’ with respect to it. Magical rituals directed at constructing subjective geo-social maps establish social actors as creative consumers, freeing them from the commotion of the disordered marketplace by letting them play with their boundaries. This effort can be described as magical as the social actors try to order the disordered, classify the unclassified, and familiarize the unfamiliar.

Consumers resort to magic when they are faced with inflexible social problems (Arnould, Price and Otnes 1999). Magic, as a practice of power, becomes a practical alternative for consumers when they are creating their social life worlds. These magical rituals establish suitable ways of living with respect to others. Horton (1993) describes magical praxis as the mixture of practical motives and emotional and aesthetic ones. These practical, emotional and aesthetic motives are used to create and recreate the social world around human beings. Arnould et al. (1999) maintain that magical practices thrive in the context of “freely floating signifiers” of the postmodern marketplace as they serve to transform the boundaries of a social actor’s now ‘structured’ world.

Such magical shaping is related to the sacred and profane, a dimension which structures social life (Belk, Wallendorf, and Sherry 1989). Similarly, Douglas (1991) distinguishes between purity and danger in the general social order. Dirt or matter out of place creates a disorder in the social life worlds and thus needs to be purified, ordered, or sacralized (Belk et al. 1989; Douglas 1991). The related distinctions between order and disorder, clean and dirty, and sacred and profane are important structural elements. Through the magical rituals related to the subjective meanings of clean and dirty, the consumer tries to maintain a particular ‘reality,’ which can be defined as his/her geo-social position on the elusive map of social relationships. Ritual behaviors, which are “symbolic expressions through which individuals articulate their social and meta-physical affiliations” (Rook 1984, p.280), communicate what one is and categorize what others are through locating where one stands and placing boundaries relative to others, destroying these boundaries, or shifting them. They are seen to be psychologically complex and intense behaviors aimed at resolving conflicts one faces during everyday social life (Rook, 1985). As Durkheim (1915) argues for sacred rituals, magical rituals and practices of clean and dirty are powerful processes that create particular sacred realities despite

profane threats of the commotion of the contemporary market place.

VOYAGING THROUGH THE BORDERS

Ritual has been likened to building dams and walls to “keep back the dangers of the unconscious” (Jung 1959, p.22). The unconscious in this view can be extended so as to circumscribe the unknown and the borders are created through rituals to help keep out the dangers of the unknown. Erikson (1982), on the other hand suggests that the fundamental purpose of rituals is to institutionalize or rationalize contradicting behavior. Therefore, taken together, it can be argued that rituals not only create boundaries but also through the processes of institutionalization or rationalization, transcend these boundaries by eliminating or shifting them. In this section we discuss how the magical rituals and practices of cleanliness might create ordered subjective realities within an otherwise unmanageable social world.

Upper and Lower Classes

We already discussed how the notions and practices of cleanliness and dirtiness played a significant role during the project of modernization and civilization and the formation of a middle class in the West. Today, a similar concern for cleanliness can be observed in developing societies that are in the process of establishing a middle class. It is interesting that usually the first international companies to go into developing markets such as China, Kazakhstan, and Turkey were those that sell cleaning products, like Unilever and P&G.

In *Lifebuoy Men and Lux Women* (1996), Burke examines the emerging needs for cleanliness during the making of modern Zimbabwe. He focuses on both the post-colonial impacts of global capitalism on the formation of needs for cleanliness and the magical uses of cleaning products—such as soap advertising that claims to make the consumers whiter. In Turkey, dirtiness is associated with poverty and backwardness, while cleanliness represents modern civilization and respectability (Ger 1999). Accordingly, a multinational detergent producer’s research indicates that Turkish consumers’ preferred degree of whiteness is whiter than in many other countries, indicating the extreme importance given to cleanliness. Moreover, rural migrants in Turkish cities are considered to be outside, unfamiliar, and dirty. Although most middle class homes are cleaned by rural migrant maids, the latter are established as being dirty by such practices like reserving for them a separate set of cutlery, glass, and towel, or not letting them cook for the household, thus setting up a boundary. These examples suggest that the practices of cleanliness have significance in societies that are in the process of modernization and establishing their middle classes. Consumers use cleaning and grooming products in order to magically transgress boundaries between lower and upper classes in developing societies, where to be clean symbolizes modernity, civilization, respectability, and a distance from poverty.

However, the use of cleaning products and services for distinction is not limited to developing countries. The upscale British lifestyle magazine *Wallpaper* maintains that it is now fashionable to be seen doing the housework and cleaning has attained a cult status with designer kits and products (Kirwan-Taylor 2003). In this case, it is not cleanliness per se that differentiates, but rather the fragrance of the detergent one uses—citrus mint yling ylang or jasmine lily or green tea patchouli—or how hip the cleaning kit one uses. Furthermore, in more affluent parts of the world, where the use of commodities like soap, detergents, and shampoo, services like hot water and plumbing, and appliances like washing machines and dishwashers are taken for granted, dirt becomes a playground for

consumers. The border this time endures between the upper and lower classes' nature of playing with dirt—the upper classes choose to quietly harmonize with it by skiing or climbing, whereas the lower classes enjoy noisily dominating it with truck races or motorbikes. On the other hand, in less affluent societies dirt remains to be a threat to civility that should be fought with as many cleaning products and utensils as possible (Belk and Ger forthcoming).

Inside and Outside

Practices and meanings of clean define and are defined by the border between the inside and the outside. This border specifies what one lets in and keeps out. Delaney (1991) finds that this distinction plays a very important role in a Turkish village. The villagers consider the city to be dirty and their village clean, in an abstract sense, as they maintain that their village is 'closed' to the 'polluting' influences from the city, which is open to contamination. Thus, they create an identity for their village and categorize the city as the outside as they establish a border between their clean village and the dirty city. This border becomes evident especially when the villagers mention that the road that links their village to the city is repulsive as it opens up the village (inside) to the impurities of the city (outside). In addition to these moral distinctions between clean and dirty, there is also a more physical boundary: inside versus outside of the home. Although villagers keep their houses very clean, and in the process consume a wide variety of cleaning products, they do not tend to the space outside the home: the dusty village roads and alleys are covered with mud, garbage, old machinery, and animal defecation. Similarly Chapman and Jamal (1997) find that there are different perceptions of inside and outside and of cleanliness and order between English and immigrant Pakistani households living in the same neighborhood. Pakistanis keep their homes clean but not their backyards. Their English neighbors, who see only the backyard but not the indoors, distance themselves from the Pakistanis whom they label as dirty.

In both Delaney's (1991) and Chapman and Jamal's (1997) findings, borders (between the city and the village or inside and outside the home) frame the meanings and experiences of clean and dirty. These meanings are not static; they vary depending on whether one refers to the inside or the outside, in whatever way these spaces are defined. For example, the city is not dirty per se relative to the village in a material sense; but by playing with the word's meaning, villagers are able to magically (the village does not become 'clean' all of a sudden) set an inside/outside border to identify themselves. These different conceptions regarding cleanliness, ordering, and borders show that the meanings given to clean and dirty provide keys to a particular construction of reality and coherence for social life.

Familiar and Unfamiliar

Another way in which social actors locate themselves and others on their geo-social map is by defining what is familiar and what is not. Through sacralizing rituals and practices of cleanliness one establishes, purges, or shifts boundaries to determine what is familiar or unfamiliar. For example, most people would consider a left over food in a restaurant dirty and would not eat it and summon the waiter to 'clean it up,' although they might take a bite from a friend's or a spouse's sandwich. This does not mean that the friend's sandwich is 'cleaner' than someone else's. However, this practice makes the sandwich magically clean while establishing the friend as familiar. In clothes shopping, many consumers do not hesitate to try the clothes on in the store and do not consider them to be dirty; however, they wash these same clothes before wearing them for the first time after purchase (Co?kuner 2002). This washing ritual,

Co?kuner argues, is a way of appropriating the new garment, making it one's own, and purifying it from alien particles and smell. Similarly, when we first move into a new home, we make it our own by cleaning it, as part of the possession ritual (McCracken 1999).

These rituals are not performed for the sake of cleanliness or hygiene. Instead, they take the person, the new garment, or the new house away from the domain of the unfamiliar and bring them over the border in to the familiar realm, where they are established as a friend, one's own outfit, or home sweet home. Perhaps a more striking example would concern how the bodily fluids of strangers are considered to be dirty and even disgusting, whereas that of the loved one's clean and sensual. The allure of or disgust with bodily fluids classify what is familiar and what is not in social relationships. What is important is not cleanliness per se, but rather how, through a magical ritual or practice, one transcends the meaning of cleanliness in order to locate the border between the familiar and unfamiliar.

Culture and Nature

Cleanliness has been an indication of the triumph of culture over nature, of civilization over the primitive in a modernist sense (Elias 1995; Vigarello 1985). However, today civilization is also identifiable with dirt—pollution. The boundary between nature and culture and its relationship with cleanliness becomes very apparent in an extreme example. Werner Herzog's documentary film *Ten Thousand Years Older* (2001) depicts the tragic disruption of the nomadic lives of the last unknown indigenous tribe on this planet. After the 1981 encounter between remote Brazilian tribespeople and a camera crew that took the natives from a Stone Age existence to modern times, within months, many in the tribe died of small pox and other diseases, as they did not have an immune system against the diseases of civility. After only a decade, their old way of life completely passed away and their children felt embarrassed by their "savage" parents. Although culture and civilization are associated with cleanliness, although the "civilized" children of the tribe regard their ancestors as dirty savage people, culture and civilization pollute both the culture and the bodies of the natives.

These paradoxes are encountered continuously in everyday social lives. Artists like Tracey Emin, who employs from used tampons and pregnancy test kits to soiled sheets and day-old underwear in her works, and Chris Ofili, known for using elephant dung, by playing with dirt in their artworks, try to draw attention to such paradoxes in the modern. They not only tear down the borders within the art world (high art versus low art), but also criticize the borders within the society between a 'civil' and a 'natural' way of living.

Let's consider some contradictions related to the culture/nature distinction. Some consumers voluntarily choose simple consumption practices so as to preserve a natural way of living and reduce the polluting hazards of civility to the nature by using fewer cleaning products and water, leaving the dishes and clothes 'dirty'. However, the numbers of these consumers are limited and pollution in urban societies is a major problem. Consequently, many urban consumers run from their civilized dirty cities to nature where it is clean and pure. However, the city can also be seen to be 'clean' with its asphalt roads and cemented pavements. One would consider mud or soil in the middle of the city 'dirty,' whereas one might love to lie on the ground in the woods, feeling the livelihood beneath, with the stars as a blanket and sleeping out in the open 'clean' air. Soil per se is not dirty, but it is in the city where it is not nature (-al). After having spent a few days in the pure clean nature, maybe even taking a mud bath, one then returns to the 'dirty' city and runs to the shower, to the favorite shampoo, bath salt, conditioner, and

soap, which were denied during camping. All these instances show that the culture and nature distinction is laden with several paradoxes. Not only the boundary between culture and nature is set and played with through clean and dirty practices and rituals, but also the meanings of clean and dirty change according to the boundary between culture and nature.

“HOME” IS WHERE WE ARE SAFE AND AWAY FROM DANGER

Perhaps the boundary between what is safe versus threatening is the fundamental melting pot of all the discussed distinctions. The above examples involve ways of creating a safe ‘home’ in the face of the threats generated by the commotion of the disorderly world. Let’s consider another example. Children are commonly considered to be clean, innocent, and pure, not contaminated by the dirtiness of the world, even if they have runny noses and smelly diapers. However, homeless children living in the streets are usually considered to be dirty. It is not uncommon in Istanbul to come across a homeless child who has no place to wash. Most people regard these children not only as dirty (dirty per se as well as contaminating their city), but also as threatening. However, as long as these children are contained in the slums of the city where they “belong”, there is no urgent threat for the ‘society.’ Here we also see a convergence of several boundaries—between the slum and the city, in place and out of place, and the boundaries within the society. The various boundaries we discussed relate to the threats we encounter in our daily lives and efforts of sometimes keeping them away by building up walls or sometimes establishing them as safe by transcending those walls.

Social life is becoming more and more commodified through mass production and mass marketing and with the massive overproduction of commodity signs. Social relations are dissolving into relations between commodities and consumption practices (Holt 1997; Taussig 1980). The new reflexive modernization, Beck (1992) argues, creates market dependency in all dimensions of living by the mass consumption of not only commodities, but also opinions, habits, attitudes, and lifestyles. Technological advancements, mass communication technologies, and flows of globalization accentuate this process. The meanings that are ascribed to commodities proliferate and change so rapidly in today’s marketplace that it may not be possible for consumers to control what their social actions communicate. This ever-expanding colonization of social domains by such marketplace symbolism ‘deterritorializes’ the social actor in his/her own territory (Deleuze and Guattari 1983) and delivers them over to an external control and standardization (Beck 1992). The lack of control over one’s own social world creates what Beck (1992) calls the risk society where there exist incalculable, unaccountable, uncompensatable, and unlimited threats for the individual. Therefore, the individual feels anxious, insecure, deterritorialized or out of place—and note that for Douglas (1991) dirt is matter out of place—and alienated or a loss of control over his/her social relationships. In an attempt to re-territorialize and reclaim control over their social life worlds, actors utilize magical rituals and practices. These magical rituals and practices institute a response, a creative moment against the threats of the marketplace as they determine the self, the other, and their respective places in the geo-social map that is (re)ordered through the continuous construction, elimination, and modification of boundaries between what poses a threat and what makes one feel safe. Consumption rituals and practices help consumers create a world of their own, one which is familiar and safe, out of the threatening disorderly material world. Taussig (1980) suggests that such moments of creative resistance create particular social realities through fantasy. These

fantasies of cleanliness are a way of bringing back the social relations that were taken away by commodity fetishism, a way of re-territorialization of the human social life in order to feel at home, in order to feel safe.

IMPLICATIONS FOR RESEARCH

In contemporary societies, where consumers have lost control of their social domains over to marketplace symbolism, they respond by consumer symbolism—they play with the boundaries in their geo-social maps. Magical rituals and practices of cleanliness serve to communicate and categorize themselves and others in order to feel safe and at home. Research about such practices will help us understand how consumers cope with the commotion of consumer society and the paradoxes of this order-creating process.

One fruitful research area would be the relationship between consumers and their brands of cleaning and grooming products. For example, when do people feel the need to clean their body or homes; when do they feel the need to put on make up, or fragrances, and wear clean clothes? It might be that this need arises especially when one invites someone into his or her various boundaries. Most people clean their houses when they invite people over and shower before a date and cleaning and grooming rituals are very important in trying to make a good first impression. Another question is what aspects of different brands and products make consumers feel safe in various threatening breaches of boundaries in social relationships? These questions imply that the brand relationships may be based on anxiety and a feeling of safety rather than love and a historical bond. There are also implications for brand loyalty as this kind of relationship may be connected to fashion and can be manipulated through marketing efforts that play with the notions of safety.

Another research topic relates to a macro issue: the use of cleaning and grooming products leads to global warming, contamination, ozone depletion, and pollution. Thus, while consumers try to construct a safe and orderly haven by cleaning or playing with dirt, they simultaneously create new risks and threats at a macro level, they contribute to the disorder and the risk society (Beck 1992). This paradox is worth studying in order to see how ecological issues fit with the practices and rituals of cleanliness and to explore how meanings of cleanliness and dirt change in personal and environmental domains.

Finally, the festive nature of cleanliness seems to be a worthwhile topic of study. Bakhtin (1965) sees the marketplace to be a space for human festivity betrayed and distorted by the religious, political, and moral hierarchies. What if that marketplace, having become the domain of hegemonic capitalism, is now itself betraying human festivity? If the human festivity is to be turned over to everyday social life worlds of consumers, can magical rituals and practices of cleanliness play a role in this overturn? In other words, is cleaning a festive moment? In the article ‘Cleaning Idols,’ the upscale magazine *Wallpaper* claims that the ritual of cleaning has a deeply calming effect and its end result—order—is surprisingly rejuvenating. Rejuvenation is also what Bakhtin’s carnival brought to social life. How about playing with dirt? Is taking a mud bath or camping out in the nature rejuvenating? If both cleaning your car or taking a shower and taking a mud bath are festive, what do these activities have in common? That is, how do consumers use these playful moments—festivity of carnival, art, chasing of dirt, and mud games—to negotiate the safety of their spaces?

We conceptually explored various issues about the role of consumer rituals and practices of cleanliness in social relations. Research on such issues would provide an interrogation of post-structuralist conceptualizations of social orders and an understand-

ing of the negotiation processes of consumers who are cleaning and re-cleaning and trying to create their own social orders on a daily and even a momentarily basis.

The Memetics of Transcendent Places

Charles S. Gulas, Wright State University

Kim McKeage, University of Maine¹

ABSTRACT

This paper examines transcendent retail places and uses the emergent theory of memetics to situate transcendence in the retail landscape. First, memetics will be discussed. Next transcendence will be defined. Then, the paper describes three retail food establishments and their transcendent elements, demonstrating why transcendence raises them above the sum of their parts to memetic stature.

THE THEORY OF MEMETICS

Lynch (1996) characterized memetics as the new paradigm of "how ideas acquire people," contrasted with more traditional notions of "how people acquire ideas" (p. 18). Williams (1999) refers to memetics as "the contagious transfer of intellectual and/or cultural information" (p. 113). Memes, like viruses, exist for their own purposes, and their aim is to get copied and spread. This is the biological metaphor Dawkins (1976) originally promulgated from sociobiology when he established the nascent field of memetics. For purposes of the current study, memetics will be considered as a theory of ideas, their dissemination, and demise (Blackmore 1999).

The theory of memetics takes its subject matter to be "memes." A meme, most broadly, is a complex idea. Gelb (1997) defined a meme as "any communication that produces its own repetition, possibly in a new form (p. 57). Discussing memes in the world of commerce, Williams (1999) included slogans, catch phrases, melodies, icons, inventions, and fashions as memes. In the current study, memetic analysis will be used to illuminate the transcendent nature of retail establishments whose "mystique" cannot be accounted for in the traditional sense. Atmospheric, relationship marketing and retail image are established constructs used to understand the interaction between retailer and patron. However, the current study posits that these constructs do not fully explain the phenomenon of transcendent places. Thus we turn to a memetic analysis.

Lynch (1996) set out a number of modes of memetic transmission. Several of these are important in the context of the current study. The first, and perhaps the most familiar in the context of marketing, is proselytizing. This is the widespread transmission of persuasive messages designed to "convert" the audience to a particular stance (meme) (Gelb 1997). Lynch (1996) proposed that proselytizing was the fastest way to spread memes.

A second powerful mode of transmission of memes is through cognitive advantage. Lynch (1996) noted that ideas that seem to be coherent and well founded are adopted by others and retained by their adherents. The fact that people find the idea cogent leads to its cognitive advantage. This is basically the idea of face validity, which is well established in social science.

One reason that some memes spread widely is that they are easy for people to imitate. Blackmore (1999) notes that "Wrong theories in science may spread simply because they are comprehensible and fit easily with existing theories ..." (p. 59). Related to this idea is that of learnability (Williams 2000). That is, ideas spread that are easy for the host to learn and remember which in turn depends on how simple they are and how genetically and culturally programmed we are to learn them (Williams 2000).

Another factor is how compelling the meme is (Walker 2000). Compelling memes get their hosts to talk about them (Lynch 1996; Blackmore 1999). To some extent, this can be a function of the structure of the meme. For example, chain letters contain within their structure powerful injunctions against breaking the chain of replication. Furthermore, marketers will not be surprised to learn that ideas that grab people's attention are considered more compelling (Blackmore 1999). Gelb (1997) notes that one way to make your meme more interesting is to use words in novel ways.

Finally, there are characteristics of hosts that make them better replicator prospects, and Blackmore (1999) calls these advantageous hosts "meme-fountains" (p. 163). These include people who are powerful, or look powerful, who are perceived as experts, or are in positions of authority.

APPLICATIONS OF MEMETICS IN BUSINESS/ MARKETING

There have been a number of applications of memetics in marketing. Gelb (1997) and Williams (1999) note a number of advertising campaigns that gained widespread acceptance and subsequently became part of consumer culture to a degree unintended by the original advertisers and, indeed, unrelated in some cases to the intentions of those advertisers. An example both note is, "Where's the beef." This line was originally a Wendy's tag line, but later was co-opted into politics, and finally has become a general-purpose expression meaning, roughly "where's the substance here?"

Similarly, viral marketing, defined as "when the product (or users using the product) sells itself" has been examined from a memetic perspective (Walker 2000, p. 103). Walker (2000) notes that a number of companies, especially e-marketers, are using memes/viral marketing to "sell products, create a buzz among target audiences, build databases and increase brand recognition" (p. 103). One such example is an online greeting card company that lets you know how to get to their site and send a card yourself.

Of interest in the current study are "transcendent places" which, like "Where's the beef?" have somehow risen above the merely commercial to achieve legendary status. The traditional tools of analysis such as retail image, do not fully explain this status. Furthermore, these places are examples of the meta-meme of "transcendence" which can be applied in a variety of contexts.

TRANSCENDENCE

Belk, Wallendorf, and Sherry (1989) approached the idea of transcendence when they described the sacred and the profane in consumer behavior. As they noted, certain products can acquire special significance to a consumer and thereby become sacred. Similarly, in the context of the current study, transcendence is the ability that some places have to acquire special significance above their mere functional nature.

In their discussion of how transcendent experience can be triggered by a forest environment, Williams and Harvey (2001) identified five key characteristics of the transcendent experience. These are strong positive affect, feelings of overcoming the limits of everyday life, sense of union with the universe or some other power or entity, absorption in and significance of the moment, and a sense of timelessness (Williams and Harvey 2001). We will examine transcendence in the context of a commercial environ-

¹The authors would like to thank Carrie Rich for useful assistance in the preparation of this paper.

ment, positing that over time, some retail places transcend their down-to-earth elements and become memes in their own right.

THREE TRANSCENDENT PLACES

This research considers three retail establishments, all of which encompass a food service component. “Young’s Dairy” was founded as a farm in the 1800s. Young’s Dairy has been in the same family ever since, however, it has undergone a significant transformation over the years. Currently, it features a restaurant, ice cream store, and recreational facility.

The “Counter Culture Bakery”² was founded in the mid-1980s in a college town as a high-quality deli and bakery. It eventually took on aspects of a coffee shop, restaurant, and small specialty grocer, and continues in these functions currently.

The Billy Goat Tavern is a Chicago legend. Although there are now multiple locations of the Billy Goat, we will concentrate on the most famous of these which is located on the subterranean Lower Michigan Avenue. It is in the heart of the Chicago business district, minutes away from the upscale shops and hotels of the Magnificent Mile, yet it is an out of the way place underground that you would never find were you not looking for it.

METHODOLOGIES

A multi-method approach has been utilized in studying the manifestations of transcendence in these three food-related establishments. The study of Young’s Dairy utilized analysis of customer comments that capture the consumer’s experience in their own words. One of the promotional tools used by Young’s Dairy is a birthday club. Patrons who register for the birthday club are mailed a post card near the date of their birthday each year. The birthday postcards are redeemable at Young’s Dairy for free ice cream. Several thousand patrons ultimately registered as members of the birthday club, and this data base has been sampled periodically to gather marketing information for Young’s Dairy. The authors were given access to one of these surveys in which responses from 303 patrons were obtained. One of the authors has also visited Young’s Dairy on multiple occasions as a participant-observer and has had the opportunity to meet with the CEO. From these data sources a picture of Young’s Dairy has emerged.

Information on the Counter Culture Bakery was gathered over a period of two months through in-store observation and two depth interviews. One of the authors conducted eight hours of observation in the business, and conducted over two hours of depth interviews with one owner and one employee of the business. Indications of the transcendent nature of the business were subsequently culled from the resulting field notes.

To gain insights into the nature of the Billy Goat Tavern, an analysis was made of patron comments published on the World Wide Web. Many travel and entertainment oriented web sites allow for patrons to submit reviews which include space for open ended comments. An analysis was made of these consumer comments posted on three of these sites, Fodor’s (fodors.com), City Search (citysearch.com) and Centerstage (centerstage.net). These three sites yielded a total of 118 patron reviews. Insights to the Billy Goat were also obtained through published material and on a site visit by one of the authors.

Young’s Dairy Yellow Springs, Ohio

Old-Fashioned Atmosphere among the Hippies. Young’s Dairy is located in a rural area on a major road less than ten minutes away from two colleges: a liberal arts school well known for its progressive perspective and a conservative Christian college with a focus

on ministry and mission work. Also within ten minutes are a state park, two nature preserves and a bike trail that is part of a major network of trails spreading through the region. A forty-five minute driving radius includes at least six other colleges and universities, a major military base, and a population base of nearly one million people.

Although Young’s Dairy is best known for its ice cream shop, the complex also includes a separate family restaurant, and a family recreation center which features a miniature golf course, a driving range, and batting cages, as well as a seasonal corn field maze. In addition to cows, the farm is also home to numerous goats that patrons are encouraged to feed.

Young’s Dairy does have very good ice cream. This is attested to by the vast majority of the survey respondents. The success that Young’s Dairy has had over many decades is not likely to have occurred without a quality product. However, attempts to sell Young’s Dairy ice cream through grocery store channels have not proven successful. There may be many reasons for the lack of success in this channel. However, the survey results suggest a critical factor. The fact is that the experiential aspects of eating the ice cream at Young’s Dairy cannot be packaged.

In response to the open-ended question, “Why do you come to Young’s Dairy?” survey respondents are nearly as likely to mention the atmosphere as they are to mention products or services. Common responses include; “homey atmosphere,” “family atmosphere,” “old-fashioned atmosphere,” “country atmosphere,” and similar statements. It is interesting to note that two or more very divergent populations intersect at Young’s Dairy. Parents and grandparents taking children on a family farm outing intersect with students and faculty from a progressive liberal arts college. This juxtaposition was captured by a respondent whose reason for coming to Young’s Dairy was “old-fashioned atmosphere among ‘the hippies.’”

Collages made from photos sent in by patrons adorn the walls of Young’s Dairy. These photos show patrons wearing Young’s Dairy t-shirts in front of landmarks throughout the U.S. and around the world. Many of the backdrops feature traditional tourist sites such as Mount Rushmore, The Eiffel Tower, The Great Wall of China, The Sydney Opera House and traditional tourist destinations such as Las Vegas, and Florence Italy. Less typical locales such as Changoene Mozambique, Nishinasuno Japan, Gambia West Africa, Arrowtown New Zealand, Al Kharg Saudi Arabia, Republic of the Marshall Islands, Nazca Peru, Addis Ababa Ethiopia, Kazakhstan and Antarctica are also featured among the scores of photos posted. T-shirts emblazoned with brand logos are not unique. They are sold by countless businesses. However, a business whose patrons feel motivated to pack a logo t-shirt on a trip so that they may be photographed wearing it, and send the photo back to the business is rare indeed.

The Emergent Meme: Ice Cream Tastes Better if You Can See a Cow. It is apparent from the responses to the question, “Why do you come to Young’s Dairy?” that it has transcended the mundane to become more than an ice cream shop and family restaurant. Responses include: “Yellow Springs trademark,” “it has a lot of tradition,” “special place we take out of town visitors” “we fed our children at Young’s Dairy now we feed our grandchildren,” “I like telling my friends and guests about it,” “we have introduced Young’s Dairy to at least one family a month every year since we moved here seven years ago.” These and many similar comments suggest that Young’s Dairy is more than the sum of its parts. It is more than good ice cream, reasonably priced food and family entertainment. In fact, many patrons who expressed a deep affection for Young’s Dairy also expressed some level of dissatisfaction with one or more aspects of Young’s Dairy products or services. Indeed, once established, the meme is strengthened by supporting

²The name has been changed to protect proprietary information.

evidence while disconfirming evidence is discounted. Thus the transcendent nature of Young's Dairy buys it some latitude for imperfection.

The nature of the environment of Young's Dairy lends itself to transcendence. Where better to buy home made ice cream than on a dairy farm? As the CEO stated, "ice cream tastes better if you can see a cow." This leads to a cognitive advantage for Young's Dairy. There is face validity that ice cream produced on a dairy farm is home made in the truest sense of the term and therefore it must be good. It is easy for patrons to assume unique qualities for the product given the unique location. Another aspect of face validity is the popularity of Young's Dairy. It can get very crowded, particularly on summer weekends. Success breeds success—can all of these people be wrong? These aspects help build the Young's Dairy meme.

The location, an easy drive or short bike ride from several colleges, also helps in the perpetuation of the meme. Students at nearby colleges are frequent patrons at Young's Dairy. It is likely that new students are initiated into the meme of Young's Dairy directly or indirectly by more senior students. By such a mechanism it becomes a college tradition and a likely destination for alumni visits.

Selling t-shirts with "Young's Dairy" emblazoned on them, and by example, encouraging patrons to wear them around the world is only part of the marketing effort at Young's Dairy but a part that fits well with the meme of the transcendent place. This is a clever method of proselytizing the meme. The presence of the photos helps to reinforce the transcendence meme by suggesting that Young's Dairy is world famous. It also stands as a silent challenge to patrons to replicate the meme by buying a Young's Dairy t-shirt and having their photo taken wearing it with interesting or unlikely locations as a backdrop as they travel. Since college students, college faculty, missionaries (from the nearby Christian college) and military personnel are particularly well traveled groups, this challenge is readily accepted.

The meme is also proselytized through annual events such as a bike ride, an art exhibit and auction, and a children's Easter Egg Hunt. Young's Dairy is arguably more centrally anchored into the community than any other business in the area, and that just adds to its transcendent nature.

The Counter Culture Bakery

In Search of the Mystique. One of the very first notions the owners put forth when introducing the researcher to the Counter Culture is the idea that the shop has a "mystique" about it. The owners have met people across the U.S. who have visited the Counter Culture and thought well of it. Even through recessions that hurt the local economy, and despite their high prices, the Counter Culture has continued to do well and maintain a very loyal clientele. The owners call it a "mystique" because they cannot define it, and believe that it stems from more than just the "terrific" food and the "eclectic and interesting" staff. It is, indeed, some transcendent quality.

Quality is the watchword when it comes to Counter Culture products. The owners and managers are constantly assessing the quality of the products they sell compared with those of local competitors. They even note that not all of their products yield the return they want financially, but they result in goodwill among the customers and help support the high-quality positioning of the store. It's also worthwhile noting that substitute products, often of very high quality themselves, are widely available in the area, yet Counter Culture customers remain fanatically loyal to this place.

The atmosphere in the Counter Culture has been described as cozy, eclectic, and engaging. Art features prominently, including

original artwork by the employees and "bread art" (shaped and preserved bread pieces). In general, even the more functional displays tend to be decorative, and wherever possible aesthetics are not sacrificed for functionality. The owners feel it is very important to tend to both the business side and the aesthetic side of things.

The Counter Culture's owner built the shop with a vision of a "laid-back, ex-hippie" pro-social, environmentally-friendly sort of place. This founding vision seems to have permeated the place and remained throughout decades of change in the "outside world."

The Counter Culture is noted for being a part of and building a sense of community. In this college town, the store provides space and tacks for people to post notices of community happenings, many of which are political or alternative in nature. The business is a sponsor of local public radio, and provides baked goods that are responsive to local needs, such as Challah on Fridays and special items for a variety of holidays. The owners are very particular about which professional organizations they join, and make those decisions based on the politics of the association rather than on pure marketing concerns.

The customers in the Counter Culture also seem to feel a sense of community. They sit together when it's busy, and ask each other for copies of the local bus schedule or newspaper. The store policies tend toward personalized treatment of customers which may encourage this sense of community. Employees call people by name to pick up their orders (rather than assigning numbers), and customers can call ahead and have fast-selling items held for them. Employees will even trust regular customers to pay them another day if they forget their money. Being aware of the effect of high prices on some customers, employees will suggest good deals to customers with limited funds, and treat them as just as important as more lucrative customers. While the owners have noticed that it bothers some customers to have to wait in line during busy times, they are committed to taking the time to treat each customer as an individual. As one owner said, "each customer is a friend." They let people in a hurry cut in line and just leave money on the counter, and they will even save the change for the person and give it to them later if they don't have the exact change.

The owners very much see their clientele as friends, or even part of the family. One of the owners said that owning the Counter Culture is "like throwing a party in your house for 200 people every day."

There is a sense of ownership among both customers and employees of the Counter Culture. The owners encourage this in the employees through the use of policies such as giving them a "music allowance" to buy some music of their own choosing to play in the shop. Employees are also prone to writing graffiti on the signs that abound behind the scenes, and this graffiti often becomes an irreverent dialogue between "management" and "labor." Employees are generally intelligent, well-educated, and independent. Many are or were local college students, most are women, and both management and employees promote an atmosphere that is not oppressive to women.

During slow times, patrons may "camp out" for longer stretches, reading or studying or chatting. "Regulars" form a community. Customers will greet one another and often know about each others' lives outside the store. Customers will also talk and joke with the help, and the conversations indicate that the workers and customers know quite a bit about each others' lives.

If customers are annoyed, they're likely to speak up right then and there. One famous line was "are you having a tea party or making my sandwich?" It is apparent that customers do not just relegate responsibility for monitoring employees' behavior to the management, but rather take it upon themselves in a more communitarian spirit.

Reinforcing the Meme. Art and music are important parts of the Counter Culture's connection to the community. In addition to local artwork, the Counter Culture is known as an annual sponsor of the local summer jazz festival. Thus patrons of the "arts experience" are likely to spread the word. Indeed, music companies with names similar to the Counter Culture have been mistakenly assumed to be associated with the Counter Culture deli.

As with Young's Dairy, the Counter Culture offers face validity that it is truly something special. The aesthetics of the décor as well as of the products are unique. The high level of social interaction between actors in the shop, whether customers or employees, is testimony to the "real" (as opposed to merely commercial) nature of the relationships therein.

The Counter Culture is a compelling meme as well. Knowing the "best place in town" for coffee, baked goods, lunch, etc. conveys a type of social status. Being able to introduce others there and demonstrate that the employees know you by name is even more status. It's "cool" to be "in the know" about "cool" things.

The meme fountains that surround and spout the Counter Culture meme are generally local, but powerful. These include regulars—so called "members of the family"—as well as continuing cohorts of college students who operate in the same fashion mentioned earlier for Young's Dairy. Community activists, who see the Counter Culture as a locus of information and support, also tend to be opinion leaders within certain market segments. Finally, people who want to be "in the know" about the cool places to hang out in town spread the meme far and wide both verbally and on the Internet.

Billy Goat Tavern—Chicago, Illinois

Cheesborgor, cheeps, and a Pepsi. The Billy Goat Tavern is a bar and grill with a limited menu centered on cheeseburgers. It has reasonable prices, given its location. The Billy Goat was the 2002 Audience Winner in the category of "best burger" on the Citysearch web site. However, a review of patron comments on the site suggests that many people who consider themselves fans of the Billy Goat find the food unremarkable at best. One patron review states: "I have been going to the Billy Goat since the 60s and it has never been about the food. This is all about Chicago, tradition, and just good fun." Another states, "It's not the burgers it's the ambience, that's the only reason I love this place. The burgers are just OK, but the atmosphere, knowing that Mike Royko would go on his famous rants here is just awesome." A third writes, "If you come here expecting a great cheeseburger don't bother. But if you are into Chicago journalism, come here, grab a beer and a cheeseburger and shoot the breeze with the cooks and the other newspaper guys that still come here... You NEED to come here if you used to follow Royko's... columns." All three of these patrons gave the Billy Goat a perfect score of ten on the rating scale. Many patrons expressed similar feelings.

While some patrons did give the cheeseburgers high ratings, it appears that atmosphere, rather than food, builds fans of the Billy Goat. The atmosphere of the Billy Goat might be described as endearingly bad. Little, if any, redecorating appears to have occurred since 1964 when the Billy Goat moved to its present location, (the original location was demolished to build the United Center). The basic furnishings are well worn and somewhat dingy. The perpetual darkness of the Lower Michigan location amplifies this dinginess. The atmosphere has been described by patrons as follows: "this is in every sense a dive," "I can't say the place is the cleanest...this is a hole in the wall," "original grease from the 40s still on the walls!" "the place is smoky, the staff is loud—what more could you ax (sic) for?" These comments all come from patrons who gave the Billy Goat high marks on the rating scale. It appears

that it is the utter lack of the accoutrements of other restaurants that creates the unique character of the Billy Goat. With better food and a pleasant décor the Billy Goat would likely lose its authenticity and its charm.

The publicity genius of William Sianis built the Billy Goat into a legend frequented by eminent Chicago writers and by professional athletes and team owners. Columns featuring the Billy Goat, and photos of celebrity patrons, adorn the Billy Goat's Wall of Fame. This memorabilia reinforces the world famous status of the Billy Goat thus replicating the meme. Why would so many people write about the Billy Goat, if it was not special? To paraphrase Boorstin, the Billy Goat is well known for being famous.³

The Importance of a Meme Fountain. Many fans of the Billy Goat find the food mediocre. The atmosphere is dingy and not attractive in the traditional sense. Yet the Billy Goat has attained legendary status. One reason that this has occurred is that the Billy Goat has benefited from three "meme-fountains" namely Mike Royko, John Belushi and the founder William "Billy Goat" Sianis.

Meme fountains are opinion leaders. Memes held by these individuals are more likely to be replicated. In the case of Mike Royko he was a highly regarded newspaper columnist with a large and loyal following. He regularly wrote about the Billy Goat and the cast of characters that populated it. Royko's writings added to the status of the Billy Goat as did Saturday Night Live. During the 1970s a recurring skit featured an unnamed diner where all patrons were given a "cheesborgor, cheeps, and a Pepsi" regardless of their order. The original skit was written by Don Novello of the Saturday Night Live cast. Since Novello, John Belushi, Bill Murray, and Dan Aykroyd all had a Chicago connection, it was soon recognized that the restaurant featured in the skit was the Billy Goat. The "cheesborgor" guys were very popular during what many believe to be the heyday of Saturday Night Live. Many patron comments still make reference to these skits that were performed a generation ago.

While Belushi and Royko enhanced the mystique of the Billy Goat this mystique was created by the founder, William "Billy Goat" Sianis. Sianis was a larger than life character with a flair for the dramatic. The drama began with the naming of the Billy Goat. The original Lincoln Tavern was renamed the Billy Goat after a goat wandered in one day. Sianis adopted the goat, changed the name of the tavern, and adopted the nickname Billy Goat for himself. Sianis was the quintessential promoter. In 1944, when the Republican Convention was in Chicago, he posted a sign saying, "No Republicans Allowed." The resulting notoriety drew both gloating Democrats and Republicans demanding to be served. In 1945, Sianis bought two tickets to the World Series, one for him and one for his goat. When the goat was denied entry, Sianis publicly placed a curse on the Chicago Cubs (Sutcliff and Venci 2001). The legend of "the curse" grew over the years as the Cubs had one disappointing season after another. He finally removed the curse in 1969. Sianis died in 1970. His nephew inherited the Billy Goat, and following in the founders footsteps, tried to take a goat into Wrigley Field in 1973. When the goat was denied admission the curse was reinstated (Sutcliff and Venci 2001).

DISCUSSION

Humans have always revered certain places. Sacred places predate recorded history and adherents to many contemporary religions treat certain places with particular reverence. The current study posits that there is a parallel to this phenomenon in the secular world. We are all familiar with special commercial places. These

³"A celebrity is a person who is known for his well-knownness" (Boorstin, Daniel)

are the “must sees” on a visit to any given city or region. Typically these “must sees” are bars, restaurants, diners, bookstores, or coffeehouses, but this list may include sporting goods stores, grocers, bakeries, gardening stores or virtually any other type of business. These commercial places have the ability to create transcendent experiences. The businesses examined in the current study create these transcendent experiences in many ways.

Strong Positive Affect

Many of the participants in the study specifically use the term “love” in describing some aspect of the relationship with the respective transcendent place. Indeed the 303 respondents in the Young’s Dairy survey used the word “love” forty-seven times. In addition, the family metaphor is widely used with regard to the Counter Culture, with the attendant feelings of warmth, acceptance, and caring. Clearly, these transcendent places engender strong positive affect.

Overcoming Limits of Everyday Life

For many of the respondents a visit to one of these transcendent places is a pilgrimage of sorts. The Billy Goat is a very common tourist destination. Out-of-towners visit to get a taste of “real Chicago.” Similarly, for many visitors to Young’s Dairy a visit constitutes a trip to the country, a way to get in touch with a pastoral vision of America. Customers of the Counter Culture see the shop and its products as an escape into a fantasy world of rich, decadent, expensive fantasy food and drink.

Sense of Union

Patrons of Young’s Dairy often note the “family atmosphere.” This is a place where people take children and grandchildren to experience a family farm and to associate with similar families. These patrons are buying a set of values to accompany their ice cream. Similarly, regulars of the Counter Culture are “family” and there’s a strong sense of community among the patrons and employees.

The Billy Goat has been described as a “blue-collar bar.” People who proudly adopt the blue-collar role seek this environment. As one patron who rated the Billy Goat as a ten stated, “Please don’t go here if you were ever in a fraternity or if you are upwardly mobile... Go to Applebee’s and leave this place for the people who really enjoy it.” People who do not have blue-collar jobs, but who adopt a blue-collar persona, like Mike Royko, also find a home at the Billy Goat.

Absorption in the Moment

Young’s Dairy reflects a simpler time thus a visit to Young’s Dairy may create an idealized family moment that can be a respite from modern family reality. Similarly, for the first time visitor a trip to the Billy Goat can be other worldly. Its location on an underground street at the base of a grimy staircase can be intimidating to some. Several patron reviews specifically exhorted the hesitant to not be afraid to venture down for a visit. For first timers and regulars alike, the very process of getting to the Billy Goat provides a transition into the moment. At the Counter Culture, the compelling sights and sounds, the aroma and the sense of belonging take patrons outside their everyday lives, at least for a few moments.

Sense of Timelessness

One patron proclaimed that the Billy Goat was “Chicago frozen in time”. After moving to its current location, the Billy Goat has been essentially unchanged for nearly forty years. One Young’s Dairy patron noted that Young’s Dairy “reminds us of like estab-

lishments that existed where we grew up in the late 40s.” While Young’s Dairy has undergone substantial changes over its lifetime, its essence remains the same. The Counter Culture is the essence of “ex-hippie” 1960s by design, and remains true to those values despite the fact that it was indeed established in the 1980s and despite the shifts in the social world around it over the course of almost 20 years.

Memes and Meta-memes of Transcendent Places

What emerged from this study are two powerful memetic notions. One is the ability of these three food establishments to transcend everyday retail branding and become memes. The second is the introduction of the meta-meme of the transcendent retail place. There are three important aspects to this process: a transcendent experience is triggered in the place as described above; over time the meme gets replicated as it passes from person to person; once established the meme is resistant to disconfirming evidence. The memes of Young’s Dairy, the Counter Culture, and the Billy Goat are evocative, powerful ideas in a memetic sense that their owners could have only dreamed of originally.

EXTENDED ABSTRACT

Conceptualization

It is not easy to stir consumers' emotions with a routine advertisement because a multitude of advertisements surround them (Armstrong 1995). Advertisers have found a new, albeit controversial way to get their message across. They have begun using shock ads to attempt to capture consumers' attention from within a media clutter.

Provocative Advertising

Vezina and Paul (1997) suggested the three main characteristics of provocation: distinctiveness, ambiguity and transgression of norms and taboos. Distinctive advertisements have been shown to get greater attention than nondistinctive advertisement (Engel, Blackwell, and Miniard 1986; Rossiter and Percy 1987). If ambiguous ads contain factors which irritate or challenge social norms and standards, they can be called as provocative ads.

Provocative and Humorous Advertising

Humorous provocative advertising can be regarded as the mixture of the humor and the provocative appeal. Though the results of humor appeals in ads remains uncertain, it seems clear that humorous ads have a positive impact on increasing attentions and the liking of the source.

Emotional Response

The Thayer Arousal Model (Thayer 1986; Thayer and Carey 1974) suggests that arousal is a complex phenomenon that comes from the interaction of two dimensions: energy and tension. If the feeling of tension is not excessive, it activates to generate energy, which causes to positive cognitions (La Tour and Pitts 1989). Humor can be used to weaken feelings of tension.

Measures of Emotion: The Self-Assessment Manikin

The self-assessment manikin (Lang 1980) is better than the verbal check list for measuring a respondent's emotional responses, because the visual method (see Figure 1) eliminates cognitive processing (Lang 1985; Morris and Waine 1993). The validity of SAM and AdSAM (Morris, Woo, Geason, and Kim 2002) a variation of SAM, has been established in a number of studies (Lang 1980; Morris, Bradley, Lang, and Waine 1992; Morris and Waine 1993; Morris, Woo, Geason, and Kim 2002; Morris, Woo, and Cho 2003).

Hypothesis

Hypothesis 1: Provocative ads and humorous provocative ads will generate higher emotional responses on the arousal and dominance dimensions than general ads as measured by the Self-Assessment Manikin (AdSAM) and PAD.

Hypothesis 2: Humorous provocative ads will generate significantly higher levels of pleasure than provocative ads as measured by the Self-Assessment Manikin (AdSAM).

Hypothesis 3: Pleasure levels rather than arousal and dominance in emotional responses to ads as measured by the Self-Assessment Manikin and PAD will have a stronger relationship to the attitude toward advertising, the brand attitude, and the purchase intention.

Methodology

Pretest and Stimuli Selection

Nine print advertisements were created or selected from existing campaigns for pre-testing. There were three potential provocative, three potential humorous provocative, and three potential traditional 'general' ads. Since nine print advertisements were selected as stimuli based on the authors' subjective judgment, they were pre-tested to make sure that they fit the present study. One more advertisement was created as a control.

Respondents

One hundred four students at the university participated in the study. A convenience sample of 55 subjects was recruited from the advertising elements class and 49 responses were randomly collected on campus. The subjects consisted of 56 female students and 48 male students with a mean age of 22.

Procedure

The seven advertisements were randomly ordered in seven different ad sequences. The seven order levels make a block factor and a common group period effect/ no residual effect was assumed since the cross-over design satisfied the strong condition for balance. After viewing each ad, subjects were asked to fill out each seven questionnaires, examining their emotional response, attitude toward the ad and their brand attitude and purchase intention.

Dependent Variables

The AdSAM (Morris, Woo, Geason, and Kim 2002) was used to measure subjects' emotional responses. The Aad and Ab scale contained four-bipolar scale items with .99 and .98 Cronbach's alpha, respectively (Holbrook and Batra 1987). Purchase intention was measured based on the summed score of a three-item scale (Cronbach's alpha=.88) used by Bearden, Lichtenstein, and Teel (1984).

Results

Ad execution had a significant effect on pleasure ($F=71.393, p<.05$), arousal ($F=83.936, p<.00$), and dominance ($F=71.393, p<.00$) and following multiple comparison test using Tukey's HSD showed that the humorous provocative advertisement has a greater influence than the simple provocative and general ad. For the attitude measurement, ad execution had significant effects on Aad ($F=52.728, p<.05$), Ab ($F=20.406, p<.05$), and PI ($F=5.051, p<.05$), and consequent post-hoc tests using Tukey's HSD concurrently indicated that humorous provocative advertisement had more effect than simple provocative ad on attitude and intention.

Multi-group LISREL (Jöreskog and Sörbom 1997) structural equation modeling reproduced Pearson's correlation coefficient confirmed the overall linear relationship between the three dimensions of emotional response and attitude dimensions of Aad, Ab, and PI (SRMR=.05 (.04) and CFI=.96 (.98) for provocative (humorous provocative) response grouping. According to the likelihood ratio test (LRT), humorous provocative responses had significantly stronger linear loading patterns than provocative ads.

Conclusion and Discussions

The provocative ad and humorous provocative ad, both of which had provocative factors, were expected to have a strong impact on consumers' emotional responses. In arousal and dominance, the provocative ad and humorous provocative ad got signifi-

FIGURE 1
AdSAM

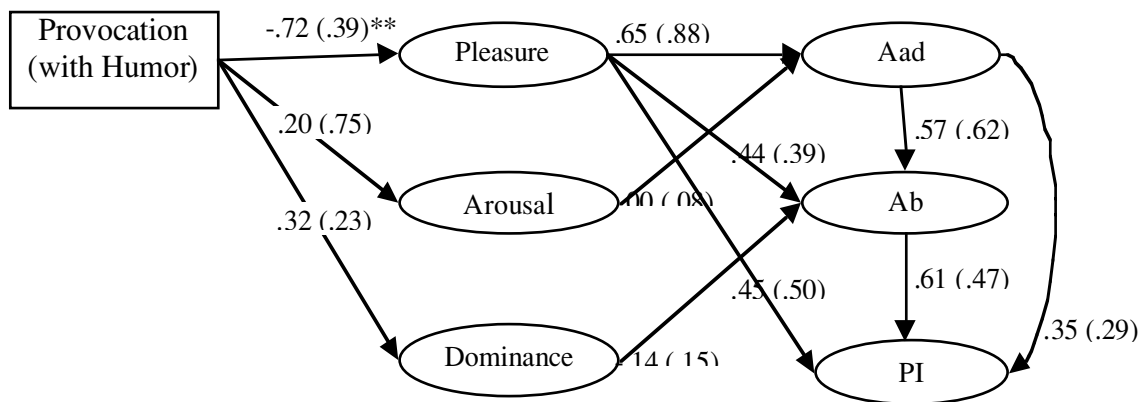

FIGURE 2

Multi-group LISREL Structural Equation Modeling with correlated measurement errors between Aad and Ab.

cantly higher scores than the general ad and the brand name only ad. On the pleasure dimension, the response to the provocative ad is significantly different than to the humorous provocative ad. Based on the MANOVA results, perceived pleasure levels for the humorous provocative ad and the general ad are significantly more positive than the provocative ad and the brand name only ad.

Overall, if one were to choose the general ad over the humorous provocative ad because of the Aad score the level of PI would be lower. If PAD were to be used in combination to select the ad with the better relationship to purchase intention, then the humorous provocative ad would have been selected. The combination of the PAD, therefore, provides better information than Aad when selecting between a provocative, a humorous provocative and a general ad.

Relational Listening and Impression Management in Salesperson-Customer Relationships

Avinash Malshe, University of Nebraska-Lincoln

Susie Pryor, University of Nebraska-Lincoln

EXTENDED ABSTRACT

This paper reports on a qualitative study that investigates how salesperson-customer relationships are affected by the listening behaviors exhibited by salespersons, impression management strategies employed, and the interaction between these.

Interpersonal communication between salespersons and customers is recognized as an important part of successful sales interactions (Comer and Drollinger 1999). While communication has two distinct aspects—expressive behaviors (e.g., talking) and recognition behaviors (e.g., listening) (Nichols 1995)—studies of communication behaviors have remained grounded in expressive aspects. Poor listening behavior has been identified as a key component of salesperson failure, costing American businesses billions of dollars (Brownell 1990; Steil, Barker, and Watson 1983). However, listening still remains the least understood component of the communication process (Ramsey and Sohi 1997).

This paper derives its theoretical foundation from seminal work on impression management as well as more narrowly focused work on the role of listening in salesperson-customer interactions. Though marketing scholars have studied impression management in the context of personal selling (cf, Harris and Spiro 1981), this work fails to consider the role of listening among impression management strategies. To fuse these two conceptual bases, we adopt a relational perspective of listening.

From an analytical perspective, impression management may be described as a macro-level term that encompasses micro-level processes (e.g., attention to demeanor, attire, expressive communication, and listening). Studies of service encounters and sales performance traditionally employ quantitative methods, unpacking key components of interactions and failing to capture the role of impression management. We employ a qualitative approach to reconstitute these variables.

Data were collected from 11 informants (customers of realtors) via in-depth, semi-structured interviews, resulting in thick description of issues from informants' perspectives, and enabling interviewers to probe about listening behaviors, idealized images of realtors, marketing outcome variables, and motivations and explanations for behaviors uncovered.

The results of our study, consistent with Nichols (1995), revealed that listening was clearly identifiable as a unique aspect of communication. Two informants highlighted listening as *the key criterion* distinguishing good sales performance. The remaining identified listening as a significant component of the salesperson-customer relationship.

All of the components of listening found by Ramsey and Sohi (1997), sensing, evaluating, and responding, appeared in our data. This typology is predicated, in part, on the work of Castleberry and Shepherd (1993, p. 36) who define salesperson listening as "the cognitive process of actively sensing, interpreting, evaluating and responding to the verbal and nonverbal messages of present or potential customers." By including an affective dimension, we found we were better able to account for our informant's depictions of listening. Our data revealed six components of listening: cognitive sensing, cognitive evaluating, cognitive responding, affective sensing, affective evaluating, and affective responding.

Cognitive sensing includes aspects of listening related to focusing on one's audience (e.g., maintenance of eye contact and alertness). Affective sensing refers to a more relational level of

understanding. Cognitive evaluations involved salespersons asking direct questions of the customer, while affective evaluations related to the salesperson trying (in the words of one informant) to "see the house through the customer's eyes." Cognitive responding related to performing tasks material to the transaction itself (e.g., showing houses appropriate to customer criteria and scheduling appointments convenient to informants). Informants experienced affective responding as attending to underlying needs and desires, requiring increased sensitivity to customers by realtors. The affective dimension should not be associated with positive impressions; it is the nature of the listening and not the outcome that distinguishes cognitive from affective components.

Findings suggest that listening behaviors contributed to overall impressions created by realtors. Further, the extent to which actual behaviors exhibited by realtors corresponded with idealized expectations held by customers determined customer satisfaction with the salesperson. Intriguingly, our informants demonstrated a readiness to justify behaviors of salespersons in order to bring idealized and actualized behaviors into greater correspondence, ultimately producing a positive perception of the overall service experience.

This study expands our understanding of listening in the context of sales communication. It tests and extends the scales of Ramsey and Sohi (1997), suggesting cognitive and affective dimensions of these. The results build into this existing model the concept of the salesperson's idealized image, perceived image and the overlap between the two. In this sense, the work also contributes to the literature on impression management. It explicitly links salesperson's listening behavior to impression management activities, unfolding an unexplored facet of impression management. In highlighting the underlying dynamism in this process of overlap, we argue that customers help salespersons co-construct the overall service space impression through a variety of strategies. When impressions match expectations, customers use strategies such as constructing motives behind a salesperson's actions and highlighting aspects of salesperson behavior to reinforce the positive experience. When expectations do not match reality, customers utilize strategies aimed at creating an overall positive impression of the full service-space, including assigning meanings to certain salesperson activities, trying to reconcile others, justifying the outcomes, or expressing helplessness.

This paper highlights this mediating role played by impression management. It is this mediation that allows us to understand those situations wherein there is only a partial overlap between the expected images and actual impressions and the process through which customers reconcile these, overlooking incongruent elements to gain a better overall impression.

The context of our study differs significantly from that of Ramsey and Sohi (1997) and plays an important role in the overall findings, shedding light on the distinction between extended service encounters and other commercial sales activity that is more limited in duration. This allowed us to discern differences between realtors and car salespersons, for example, in the extent to which each has the capacity to utilize listening skills to create and maintain impressions. Our study suggests that there exist cognitive and affective dimensions of listening, and that a temporal dimension may moderate these. Many informants noted that listening behaviors exhibited by salespersons, and the overall impressions created,

changed as the relationship evolved. This may make the affective dimensions more pronounced in more relational selling environments and affect the degree of correlation between listening and impression management.

Materialism and Illegal Enterprise: A Life Stories Analysis

Jon Littlefield, Virginia Tech

Eloise Coupey, Virginia Tech

ABSTRACT

The years of economic growth and concomitant personal prosperity and consumption of the 1990's were mirrored by rapid growth in the U.S. prison population. Many of the crimes leading to incarceration were related to illegal enterprises that met consumption needs and desires. The researchers conducted depth interviews with male inmates at a minimum-security prison to examine the marketing characteristics of illegal enterprise, incorporating sociological and psychological theory to guide the interviews and interpret the data. Research conclusions provide insights into consumer misbehavior, and its antecedents and consequences.

In 2002, two seemingly unrelated trends were occurring in the United States. First, after the end of a recession in 1992, strong economic growth combined with productivity increases in the last five years of the decade (Jorgensen and Stiroh 2000) to produce an economic boom. The major stock market indices soared to unprecedented levels, and unemployment dropped significantly. Most American consumers enjoyed the fruits of their prosperity. *Per capita* income and household assets increased across all ethnic segments, resulting in high levels of disposable income and spending on luxury items.

During the same time period, however, U.S. prisons were full, reflecting two decades of sharp increases in both crime and convictions.¹ The Department of Justice noted in its 2001 annual report that 3.1%, or 1 one in every 32 adults in the U.S. was currently in the correctional system (www.usdoj.gov).

The contradictory patterns of increased consumer wealth and increased prison population growth suggest that not everyone benefits from economic growth in the same way. We follow longstanding sociological theory in suggesting a structural explanation for some consumption practices that casts doubt on the assumption of personal agency prevalent in marketing research. Specifically, we propose that while the salience of material acquisition and the *desire* to consume may have been commonly experienced, the *routes* for achieving personal consumption objectives differed widely among groups of consumers. In this paper, we describe research findings suggestive of a discrepancy between the desire to consume and the ability to consume which creates anomie, or perceived strain. We show examples of strain theory (cf., Merton 1957), in which divergence between the desires and opportunities of people in a society may motivate people to circumvent socially acceptable means of achieving socially desired goals.

This paper explores the specific motivations of criminals. We conducted depth interviews with inmates in a men's minimum-security prison to examine the prisoners' motivations, looking for the existence of materialism as a socially desired goal and of anomie, or strain, as a motivator for achieving the goal. Of particu-

lar interest were the specific mechanisms that criminals use both to address the disparities they see in their lived experience and to increase their chances of success in their chosen actions and lifestyles. Our objective is to provide insight into the lives and consumption practices of this under-researched set of consumers, as well as insights into consumer behavior through an enriched understanding of misbehavior.

This paper is organized as follows. First, we present the general research questions that motivated the study. These questions also guided the form and content of the interviews that served as the basis of data for this research. Next, we describe the research method, including the group studied, the setting, and the interview format. This description provides insight into the strengths and limitations of the study method, and it provides a context for the results discussed subsequently. Analysis and interpretation of the interview data is developed within the context of a general theoretical model. Key emergent themes and their relevance for illegal consumer behavior are also discussed.

RESEARCH MOTIVATION

While consumer behavior research has gained significant momentum in the past three decades, it has typically looked for mechanisms to explain how consumers generally behave. Research that tests the limits of this behavior, however,—what we will call misbehavior—has been nearly non-existent. Several consumer researchers (e.g., Albers-Miller 1999) have noted that consumer misbehavior is a subset of consumer behavior, and that insights about the broader topic of consumer behavior may be obtained by considering the forces and characteristics of behaviors that contravene societal norms. Holbrook (1987) includes consumer misbehavior in his cross-disciplinary constellation of consummation.

One purpose of our research was to develop a preliminary understanding of when and how consumer misbehavior occurs. Sociological research on deviant behavior and criminology suggests strain theory and its variants as one mechanism to explain misbehavior. A simplified description of strain theory is that strain occurs due to the inability to get what others have, and deviant behaviors serve as a means to reduce the strain.

Clearly, however, not all forms of perceived strain lead to the same expression. While some might react to strain by trying harder through legitimate means, others may be similarly motivated to use illegitimate means. For yet another group, strain may lead to attempts to minimize the perceived discomfort through such escapist behaviors as drug use or drinking. The latter two expressions of strain are the focus of this paper.

To investigate the antecedents and consequences of consumer misbehavior, we focused on the independent roles that materialism and the environment play in consumption-related behavior. Materialism was deemed important because the centrality of possessions can serve as a precondition for strain. Given their tangible, conspicuous nature, material goods are often a very salient indicator of success. The concept of one's environment—both proximate and historical—was addressed because it may create a context that affects ability to consume. For instance, growing up in an environment in which education is neither valued nor facilitated may lead a person to undervalue the importance of educational achievement for attaining life goals, many of which may be consumption-related. Family structure may similarly affect the relationship between

¹One reviewer has suggested that changes in laws and in the degree of enforcement of laws would also explain the increase in crime statistics. We take the position that, prior to committing their crime, criminals are to some extent aware of changes in the legal system relating to laws and enforcement of those laws. Thus while both what is considered a crime and the probability of being caught may change over time, the existence of the decision to engage in criminal behavior remains constant.

materialism and strain. Rindfleisch et al. (1997) found that young adults that came from disrupted families (i.e., single parent families) were likely to be more materialistic and to participate in compulsive consumption behavior. We suggest that strain may have been the mechanism by which these results occurred.

Because we see consumption-related behavior as an interaction between materially focused goals and inability-induced strain, we focused our study on these behaviors, anticipating that different forms of consumption, such as consumption to meet short versus longer-term goals, might provide useful insights into the strategies used to reduce perceived strain.

RESEARCH METHOD

Research Setting

The interviews used to develop the data for this research were conducted at a men's minimum-security prison in southeastern Oklahoma. Permission to interview inmates was obtained from the Oklahoma Department of Corrections, following submission of a research proposal that delimited the scope, goals, and anticipated impact of the study on the participants.

This particular prison was selected for two reasons. First, the nature of crimes for which the inmates were serving time was commensurate with the marketing and consumption focus of this research. Prison statistics indicated that the majority of crimes involved the illegal transfer of property, such as burglaries, larcenies, and drug distribution. Second, the sensitive nature of the research topic created the potential for difficulty getting inmates to agree to be interviewed, as well as difficulty in obtaining detailed, open descriptions of their life events. Trust between the inmates and the interviewer had to be established. The interviewer's mother was a teacher at the prison, and had worked with several of the inmates who agreed to be interviewed. Their respect and trust in her led them to recruit other inmates, and to willingly discuss incriminating, but not prosecuted, consumption-related activities. Several of the inmates commented either during or after the interviews that they would not have participated if they had not believed they could trust their teacher.

Participants and Procedure

The inmates interviewed for this research were twelve men who were serving time for a variety of crimes, including burglary, drug distribution, and manslaughter. The men volunteered their time and histories following an announcement by a teacher in the education program. Seven of the inmates were students in the program; four were friends or dorm mates of the students. The men ranged in age from eighteen to forty-two. Eight of the men were African-American, one was Native American, and three were Caucasian. The interviewer was a woman in her early thirties, and in her eighth month of pregnancy.

The men were interviewed individually. The interviews took place in a rear office in a mobile home on the prison grounds, while classes were held in the front room. The inmate sat facing the interviewer across a thirty inch table. On the table were two tape recorders, and pencils and paper for the interviewer's notes.

Participants were escorted to the interview by a uniformed guard. The interviewer requested permission to record the interview, which was granted in all cases.² Eleven interviews were

obtained for analysis. The interviews ranged in length from thirty-five minutes to two and one-half hours, and they resulted in 11,267 verbatim lines of transcript (245 pages).

The interviews followed the long interview method detailed in McCracken (1988), with a goal of developing a life story (Tagg 1985) for each inmate. The interviewer began with a set of demographic questions, which provided the researchers with basic information and put the inmates at ease. Responses to these questions served as jumping-off points for developing the life stories. Following the guidelines for qualitative research proposed by Corbin and Strauss (1990), the interviewer adjusted the form and content of questions and prompts, building flexibility into the research process to reflect changes in understanding and insight afforded by previous comments.

Data Analysis and Levels of Content Comparison

Data analysis post-interview was completed in stages. First, the interviews were transcribed and numbered, line-by-line. Next, the researchers read the transcripts, noting concepts representative of the three *a priori* research categories. Comparisons across the researchers' notes and memos were conducted to ascertain whether the researchers noted similar concepts, and the extent to which the emergent concepts were based on the same interview material. In the next stage of analysis, concepts were abstracted to reflect categories of content related to the three foci of this research. One objective in this stage was to establish whether concepts that shared a category assignment provided insight into the antecedents and consequences of the illegal enterprises and other deviant behaviors.

CONCEPT CONSTRUAL AS EMERGENT THEMES

Content analysis of the transcribed data was conducted after the interviews were completed, although informal evaluation during the interview process enabled the interviewer to adjust questions and prompts so that later interviews explored areas of interest that had been uncovered in earlier interviews.

The focus on material goods was clear throughout many of the interviews, while a discrepancy between society's emphasis of material goods and the lack of opportunities the prisoners had to acquire these goods became clear to the researchers independently during the analysis process. An additional theme, involving the acquisition and use of an intuitive understanding of the marketplace, emerged in the data analysis and interpretation process. These themes will be explored in the following sections.

Theme #1: We are living in a material world.

Richins and Dawson (1992, p. 304) cite Mukerji (1983) in defining materialism as "a cultural system in which material interests are not made subservient to other social goals," and suggest that materialism includes acquisition centrality, acquisition as the pursuit of happiness, and possession-defined success. Belk (1985, p. 265) sees materialism more specifically as the second dimension, and provides the term "happiness-seeking via consumption." Historically considered incompatible with religion (Belk 1985), it is not surprising that social stereotypes exist pertaining to the types of products materialists value, as differentiated from non-materialists (Richins 1994).

Any discussion of materialism must also elicit the question of what role possessions play in our lives. Is materialism symbolic of a deeper, more important need or value? Bourdieu (1986) sees capital in general as "accumulated labor," gained throughout generations of work, of which economic capital is one part. In this sense, then, it is possible to view materialism as the desire to attain economic capital in lieu of (or as an indicator of) other forms of

²One inmate returned to the interview room and demanded that his interview be erased. The interview included details of plans for a prison uprising. The researcher handed the cassette to the inmate with alacrity. He thanked her and left.

capital (i.e., social capital or cultural capital) particularly among groups who are disadvantaged in society. It may be that the desire for (and happiness derived from) possessions merely signals the attainment of this capital as a signaling mechanism.

The difficulty involved in identifying materialism derives partly from the existence of two types of meaning of possessions—public and private (Richins 1994). Private meanings result from the personal satisfaction of possessing, while public meanings consider the communicative function of possessing. Materialism is not acquisition *per se*, but rather an effect of the motivation for acquisition that includes a preference for possessions above the preference for other goals (Mukerji 1983). The prisoners interviewed in this study, however, showed clear indications of the desire for possessions over other types of capital. They may have seen the acquisition of possessions—economic capital in Bourdieu's (1986) framework—as a substitute for the lack of social or cultural capital available to them.

Michael³ provides a clear example of the type of materialism encountered in the interviews. He describes his motivation not as need for money, but rather as a want for money. “*I sold drugs for the money. Greed is what it was.*” Interestingly, he shows a desire to follow the socially accepted route to achieving his material desires. As the manager of a clothing store, he describes going with his nephew to make a car payment, and

They had this Cadillac. This 1988 Fleetwood Cadillac, and I saw it, and I said ‘that’s beautiful, man.’ It was champagne. I mean it was beautiful. It was beautiful!

It seems clear that Michael is showing materialism for the goods themselves (the car), but is also exhibiting the type of materialism referred to by Merton (1957, p. 189) as a “heavy emphasis upon monetary success as a goal in a society.” This represents a situation where the focus has moved from an emphasis on the goods that money can acquire to an emphasis on the money as a goal in itself.

Throughout the interviews were references to material goods. Raymond remembers that he “*wanted to dress nice*” while in high school, and that his friends “*had their own car [and] . . . dressed nice.*” Numerous mentions of high-priced cars, such as Cadillacs and Lamborghinis were made across inmates. Comparison with others who had nice cars was evident in Leon’s comment: “*They all out on the streets, you know, big Caddys . . . [and] I’m locked up, man.*”

Other uses of material goods were seen. Some uses were symbolic. For instance, Michael received the gift of gold tooth jewelry in the shape of a dollar sign from one of his prostitutes. Leon, a gang member, discussed the use of gang colors to show allegiance to the gang, and his mother’s lack of awareness when he requested she buy him blue clothes to represent his gang. Possessions represented the achievement of material success for Carl Gene. His success consisted of “*a three bedroom house, . . . a cellar in my backyard, a two-car garage with a[n] apartment above it.*” Lastly, Lloyd used his television as a mechanism to avoid becoming attached to friends. With two, twenty-year sentences, he avoided becoming “*attached to ‘em [people], because they gonna, they gonna leave. . . . That TV will be my friend. McGyver? I watch McGyver.*”

Money also served as an ultimate rather than an instrumental goal (Richins & Dawson 1992). Raymond did “*everything but murder and rape. . . . Everything between those that you could call*

illegal to obtain some money.” For Leon, making money was a justification for his family moving to Oklahoma. “*You know it’s alright. I don’t like it, but you know they making money, so [laughs].*” Steven, discussing his motivation for selling drugs as opposed to stealing cars, says that the motive for car theft was the thrill, and to “*get away with it,*” while selling drugs was to “*get more money.*”

Theme #2: You can’t always get what you want.

Anomie Theory, also known as Strain Theory, was developed by Durkheim (1893, 1984) and popularized by Merton (1957). The theory postulates that strain occurs when wealth opportunities are not equally available to all members of a society. A segment which feels blocked from access may experience frustration at the divergence between its current level of wealth (for example) and that level valued by society. This frustration leads to the use of mechanisms to attain wealth that are not sanctioned as appropriate by the society—specifically, criminal activities. Merton suggested that the existence of anomie would be particularly evident among societies where there is an “exceptionally strong emphasis upon specific goals without a corresponding emphasis upon institutional procedures” (Merton 1957, p. 188). This characterizes the typical social surroundings of the prisoners studied.

Sociological theories of deviant behavior are of two general types: those that emphasize social structure’s impact on behavior and those that emphasize the learned nature of the behavior (Clinard and Meier 1989). Strain Theory represents the structural approach, and explains criminal behavior as a logical result of a society that values wealth, but which also simultaneously prevents some segments of that society from achieving that wealth. Typical segments include “the poor, those who belong to the lower class, and persons of certain racial and ethnic groups who are discriminated against” (Clinard & Meier 1989, p. 81). In order to provide support for Strain Theory in the data, it is necessary to show that (1) the prisoners represent some socially disadvantaged segment of society, and (2) that they value the socially-encouraged goal of materialism to the extent that they are willing to sidestep the socially accepted mechanisms for achieving it. The next section shows that the data support these criteria.

Social disadvantage among the prisoners studied comes from a variety of sources. Many of the subjects discussed either personal or family problems with alcoholism or drugs. Chris, when speaking of growing up in a single-parent household, mentioned his father’s death in 1980: “*He was doin’ drugs and drinkin’.*” Poverty was mentioned in a number of the cases. Chris describes working on an apartment, “*because the place was in so bad a shape that they let us live there for a year [rent free] if we’d fix it up.*”

Many of the inmates were brought up in single-parent households, and a number experienced the death of a parent early in life. One had a parent who also had a criminal history. Indicative of these early losses, a number of the prisoners mentioned the self-defense motivation as a reason for committing their crimes, although it wasn’t clear that this was not merely an attempt to avoid responsibility for their actions. For instance, one prisoner described his gang membership as “just protecting yourself” and describes the randomness by which he perceives the potential actions of others by describing people with “crazy moods:”

Like, I could be sitting over there on a certain day or something and someone drives up and says ‘Hey, there’s a Crip. We ain’t got nothing better to do. Let’s shoot him’ (Interview, Steven).

Socially acceptable mechanisms for achieving material wealth include working, saving, or sacrificing in order to purchase goods.

³The names have all been changed to preserve the anonymity of the inmates.

The prisoners showed the opposite tendency by acquiring desired goods in the short run. It is also apparent, in a number of interviews, that alcohol played a role in the sub-optimal decisions. For example, one prisoner describes the sequence of events leading to his capture:

I was out partying. Got into the car with some good friends at the time. We went out to take out some frustrations. Driving around, got hungry. We left our wallets back at the hotel that we were partying at. Walked into a store. I figured we'd just take what we wanted and he'd let us. But he didn't. So we ended up robbing the place instead of just something to eat. (Interview, Chris)

Asked whether he would be attracted to drugs and alcohol after he left the facility, Chris pointed out that both “are very available here where I’m at.” Another pointed out “I couldn’t even honestly say that if I was to be let out today if I wouldn’t in a short time go back to [using drugs] again” (Interview, Morris).

Examples of alcohol and drug use also relate directly to the previous discussion of strain. Explaining how his life turned to crime, one prisoner discusses partying with a bunch of guys out at the lake. “Drugs. Then we started stealing, so we could party without having to worry about paying for it (Interview, Chris).

Another inmate mentions the role of other people in his criminal activities:

I was involved with five other people . . . I was pretty young then. And one of them had a circle that had a beer joint . . . a bar? And so we were out drinking and we wanted some more money so we went by his uncle’s bar and he got in a big argument with him and so we left and came back. And him and his friends went in there and robbed his uncle. They beat his uncle up and took the money for some beer (Interview, Morris).

While for some prisoners, the involvement in drugs provided an incentive for committing the crime, for others, the drug involvement was a more direct result of strain. For example, Morris put it succinctly: “Mostly pot, But I’m not opposed to dealing with anything else if I can . . . if I see that there’s a profit in it.”

Another prisoner, a cocaine dealer convicted of manslaughter, described his drug sales income as “at least \$2000 a week” and, when asked about his future criminal activity, he described the probability of continuing when we got out of prison as a function of future employment opportunities not in line with his skill and experience level:

I wouldn’t do it if I could make some money. Like what an average person would make. Not no working at McDonald’s, then I wouldn’t take that kind of job (Interview, Rich).

It is apparent that Rich’s “average person” is not a minimum wage earner, as when he was later asked about a minimum wage job, he replied definitely, “I wouldn’t take that job.” His future goal was to get his GED and become an attorney. Again, however, he seemed to show expectations inconsistent with his skill and experience set. His expectations seem to indicate his continued willingness to go outside the social structure by committing crime, as he discusses his career goal:

If I can make that, then I wouldn’t do what I have to do. But then if I couldn’t, then I would probably go back to the same old thing [selling drugs] (Interview, Rich).

Motivations for selling drugs and stealing cars, jewelry, and money were different for Steven. For stealing, it was the pleasure of joy riding in someone’s car, and the feeling of getting away with it. He also mentions the process of selling the cars for a profit through the use of “swap shops.” It was possible to “just drive in and have everything redone,” to allow the sale of the car. For drug sales, however, the motivation was simply monetary.

An additional aspect of strain discussed by Rose (1966) is a “cultural apathy,” which implies withdrawal from the culture. At numerous points in the data there seems to be a lack of consideration for the personal and social consequences of the criminal actions undertaken by the criminals. It may be, however, that rather than a withdrawal from the culture in general, this strain is the result of an allegiance to a subcultural norm that is different from norms found in the dominant culture. For example, one nineteen year-old describes his rise through the ranks of the Los Angeles Cripps as a “baby gangsta,” noting rituals and traditions that guide gang behavior. His information supports work by Rosenfeld (1989), who suggests that there must be conformity to some alternate norm for deviance to occur.

Theme #3: Knowing your market, and satisfying it.

Another theme that emerged during analysis was that of intuitive consumer marketing insight. The prisoners, typically with a low level of education, cited situations which indicated an understanding of effective business activities, describing techniques and processes with which they increased their efficiency and effectiveness in carrying out illegal enterprise and fostering illegal consumption. The prisoners employed practices that reflect commonly held business objectives, including understanding the psychology (e.g., needs, wants, desires) of the consumer; building the brand; developing customer loyalty; establishing reliable channels of distribution; and making money.

Iterative comparisons of concepts extracted by the researchers revealed groupings and linkages between the concepts that enabled concept categorization. The concepts consisted of three general types: (1) awareness of benefits deriving from the products/services provided; (2) awareness of the infrastructure involved in product/service provision; and (3) use of an opportunistic approach to maximizing the potential revenue stream of the market. These categories are consistent with commonly used criteria for gauging the potential efficacy of a business model. For example, Osterwalder and Pigneur (2002) characterize a complete business model as containing 1) a value proposition through product innovation; 2) a delivery infrastructure; and 3) financials.⁴

Awareness of product/service benefits took a number of forms. One example is the adoption of a personal shopper approach in order to more appropriately meet consumer needs. Bobby describes the service he provided in acquiring previously demanded products:

I would already have somebody who’d want to buy it, and they would come to me and ‘Bobby, I need a screen door, I need a . . .,’ I’d go get it, or a TV. I’d break into the house and get a TV, a radio, whatever I could find.

Steven provides additional examples when recounting his transition from using drugs to selling them. “I sold drugs since I can

⁴The authors also include a fourth component, customer relationships, which they believe attains additional importance for their focus on e-business. Other treatments of models in traditional marketing environments subsume relationships within the delivery infrastructure component.

remember . . . My friends tell me 'Hey, I need such and such' . . . I give it to them." Providing personal shopping services for friends was echoed later as well. Steven broke into a store because he "wanted something new to wear, and we missed the shops before they closed, and my girl wanted something."

Recognizing the importance of providing benefits to the consumer was also observed in Michael's description of the training process through which he put his prostitutes. He explains the technique involved in determining what the customer's needs/wants are: "You analyze the situation. . . . You had to look at each individual situation . . . I mean, what would work on him might not work on him." Michael also indicates recognition of the importance of providing benefits through building the brand and maintaining the brand image. A prostitute was motivated to continue in his employ because, "she wanted that prestige that went along [with working for me] . . . because, you know, just like a good pimp is held high, a good prostitute is too."

The second set of long-term practices involved an awareness of the infrastructure involved in product/service provision. Topics covered in this area include management of stakeholders and employees, relationship development and management, and issues relating to the distribution channel for the illegal products and services. Michael indicates a consideration for his employees and customers that borders on the romantic. "You know, although women may see it as love. . . I sell dreams. You know, I sell a lot of dreams." He reminds us that no matter what his employees think, he is in business for the money, in contrast with some of his prostitutes, who are in it because they like the pimp. His relationship with the prostitutes was characterized by an instrumental paternalism. "I take care of them, you know."

The importance of relationship development was particularly apparent in the distribution channel for drugs. Rich describes the care taken to minimize the risk of arrest in the selling process by continuing a past relationship with a customer. "Sometime[s] I would [be scared to sell to the wrong person]. It [would] depend on who it was, and if I didn't know him . . . then I'd be scared." Morris discusses the role of his past experience and intuition in determining whom was safe to sell to and in finding new customers. "I don't have no difficulty. I can just go into like a city and within a very short period of time. . . I keep right on top of the drug network." Michael discusses the importance of connections in the process of transacting call girl business with a new customer. He describes a hypothetical new meeting:

There's a lot of references involved, you know. . . . Who's this, man? Is this Snake, man? I'm a friend of Danny. Yeah, Danny Boy? Yeah, look here man, I need to send you a picture or what? Nah, man, Danny Boy's cool. I know Danny Boy. I know he's cool man. Just send him on down here, man. I'm ready.

Steven shows a detailed understanding of the profit structure of a distribution channel in his explanation of "swap shops"—specialized operations that repaint and re-title stolen cars, representing the demand side of the channel. These shops buy stolen cars, paying as much as \$15,000 or \$20,000 for a \$35,000 Cadillac. Value chain contributions are made as the shops "paint 'em [and] change everything else back out [so the car is] legal. [Then] sell 'em to the car lots."

The third long-term goal relevant to the development of a business model revealed efforts to improve the efficiency or effectiveness of the revenue or profit stream in the business situation. For some of the prisoners, protection of the revenue stream simply meant putting practices into place to avoid getting caught for the illegal enterprise. Raymond describes how his drug addiction was

the key factor in his capture and in the subsequent interruption of revenue. "I been selling [cocaine] since '85, and [didn't get caught] 'til '89 [pause], till I started smoking cocaine." Another drug dealer had two jobs in order to avoid raising the suspicion of police.

I was still [emphasis] servin' dope, . . . I [worked] just to keep police off of me. 'Cause they see me ridin' around in a big Cadillac or something, this young, and I ain't got no job, they keep sweatin' it. But I had two jobs, so they can't really sweat it (Interview, Leon).

TOWARD A MODEL OF ILLEGAL CONSUMPTION AND ENTERPRISE

Our analyses suggest the presence of a relationship between the social and economic context of the prisoners; their exposure to and awareness of the idea that the acquisition of material goods is a socially recognized, beneficial norm; and the resulting application of strain theory to explain participation in illegal enterprise. Specifically, we found that the lack of ability to achieve material goals resulted in strain that motivated the criminal activities. While it was clear that the prisoners were disadvantaged in some of the traditionally recognized ways, it was also apparent that they had an intuitive awareness for marketing mechanisms which increased the efficiency with which their material goals were achieved.

Crimes such as burglary and theft seem motivated directly by one of the dimensions of materialism hypothesized by Richins and Dawson—that of the "pursuit of happiness through acquisition" (Richins & Dawson 1992, p. 304)—as indicated by the references to cars and jewelry in the data. The materialistic desires of the subjects were for particularly socially supported material items that would be used for public rather than private consumption.

Given that materialism was recognized by the prisoners as a "culturally defined goal," (Merton 1957, p. 187) and that the prisoners were not able to use socially appropriate means to achieve this goal, we believe that a strain developed which served as a motivation to circumvent the traditional means of acquisition. A disconnect occurred between the acceptable means of achieving goals and the deviant means to doing so, such that the former lost their status.

It is important to note, however, that not all members of disadvantaged groups turn to crime as their solution, although one must expect that they feel the same strain as the criminals. Opportunity Theory (Cloward and Ohlin 1960) suggests that, given strain, differential opportunity for committing crime exists such that there must be some exposure to deviant behavior for the member of the disadvantaged group to adopt the behavior. This suggests that what is required for deviant behavior is not only strain between a socially desired goal and its achievement, but also the opportunity to participate in the behavior. We learned from the life histories of the prisoners studied that this opportunity, while presenting itself in a variety of ways consistent with the varied geographic, ethnic, and familial backgrounds of our subjects, existed in nearly all instances.

The inmates we interviewed had a clear, if intuitive, understanding of marketing practices for illegal enterprise, including the awareness of the importance of the benefits provided to their customers, the need for a delivery infrastructure, and the importance of a revenue stream and profit through the illegal sales activity. Experience with the consumption of illegal products, or with the distribution of such products, may not only obviate recognition that such activity deviates from social and legal norms, but may also provide incidentally acquired knowledge and expertise about how to manage illegal marketer-consumer transactions.

CONCLUSIONS AND LIMITATIONS

The concepts and categories extracted from the interview indicate that tendencies toward the major constructs of the study (i.e., materialism, strain, and context) are shown in the prisoners' behaviors. In addition, the analysis and interpretation reveal the use of intuitive marketing practices as a means for managing perceived strain.

The interviewed prisoners were typically from disadvantaged backgrounds, growing up in single parent households, frequently with a tendency (either familial or personal) for alcohol or other drug abuse. Their backgrounds, however, did not prevent (and perhaps encouraged) their awareness that acquisition of material wealth plays a major role in social life in the United States. Significant in our findings are the role that materialism played in the prisoners' lives in general and their crimes in particular, the strain that resulted from their lack of ability to achieve material success, and the use they made of what we have termed intuitive marketing practices to achieve material goals.

This study has several limitations. First, the somewhat small sample size of prisoners prevents the research from achieving the optimal degree of data saturation. Ideally, interviewing would continue until the researcher began experiencing redundancy in the data. In other words, when s/he began receiving only repetitive information without gaining new insights, the interviewing process would stop. In response to this limitation, we suggest that the insight gained from this unique access opportunity offsets the sample size concern.

Second, the compressed time frame of the interviews, due to the limited window of access to the population, did not allow the degree of immersion desirable of many qualitative research endeavors. Subsequent research, if access to a similar population is obtained, would ideally cover a longer time frame. Last, traditional procedures of data verification were not possible. For instance, the usual practice would be to attempt to triangulate interview data with other data sources such as prison records and interviews with family members in order to improve validity. To address this concern, time lines were constructed with the information from the interviews, and events occurrences were cross-checked for coherence and plausibility. In addition, descriptions of events within the prison environment were corroborated in discussions with the prison warden and other personnel.

A last limitation of the study results from the delay between the commission of the crime and the participation in the interview.⁵ It may be that the motivations for committing the crime are imperfectly accessible to the prisoner months or years later during the interview. Further, it is possible that the prisoner's construction of reality may have changed between the crime and the interview such that events are recalled in a way inconsistent with their original construal. Given that one goal of incarceration is reform, we see this as a legitimate criticism. It may be that the incarceration process systematically changes the construction of prisoner's reality such that their recollection of past events is through the looking glass of present reality. While impossible to quantify, we see the purpose of this research as providing insight into criminal behavior which may be expanded upon in subsequent study.

Direct-to-Consumer Advertising: Obligated to be Healthy

Andrew Jardine, University of Otago

ABSTRACT

Direct-to-consumer advertising (DTCA) of prescription drugs is a relatively recent form of marketing communication. Advocates suggest that DTCA both informs and empowers patients/consumers. But viewed from a wider sociological perspective, DTCA is premised upon and extends aspects of lifestyle choice, self-responsibility and risk assessment. As a result, DTCA promotes a medicalized view of society, where everyday aspects of life come to be defined as medical problems seeking the input of medical specialists and medical technology. The anti-obesity drug Xenical provides context for DTCA in this paper. Xenical, as an example of a 'lifestyle drug', uses the body as a focus of disciplinary power for surveillance medicine. Within a health promotion framework, individuals targeted by DTCA are obliged to govern themselves in the interests of their own health.

Direct-to-consumer advertising

The advertising of prescription drugs was once targeted solely at health care professionals through medical journals and health care trade publications. But more recently, the advertising of prescription medications has begun to bypass these traditional communication channels. Pharmaceutical companies are increasingly targeting their marketing messages directly at the patient/consumer through efforts such as direct-to-consumer advertising (DTCA). DTCA is defined here as the communication of product-specific information on prescription drugs that is targeted at end-users and designed to encourage consumers to take a more active role within the prescribing process.

Since the easing of advertising restrictions by the US Food and Drug Administration in 1997, the US has seen rapid growth in DTCA (Mintzes 2001). Spending on DTCA in the US for the year 2000 was approximately \$2.5 billion (Jewesson 2002) and budgets look set to increase with DTCA predicted to be the fastest growing major advertising category, outperforming technology, fast food, and soft drink categories (Pinto 2000). Despite this rapid growth, the United States and New Zealand remain the only two developed countries that currently allow DTCA of prescription drugs (Calfee 2002).

DTCA enables pharmaceutical companies to bypass the traditional and long-standing conventions governing the doctor-patient relationship where the health care professional was seen as the possessor of 'expert knowledge' (Nettleton 1995). Surrounded in medical mystique, the role of the doctor was once seen as manager of disease, having authority to dispense medical therapies and working in the interests of what was best for the patient (Pines 1999). In contrast, the role of the patient was passive with diminished capacity for independent thinking (Henderson and Petersen 2002). But Pines (1999, p. 498) asserts that 'the mystique of the medicine chest has eroded' and in this new 'information age' patients as consumers often have access to as much information as physicians about possible health care products. This new active citizenship, where the 'patient' is the client or consumer (Henderson and Petersen 2002) implies that individuals are able to make decisions independently and use information that is available to them.

Advocates suggest that DTCA is beneficial, because patients as customers are likely to be more participative in the decisions that affect their health (Wolfe 2002). Supporters of DTCA also point to the potential for patient empowerment through health education (Berger, Kark, Rosner, Packer, & Bennett 2001).

But critics question whether DTCA really represents progress in empowering patients or if instead, it is a way for pharmaceutical companies to make additional money (Drazen 2002). While providing educational information may be one of the industry's motives, Hollon (1999) suggests that "the bottom-line desire for profit is undoubtedly another". Jenkins (1998) describes DTCA of prescription medicines as a 'wonder drug' for the pharmaceutical industry itself because of its ability to affect patient demands that in turn might affect doctors' prescribing behavior.

This paper argues that DTCA, despite being a relatively new phenomenon, is a natural consequence of what Petersen & Lupton (1996) have termed the 'new public health', where health is seen as a moral enterprise that dictates and prescribes how we should live our lives individually and collectively. Since the mid-1970s, there has been a clear ideological shift away from the notion that the state should protect the health of individuals towards the idea that health is a self-governed lifestyle choice and that individuals should take responsibility to protect themselves from risk (Petersen 1997). As will be argued, the existence and growth of DTCA is a direct and natural consequence of this same ideological shift.

Having a healthy body and having the ability to achieve good health are predominant concerns of our age with a focus on lifestyle manifested by the increased attention given to body shape, diet and exercise (Burrows, Nettleton, & Bunton 1995; Petersen & Lupton 1996). DTCA privileges a medical perspective that is inherently bound up in the political and cultural discourses related to health and lifestyle. In addition, it is an important contention of this paper that the reality of DTCA, while ostensibly offering choice for consumers under the guise of freedom, actually suggests that power rests in the hands of marketers (Rose 1990; Venkatesh, Meamber, & Firat 1997).

Lifestyle drugs

Pharmaceutical companies have identified 'lifestyle' drugs as a growth market (Lexchin 2001), and DTCA has been intricately linked with the release of a number of these highly publicized 'lifestyle' drugs over recent years. Indeed, much of the growth in DTCA parallels the growth in the lifestyle drugs market. Lifestyle drugs can be defined as products that are used for health problems that might be better treated by a change in lifestyle (Gilbert, Walley, & New 2000). Sevon & Mitrany (1999) suggest that one consistent definition of lifestyle drugs is that they improve patients' satisfaction with the quality of their lives but do little to improve medical outcomes or reduce overall health care costs. According to Gilbert et al. (2000), lifestyle drugs are intended or become used for conditions that currently lie at the socially constructed boundary between lifestyle wishes and health needs.

In 1999, nearly \$325 million was spent on DTCA for just four lifestyle drugs in the US (Lexchin 2001): Propecia (finasteride) for the treatment of male pattern hair loss; Viagra (sildenafil) for the treatment of erectile dysfunction; Xenical (orlistat) for the treatment of obesity; and Zyban (bupropion) for the treatment of smoking.

DTCA has proved to be an ideal vehicle for promoting the conditions that lifestyle drugs are designed to treat because such conditions are easily understood, easily self-diagnosed and often self-evident (Lexchin 2001). Product development in the pharmaceutical industry is both difficult and expensive, and as a result, drug companies have increasingly focused on the unmet medical needs of the aging 'baby boomer' population. Age, gender and

lifestyle as risk characteristics mean that baby boomers become an ideal target because, as a population, they have easy access to medical information, are increasingly dissatisfied with the performance of healthcare systems and, most importantly, they have grown up being conditioned as consumers (MacNaught 2001). The growth in DTCA owes much to the confluence of these same factors. DTCA can be seen as an example of what Thompson and Hirschman (1995, p. 144) refer to as promotional discourses, where “the correct lifestyle and the correct application of consumer technologies offer a means to resist the forces of nature that might otherwise affect the body.”

In late 1999, Americans were exposed to an average of nine television advertisements for prescription drugs a day (Mintzes 2002) and according to Mintzes (2002 p. 909), these advertisements portray “the educational message of a pill for every ill—and increasingly an ill for every pill”. As a result, critics accuse the pharmaceutical industry of actively sponsoring the definition of diseases and promoting them to both prescribers and consumers: ‘the social construction of illness is being replaced by the corporate construction of disease’ (Moynihan, Heath, & Henry 2002, p. 886). According to Moynihan et al. (2002), informal alliances between the pharmaceutical industry, doctors and consumer groups are often created with the intent of raising the public awareness of undiagnosed and undertreated problems. But in the process, these alliances also promote the view that health problems are widespread, serious, but medically treatable. As a communication vehicle for disease awareness in itself, DTCA plays an integral part in this process. Moynihan et al. (2002) contend that health campaigns are commonly linked to companies’ marketing strategies that aim to expand the market for new pharmaceutical products. Alternative approaches, such as the self-limiting or relative benign natural history of a problem, or the importance of personal coping strategies—are played down or ignored. “To tell us about a disease and then to imply that there is a high likelihood that we have it ... is to gnaw away at our self-confidence” (Payer 1992, p. 6).

Medicalization

Such concerns are not new and serve to illustrate the way in which medicine operates as a powerful institutional tool for social control. This is a central thesis of the current paper, where it is alleged that DTCA is yet another means of communication that furthers the medicalization of society. The medicalization critique was one of the most dominant perspectives in the sociology of health and illness in the 1970s and it still remains a dominant approach as evidenced by recent articles within the *British Medical Journal* (for example see Mintzes 2002; Moynihan et al. 2002). Rather than improving people’s health, Illich (1975) argued that contemporary scientific medicine actually undermined it, both through ‘iatrogenesis’ side-effects caused by doctors, and by diminishing people’s capacity for autonomy in dealing with their own health care. Medicalization then, can be described as the definition of a problem in medical terms, the use of medical language to describe a problem, the adoption of a medical framework to understand a problem, or using a medical intervention to ‘treat’ such a problem (Conrad 1992). It should be clear that DTCA promotes the medicalization of society on all four counts. Within Western society a medicalized view that privileges medical technology and intervention benefits the pharmaceutical industry as a whole, but other beneficiaries include insurance agents and the media, as well as health professionals such as physicians, psychologists, psychiatrists, and therapists. As consumers, we are constantly urged to conduct our private lives in order to avoid potential disease or early death. DTCA encourages us to take stock of our lives, to

question our appearance and the way we function, and to make certain choices in terms of the way we choose to live.

The pharmaceutical industry and other advocates of DTCA propose that through DTCA, people become more informed about medical matters, and that the information provided enables greater freedom of choice and consumer empowerment through health education. Ironically, critics of medicalization also emphasise freedom of choice and consumer empowerment through health education, where patients as consumers are urged to take control of their health and to challenge the decisions and knowledge of health professionals. But encouraging individuals to be more active in acquiring medical knowledge and urging participation in preventative health activities, actually adds to the medicalization process. Paradoxically, making people more aware moves medical and health concerns even more into our everyday lives and we become even more dependent on contemporary scientific medicine (Lupton 1997).

An example of DTCA: Xenical as a medical solution for obesity.

For many obese people, the launch of Xenical (orlistat) by Hoffman-La Roche/Roche Pharmaceuticals was seen as a ‘magic bullet’ for the treatment of obesity. As an anti-obesity drug, Xenical inhibits the action of pancreatic lipase thereby reducing fat absorption (Ballinger & Peikin 2002). Hoffman-La Roche spent over \$75 million promoting Xenical to consumers in the United States (Lexchin 2001) where the DTCA campaign began in 1999. In New Zealand, the DTCA campaign began in 1998 and was one of the first DTCA campaigns for a prescription drug to be launched in the country.

The decision to use DTCA for Xenical in New Zealand was based upon research suggesting that patients/consumers were unlikely to discuss weight loss with their doctor and that doctors were reluctant to initiate treatment for potential patients (Purdom 2002). From the pharmaceutical industry’s perspective then, DTCA for Xenical was justified and fits within the definition provided at the beginning of this paper: to inform potential consumers of the health risks associated with being obese/overweight, and encourage discussion with a doctor. Ryan & Carryer (2000 p. 34) suggest that the DTCA campaign for Xenical in New Zealand was also “designed to link both social and health outcomes to body size by depicting large-bodied people as unhappy, socially maladjusted and in need of assistance.” DTCA for Xenical positioned obesity as a medical and social problem for which Xenical was offered as a medical solution.

The timing of the worldwide launch for Xenical was ideally suited to the growing concern among the medical and health professions of the increasing prevalence of obesity/overweight worldwide. In the *British Medical Journal*, an article headed “Fat is a medical issue” (Ferriman 1999) reported that The Royal College of Physicians favored using drugs to combat obesity in certain circumstances. Ferriman (1999) cites a report by the College (Royal College Of Physicians of London 1999) on the increasing prevalence of obesity as a “serious medical issue rather than a perversity of current fashion.” This same report maintains that the rise in prevalence is due primarily to environmental and lifestyle factors (Ferriman 1999).

Within the last few years, medical journals (along with the media in general) have been proclaiming obesity as a chronic disorder and an increasingly serious health problem worldwide (Noel & Pugh 2002) that has reached epidemic proportions globally (*The Asia-Pacific perspective: Redefining obesity and its treatment* 2000). Manson & Bassuk (2003) report that obesity has become pandemic in the United States, where currently 2 in 3 US adults are

classified as overweight or obese. Obesity is a risk factor for a vast (and expensive) range of illnesses/diseases including hypertension, diabetes, degenerative arthritis and myocardial infarction (Jeffcoate 1998). Indeed, Jeffcoate (1998, p. 903) states that "obesity should be regarded as a disease" in its own right. To this end, various health professions within the medical community have successfully negotiated a disease designation for obesity that is listed in the *International Classifications of Diseases* (ICD-9-CM 1990) (Sobal 1995).

The perception that one is overweight is a highly aversive state, particularly for women (DeJong & Kleck 1986). Consumer culture promotes slimness, and slimness has become associated with health. Askegaard, Jensen, & Holt (1999, p. 331) suggest that modern societies are 'lipophobic' (scared of fat) and that the slogan "Fat is bad" has become one of the most widespread and commonly recognized dogmas of our daily consumer lives in the course of the 20th century." Health promotion messages warning of the health risks associated with being obese/overweight have become absorbed into our conventional wisdom (Featherstone 1991), and the DTCA campaign for Xenical was based upon these same discourses.

Xenical (along with Viagra) has been labeled a lifestyle drug in the popular imagination (Gilbert et al. 2000). Importantly, the use of the label 'lifestyle drug' is not meant to trivialize the serious medical conditions that are associated with obesity (Gilbert et al. 2000). Instead, the term lifestyle drug is meant to convey the idea that such a drug could be regarded as an issue of personal choice rather than illness. DTCA for Xenical illustrates the arguments that are central to this paper, namely that DTCA is built on the premise that the individual is responsible for protecting herself/himself from risk and that individuals should make appropriate lifestyle choices as a result.

Obesity can be described in terms of biological phenomena (for example as genetic deviance or endocrinological disturbance), but importantly, to medicalize obesity, fatness has had to be designated and officially recognized as a disease (Sobal 1995). As already discussed, various health professions within the medical community have successfully negotiated a disease designation for obesity. Disease status adds legitimacy to DTCA of drugs (such as Xenical) purporting to treat obesity. DTCA for Xenical promotes a medical solution to the medical problem of obesity. Importantly, competing medical perspectives are ignored. For example, as Lewis (1997) asks, should obesity be treated at all? Some researchers believe that the direct medical risks associated with obesity have been overstated (Ernsberger & Koletsky 1999); and Miller (1999), suggests that we need to question the notion that thinness necessarily equals health and fitness.

The example of DTCA for Xenical provides a useful introduction to sociological perspectives that relate to studies of the body, medical sociology, the socially constructed nature of disease and the role of medicine in regulating individuals through the regulation of their bodies. Discussion now turns to the way in which DTCA is premised on discourses of risk and the responsibility of one's health, medicine as a new religion, and the body as a focus of disciplinary power. In conclusion, it is argued that DTCA is primarily a communication vehicle for shaping people's behaviour.

Risk and self-responsibility for health

A number of authors (Beck 1992; Giddens 1990) have suggested that we live in a society characterized by the 'politics of anxiety' (Turner 1991). This anxiety relates to the concept of risk—now a common theme in news media headlines and increasingly the subject of health promotion campaigns (Lupton 1999), and as argued here, a prevalent theme within DTCA campaigns. Beck and

Giddens suggest that the risks of modern-day living are products of social organization and decision-making. Armstrong (1993) contrasts the health risks of today against the health risks of the nineteenth century, suggesting that the environmental factors that impact on present day health are a consequence of human actions. As a result, Armstrong (1993) argues that we now live under a new form of governance, one that is outside the walls of the hospital and beyond the doctor/patient relationship. This new form of governance includes a whole range of agencies dispersed throughout society that require the individual to extend his/her concerns 'with body boundaries' and 'individual psychology' to 'lifestyle' more generally (Armstrong 1993). Bunton & Burrows (1995) describe the contemporary citizen as someone who is increasingly faced with the responsibility of maintaining and improving her/his own health via the recommendations of 'experts' and 'advisors' from a diverse range of institutional and cultural sites, and DTCA can be seen as one further means of communicating this form of governance.

These changes have meant a transformation in health care, described by Nettleton (1995) as a new paradigm. The focus is no longer on 'dangerousness' but instead 'risk' (Castel 1991). According to Castel (1991), health professionals once erred on the side of caution to prevent any manifestation of disease and patients deemed ill were treated as potentially 'dangerous'. But there has been a shift away from the *symptoms* of individuals to their aggregated *characteristics* (age, weight, social class, gender, lifestyles and so on). The new targets for medical care are risk factors that are in turn reflected within the discourses of health promotion and prevention and as argued here, these same discourses underlie DTCA, as evidenced by the campaign for Xenical already described.

Medical sociologists propose the term 'healthism' as the idea that one's health is the enterprise of oneself (Greco 1993, p. 357). Healthism suggests that the individual has a choice in preserving his or her physical capacity from the event of disease (Petersen 1997). Increasingly, we are living in a healthist society that is associated with commercialization, commodification and consumption of health and healthy lifestyles (Nettleton 1995), and the failure of the individual to regulate his/her lifestyle and modify her/his risky behavior becomes, at least in part, "a failure of the self to take care of itself" (Greco 1993, p. 361). A woman is able to communicate to those in power that she is managing herself when she is able to gain control over her body and shrink in size (Sault 1994). To have a healthy body is "the mark of distinction that differentiates those who deserve to succeed from those who will fail" (Crawford 1994, p. 1354). Importantly, the terms 'healthy' and 'unhealthy' are now synonymous with being normal and abnormal. Individuals whose behavior is at variance with the pursuit of a 'risk-free' existence are likely to be seen, and to see themselves, as lacking self-control, and "not fulfilling their duties as fully autonomous, responsible citizens" (Petersen 1997). Provocatively, Skrabanek (1994, p.17) likens the concept of healthism to religion:

Healthism is a powerful ideology, since in secular societies, it fills the vacuum left by religion. As an ersatz religion it has wide appeal, especially among the middle classes who have lost their links with traditional culture and feel increasingly insecure in a rapidly changing world. Healthism is embraced eagerly as a path to surrogate salvation. If death is to be the final full stop, perhaps the inevitable can be indefinitely postponed. Since disease may lead to death, disease itself must be prevented by propitiatory rituals. The righteous will be saved and the wicked shall die.

Medicine as a new religion

Although provocative, the comparison made by Skrabanek (1994) between healthism and religion should not be so surprising. Many writers have acknowledged the trend for religion to give way to science, where the scientist has taken over the role of priest and where a process of secularization has become a feature of modern western society (Fitzpatrick 2001). As cited by Belk, Wallendorf, & Sherry (1989, p. 12), Miner (1956) “pointed out that contemporary body care rituals regard the bathroom as a shrine, the medicine cabinet as a treasure chest of magical potions, and doctors and pharmacists as priests.”

In the early 1970s, the American sociologist Irving Zola (1972, p. 487) argued that medicine was becoming a major institution of social control, ‘nudging aside, if not incorporating, the more traditional institutions of religion and law’ (see also Freidson 1970). Echoing Zola’s sentiment, Lupton (1999) goes even further and contends that medicine and public health have replaced religion as the central institutions governing the conduct of human bodies. Turner (1992) suggests that the growing importance of preventative medicine and the concept of lifestyle as a form of social self-control means that in areas of family life, the local GP has replaced, at least in functional terms, the confessor and the priest. Diet and lifestyle choices, according to Lupton (1999), can be seen as viable alternatives to prayer and righteous living and provide a means of making sense of life and death where ‘healthiness’ has replaced ‘Godliness’ as the yardstick of what can be considered right. As the surveillance of the village and church has declined, the individual has been increasingly expected to scrutinize him/herself, and “self-policing becomes an expected behavioral practice” (Crawford 1994, p. 1359). The increased emphasis on the aesthetic quality of the body in relation to consumerism promotes virtues such as thinness and self-regulation in the interests of looking good (Turner 1992), and the DTCA campaign for Xenical becomes an example of this process.

Even though people in Western society live longer and healthier lives than ever before, we are increasingly preoccupied by our health. As evidenced by the increased prevalence of obesity, our modern Western diet and lifestyle are seen as being distinctly unhealthy and as major contributors to the contemporary epidemics of cancer, heart disease and strokes. The DTCA campaign for Xenical illustrates the manner in which the *body* can be used as a site of control for individual conduct (Joy & Venkatesh 1994), and where the body has become a focus for disciplinary power. As suggested by Meamber & Venkatesh (1999, p. 190) “It is through the use of the body as a symbol that societies come to create the mechanisms which control.”

The body as focus for disciplinary power: surveillance medicine

Of particular relevance within the present research context is the work of Foucault (1926-84). Foucault’s work has become widely used and quoted within sociological analyses of health care (Symonds 1998). The body was of major significance in Foucault’s work, and his unique perspective on the body as a focus for disciplinary power and control served to recast thinking about the nature of the body and about the operations of power in modern societies (Turner 1997).

Foucault was interested in the forms of governance involved in the investigation and regulation of the body of the individual and bodies of populations (Nettleton & Bunton 1995). Foucault described a system of control and surveillance which emanated from Jeremy Bentham’s notion of the Panopticon, a system which involved maximum supervision with minimum effort (Armstrong

1983; Foucault 1980), (for a description of the Panopticon concept, see Thompson & Hirschman 1995). The analogy of the Panopticon is useful in describing how people come to govern themselves through regulatory processes. Governance in this sense relates to disciplinary power that is manifested through a relationship of observations, where individuals, knowing they are under surveillance, transform their actions and their identities (Armstrong 1987). The Panopticon’s potential for surveillance nurtures self-discipline by causing individuals to ‘gaze upon themselves’ (Eckermann 1997).

Within medicine, epidemiology, statistical techniques for aggregating social data, clinical medicine and the application of science to the social sphere means that bodies can be transformed into ‘objects’ where ‘self-surveillance emerges as a practice of control’ (Eckermann 1997, p.157). Armstrong (1987, p. 70) discusses the parallels between medical and Panoptic power: “The prisoner in the Panopticon and the patient at the end of the stethoscope both remain silent as the techniques of surveillance sweep over them.”

Medical power is a particular form of influence that is closely associated with perspectives of the body, especially in terms of the discipline of the body and body control. Medicine (along with law and religion) was described by Foucault as being an institution of normative coercion (see Turner 1992) because of its ability to discipline individuals and exercise forms of surveillance over everyday life so that actions are both produced and constrained (Turner 1997). Medicine as an institution does not need to be coercive in a violent or authoritarian sense because the institution of medicine is accepted as legitimate and normative at the everyday level, where it exercises a moral authority over the individual by explaining individual ‘problems’ and providing solutions for them (Turner 1997). As a communication vehicle for the institution of medicine, DTCA operates within this same moral discourse, where individual medical problems are portrayed as having medical solutions.

DTCA: obliged to be healthy

DTCA, under the rubric of public health and promotion, is a vehicle for shaping people’s behavior. Minimal justification is needed for such efforts because they are in the interests of our health. Rather than being subjected to overt punishments for being obese/overweight, we tend to largely self-police ourselves. Individuals not conforming to ‘health messages’ expose themselves to the mechanisms of self-surveillance, evoking feelings of guilt, anxiety and repulsion towards the self, as well as the admonitions of those close to them for ‘letting themselves go’ or inviting illness (Lupton 1999; Thompson & Hirschman 1995). Self-scrutiny is a constituent of modern, individual autonomy and freedom where self-policing is an expected behavioral practice (Crawford 1994). Nikolas Rose (1990) usefully articulated the conceptualization of ‘the self’, which in turn, he argues, is inseparable from modern forms of ‘government’. According to Rose (1990), consumption requires individuals to make a choice from a number of products in response to a repertoire of wants that are shaped and legitimated by advertising and promotion, but which must be experienced and justified as personal desires. Every aspect of life, according to Rose, is like every commodity, “imbued with a self-referential meaning; every choice we make is an emblem of our identity, a mark of our individuality, each is a message to ourselves and others as to the sort of person we are, each casts a glow back, illuminating the self of he or she who consumes” (Rose 1990, p. 227).

For Rose, the self is not just enabled to choose, but *obliged* to construe a life in terms of the choices, powers, and values available:

“Individuals are expected to construe the course of their life as the outcome of such choices, and to account for their lives in terms of the reasons for those choices” (Rose 1990, p. 227). Importantly then, this paper has argued that DTCA should not be seen as a practice that overtly seeks to constrain individuals’ freedom of action, but rather DTCA invites individuals *voluntarily* to conform to their own objectives, to discipline themselves, to turn the gaze upon themselves in the interests of their health. In doing so, DTCA offers medical solutions for medical problems and in return, we as consumers are obliged to choose from a repertoire of solutions according to our lifestyle needs and wishes.

Future Research

Within this paper, DTCA discussion is focused at the macro-level, where it is argued that DTCA contributes to the medicalization of health and lifestyle choice. Future research will analyze DTCA at the micro-level by deconstructing a series of three advertisements used for the promotion of Xenical to potential consumers. While the construction of message content within advertisements must be seen within the wider context of the cultural, political and historical perspectives from which it originates, a micro-level analysis of DTCA for Xenical will examine advertising meaning from three perspectives. Based upon interviews with the advertising agency/marketing manager of the campaign, advertising meanings will be analyzed from the perspective of the ‘producer/author’; advertising meanings will also be analyzed from the perspective of the ‘consumer/receiver’, based upon interviews with people who perceive themselves to be overweight/obese; and finally, advertising meanings will be examined from an ‘analyst/ interpreters’ perspective through a process of advertising deconstruction and discourse analysis.

Consumer Complaint Behavior: Do “Other Customers” Make a Difference?

Ruoh-Nan Yan, University of Arizona

Sherry Lotz, University of Arizona

EXTENDED ABSTRACT

Introduction

A possible neglected area in the consumer complaint behavior (CCB) area is the potential effect of other customers on an individual's complaint behavior. More specifically, it is possible that the mere presence of and/or interaction with acquainted or unacquainted others at the time of service failure may influence consumers' complaint decision-making processes and, ultimately, their complaint behavior. Although no known research has directly investigated this issue, there is evidence to suggest such a proposition. For example, the importance of social significance in consumer satisfaction was mentioned by Day (1977). Folkes (1984) also acknowledged the possible influence of others' presence on consumer reactions to product failure.

The objective of this study is to determine whether there may be effects of the presence of other customers in a complaint behavior setting with a focus on both acquainted and unacquainted customers. This exploratory study examines CCB from a social-psychological perspective. In addition to precepts from CCB literature, the present investigation utilizes the interpersonal influence literature (McGrath and Otnes 1995) and theory of social facilitation effects (Zajonc 1965) as a framework.

Literature Review

Interpersonal Influence

The importance of social influence has been addressed in the field of consumer behavior with the focus on interpersonal influence from *acquainted* consumers, such as family and peers. Researchers have also recognized interpersonal influence from *unacquainted* consumers (e.g., McGrath and Otnes 1995). McGrath and Otnes (1995) studied stranger interaction in the retail setting and concluded that interactions among unacquainted consumers can either help or hamper shopping experiences in various manners.

Social Facilitation Effects

Social facilitation theory recognizes the importance of social environment on individuals' behavior. According to Zajonc (1965), theoretical tenets predict that the mere presence of others affects individual behavior and performance. Empirical research in retailing found that the presence of others extends the length of stay and, thus, increases purchases (Sommer and Sommer 1989). Therefore, this study proposes that the presence of other customers influences consumers' complaint behavior.

Method

Undergraduate students majoring in business-related programs were recruited to participate in the study and required to recall past experiences regarding complaint behavior, including the situations and possible factors that encouraged and/or discouraged their decisions to make complaints. More specific questions were posed to ensure sufficient information regarding the role of others in a complaint behavior setting would be obtained.

A total of 97 respondents were recruited, resulting in 97 incidents. Of the 97 incidents, 34 were in the context of restaurants, 20 in airlines, 11 in phone services, 13 in retail services, and the balance in automobile rental, hotel, and other service industries. Of the total sample, 27 respondents were dropped from further analysis due to the fact that no relevant information regarding other customer(s) was mentioned, culminating in 70 usable incidents.

Data collection and analysis was based on critical incident technique (CIT) and involved several stages. First, each of the researchers carefully read and sorted the incidents into categories. The critical incidents were reviewed for similarities and differences that pertained to the influence of other customer(s) in reported experiences. Second, the researchers compared the results of the initial stage of analysis. Differences in categorical results were discussed until a consensus on categories was achieved. Interjudge agreement on the assignment of incidents into categories was 87%. Third, the researchers labeled categories through further discussion.

Findings, Conclusions, and Limitations

Two major categories emerged from this study. The first category, *Acquainted Customers*, consists of three subcategories: (1) Encouragement/Confidence/Support, (2) Embarrassment Avoidance, and (3) Obligation. The second category, *Unacquainted Customers*, encompasses eight subcategories: (1) Confidence/Support, (2) Embarrassment Avoidance, (3) Altruism, (4) Problem Awareness through Service Comparison, (5) Leadership, (6) Diffusion of Responsibility, (7) Accessibility, and (8) Revenge.

One of the major findings is that the mere presence of other customers appears to have an impact on consumers' decisions to complain. Specifically, the presence of other customers, acquainted and unacquainted, either encourages the consumer to voice the complaint (e.g., obligation or altruism) or deter complaint actions from occurring (e.g., embarrassment avoidance).

Regarding the influence of acquainted customers, this study reveals that close relationships with and/or concerns about acquaintances may provide strong triggers to complaining behavior. However, under similar circumstances related to relationships and concerns, it may be that acquaintances of those individuals who wish to avoid the spotlight may have the effect of dampening the tendency to complain. In terms of the influence from unacquainted customers, the results suggest that these strangers may characterize more types of influences than acquainted customers. A consumer may complain in the presence of unacquainted customers out of concern for their welfare or to hurt the service provider's business by raising surrounding customers' awareness of poor service received.

Although the focus of this research was on other customers who are present at the time of service failure, this study found that both acquainted and unacquainted customers not present at the time of service failure may also have an impact on consumers' decisions to complain. Therefore, further research is warranted to explore the influences of other customers who are not physically present.

Several limitations of this study should be stated. First, the researchers asked directly how the presence of other customers may have affected the subject's complaint decision process. Although not every participant acknowledged the influence of other customers, a potential demand effect may have occurred. Second, this research employed modified CIT based on retrospective reports. Information regarding the subjects' unsatisfying experiences may be underreported due to temporal issues, or overemphasized because of dissatisfaction; recall bias may have occurred. Third, most research studies involved with CIT-collected data are associated with relatively large samples (Gremler 2003); however, this study's sample size was relatively small. The small sample size raises concerns about generalizability of findings, the large number of

construct emergent categories, and frequency counts of the categories. Future work is warranted to determine the representation of this study's results.

Cultural Determinants of Behavior in Negotiations with Incomplete Information

Ana Valenzuela, San Francisco State University

Joydeep Srivastava, University of Maryland

Seonsu Lee, Wonkwang University

Bargaining and negotiation are perhaps the most fundamental of marketing processes through which buyers and sellers establish terms of exchange. Bargaining is a key aspect in organizational and consumer purchases. However, much of the existing bargaining literature consists largely of experimental simulations investigating theoretical frameworks developed using evidence from Western cultures, predominantly the United States (cf. Graham et al. 1988). Relatively little is known about the generalizability of these theoretical frameworks across diverse cultures. The cultural psychology literature, for example, highlights the differential influence of cultural orientation on persuasion processes (e.g., Aaker and Maheswaran 1997), decision making (e.g., Briley, Morris, and Simonson 2000), causal attributions (e.g., Choi, Nisbett, and Norenzayan 1999), and individual characteristics (e.g., Triandis 1995). Despite the practical impetus and the growing theoretical interest in cultural psychology, relatively little work examines the effect of cultural orientation on bargaining processes and outcomes.

The main purpose of this research is to examine the role of cultural orientation in bargaining. The general premise of this research, following the recent literature in cultural psychology, is that many judgments and decisions are the result of cognitive processes that are culturally imposed (e.g., Briley et al. 2000). The rationale is that exposure to different ecological factors and social structures perpetuates different cultural values and ideals and thus certain judgment "biases" are likely to be more prevalent in one culture than another (e.g., Triandis 1995). More specifically, this research examines how differences in cultural orientation influence bargainers' causal attributions and inferences and thereby the bargaining outcomes in an incomplete information situation. While much of the existing consumer behavior literature on bargaining focuses on complete information situations where bargainers have full information about one another's payoffs (Buchan et al. 2004; Corfman and Lehman 1993), actual bargaining is unlikely to conform to situations where bargainers have access to objective referents and standards against which to judge potential bargaining outcomes (Eliashberg et al. 1986; White and Neale 1994). Importantly, in incomplete information situations, bargainers may search for causal explanations for an opponent's behavior (Morris, Larrick, and Su 1999). The nature of causal attributions may differ based on a bargainer's cultural orientation thereby affecting bargaining processes and outcomes (e.g., Morris and Peng 1994).

In this research, we demonstrate in three experiments that bargainers from Western cultures have a tendency to seek causal explanations for an opponent's behavior in terms of individual personality traits. In contrast, bargainers from Eastern cultures are more likely to recognize that an opponent's behavior may be dictated by situational factors. The experiments use ultimatum bargaining as the setting to study the role of cultural orientation (e.g., Buchan et al. 2004). We run one-sided incomplete information ultimatum bargaining games simultaneously in western United States and Seoul (Korea) as the setting to study these research questions. All subjects played the role of Responder. Proposer's offers were part of the stimuli and included two values: a relatively low value and a relatively high value. Questionnaires were back translated and offer sizes were adjusted in terms of currency and purchase parity. Experimenters in both countries were trained to reduce procedural disparities.

Experiment 1 showed that in an incomplete information setting, there was no difference in bargaining outcomes across Western and East Asian cultures as bargainers from both U. S. and Korean were equally likely to attribute a low offer to opponent's personality traits. However, when situational constraints were made salient, Korean bargainers were more sensitive to the situational determinants of observed behavior relative to U. S. bargainers and were, thus, more willing to accept a low offer. Consistent with earlier work (e.g., Choi and Nisbett 1998), our results suggest that East Asian cultures are more likely to correct for the overattribution bias when situational constraints are made salient. In other words, when there is no accessible information to discount the personality trait attributions, both Western and East Asian cultures are prone to the overattribution bias. These results also suggest that cultures perhaps differ in their implicit theories of the influence of external situational constraints rather than in their implicit theories of personality dispositions (Chiu et al. 2000; Krull et al. 1999).

Based on the assumption that the group is a natural unit of agency for East Asians and the individual is the unit of agency for Western cultures (Choi et al. 1999; Menon et al. 1999), experiment 2 shows that Korean bargainers are more sensitive to the potential group influence in affecting an opponent's behavior. Specifically, while there was no difference in bargaining outcomes between U. S. and Korean bargainers in an individual decision context, Korean bargainers were more likely to accept low offers when the proposer was supposedly making the decision in a group context. It is important to note that groups occupy the physical space surrounding individual actors and, in some cases, can be considered merely an additional situational constraint (Menon et al. 1999). However, groups may also be more than just a passive non-social situational constraint. Rather, the group may be perceived as a social entity that can direct action. As with individual dispositions, groups may also be perceived as possessing unique dispositions (Higgins and Bryant 1982). While our findings support the idea that cultures differ in their sensitivity to group influence, future research should expand the inquiry of groups to include specific dispositional attributions and inferences. In addition to experiment 1 and 2, experiment 3 unambiguously shows that differences in causal attributions mediate the influence of cultural orientation on bargaining outcomes.

Together, the results indicate that culture does not have a perennial influence on judgment and decision making in general and bargaining in particular. Rather, there are certain conditions under which cultural differences are manifested supporting the more recent, dynamic view of the influence of cultural orientation (Briley et al. 2000; Choi and Nisbett 1998). In our context, penalization of apparent competitive (or unfair) intent seems to be a universal phenomenon as bargainers from both U. S. and Korea exhibit the overattribution bias. However, when there is accessible information that can be used to discount the personality based attributions, cultural difference emerge. In particular, Korean bargainers are more likely to recognize and acknowledge alternative reasons for observed behavior, which tend to correct the initial tendency to seek causal explanations in terms of personality dispositions (e.g., Choi and Nisbett 1998).

Beyond Polarized Cultural Values

A New Approach to the Study of South Korean and US Newspaper Advertisements

Hye-Jin Paek, University of Wisconsin-Madison
Michelle R. Nelson, University of Wisconsin-Madison
Douglas M. McLeod, University of Wisconsin-Madison

ABSTRACT

This study content-analyzed US and South Korean newspaper ads for the year 2000, to challenge bipolarized cultural value frameworks prevalent in cross-cultural advertising studies and to establish more rigorous methodology. Our multi-group confirmatory factor analysis showed that the two-factor model of individualism/collectivism dimension was not equivalent across the two cultures, while the future/past time orientation dimension was comparable. As predicted, both Korean and US ads conveyed more individualistic than collectivistic indicators. In addition, Korean ads were more future-time oriented than the US ads. Findings are discussed in terms of theoretical, methodological and socio-cultural considerations.

"The right relationship is everything"—CHASE bank slogan (US)

"Investment for future"—CHEIL bank slogan (S. Korea)

Polarized views of cultures and values dominate advertising and consumer behavior literature, particularly comparisons of US and East Asian cultural frames (see Cho, Kwon, Gentry, Jun, and Kropp 1999; Moon and Franke 2000). On the whole, these studies are based on the assumptions that: (1) There are clear distinctions between Eastern versus Western cultural values; (2) cultural values are mutually exclusive and bipolar; and (3) the cultural dimensions constructed with multiple cultural indicators are equivalent across the compared cultures. But what if Eastern and Western cultures share values—or if indigenously individualist nations promote collectivist values like the US bank slogan above? Most cross-cultural advertising research examines cultural values reflected in advertisements, using a bipolar cultural typology such as Hofstede's (1980, 1991) individualism/collectivism, uncertainty avoidance, and power distance, or the cultural distinction of time orientation (e.g., Albers-Miller and Gelb 1996; Cho et al. 1999; Tak, Kaid, and Lee 1997). Although these studies have usually hypothesized that ads in Western cultures (e.g., the US) hold more individualistic and future-oriented value indicators and those in Eastern cultures (e.g., China, Japan, South Korea) employ more collectivistic and traditional value indicators, their results do not always follow their predictions.

Inconsistent results across content-analytic studies may reveal problems inherent in their assumptions or/and methodology. For instance, most cross-cultural studies examining Western versus Eastern ads do not take into consideration the fact that advertising—whether it is Western or Eastern—is a multi-faceted and multi-dimensional cultural by-product that reflects socio-economic and political changes, as well as corresponding value changes (Pollay 1986). While Hofstede's typology provides a parsimonious layout for the comparison of cultural values, the typology was based upon surveys of international IBM employees in the late 1960s. Due to globalization forces in media, marketing, and economics in past decades, new examinations of culture and advertising are needed. In fact, recently researchers have questioned the bipolar theoretical assumptions about the individualism and collectivism dimension (Oyserman, Coon, and Kimmelmeier 2002) and about traditional views of advertising in Eastern cultures (Zhang and Shavitt 2003).

Another potential shortcoming of previous cross-cultural advertising studies pertains to a certain lack of methodological rigor. One of the primary methodological issues in cross-cultural research is to establish comparability in the compared cultures (Van de Vijver and Leung 1997). In cross-cultural advertising research, for instance, the individualism/collectivism dimension has been assumed rather than tested based on certain cultural indicators set from previous studies. Such assumptions could cause a bias that eventually threatens the validity of the cross-cultural comparison (see Van de Vijver and Leung 1997, for detailed cross-cultural methodological issues).

The purpose of this study, therefore, is to contribute to the cross-cultural advertising literature in two ways. First, we challenge assumptions that ads in Eastern versus Western cultures today will carry distinctly polarized values by considering social and value changes due to globalization forces. Second, we statistically test whether the accepted cultural factors that have been used previously for Eastern versus Western cultures are equivalent across the two cultures by adopting an advanced and rigorous statistical method.

In this study, US and South Korean newspaper ads are compared. South Korea (Korea, hereafter) was selected because of its economic importance, as the US' ninth largest import and export market in 1998 (Moon and Franke 2000) and as the world's tenth largest advertising market in 1999 (Ad Age International 1999). With close ties between the two countries, a number of cross-cultural studies between the US and Korea have been conducted including examinations of cultural values reflected in ads (Cho et al. 1999; Han and Shavitt 1994; Tak, Kaid, and Lee 1997), advertising execution styles and appeals (Miracle, Chang, and Taylor 1992), consumer attitudes (Yoon, Muehling, and Cho 1996), and work ethics (Moon and Franke 2000). We add to the knowledge of advertising and values for these two national cultures by examining advertising value content, focusing on one widely used cultural dimension (individualism/collectivism) and one relatively neglected cultural dimension (time orientation).

Why Examine Advertising and Cultural Values?

Cultural values, the deepest manifestations and expressions of culture and collective mental programming (Hofstede 1980), are thought to be relatively stable features of individuals and societies and correspond to personality and cultural characteristics (Triandis 1995). How these cultural values are transferred to the individual might be explained according to social adaptation theory (Kahle 1983), which posits that values form the point of intersection between individuals and society. Essentially, this means that some of culture's values are learned or internalized through socialization processes from family, friends, media, and other cultural influences. Thus, cultural values influence one's personal values. If values lie at the deep structure of personality that influences perceptions, attitudes, and behaviors (Pollay 1987, p.106), then we can learn about cultures and individual consumers within those cultures by understanding their media and ads. Indeed, advertising influences and reflects cultural and personal values so that messages are more readily accepted by and more persuasive to the consumers within a given culture (Albers-Miller and Stafford 1999; Tse, Belk, and Zhou 1989).

Individualism/Collectivism (I/C, hereafter)

I/C is the most well known and widely studied construct of cultural values used mainly to understand differences between Western and Eastern cultures (Oyserman et al. 2002). I/C can be defined as “people taking care of themselves and their immediate family only in a loosely knit social structure, versus people belonging to in-groups to look after them in a tightly knit social organization” (Hofstede 1980, p.87). In individualistic cultures, people are “I”-oriented and self-accomplishment is important. In collectivistic cultures, people are “we”-oriented and their identity is based on the society and groups in which they belong (Cha 1994). Advertisements in individualistic cultures appeal more to individuality, self-reliance, success and self-benefit, while ads in collectivistic cultures typically relate to group belonging, benefits to others, harmony with others, and group fulfillment (Cho et al. 1999; Han and Shavitt 1994; Miracle et al. 1992; Mueller 1987).

Although cultural theories might predict that the advertising of Western countries reflects individualism and that of Eastern countries reflects collectivism, studies have shown inconsistent results. For instance, Han and Shavitt (1994) found that magazine ads in the US employed more individual benefits, self-accomplishment, and independence than those in Korea, while Korean ads emphasized group benefits, harmony, and family integrity to a greater extent than did US ads. In contrast, Cho et al. (1999) found that Korean television commercials did not employ collectivistic appeals more frequently than individualistic appeals. Meanwhile, some studies highlight changes reflected in advertising in a given culture (Cheng and Schweitzer 1996; Zhang and Shavitt 2003). Zhang and Shavitt (2003) found that Chinese ads (especially those in magazine ads targeting generation Xers) actually reflected modernity and individualism values rather than traditional, collectivist values.

This body of research suggests ads in Eastern versus Western cultures may not solely reflect the polarized indigenous cultural values as currently conceptualized, and that individuals within those cultures may not prefer ads conveying those indigenous values. Shavitt, Nelson, and Yuan (1997) found both American and Taiwanese subjects preferred collectivistic to individualistic appeals. These results are inconsistent with the finding of Han and Shavitt (1994) that U.S. subjects in their experiment were more persuaded by individualistic benefits, while Korean subjects preferred collectivistic appeals.

Perhaps I/C is not a polarized construct but may represent dynamic and multi-faceted values (Triandis 1993), such that all individuals contain elements of individualism or collectivism, but they differ with regard to ‘how often’ or ‘under what circumstances’ they rely on particular values (Triandis 1995). According to Triandis (1995), individualistic values are a consequence of cultural complexity and heterogeneity, affluence, and social and geographic mobility. In the context of Korea, the country experienced drastic socioeconomic changes in a short time period, including a foreign money crisis that attacked Asian countries in 1998 (i.e., the “IMF event,” see Paek, Nelson, and McLeod 2002; Shim and Cho 2000 for more detailed discussion). Such unexpected economic hardship and corresponding social mobility changed consumers’ values as well as specific lifestyles (Shim and Cho 2000). Korean society has faced a tidal entry of multinational media such as Cosmopolitan and MTV, global advertising agencies, foreign retailers and business practitioners. During this period, multinational advertising agencies recorded an increase in market share from 4% in 1996 to 37.5% in 2000, explosively increasing by 124.2% from a 169.1% increase in 1999 (Lee, 2001). Advertising, as a very-sensitive trendsetter and value indicator, may reflect such social changes, reflecting more individualistic and westernized values in Korea.

Past and Future Time Orientation (P/F, hereafter)

A second cultural dimension that can be examined within the context of Eastern versus Western culture is that of time orientation. Time orientation has been defined in various ways distinguishing East and West including long-time versus short-time orientation (Chinese Culture Connection 1987) and monochronic versus polychronic time orientation (Hall 1976). These conceptions share a couple of common ideas: (1) time orientation is conceptualized as looking toward the past, present, or future (Hall 1976); and (2) people from East Asian countries such as China, Japan, and Korea tend to be past-oriented, and Westerners such as Americans and Northern Europeans show more of a future-time orientation (de Mooij 1998). As a product of a culture, though, time orientation has received little attention in the content analysis of cross-cultural advertising with a few exceptions (e.g., Cho et al. 1999; Ko and Gentry 1991; McCarty and Hattwick 1992).

While the time orientation dimension needs more work for a clear scale construct (Ko and Gentry 1991), the scale used in previous studies suggests that a past-time orientation emphasizes tradition, history, past accomplishments, and maintenance of the past; future orientations place more value on plans for tomorrow (Cho et al. 1999). Usually youth are likely to appear as models, and copy such as “future generations,” “new and innovative,” “improvement,” and “progress” is used in ads (Cho et al. 1999).

Hypotheses and Research Questions

We operationalize the I/C and P/F dimensions based on the previous studies (see Table 1 below). Rather than assume that the two cultural dimensions will be comparable across the two cultures, however, we start with the following research question to test statistically for equivalence of the cultural dimensions across the two cultures:

RQ1: Do US and Korean ads share a common factor structure that can be constructed by the given cultural indicators?

One rationale for the disconnection between cultural expectations and advertising content findings may lie in the argument put forth by McCarty (1994), who argued that advertising, particularly in developing societies, might not reflect current value orientations but the orientations of a society that the culture is progressing toward. As cultures progress, they tend to become more individualistic and future-oriented (Triandis 1995). This argument is consistent with Mueller (1987), who proposed that cultural values mirrored in developing countries’ advertising may not be the indigenous ones that the culture holds, but the ones in the same direction as the culture is evolving toward.

Given seemingly inconsistent findings of previous cross-cultural studies that have examined the I/C and P/F cultural dimensions, and allowing for the possibility of changes in social values, we hypothesize that Korean ads will actually employ more future-oriented and individualistic cultural values than past-oriented and collectivistic cultural values. We hypothesize the same value dimensions and directions for the US ads. Thus, the following hypotheses will be tested:

- H1a: Korean ads will have more individualistic than collectivistic indicators.
- H1b: US ads will have more individualistic than collectivistic indicators.
- H2a: Korean ads will have more future-oriented than past-oriented indicators.
- H2b: US ads will have more future-oriented than past-oriented indicators.

Following McCarty's argument (1994), ads in such a developing and drastically changing society as Korea might be even more individualistic and future time-oriented than those in the US, but there is no rigorous theoretical background and literature supporting this argument. Thus, the following research questions are addressed:

RQ2: Which country's ads employ more individualistic indicators?

RQ3: Which country's ads employ more future-oriented indicators?

METHOD

Content analysis was used to compare cultural value differences in US and Korean newspaper advertising. Newspaper advertisements were chosen because they are relatively comparable and generalizable for all target segments due to the vast differences in media environment, but are rarely used much in cross-cultural advertising studies.

Sampling. Advertisements in Chosun-ilbo (Korea) and the New York Times (US) were selected randomly. Both newspapers are relatively well matched (Tak et al. 1997) in that each is arguably the most salient and influential newspaper in each country and has nationwide readership. Based on constructed week sampling, newspapers throughout the year 2000 were collected. Sunday-issued newspaper, duplicate ads, local ads, classified and movie ads were excluded to avoid lack of matching and sampling bias. In addition, international product ads in the Korean newspaper were excluded to focus on the cultural dimensions inherent in each country's ads. As a result, 1262 (638 for Chosun-ilbo; 624 for The New York Times) ads were analyzed.

Coding Procedure. This study developed mutually exclusive, exhaustive and reliable coding categories, based on previous research on I/C and P/F cultural indicators (e.g., Cho et al. 1999; Han and Shavitt 1994; Ko and Gentry 1991).

Two bilingual graduate students coded the ads. Considering the potential for gender differences and cultural biases (Miracle 2001), one female bilingual Korean American who lived in the US for more than 15 years coded the entire data set. The other coder was a Korean male who had just arrived in the US. He coded 170 randomly selected sample ads, which exceeded ten percent criteria (Wimmer and Dominick 1994), to calculate intercoder reliability.

Throughout multiple training sessions, the hypotheses-blind coders worked independently, to examine all elements of the advertising such as headline, subhead, body copy, illustration, caption, and slogan when making coding decisions. After examining the ad in its entirety, the coders were instructed to enter a simple "yes" or "no" to indicate the presence or absence of each cultural value indicator. In the next step, scales were constructed of each cultural dimension as shown in Table 1 below. For the intercoder reliability, this study adopted Krippendorff's alpha, which takes chance agreements into account (Krippendorff 1980). All reliability values of the variables were at or above the conventionally accepted value of .75 (Wimmer and Dominick 1994), ranging from .79 to .98. One item, 'conformity,' with substandard agreement was discarded for the construct of collectivism. Before calculating t-tests, Cronbach's alpha was computed. All items of each cultural dimension were within an acceptable reliability (Nunnally 1978), ranging from .70 to .81.

Measure. Cronbach's alpha warrants internal reliability, but does not guarantee cross-validity for comparing each scale between the two cultures. For RQ1, multi-group confirmatory factor analyses (MGCFAs) were performed to ensure cross-culture comparability of the factor structure. Since all the items have binary values

(yes=1, no=0), in the first step, tetrachoric correlations were performed among the items within each of the cultural dimensions using the PRELIS program (Jöreskog and Sörbom 1996a), to reduce the problem of underestimating the correlations in product-moment correlations. In the second step, MGCFAs were performed using the LISREL program (Jöreskog and Sörbom 1996b). As a prerequisite for a valid comparison across the two cultures, the goal of these analyses was to obtain a common factorial model that could be comparable across ads in the two cultures.

RESULTS

First, a MGCFAs model was conducted to examine the degree to which the two separate two-factor models of cultural value factors (I/C model and P/F model) capture the structure of correlations among the value items and whether the structure remains comparable between the two cultures. The results show that the two-factor model of P/F yields a good fit ($\chi^2(32)=74.47$, $p=.00$; RMSEA=.044, NNFI=.99, and CFI=.99). Since the chi-square test is sensitive to a large sample size, several goodness-of-fit indices are considered together (Kline 1998). The model that allowed the factor loadings to be invariant across the two groups still demonstrates a good fit, implying the time orientation dimension is a very rigorous factor structure that is stable across the two cultures ads. The loadings for the time-orientation factor in which the ads from the two national newspapers share range from .57 to .75 and the total variance accounted for by the model is up to .68 (see Table 2).

While the factor structure for the P/F dimension supported the comparability of the ads across cultures, the two-factor model of I/C failed to produce a good fit. Lack of fit in the model implies that the factor structure of the I/C dimension with the given indicators may not be stable across the ads. Therefore, for the I/C cultural value comparison, we examined each indicator rather than focusing on the overall dimension, when comparing ads in the two cultures.

The first two hypotheses predicted that both Korean and US ads would carry more individualistic than collectivistic indicators. Table 3 shows that these hypotheses were supported, in that Korean ads contained more individualism indicators than collectivism indicators. Likewise, the second hypotheses predicted both Korean and US ads would convey a greater number of future-oriented indicators than past-oriented indicators.

Along with within-culture analyses, the two research questions asked which country's ads would employ more individualistic (RQ2) and future time-oriented cultural indicators (RQ3). Independent samples t-tests were performed, using a Bonferroni-type correction to guard against type 1 error for multiple mean comparisons, which adopts a more stringent alpha level.

To investigate RQ2, each cultural indicator was compared rather than the overall I/C dimension, based on the finding with respect to RQ1 that the factor structure for this dimension was not comparable across the two cultures. As shown in table 4, mean differences between Korean and US ads for each cultural indicator show mixed results.

In the collectivism dimension, Korean ads appealed more to 'relationship/ harmony' cultural item than did US ads. In the individualism dimension, Korean ads focused significantly more on status of the consumer (KO=.84, US=.77, $t_{(1225.9)}=3.33$, $p<.001$), 'self-indulgence' (KO=.26, US=.19, $t_{(1249.5)}=3.09$, $p<.01$), and 'benefits to an individual target audience' (KO=.73, US=.62, $t_{(1245.2)}=3.82$, $p<.001$) cultural indicators than their US counterparts. In contrast, US ads contained a greater number of 'belonging' indicators in the collectivism dimension than did Korean ads, and a greater number of 'self-reliance' items in the individualism dimension than did Korean ads.

TABLE 1
Operationalization of Cultural Dimensions and Indicators

Collectivism: (.81)
1. Appeals about the integrity of or belonging to family or social groups (.90)
2. Emphasis on harmony. Being together. Friendship, partnership, companion. (.87)
3. Sharing, gift-giving (.89)
4. Emphasis on the accomplishments of the family or social group (.86)
5. Emphasis on the benefits to families, group members, or others (.87)
Individualism: (.70)
1. Focus on the individuality or status of the consumer (.97)
2. Uniqueness, creativity, originality. Focusing on being different, or standing out. (.96)
3. Escape or stay out of the current position (.89)
4. Self-indulgence: excessive or unrestrained gratification of one's own appetites, desires, or whims. Enjoyment, fun, pleasure, instinct gratification (.93)
5. Mentioning of ranking, competition, winning, the best and the most (.92)
6. Self-direction or self-reliance. Freedom, choosing own goals, self-esteem (.87)
7. Self-fulfillment or self-development (.84)
8. Self-benefit (.90)
Past-Time Orientation: (.76)
1. Emphasis on being classic, historical, memorable, old, or antique. Worth of age of product itself (.94)
2. Emphasis on accumulated experience or knowledge. Mentioning the companies' history (.91)
3. Respect for tradition, legacy, heritage, elders and ancestors (.87)
Future-Time Orientation: (.81)
1. Emphasis on youth. Challenge, adventure, being new of company or people (.92)
2. Introducing a new product/service or new benefits (.86)
3. Emphasis on the future of being progressive (.98)
4. Focus on positive change such as innovation, development, improvement, and success (.98)

Note: Numbers in the parenthesis of each dimension indicate the alpha reliability
Numbers in the parenthesis of each item indicate the intercoder reliability

TABLE 2
Multi-group Confirmatory Factor Analysis for Time Orientation

Cultural Values	Korean Ads (n=638)	Common metric loadings	The US Ads (n=624)
	R ²		R ²
<i>Past-time orientation</i>			
Antique	.63	.75	.49
Experience	.56	.72	.48
Tradition	.48	.73	.61
<i>Future-time orientation</i>			
Youth	.57	.79	.68
New Product	.29	.59	.44
Future	.42	.61	.33
Change	.37	.57	.29
Global goodness-of-fit indices	$\chi^2(32)=74.47$ ($p=.00$), RMSEA=.044, NNFI=.99, CFI=.99		

Note: Coefficients are from the completely standardized solutions. The factor loadings and the latent factors are invariant across the two cultures.

TABLE 3
One-sample t-tests for Cultural Indicators

Cultural Values	Mean	SD	t-value (two-tailed)	p-value
<i>Chosun ads (N=638)</i>				
Collectivism/Individualism	2.21	2.71	6.62	.000
Time orientation	2.05	1.65	23.74	.000
<i>The NYT ads (N=624)</i>				
Collectivism/Individualism	1.94	2.79	3.98	.000
Time orientation	1.27	1.53	12.52	.000

Note: For the comparison of the cultural dimensions within each culture, the bipolar scale was constructed. That is, for the collectivism-individualism scale, collectivism indicators were rescaled as -1 (instead of 1) and 0, and summed with individualism indicators. As a result, the I/C unidimensional scale ranges from -5 to 8 and thus, test value is set as 1.5. The same process is applied to the time dimension (ranging from -3 to 4; test value, .5)

TABLE 4
Statistical Results of Cultural Indicators between Korean and the US Ads

Cultural Indicator	Mean		t-value	df	p-value (two-tailed)
	Korea	US			
<i>Collectivism</i>					
Belonging	.28	.37	-3.66	1247.7 ^a	.000
Relationship/harmony	.19	.12	3.59	1222.9 ^a	.001
Sharing/gift-giving	.16	.16	.14	1260	ns
Co-Fulfillment	.08	.09	-.52	1260	ns
Co-Benefit	.11	.11	-.67	1260	ns
<i>Individualism</i>					
Status/Individuality	.84	.77	3.33	1225.9 ^a	.001
Uniqueness/creativity	.23	.21	.61	1260	ns
Escape	.05	.07	-1.74	1211.6 ^a	ns
Self-indulgence	.26	.19	3.09	1249.5 ^a	.002
Competition	.39	.35	1.50	1260.0 ^a	ns
Self-reliance	.23	.34	-4.65	1232.8 ^a	.000
Self-fulfillment	.30	.24	2.63	1256.1 ^a	ns
Self-benefit	.73	.62	4.08	1245.2 ^a	.000

Note: ^a because Levene's test for equality of variances was statistically significant (p<.05), equal variances were not assumed. Bonferroni-type correction adjusted the critical value to .004.

For RQ3 examining which country's ads have more P/F cultural dimensions, results of independent-samples t-tests indicate that Korean ads were more future time-oriented than the US ads (see table 5). More specifically, although not reported here, Korean ads conveyed significantly more of all the four items indicating a future-time orientation, such as 'youth' appeal ($t_{(1250.4)}=7.87, p<.001$), emphasis on future ($t_{(1247.5)}=6.17, p<.001$), positive change ($t_{(1251.6)}=6.18, p<.001$), and introducing new products ($t_{(1191.3)}=9.04, p<.001$). In terms of past-time orientation, however, ads in both countries were not statistically different.

DISCUSSION/CONCLUSION

The purpose of this study was to challenge the dominant polarized framework of cultural values reflected in Western and Eastern culture ads. In addition, the study advances a more valid and rigorous methodology to compare ads cross-culturally.

A majority of cross-cultural studies adopting Hofstede's cultural typology framework have supported their hypotheses that advertising in Western countries reflects individualistic values and a future-time-orientation, whereas advertising in Eastern countries reflects collectivist values and a past-time orientation (Han and

TABLE 5
Statistical Results of the Time Orientation Dimension in Korean and US Ads

Cultural Dimension	Mean		t	df	p-value (two-tailed)
	Korea	US			
Past Time	.18	.20	-.41	1260	ns
Future Time	2.20	1.47	9.18	1256.2 ^a	.000

Note: ^a because Levene's test for equality of variances was statistically significant ($p < .05$), equal variances were not assumed.

Shavitt 1994; Mueller 1987). Some other findings have shown mixed results, in that collectivistic and individualistic indicators are confounded in the US ads and those in Eastern cultures such as China (Lin 2001), Taiwan (Huang 1995), Japan (Mueller 1992), and Korea (Cho et al. 1999). For instance, advertising in developing Eastern countries such as China plays a role as "the pacesetter for Western cultural values" and "a double distorted mirror," revealing the commercial nature of advertising (Cheng and Schweitzer 1996). Recently, Chinese ads have been found to adopt more modern and Western appeals (Lin 2001; Zhang and Shavitt 2003).

This study demonstrates the complexity of cultural values and supports the notion that individualism and collectivism are not mutually exclusive categories existing solely in ads from one culture or another. We showed empirically that South Korean newspaper ads do not merely convey traditional Eastern cultural values such as sharing with others, collective fulfillment, and respect for tradition and emphasis on antiques. Rather, such ads appeared to readily accept individualistic values such as indulgence, accomplishment and competition, and future-oriented values such as youth and change. Similarly, the US ads promoted group belonging as well as individualistic and future-oriented values. These value results, while contradictory with some past advertising studies (Han and Shavitt 1994; Miracle et al. 1992), are in line with the ones reported in a meta-analysis of I/C psychology research (Oyserman et al. 2002). Oyserman et al. (2002) concluded that Americans may not be significantly different in collectivism from Koreans, and "may even report higher collectivism than others when collectivism is assessed with sense of 'belonging' and 'seeking others' advice" (p. 20). Thus, it may be more accurate to measure each cultural indicator separately, rather than to measure mean-scored I/C dimensions. In addition, our multi-group confirmatory factor analysis indicated that a priori assumptions about cultural dimensions constructed by given indicators might not be valid across cultures. In line with more rigorous cross-cultural methodology advocated by Van de Vijver and Leung (1997), we suggest that the factor structures of cultural dimensions should be statistically tested and confirmed.

Alternative explanations of our findings suggest that Korean ads may in fact reflect the evolving value orientations of the culture (McCarty 1994). Experiencing social change and Westernization in the globalization process, Korean ads may portray future orientations rather than past beliefs. If advertising reflects desired or future values, then the content analyses may not match cultural value expectations. For instance, Cho et al. (1999) found that Korean ads were not more collectivistic than the US ads, even though Moon and Franke (2001) reported that Korean advertising practitioners held more collectivistic and traditional work ethics than their US counterparts.

Finally, the question of whether advertising reflects current cultural values might be explained by the commercial nature of advertising itself. For example, Mueller (1987) pointed out that Japanese advertising would adopt Western appeals, "if it fits the consumer needs." Korean advertising might also adopt more Western and individualistic values to appeal to the interests of younger target audiences. For instance, the headline of one camera ad, "My baby doesn't need a father (Because I can use this product for my baby without its father's help)," featured a young businesswoman holding her baby. The emphasis in this ad may not reflect mainstream cultural values, but might appeal to independent-minded young Korean women. Such an argument lies at the core of Pollay's assertion (1986) that advertising is a distorted mirror, because it reflects only certain values and lifestyles, not a full array of them. Thus, the cultural values portrayed in Korean ads may not be well correlated with past values. We suggest that cross-cultural advertising studies should go beyond bipolar (Western versus Eastern, Individualism versus Collectivism) frameworks and reconsider assumptions that advertising reflects aggregate cultural values that are fixed and constant over time. Considering that advertising is influenced by every facet of political, economic, social, and cultural life from within and between cultures, we should understand advertising content under a greater variety of social contexts (Lester 1994).

Although this study leaves more questions than answers, we believe that we addressed some important issues for cross-cultural advertising literature, within limited data and space. Future studies may explore further to what extent advertising reflects cultural values in the very society along with theoretical modeling to fit better for Western versus Eastern advertising comparison.

Cultural Differences in Fan Ritualization: A Cross-Cultural Perspective of the Ritualization of American and Japanese Baseball Fans

Seungwoo Chun, University of Nebraska-Lincoln

James W. Gentry, University of Nebraska-Lincoln

Lee P. McGinnis, Washburn University

ABSTRACT

The purpose of this paper is to conceptualize the fan ritualization process through which an individual acquires ritualized sports fandom, as characterized by symbolized, role-assimilated, and self-enacted sports-related consumption experiences. Sports fans employ several fan ritualization strategies including formalism, symbolic performance, traditionalism, and socializing in order to secure ritualized sports fandom. However, these strategies of fan ritualization are culture-specific because sports fans authorize and legitimize ritualized sports fandom according to their cultural values. This paper offers several propositions regarding cultural differences in fan ritualization between American and Japanese baseball fans.

At least two-thirds of Americans consider themselves to be sports fans (Lieberman 1991). In spite of the pervasiveness of sports as entertainment, media consumption, or the focal point of conversation, little research, less than five percent of the work in sports psychology and sports sociology (Wann and Hamlet 1995), has investigated the thoughts and behaviors of fans. This had resulted in a lack of understanding of sports fans and their behavior.

The sports literature has only generically identified sports fans as individuals with an enduring interest in sports, and the definition of "sports fan" has not been clearly distinguished from that of a "sport spectator" (Wann et al. 2001). Sports fandom is in a limited fashion defined as "the degree to which subjects considered themselves to be sport fans" (Wann 1998, p.287). On the other hand, some scholarly literature on fans (Jenson 1992) has highlighted fans as "deviant from normal," focusing on the excessiveness of their behavior and treating them as abnormal and disreputable, even dangerous.

This paper will view sports fandom as ritualized experience. This ritualized fan experience includes the cognitions and feelings that a sports fan experiences; these cognitions and feelings are symbolized, role-assimilated, and self-enacted during the use of a sports-related product or service. Tetreault and Kleine (1990) associate ritualized behavior with role-assimilated and self-reflected mundane repetition across time and place. This ritualized behavior is symbolic-laden as well (Rook 1985). Sports fans may derive the ritualized experiences from their or others' ritualized behavior in sports consumption. This view extends our understanding of sports fandom to a phenomenon symbolized and structured in the cultural values of the particular society in which a sports fan is situated.

In addition, the ritualized fandom perspective acknowledges that individuals may initiate and develop their identities and roles as sport fans through participating in various sport fan rituals, and that these fans can maintain their sports fandom through continued ritual engagements. This may broaden current sports fan socialization theory, which has focused on socialization agents (e.g., family, friends, school, etc.) and sports fan motives (e.g., group affiliation, self-esteem, entertainment, etc.) in the fan socialization process (McPherson 1976).

In this paper, we turn our attention to the "ritualization process" rather than the "ritual." Bell (1992) defines ritualization as a process in which an individual possesses and maintains a

cultural "sense of ritual" through differentiating ritual from non-ritual activities. This differentiation enables the individual to enumerate and legitimize symbolic meanings of a ritual. However, the strategies of ritualization are culture-specific because each culture differentiates ritual from non-ritual activities according to its own value system. Based on Bell (1992)'s definition of ritualization, we define fan ritualization as the process in which an individual acquires ritualized sports fandom through continued fan ritual engagements and through differentiating ritual from non-ritual activities based on the society's cultural values and social relations.

We will investigate cultural differences in fan ritualization, selecting American and Japanese baseball fans as the research domain. Baseball has been popular both in the United States and Japan for a long time despite the cultural differences between these two countries. A variety of the fan rituals have been developed throughout the long history of baseball in both countries. Baseball is an extremely ritual-laden activity that lends itself to such observation.

In the first section of the paper, we discuss how sports fandom is defined as ritualized experience. Next, we discuss how an individual acquires and maintains ritualized sports fandom through the fan ritualization process. Then, in our discussion of cultural differences in fan ritualization, we explain how culture influences the ritualization processes, and generate several propositions about differences in the fan ritualization process between American and Japanese baseball fans. Finally, we will discuss the implications of this perspective in terms of extending current theories of sports fandom and fan socialization.

SPORTS FANDOM AS RITUALIZED EXPERIENCES

Some aspects of sports fans' ritualized behavior are readily observable. It is not uncommon to note the ritualized sport fans wearing their favorite team colors on game day, preserving traditional values, celebrating patriotism at international games by decorating their body with national flags, and symbolizing personal meaning through sport-related material possessions (Eastman and Riggs 1994; Summers, Johnson, and Kennedy 2001).

This view of sport fandom as ritualized experience offers extensions to the current understanding of sports fandom, which has been limited to the degree to which individuals consider themselves to be sports fans or the amount of money and time that they spend on sports-related consumption each year (Wann 1998). Ritualized sports fandom can be characterized as "symbolized, role-assimilated, and self-enacted" sports-related consumption experience. Each of these three components is explored below.

First, symbolized consumption experiences are easily observable in sports fandom. Through objects and activities (e.g., apparel colors and types of cheering), sports fans develop, maintain, and manipulate various types of symbolized meanings and values about themselves, their favorite teams and players, games, etc. Derbaix, Decrop, and Cabossart (2002) in their study of Belgian soccer fans, reported that material possessions—colors of clothes and scarves—are strongly related to their soccer consumption, and that the goods associated with soccer have symbolic functions: identification,

integration, expression, and sacralization. Sports fans share and communicate those symbolized meanings and values with other fans, and, in addition, these symbols serve the function of categorizing them according to their favorite teams, and to their involvement and knowledge levels (Derbaix et al. 2002; Holt 1992, 1995).

The meanings and values symbolized by sports fans represent social and cultural values. Furthermore, new symbolic meanings may frequently emerge as a consequence of changes in social values or extraordinary social occurrences (e.g., war, revolution, or elections). For example, during World War II (1940-1945), many Americans, including President Roosevelt, viewed baseball fandom as vital for sustaining the nation's morale (Weiller and Higgs 1997). In the same sense, patriotism became widely embraced by American baseball fans following the terrorists' attack on September 11, 2001.

Second, ritualized sports fans are role-assimilated. There are different roles for home-fans and away-fans in terms of seat locations, cheering, or even activities outside of the stadium. Kelly (1997) observed that Japanese fans cheer only when their team is at bat, but not when it is in the field. There are "hitting marches," but no "fielding marches." Although sports fans have the freedom to enact their role in their sports consumption, on occasion they will experience embarrassing moments if they neglect those roles. Holt (1995), in his observation of Chicago Cubs' fans, reported that fans sitting in the left field bleachers show their loyalty to the team through the "throwing back" ritual; failure to throw the opposing player's homerun ball back to the field exposes the fan to immediate criticism from other spectators. Fans of several other Major League Baseball teams in the United States have currently incorporated this ritual as well.

A sports fan's role enactment may be either passive or active (Rook 1985). Some baseball fans show active role enactment; for example, one can observe devoted fans who voluntarily lead collective cheering in Japanese baseball games (Kelly 1997). Most Japanese baseball fan clubs are managed based on their fans' voluntary cooperation. Even though the fan clubs sometimes receive support from team management, for instance when purchasing group season tickets, in running the clubs most club members have self-defined roles such as providing drinks and food or playing a musical instrument on a game day (Kelly 1997).

This self-enacted volunteerism of sports fans is also representative of their fandom. Ritualized sports fans transform the roles and regularities that are, sometimes, externally prescribed in their behavior into internally self-endorsed ones. Deci and Ryan (1991) suggest that people accept values and regulatory processes that are endorsed by the social order, but are not intrinsically appealing initially, through an internalization process.

Interest/excitement has been identified as a significant factor in motivating individuals to internalize or self-enact those values (Deci and Ryan 1991). Csikszentmihalyi (1975) proposes that true enjoyment accompanies the experience of flow, providing a peculiar, dynamic, and holistic sensation of total involvement with the activity itself. Holt (1992) observed that many baseball fans felt transcended in a number of situations, such as when dramatic situations and outstanding performances occurred while watching a game in the stadium.

In addition, the other major component in internalizing the roles and values of sport fandom is their need for relatedness with others (Deci and Ryan 1991). Sports fans may have a *communitas* experience as they support their team. In the experience of *communitas*, they feel the disappearance of everyday social roles and status, and develop intense comradeship with each other (Turner 1969). In the context of Chicago Cubs baseball, Holt (1995)

describes this feeling as emerging from the consumption practice of "play," which is one of the four ways people consume.

We have discussed three major characteristics—symbolized, role-assimilated, and self-enacted—in defining sports fandom as ritualized experience. Our next step is to investigate how a sports fan acquires the ritualized fandom in his or her sports consumption. We propose that individuals may become ritualized—symbolized, role-assimilated, and self-enacted—through a ritualization process in which the individual possesses and maintains a sense of ritual by differentiating ritual from non-ritual activities. However, the ritualization process is culture-specific because each culture has its own values concerning the legitimization and internalization processes. In the next section, we will discuss cultural differences in fan ritualization between American and Japanese baseball fans.

CULTURAL DIFFERENCES IN THE FAN RITUALIZATION PROCESS

Following Driver (1998), Arnould (2001) suggests that ritual provides society with at least three functions—order, community, and transformation—and these functions are achieved by allowing people to experience emergent shared emotions through manipulating objects and symbols in the ritual. Arnould (2001) further notes that these shared emotions play a role for consumers in shaping consumption decisions and behaviors. In the same sense, a sports fan is able to initiate and develop ritualized sports fandom—symbolized, role-assimilated, and role-enacted—through the continued ritual engagements which continually provide them the emergent shared emotions.

In adapting Bell's (1997) discussion on ritualization strategies, we will introduce several fan ritualization strategies—formalism, symbolic performance, traditionalism, and socialization—which produce ritualized fans. As we mentioned earlier, culture determines the effectiveness of each strategy and, thus, plays an essential role in fan ritualization. We will investigate the differences in effectiveness of the ritualization strategies between American and Japanese baseball fans. However, stereotyped cultural characteristics (e.g., individualism and collectivism) are not sufficient for a full understanding of the baseball fan ritualization processes. Further consideration should include how baseball becomes contextualized in each society.

Formalism

Formality is one of the most frequently observed characteristics of ritual. Bell (1997) noted that the formality of a ritual is associated with "the use of a more limited and rigidly organized set of expressions and gestures, a restricted code of communication or behavior in contrast to a more open or elaborate code" (p.139). The formalization of behavior is effective in enhancing the particularity of a situation by contrasting it with less special ones, as this promotes the conventional and idealized order related to the event (Harris 1983).

This formality of behavior in ritual, in many cases, develops into sets of rules that normalize ritual activities. These normative rules may regulate ritual activities by elaborating the procedure and the limits of acceptable behavior in the ritual. One will face criticism from other group members when she or he attempts to act differently than directed by the rules of ritual. Turner (1969) explicitly argues that ritual involves obligation, and all members of a society should follow the rules of the ritual. Ritualization by means of rule-governance gives rise to the engagement of cultural and social customs in defining ritual activities.

Baseball fans commonly ritualize their behavior by formalizing, or further normalizing their behavior. The fans should stand up

as a way of displaying respect to their nations when national anthems are playing at the beginning of a game. Furthermore, some fans are likely to feel a sense of guilt or a “fear of being an outsider” if they act differently from those who follow the rules and conventions of baseball. Refusal to take an integral at-bat with seriousness can certainly capture the disdain of fellow onlookers who might view such a moment as being near sacred-like. The rules formalizing baseball fans behavior in the fan ritualization process are different between American and Japanese baseball fans.

American baseball fans seem to have self-disciplined rules in formalizing their behavior. This means that American fans mostly follow the rules of baseball for the sake of their own playful experience in baseball consumption (Holt 1992). The self-disciplined rules embraced by American baseball fans seem to be associated with their individualistic goals of pursuing self-identity as baseball fans rather than the statement of collective loyalty made by the rigidly disciplined fan clubs of professional baseball in Japan. Thus, for American fans, following rules is an individualistic pursuit, and it tends to be less influenced by social context; it is stable across time and place. Many American fans display ritualized activities, including wearing team colors, consuming special foods or drinks, or performing routine preparatory activities while watching a game on the television (Eastman and Riggs 1994). We believe that these ritualized activities in front of the TV, which are often enacted individually, are fairly consistent with those performed by many fans in the stadium. American fans are more inclined to display consistent ritualized behavior irrespective of the setting.

On the other hand, rules for Japanese baseball fans are likely to be more group-disciplined. For Japanese fans, following the rules of baseball seems to be situational, and social surroundings are crucial factors in enacting the rules. The maintenance of harmony with other fans by complying with the rules may contribute to enhancing the consumption experience. For instance, many Japanese baseball fans bring a plastic megaphone to participate in collective cheering, even though they may be not familiar with those cheering activities. Japanese baseball fans are likely to display different behaviors in a public setting versus in a private setting. For instance, we can observe some highly-identified fans who display few ritualized behaviors while watching a game in the privacy of their own home (Eastman and Riggs 1994).

Thus, we propose that American baseball fans will tend to adhere to more self-disciplined rules, while Japanese baseball fans will tend to adhere to more group-disciplined rules in formalizing behavior. This may be consistent with the idea that people from individualist cultures are more self-oriented, whereas people from collectivist cultures are more group-oriented (Markus and Kitayama 1991; Triandis et al. 1988). Moreover, Riess (1999) suggests that Americans have celebrated individualism, self-reliance, and cultural pluralism through linking agrarian/rural and democracy myths to their baseball consumption. On the other hand, the Japanese as fans and players of baseball have spiritualized its collective virtues—teamwork, harmony, authoritarian leadership—in the practice of baseball (Guttman and Thompson 2001). For the Japanese, baseball has been a powerful vehicle to promote the “Japanese management style” based on collectivism in the modernization era.

P1: American baseball fans tend to adhere to more self-disciplined rules than group-disciplined rules in formalizing behavior in the fan ritualization process.

P2: Japanese baseball fans tend to adhere to more group-disciplined rules than self-disciplined rules in formalizing behavior in the fan ritualization process.

Symbolic Performance

The performative dimension of ritual—the deliberate and voluntary doing of symbolic actions in public—is understood as something beyond routine reality (Bell 1997). Ritual performance is dramatized by highly visual imagery, dramatic sound, and extraordinary settings. These dramatized performances in ritual evoke intense emotions among participants by attaching specialness to the event, which easily induces participants to link powerful symbolic meanings with the ritual.

These symbolic ritual performances by baseball fans can be classified into two types: self- and collective-expressive ritual performances. Self-expressive rituals reflect the visibility of each individual’s ritual performance. An individual performer is easily identifiable in terms of his or her role or aesthetic expressions while performing a ritual. For example, baseball fans often hold up creative and special signs (e.g., The CUBS and WGN are #1 (Holt 1995)) to support the team and players, which can also serve to “personalize” the experience of the fan (Holt 1995). But, there is no strict rule as to what kinds of messages should be used on the signs. Some signs can be quite benign, indicating support for the team while others can be quite caustic, often used to demonstrate ire against specific players (e.g. Sammy Sosa using a corked bat), coaches, or ownership. An individual’s creativity concerning ritual performance may play a significant role in distinguishing him/her from other fans in the ritual. Setting oneself apart from the crowd may indeed be the motivation.

On the other hand, a collective ritual refers to ritual activities that represent a harmonized expression of symbolic meanings by the participants. This ritual requires unified and cooperative efforts from every participant. Examples would be a wave encircling the stadium and the displaying of a huge player’s uniform or a flag on the stands. Many collective rituals demand organized preparation and practices before fans perform them, whereas the “wave” (observed in Western venues) does not. Further, in Japan, drawing individual attention to oneself during a game, or displaying signs opposing team management, players, etc., is not likely to occur.

Thus, we argue that collective rituals are more salient to Japanese baseball fans than American baseball fans, whereas self-expressive rituals are more salient to American baseball fans than Japanese baseball fans. Collective rituals are frequently observed in Japanese baseball stadiums. Kelly (1997) reported that collective chanting and cheering accompanied by the pounding rhythm of *taiko* drums (similar to Western bass drums) continue through the whole game and that several leaders organize the chanting and cheering for better performance. He also discusses a collective ritual observed at Hanshin Tigers’ home games: the soaring of thousands of whistling balloons into the air in the bottom of the seventh inning. On the other hand, American baseball fans (with a notable exception being the Atlanta Braves’ chopping chant) tend to be more self-expressive in ritual performance. Instead of focusing on collective chanting and cheering, television cameras point to individual fans holding up creative signs supporting the team and players as well as expressing their own views.

P3: The self-expressive aspect of symbolic performance in baseball fan rituals is a more influential factor for American baseball fans in the fan ritualization process than for Japanese baseball fans.

P4: The collective-expressive aspect of symbolic performance in baseball fan rituals is a more influential factor for Japanese baseball fans in the fan ritualization process than for American baseball fans.

Traditionalism

Traditionalization is a common way of legitimizing ritual activities by attaching mythical and sacred power to “past” in the ritualization process (Bell 1997). Bell (1997) notes that, as a powerful tool of legitimation, traditionalization may be manifested in “the repetition of activities from an earlier period, the adaptation of such activities in a new setting, or even the creation of practices that simply evoke links with the past” (p. 145). In their study of the ritualization associated with inherited possessions, Arnould, Price, and Curasi (1999) found that people generally use the past as a source of ritual meanings.

Nostalgia for the past is essential to sports fans in enhancing their enjoyment in the consumption of sports (Summers et al. 2001). This sense of the past in sports consumption plays a role in the construction of a shared collective identity among the fans. This nostalgia is associated with sports fans’ enjoyable childhoods, the perceived betterness of the past generation, and the original lessons of a sport. The fans bestow mythical and sacred values on those experiences. Work on nostalgia in consumer behavior research bears a similar definition, whereby a general preference toward objects from one’s younger days is observed (Holbrook 1993).

For Americans, the nostalgia of baseball seems to closely overlap with American’s small-town, pre-industrial past (May 1989). This reason may reflect the pastoral characteristic of American baseball because baseball started in rural nineteenth-century America (Seymour 1990). As well, adult fans may have enjoyable memories of their own playing days in rural hometowns before they moved into urban areas. This perspective is consistent with the rural town setting of the nostalgic baseball movie, “The Field of Dreams.”

For the Japanese, baseball is a symbol of modernization and westernization (Kelly 1998; May 1989). After baseball was first introduced in 1873, it became Japan’s most popular modern participant sport in the late Meiji period (1868-1912), Japan’s early modernization era (Guttmann and Thompson 2001). Many Japanese have recollections of the Koshien high school baseball tournament that started in 1915 and, since 1924, has been held at Koshien Stadium in Osaka. This stadium is symbolized as the emergence of modernity to many Japanese (e.g., their first experience with flush toilets) (Kelly 1997). Since the inception of a professional league in 1938, modernization has constantly underscored baseball’s continuing popularity. The professional baseball league has prospered under big corporate ownership and throughout the last century, baseball has been a significant arena for the display of the ideologies and institutions of modern Japan (Kelly 1998).

P5: The rural and pre-industrial aspect of traditionalism in baseball fan rituals is a more influential factor for American baseball fans in the fan ritualization process than for Japanese baseball fans.

P6: The modernization aspect of traditionalism in baseball fan rituals is a more influential factor for Japanese baseball fans in the fan ritualization process than for American baseball fans.

Socialization

Socialization in the ritualization process refers to a set of learning activities through the sharing ritual activities and their symbolic meanings with other people. Individuals might learn how to perform the various activities of a ritual and its symbolic meanings from family, friends, community members, and/or media. Frequently, people join in and create ritual communities to learn ritual activities and to share ritual experiences with others (e.g., biker groups (Schouten and McAlexander (1995) and Star

Trek fan communities (Kozinet 2001)). Those who have multiple socializing agents may be concerned with the agents’ authoritative ability to legitimize ritual performance.

Bell (1992) introduced the concept of “ritual specialists” who have socially recognized authority to judge the importance of ritual and the performance’s correctness. Ritual specialists may serve to legitimize the social importance of ritual, and to diffuse the correct way of performing it. However, the status of ritual specialists seems to reflect the degree of hierarchical structure in a society (Bell 1992). In a society where the social hierarchy is strong, the role of the specialist in legitimizing ritual activities is much greater than that in societies with weaker hierarchical structures.

The concept of a ritual specialist is useful in explaining baseball fans’ socializing in the fan ritualization. As noted earlier, fans get information on correct ritual performance of a ritual and its meaning from a parent, sibling, close friend, other fans, or media. The fans—as parents, friends, co-workers, or even media—may also act as ritual specialists who provide other fans with ritual information. For example, many baseball fans join in fan clubs to share ritual experiences with others, and their fan club activities offer the chance to learn something from ritual specialists.

The source of authority seems an important factor in determining the degree of legitimacy of various social groups as ritual specialists. It seems that other-focused and high-power difference cultures (e.g., Japanese and Korean) consider officialness and representativeness in overall society to be more important than close ties in the establishment of the authority of social groups. The reason for this is likely to be that collectivist cultures conform more readily to influences based on hierarchical power structures than do individualist cultures (Smith 2001).

Therefore, we expect that the authority of social groups as ritual specialists in fan ritualization will vary between Japan and the United States. We argue that the official groups (e.g., official supporter groups or the media) have legitimacy as ritual specialists in the fan ritualization process in Japan more than in the United States. On the other hand, close social groups (e.g., family or close friends) will act as the ritual specialists in the ritualization process more in the United States than in Japan.

According to Kelly (1997), *oendan* (supporter group) plays a major role in devising fan rituals and educating less ritualized fans about Japanese baseball. Otnes and Scott (1996) pointed out that the impact of the media is much greater in symbolizing ritual meanings of advertised products in Japan than in the United States. On the other hand, Wakefield (1995), in a study of Pittsburgh Pirates’ fans, reported that perceived peer group acceptance has a positive effect on the individual’s identification with the team, and with repatronage intention.

P7: When baseball fans are socializing others in the fan ritualization process, close social groups (e.g., family or friend groups) are more influential ritual specialists for American baseball fans than for Japanese baseball fans.

P8: When baseball fans are socializing others in the fan ritualization process, socially authorized groups (e.g., media or supporter groups) are more influential ritual specialists for Japanese baseball fans than for American baseball fans.

DISCUSSION AND CONCLUSION

This perspective of sports fandom as ritualized experience views sports fans as active participants who symbolize and celebrate sports consumption by voluntary role-enactments as sports fans. This sports fandom is much more than spending money to

attend a game and to buy sport-related goods. However, most sports research measures sports fandom by asking an individual about his/her interest in sports, and the amount of money spent on sports consumption (Wann 1998). As Wann et al. (2001) mention, this operationalization in defining sports fandom may result in an unclear distinction between sports fans and sports spectators. The attempts to identify the symbolic meanings and roles associated with sports fans in their sports consumption may offer extensions to the current understanding of sports fandom.

In addition, most sports research relates sports fans' sense of self to their team/player identification, which is defined as the degree of psychological connection to specific teams or players (Cialdini et al. 1976; Fisher and Wakefield 1998). However, team/player identification is not the only factor shaping sports fans' sense of self. They actively create and build their identities as sports fans by attaching symbolic meanings to objects and activities, securing their valuable traditions, and anchoring their behavior in cultural and social orders through the fan ritualization process. Therefore, sports fans, in their roles as ritual participants, may celebrate not only successful team performance, but also symbolized cultural meanings through engaging in a variety of fan rituals.

This perspective of the fan ritualization process may broaden current sports fan socialization theories. The theories of sports fan socialization have mostly focused on the roles of socialization agents (e.g., family, friends, and peer group) and sports fan motives (e.g., group affiliation, self-esteem, and entertainment) in the fan socialization process (McPherson 1976). However, little concern has been given to sport fans' desires to connect themselves to "cultural continuities" (Arnould 2001) through sports activities. Arnould et al. (1999) argue that consumers have a desire for ritual action to secure cultural meanings of consuming mass-marketed consumer goods. The fan ritualization process enables them to link their sports experience to cultural values and meaningful social relations by acquiring and maintaining ritualized fandom.

Finally, we call for further investigation about the consumer ritualization processes in consumer research. Although several studies have examined ritualization strategies that consumers employ to link their consumption activities to cultural categories (decommodifying market products in the Thanksgiving Day (Wallendorf and Arnould 1989) or constructing descent groups to hand down inherited objects (Arnould et al. 1999)), consumer researchers have not systematically studied ritualization processes. As we argue in this paper, these consumer ritualization processes will be culture-specific because consumers symbolize and authorize their consumption experiences according to their own cultural values. It will be valuable to study the cultural differences in consumer ritualization processes concerning the same consumption phenomenon around world (e.g., sports fandom).

Men and Women Watching and Reading: Gender, Media, and Message Effects in Advertising

Veronika Papyrina, University of Western Ontario
June Cotte, University of Western Ontario

EXTENDED ABSTRACT

In marketing, gender is commonly used as a basis for market segmentation because it is one of a few variables that meet the criteria for successful strategy implementation: (1) gender is easily identifiable, (2) gender segments are accessible, and (3) gender segments are large enough to be profitable (Darley and Smith 1995). For advertisers, this practice suggests the importance of understanding how males and females respond to persuasive appeals because ad messages are one of the major ways of communicating with these consumer groups. Ads are typically targeted to one or both of these segments, and their effectiveness may depend on how males and females respond to the ads.

The goal of our study is to investigate gender differences in responses to advertising. Our basic thesis, which builds on the research by Meyers-Levy and Sternthal (1991) and Meyers-Levy and Maheswaran (1991), is that females are predisposed to a detailed information processing strategy whereas males are predisposed to heuristic message processing. Specifically, we examine how these predispositions interact with two characteristics of the ad, type of media and framing of the message, in determining males' and females' responses to advertising. These characteristics can support either detailed or heuristic processing, and our general argument is that an individual will respond to the ad more favorably when ad characteristics support the use of strategy this individual is predisposed to.

The Effect of Media. The existing literature (Chaudhuri and Buck 1995; Batra 1986) suggests that messages presented in print provide an opportunity for high message processing because in print individuals may choose an optimal pace to process the message, stopping to consider the arguments and elaborating on them at will. In contrast, broadcast ads are fleeting and not under the control of the viewer.

Integration of these findings with the notion of gender differences in information processing strategies suggests that print ads allow, while broadcast ads inhibit, the use of processing strategy females are predisposed toward, namely, detailed processing. The fact that print ads allow detailed processing, however, doesn't mean that they cannot be processed in a heuristic manner. In fact, we expect that males, by virtue of their inclination toward heuristic processing, will not use the opportunity to elaborate on print ads but instead will process them via a peripheral route similarly to how they would process broadcast ads. We further suggest that an individual will enjoy the experience of watching the ad to a greater extent when the ad permits him or her to use the processing strategy the individual is predisposed to. Thus, we hypothesize a two-way interaction between gender and type of media:

H_1 : Females will report a more favorable viewing experience for print than for broadcast ads.

H_2 : Males will report equally favorable viewing experiences for print and broadcast ads.

The knowledge of how individuals feel while viewing the ads is certainly interesting yet not very helpful for predicting consumer behavior. A more complete picture of gender differences in responses to advertising requires addressing the issue of ad effectiveness, which we conceptually define as the potential of an ad to

influence behavior and operationalize through a) intentions to buy a product; and b) likelihood of recommending the product to friends and/or family members (WOM communication). Specifically, we suggest that when a message is processed in a manner consistent with predispositions, it will not only result in a more pleasant viewing experience but will also be more effective:

H_3 : Females will report more intentions to a) purchase the product, and b) to engage in WOM communication for print than for broadcast ads (because they will process print ads in a detailed manner)

H_4 : Males will report equal intentions to a) purchase the product, and b) to engage in WOM communication for print and for broadcast ads (because they will process both in a heuristic manner).

The Effect of Message Framing. In addition to the effect of media, we also wanted to investigate whether males and females respond differently to positively and negatively framed messages. For the purposes of our study a negatively framed ad is one which emphasizes losses if one does not use the product, and a positively framed ad is one which emphasizes gains that result from using the product. Two studies (Levin and Gaeth 1988; Maheswaran and Meyers-Levy 1990) confirmed that people respond differently to positively and negatively framed messages. In general, it has been shown that when there is little emphasis on detailed processing, the ad is more persuasive when it is framed positively than when it is framed negatively; however, when detailed processing is emphasized, persuasion is greater when the message is framed negatively than when it is framed positively.

The implication of these findings for our research is that positively framed messages are more likely to be effective for males than for females because they resonate more with a heuristic, rather than with a detailed processing strategy. We expect this difference to be most salient for broadcast ads because in this case *both* type of media and message framing will support the processing strategy males are predisposed to and discourage the females' predisposed processing strategy. Thus, we suggest:

H_5 : Among all conditions, males will report the *most* intentions to a) purchase the product, and b) to engage in WOM communication for positively framed broadcast ads.

H_6 : Among all conditions, females will report the *least* intentions to a) purchase the product, and b) to engage in WOM communication for positively framed broadcast ads.

Study and Results. The experimental design involved three between-subject conditions: gender, type of media (print vs. broadcast) and message framing (positive vs. negative). Seventy undergraduate business students (34 males and 36 females) participated in our study.

The expected interaction between type of media and gender on viewing experience was close to the significant level ($p=.12$) with the means in the predicted direction. The results of simple effects

tests indicated that females reported a significantly more favorable viewing experience for print than for broadcast ads ($M_{\text{print}}=4.91 > M_{\text{broadcast}}=3.89, p < .05$), thus providing support for H_1 . Consistent with H_2 , there was no variation in males' responses to print and broadcast ads ($p > .90$).

Regarding ad effectiveness, the interaction effect between gender and type of media was marginally significant for the purchase intentions ($p < .10$) and highly significant for the likelihood of recommending product to friends and/or family members ($p < .05$). The simple effects tests revealed that females reported significantly more intentions to buy the product ($M_{\text{print}}=5.88 > M_{\text{broadcast}}=4.81, p < .05$) and to engage in WOM communication ($M_{\text{print}}=5.75 > M_{\text{broadcast}}=4.19, p < .05$) after viewing print rather than broadcast ads. Thus, hypotheses 3a and 3b are supported. Consistent with hypotheses 4a and 4b, no significant differences between males' responses to print and broadcast ads were found for either purchase intentions ($p > .40$) or WOM communication intentions ($p > .50$).

Testing H_5 and H_6 , we found that three-way interaction among gender, type of media, and message framing was marginally significant for intentions to buy the product ($p = .11$) and highly significant for intentions to engage in WOM communication ($p < .05$). As predicted by H_{5a} , males reported the highest intentions to recommend the product ($M = 4.43$) after watching positively framed broadcast ad. Consistent with H_6 , females reported the lowest scores on both intention to buy the product ($M = 3.70$) and likelihood to engage in WOM communication ($M = 4.61$) in this condition.

Taken together, these results suggest that an individual responds more favorably to the ad when its characteristics support the use of processing strategy this individual is predisposed to. Specifically, females enjoyed the experience of viewing the ad to a greater extent and reported more behavioral intentions when the ad encouraged detailed rather than heuristic processing. As regards males, they reported equally favorable responses to print and broadcast ads, however, when both type of media and message framing encouraged heuristic processing, males rated ad as the most effective.

Magnitude of Effects of Television Viewing on Social Perceptions Vary as a Function of Data Collection Method: Implications for Psychological Processes

L. J. Shrum, University of Texas–San Antonio

INTRODUCTION

Cultivation Theory

Numerous content analyses of television have shown that a number of constructs are consistently overrepresented on television relative to their real-world incidence. Such constructs include crime, violence, affluence, marital discord, and particular occupations such as doctors and lawyers, just to name a few (Gerbner et al. 2002; Lichter, Lichter, and Rothman 1994; O'Guinn and Shrum 1997). Cultivation theory posits that frequent viewing of these distortions of reality will increasingly result in the perception that these distortions reflect reality (Gerbner et al. 2002). Numerous studies have confirmed the predicted correlation between amount of viewing and beliefs congruent with the television portrayals. For example, TV viewing has been shown to be positively correlated with estimates of the number of doctors, lawyers, and police officers in the real world (Shrum 1996, 2001), the prevalence of violence (Gerbner et al. 1980; Shrum, Wyer, and O'Guinn 1998), and the prevalence of ownership of expensive products (O'Guinn and Shrum 1997; Shrum 2001). In addition, heavy television viewing has been shown to be associated with greater anxiety and fearfulness (Bryant, Carveth, and Brown 1981), greater faith in doctors (Volgy and Schwarz 1980), greater pessimism about marriage (Shrum 1999), greater interpersonal mistrust (Gerbner et al. 1980; Shrum 1999), and higher levels of materialism (Burroughs, Shrum, and Rindfleisch 2002).

Cognitive Processes and Cultivation

Recent work has begun to explore the cognitive processes that may underlie the cultivation effect. To understand the cognitive processes that underlie the effects of television is particularly important given the typically correlational nature of cultivation-type studies. Cultivation is for the most part a repeated exposure process and thus experiments are unlikely to capture effects, particularly with stable beliefs such as attitudes and values. Consequently, television viewing is typically measured rather than manipulated, and as a result is prone to problems associated with inferring causality. This highlights the importance of developing cognitive process models that can explain cultivation effects. Although such models cannot assure causality, they can increase confidence in inferring it. If models that specify particular conditions under which the effect does and does not operate (i.e., specifying mediators and moderators) can be tested and confirmed, it makes the proposed causal path more difficult to explain in terms of third-variable or reverse-causal mechanisms. This difficulty arises because not only must the reverse-causal or third-variable explanation account for the main effect, it must also account for the specific pattern of the interaction (Shrum 2002; Shrum et al. 2003).

Heuristic Processing Model of Cultivation Effects

One such model that has been developed has been termed the Heuristic Processing Model of Cultivation Effects (for a review, see Shrum et al. 2004). This model pertains specifically to the relation between television viewing and social reality judgments of set-size or probability (Shrum 1995). Examples include estimating—either for self or society—the probability or prevalence of crime, divorce, millionaires, and ownership of expensive products. The model has two general propositions. The first is that television viewing increases

construct accessibility. In particular, television viewing makes information pertaining to relevant constructs (i.e., crime, lawyers, swimming pools) more accessible, and more so for those who view relatively more television. The second general proposition is that the set-size and probability judgments typically used to test for cultivation effects are made by applying cognitive heuristics, in particular the availability (Tversky and Kahneman 1973) and simulation (Kahneman and Tversky 1982) heuristics. The use of cognitive heuristics is primarily due to three factors: 1) the types of judgments are for the most part memory-based (Hastie and Park 1986) and thus are made in real time by the recall of relevant information (exemplars), 2) the judgments are usually considered difficult, and 3) given that the data are typically collected via anonymous surveys, motivation to be accurate is often low. These conditions have been shown to facilitate the use of cognitive heuristics (Sherman and Corty 1984).

From these two general propositions, five specific propositions have been derived. These propositions are shown in table 1. In summary, the model posits that watching television results in the accumulation of numerous exemplars that are frequently portrayed on television. Consequently, these exemplars become more accessible in memory as viewing increases (Proposition 1). Because the types of judgments such as set-size and probability are often made by applying heuristics such as availability, then increased accessibility should result in increased estimates. Thus, television viewing increases accessibility, which in turn increases estimates, indicating a mediating role of accessibility (Proposition 2). However, because the accessible examples being retrieved in forming a set-size judgment such as the percentage of the work force that is lawyers or police officers are television examples, it is likely that most people would not consider these examples to be useful in forming real-world judgments. Thus, in order for the processes to occur as hypothesized, the television exemplars should not be source-discounted (Proposition 3). This lack of discounting would occur if the judgments are made relatively automatically without much effort expended in being accurate.

The final two propositions derive from conditions that have been shown to moderate the use of heuristics (for a review, see Sherman and Corty 1984). If, as hypothesized, people use the availability heuristic because they are not motivated to be accurate (i.e., not motivated to process extensively when answering), then increasing their motivation to process (be accurate) should reduce the reliance on judgmental heuristics, which should in turn reduce reliance on the accessibility of television exemplars, and thus reduce the effect of television (Proposition 4). Conversely, if people's ability to process information at the time of judgment is impaired (e.g., time pressure, distraction), it should increase the reliance on judgmental heuristics relative to conditions in which ability is not impaired and thereby increase the effect of television exemplars (Proposition 5).

As table 1 indicates, the first four propositions have been tested and confirmed across a number of studies. It is the fifth proposition, that ability to process information will moderate the cultivation effect, that is tested in the current study.

OVERVIEW AND METHOD

Ability to process information at the time of judgment is hypothesized to moderate the cultivation effect. Specifically, the

TABLE 1
Heuristic Processing Model of Cultivation Effects

Proposition	Supporting Evidence
1: TV viewing increases construct accessibility	O'Guinn and Shrum (1997); Shrum (1996); Shrum and O'Guinn (1993); Busselle and Shrum (2003)
2: Accessibility mediates the cultivation effect	Shrum (1996); Shrum and O'Guinn (1993); Busselle (2001)
3: TV exemplars are not discounted	Shrum, Wyer, and O'Guinn (1998)
4: Motivation to process information moderates the cultivation effect	Shrum (1996)
5: Ability to process information moderates the cultivation effect	The present study

relation between television viewing and judgment should be greater when ability to process is low than when it is high. To test this proposition, ability to process information was manipulated by varying the time pressure that respondents felt while providing their judgments. Moreover, the operationalization of time pressure was a novel one that may have implications for survey researchers interested in the psychological processes underlying response bias. Specifically, time pressure was manipulated via survey method. Respondents were randomly assigned to receive their survey either by telephone (high time pressure) or by mail (low time pressure). Pretests confirmed the differences in perceptions of time pressure, consistent with research showing that telephone respondents are usually unhappy with the length of telephone interviews and that interviewers often hurry respondents through the items (for a review, see Holbrook, Green, and Krosnick 2003).

Television viewing was measured via multiple measures of hours per day or week of viewing. Dependent measures consisted of having respondents estimate the prevalence of several constructs that have been shown to be overportrayed on television relative to their real-world incidence. Specifically, seven composite dependent measures were developed from items used in previous studies: Occupation (particular occupations), Vice (drug use, prostitution), affluence (ownership of expensive products), societal crime (e.g., national crime rate), personal crime (own risk of crime), personal crime in New York City (representing personal crime risk outside one's own neighborhood), and marital discord.

RESULTS AND DISCUSSION

The results were as expected. The strength of the cultivation effect was significant for six of the seven dependent variables in the telephone survey, and these relations held in the presence of multiple control variables. Only estimates of personal crime were uncorrelated with television viewing, and this finding was also expected.¹ None of the correlations between television viewing and the estimates were significant for the mail survey condition.² More to the point of testing Proposition 5, the magnitude of the cultivation effect was significantly greater in the telephone survey condition than in the mail survey condition.

These results provide support for proposition 5 of the model, namely, that ability to process information at the time of judgment will moderate the cultivation effect. Specifically, when respondents

were under more time pressure to respond, they showed a stronger correlation between the magnitude of their estimates and their level of television viewing, compared to those who were under relatively less time pressure. This finding is consistent with the reasoning that in the higher time pressure condition, respondents were more likely to process heuristically (off the top of the head³) and therefore more likely to rely on the accessibility of exemplars to construct their estimates. Because television viewing contributes greatly to the accessibility (of these particular) exemplars, television viewing is also related to the magnitude of the estimates.

The results also have implications for survey researchers interested in issues such as response bias. These results show that research method may affect the type of processing or the extent of processing when constructing judgments. Thus, not only does the survey method affect the purely descriptive aspect of the findings (e.g., the magnitude of the prevalence estimates was significantly greater in the telephone than in the mail condition), but also the theoretical applicability of the findings (e.g., differences in correlations between variables). Future research should consider investigating other possible instances in which differences in processing might result in different correlations between variables.

¹Work by Tyler (1980) indicates that people tend to use media (but not direct experience) to make judgments about societal risk (e.g., societal crime), whereas they tend to use direct experience (but not media) to make judgments of personal risk. This pattern of effects is termed the *impersonal impact hypothesis*. However, other research has shown that direct experience and television viewing can interact such that those with direct experience are particularly affected by the viewing of television crime and violence (Shrum and Bischak 2001).

²It is important not to draw strong conclusions from the lack of cultivation effects noted in the mail survey. Because of differential response rates, the power to detect relations was much less in the mail survey than in the telephone survey. Moreover, the magnitude of the correlations noted in the mail survey were similar (and in fact larger) than those found in meta-analyses (see Morgan and Shanahan 1996). The correlations in this study ranged from $r = .08$ to $r = .23$.

A Study of Effect Sizes in Marketing Experiments

Roger Marshall, Nanyang University

Loi Soh Loi, Nanyang University

Na WoonBong, Kyunghee University

ABSTRACT

An investigation is undertaken to empirically document the reported effect sizes of experiments reported in four leading marketing journals from the period 1985 to 1995, following a previous study concerned with the prior decade (Peterson, Albaum & Beltramini, 1985). Using omega-squared (ω^2), Pearson's coefficient (r) and Cohen's index (d) as measures of effect size, the results of 269 experiments, yielding a total of 1,399 experimental effects, were analyzed for the proportion of variance explained. Average incidence of reported ω^2 values has increased from 14% to 25% of experiments since the prior decade, but are still somewhat low.

Purpose of the study

In 1985 Peterson, Albaum and Beltramini conducted a meta-analysis of the effect sizes reported in a number of leading consumer behavior and marketing journals over the previous ten years. This paper reports a similar meta-analysis for the following decade, 1985-1995, allowing comparison of results of the two studies.

The major area of comparison is that of finding if there has been an increase in the proportion of experiments in the relevant journals that report effect size estimates, as measured by omega-squared (ω^2) values. There is also a comparison made between the mean ω^2 values in the two studies; that is, the average percentage of the variance in a response variable that was explained or accounted for by the statistically significant effect reported. In addition, the relationship between several different measures of effect size is also examined, as there is a literature to suggest a consistent difference between such measures should be expected (Oakes, 1986).

This paper, although not identical, is sufficiently similar to the Peterson *et al* study (hereafter called PAB) to allow some meaningful comparisons to be made. Less emphasis is placed, however, on the characteristics of the selected experiments (such as types of effects, experiments, subjects, and response variables), and more emphasis is placed on the comparison of the various measures of effect size, namely omega squared (ω^2), Pearson's coefficient (r) and Cohen's index (d).

RELEVANT LITERATURE

This brief review of the relevant literature touches first upon the importance of effect size to empirical research studies and how it is measured, then on the validity of meta-analyses. Finally, the PAB study –which provided the inspiration for the present work– is inspected in more detail.

Effect size and tests of significance

Effect size is defined as the strength of a relationship or the magnitude of a difference between variables (PAB). It is also referred to as the degree to which the phenomenon is present in the population or the degree to which the null hypothesis is false (Cohen, 1977). Effect sizes can be used both to facilitate the interpretation of research findings and to determine their practical implications (Cooper, 1981). The reporting of effect size is argued to be beneficial, especially so when reported as a supplement to significance tests.

The reason why it is beneficial to report effect size with tests of significance is because tests of significance alone do not accurately indicate of the magnitude of an effect. This is mainly because

tests of significance are not independent of sample size. In fact, it would be a serious case of abuse to even attempt to derive the effect size of rejected null hypotheses purely by analysis of the significance level. The difference between test statistics from different manipulations is by no means an indicator of the extent of the variance between the effect sizes of these manipulations. Indeed, the question becomes not so much if there is a relationship between data in a set, as much as how big the sample must be before a significant relationship is found. Research in various fields has been criticised as being over-reliant on significance testing at the expense of effect sizes, possibly due to the difficulties in quantifying effect size (Irvine, Miles & Evans, 1979).

There are clearly situations when a large effect size is not important. In a practical sense even a tiny effect size may be thought important when multi-million dollar sales is the dependent variable. Even in some academic work it could be argued that it is enough to show the existence of an effect, notwithstanding the size of it. This argument is hard to sustain, though, as even though a tiny effect might be considered "enough" by an author, surely the reader ought to have the prerogative of making that judgement themselves in the light of the sample statistics? The position taken here, then, supports the view of Peterson *et al*, that it is that it is generally better to include an effect size where the data is available as this provides information which should be revealed to the reader.

The need for a common measure of effect size

Various research models have been designed and various test statistics developed to measure effect size in experimental work, such as t , F or χ^2 . In order to apply meta-analytic procedures to these different variables, it is necessary to convert all the various summary statistics into a common measure in order to allow meaningful comparison across the studies.

The most widely used index of effect size is Omega squared (ω^2), which was popularised by Hays (1963) and expounded on by Cohen (1977). Using ω^2 , Cohen provided rough guidelines for categorising small ($\omega^2=0.01$), medium ($\omega^2=0.06$) and large ($\omega^2=0.15$) effect sizes. This was in an attempt to propose conventional effect sizes to help the making of informed decisions about effect size in socio-behavioural research. Two of the most common effect size measures selected, for the purpose of conversion from the various test statistics, are Pearson's Correlation (r) and Cohen's effect size index d . Guidelines for converting some of the summary statistics to r and d (Wolf 1986) are detailed in the Appendix. Cohen (1977) and Glass, McGaw & Smith (1981) provide guidelines for transforming less common statistics.

It is important to note at this point that while there are various measures of effect size, only ω^2 , r and d will be used in the study. It is also interesting to note that ω^2 is consistently 20-25% lower than r^2 (Oakes, 1986). The present study will, in passing, verify this observation.

Meta-analysis

Meta-analysis is an analysis of analyses (Glass 1981). It is a quantitative accumulation and analysis of various test statistics across studies, made without accessing the original study data. Rust, Lehmann and Farley (1990) challenged the assumption that, in meta-analysis, the sample of studies is a fair representation of all the work done in the relevant field. In their study, they proposed that

since journals tend to publish only statistically significant results, there could exist some publication bias, which they attempted to estimate. Similarly, Hedges and Olkin (1985) assume that since all statistically non-significant results have been omitted from the analysis, meta-analysis is not a justifiable method. However, this seems a rather unrealistic an assumption. Moreover, results of the 1990 study undertaken by Rust *et al* show that the estimated publication bias in meta-analyses is relatively small.

Previous research, the Peterson, Albaum and Beltramini (1985) study

The PAB study was conducted with the primary intention of empirically documenting the effect sizes in consumer behaviour research experiments reported in the marketing literature. In their study, articles published in seven major marketing journals or proceedings, from 1970 to 1982, were examined. Included in their sample were consumer behaviour experiments that employed at least one treatment manipulation. Furthermore, since ω^2 was selected as their measure of effect size, experiments selected also had to either report ω^2 , or contain sufficient information to permit its computation. A total of 311 articles or papers were identified in the six journals or conference proceedings as indicated in Table 1.

Of the 311 articles or papers, 115 of them contained 118 experiments that either reported ω^2 or contained sufficient information to permit its computation (only 14.4% were reported). Their study involved 1,036 effects, of which 475 were statistically significant at 0.05 or less. The scope of their study was extended to include the analysis of other variables that are potentially related to effect size, such as the type of experiment, the number and type of subjects and factors.

The four characteristics that were found to be significantly ($p \leq 0.01$) correlated with ω^2 are type of effect (main or interaction), type of experiment (field or laboratory), type of subjects and type of response variable (behavioral or others). These four characteristics were subjected to an analysis of variance in order to examine their relationship to effect size. The results of the analysis showed that the type of experiment and type of effect can be expected to affect the effect size of the experiments. For example, field experiments can be expected to report larger effect sizes than laboratory experiments; main effects are associated with higher effect sizes than interaction effects. The type of the experimental subjects is also related to the type of response variable. For example, non-college students can be expected to have a higher probability of increased response homogeneity than college students.

RESEARCH METHOD

The same general approach used in PAB is also used here, to conduct a type of meta-analysis of effect sizes of consumer behavior experiments published in selected, leading marketing journals. The period of interest covers the years from 1985 to 1995.

The sample

Four leading marketing journals were chosen in this study; the *Journal of Marketing* (JM), the *Journal of Marketing Research* (JMR), the *Journal of Advertising Research* (JAR), and the *Journal of Consumer Research* (JCR). These were among the journals examined in the PAB study. It was determined not to follow the lead of PAB, however, and include a psychology journal or conference proceedings, but stick to the main-line marketing publications.

Articles were included in the study based on the following guidelines. First, the article must involve a consumer behaviour experiment. Second, the article must either report ω^2 values or, when ω^2 is not reported, have sufficient statistical information so that ω^2 , r or d can be computed. Third, only results of main effects of experiments are to be considered in cases where ω^2 values have to be computed (this was due to resource limitation rather than to any academic reason). Finally, only test statistics from chi-squared-tests (χ^2), t -tests and F -tests were included.

185 suitable articles from the four marketing journals were identified using these criteria. These articles contained 269 consumer behaviour experiments altogether, and from these experiments a total of 1,399 unique sets of statistical values of experimental effects were gleaned. The *Journal of Marketing* provided 16 articles (8.7%) and 16 experiments (5.6%); the *Journal of Marketing Research* 44 articles (23.8%) and 59 experiments (22%); the *Journal of Advertising Research* 14 articles (7.6%) and 15 experiments (5.6%); and the *Journal of Consumer Research* 111 articles (60%) and 179 experiments (66.5%).

Methods to compute effect sizes

As the aim was to examine effect sizes as measured by ω^2 , r or d , these values had to be computed, using statistical information obtained from the articles themselves, for experiments that did not report them. Three of the most common measures of effect size have been chosen as effect size estimates of the experimental results— ω^2 , r and d values. Where sufficient information is provided, the chi-squared statistic (χ^2), the t -statistic or the F -statistic can be converted into the above-mentioned effect size measures via various formulae.

RESULTS

Distribution of the incidence and level of effect reporting between journals

Incidence of reported effects

Table 2 contains the distribution of reported effects, of both articles and experiments, between the journals in the sample. Thus, overall, 24.5% of the significance levels reported were accompanied by an effect size. Table 3 presents the distribution of the experimental effects in the various journals according to their reported levels of significance, whilst Table 4 shows the distribution of reported ω^2 values.

It can be seen from Table 4 that the majority (60.8%) of the reported ω^2 values fall between 0.01 and 0.09. A little more than 5% of the reported ω^2 values are less than 0.01, which, according to Cohen, renders them of no real effect. Large ω^2 values, of not less than 0.3, constitute a relatively small percentage. Following Cohen's suggested categorization of ω^2 values into 'small', 'medium' and 'large' effects, the distribution of the ω^2 values can be seen in Table 5.

It can also be seen that the 'small effects' category forms the majority (40.63%) of the ω^2 values reported, with 5% of these values having no experimental effect of importance. The average of these 352 ω^2 values is 0.102, with a standard deviation of 0.109.

Estimating ω^2 values from articles and experiments that do not report ω^2

There were 1,047 experimental effects for which ω^2 were not reported. Table 6 shows the distribution of these experimental

effects among the three types of statistical tests. Of the 1,047 experimental effects which did not report ω^2 , there was only sufficient information to compute 397 values of ω^2 . This amounts to only 37.92% of the reported experimental effects. The distribution of these estimated ω^2 values, computed from test statistics t and F between, first, the journals and then the test statistics, are shown in Tables 6 and 7. Note that Chi-squared tests were not included because no formula to convert the χ^2 statistic into ω^2 values could be found.

It is useful to consider the ω^2 statistics for this group of effects according to Cohen's suggested categorization of effect size, as previously. This is shown in Table 9, which (as in the previous case) shows the majority of unreported effect size values fall into the category of 'small effects'. The mean of the estimated ω^2 value is 0.11 and the standard deviation is 0.13. The aggregate mean of all the effect sizes as measured by both reported and estimated ω^2 values is also 0.11.

Distribution of experimental effects measured by Pearson's r

The second measure of effect size used was Pearson's r . It was found that 3.79% of the effect size values based on Pearson's r are less than 0.1 and so can be considered as having no effect at all. 49.61% of the effect size values fall under the range of 'small effect,' while 13.81% belong to the 'large' effect category. Distributions between journals and by effect size are shown in Tables 10 and 11.

Distribution of experimental effects measured by Cohen's d

The third—and final—measure of effect size used was Cohen's d . The distribution of effect size values, as measured by d and shown

in Tables 12 and 13, is not as varied as was the case for ω^2 and r ; the majority of the d values still fall within the category of 'small effect', however. There is, once again, a small number of effect size estimates that are so small as to be negligible (4.92%).

Relationship between ω^2 and r^2

Corresponding values of both ω^2 and r^2 from the same experiments were used to examine this relationship between these two measures of effect size. Regression analysis yields information about a close relationship; $r^2=0.94$ ($F=20920.90$, $p<0.001$). Furthermore, the calculated effect size, based on ω^2 , is very large ($\omega^2=0.98$).

DISCUSSION

General level of effect size reporting

About one quarter (24.54%) of the experiments studied reported ω^2 . There are several possible reasons for not reporting effect size. Clearly, some test statistics employed by researchers may not allow for the use of ω^2 as a measure of effect size. There are also other measures of effect sizes besides ω^2 which might have been used. Nevertheless, it is tempting to speculate that ω^2 values may go unreported because of their small values. Researchers may be unwilling to disclose these small effect sizes as they will show highly significant results to be significant only because of the large sample size of the studies. In fact, this supposition is not born out

here, as the incidence of no, small, medium and large effect sizes is very similar between those experiments reporting effect sizes and those not (see Tables 4 and 9). The fairly low rate at which ω^2 values are being reported could also be indicative of ignorance, a general lack of interest in discovering the extent to which an effect is significant or a genuine belief that only the existence of an experimental effect is important, no matter what its size.

For all this, the present study has at least found an increase in the number of experiments that report ω^2 since the 1985 study conducted by Peterson *et al.* Only 14.4% of the total experiments studied in the period between 1970 and 1982 reported ω^2 values, while 24.63% of the experiments we studied reported ω^2 . This suggests an increasing awareness of the importance of effect sizes as a complement to the traditional statistical tests of significance and the possibility that the PAB paper had an impact.

Cohen's Categorization of effect size

An analysis of the distribution of ω^2 values among the 'small', 'medium' and 'large' effect categories provides an insight into the nature of consumer behavior experiments. The results reported above are consistent with the opinion that effect sizes reported in consumer behavior experiments are usually quite small. The majority (60.80%) of reported ω^2 values documented here fall between the range of 0.01 to 0.09, while less than 10% of the experimental effects have values greater than 0.3. This could be attributed to the

fact that many of these studies are subject to unidentified and uncontrollable effects or, more simply, that the social science view that explaining even a very small part of a human's behavior is very difficult (but, nonetheless, worthy). The mean value of ω^2 in the work considered is 0.102, with a standard deviation of 0.109. This means that, on the average, the value of ω^2 for a given experimental effect in the consumer behavior literature is about 10%. This confirms what was earlier mentioned about effect sizes being generally small for behavioral experiments. 5.4% of reported ω^2 values reported here were 0.009 or less. This small number of studies poses a problem because it could be that the reporting of these insignificant effects would not serve to enhance the quality of the report but rather would reduce the credibility of the study.

Articles and experiments that do not report ω^2

The majority (55.2%) of the estimated ω^2 values fall between the range of 0.01 and 0.09 as expected. The calculated mean value of ω^2 is 0.11 with a standard deviation of 0.13. This is very close to the mean value of significant effects (0.107) calculated in the study conducted by Peterson *et al* (1985).

All three measures of effect size consistently reveal a small percentage of the experimental effects to be insignificant. Although this percentage is quite small (ranging from 3.79% to 6.13%), it should be noted that this percentage is taken out of experimental effects that do report statistically significant results from various statistical tests (e.g. *F*-tests, *t*-tests or χ^2 tests). There is a clear message here, though, for the reviewers of marketing journals.

Relationship Between ω^2 and r^2

The results here do show that ω^2 and r^2 indeed have a strong linear relationship. However, it was found that ω^2 was consistently less than r^2 by 6%, rather than the 20-25% reported by Oakes (1986). This is rather important, as the consistency of the relationship would otherwise make it possible to estimate values of ω^2 given the values of ω^2 and r^2 , and vice versa.

A possible reason for the discrepancy between this study and Oakes (1986) may lie in the fact that while r^2 can measure the proportion of the total variance explained by an experimental effect only if there is a linear relationship between the independent and dependent variables, ω^2 is not subject to the same limitation. Suppose there is no evidence of linearity between the independent and dependent variable, r^2 will be less accurate (compared to ω^2) in measuring the proportion of the total variance that is explained by the experimental effect. Therefore, the similarity between ω^2 and r^2 may be affected by the presence (or even the strength) of linearity between the dependent variables and the independent variables in the experiments.

Further research

There are several questions left begging by this study, which leaves the way for others to continue to expand the research. One such avenue follows immediately from the comments above. An investigation of how the strength and presence of linearity between the independent and dependent variables of an experiment affect the presence (as well as strength) of linearity between corresponding values of ω^2 and r^2 would clearly provide an interesting research study.

A second challenge lies with the sample bias problem. Of the 1,399 experimental effects considered here, more than half (59.47%) were taken from the Journal of Consumer Research. Whilst it is true that the nature and focus of this journal centres on consumer behaviour research, there still seems some justification for a claim of sample bias. As is so often the case with longitudinal studies of

this type, a problem arises because precise replication of an original study may ignore other, emerging journals. Further research, then, to cope with publication bias more rigorously and to expand the work to other journals, would be of value.

Social Hubs: A Valuable Segmentation Construct in the Word-of-Mouth Consumer Network

Andrea C. Wojnicki, Harvard Business School

EXTENDED ABSTRACT

As marketers reflecting on word-of-mouth (WOM), we consider highly involved experts including *opinion leaders* and *market mavens* (Childers 1986; Feick and Price 1987) as key segmentation constructs in identifying those consumers who are responsible for the dissemination of marketplace information. But there is another class of consumers that is at least as influential in this domain that is not yet on marketers' radar screens. These are the consumers who direct social traffic—we will call these consumers "social hubs." Social hubs provide access to a large number and broad variety of consumers. The objective of this research is to introduce these social hubs.

There are three elements included in the proposed literary definition of a social hub. Social hubs:

1. have relationships with many people;
2. frequently connect these people together; and
3. do so for personal pleasure, as opposed to some tangible reward.

A summary of the propositions for social hubs is as follows:

P1: The social hub scale questions will be positively correlated with the name recognition exercise, but the *survey scale will be optimal* in identifying social hubs.

P2: The social hub construct will be positively correlated with the *market maven* and *opinion leader* constructs, but will also have distinct characteristics from these constructs.

P3: Social hubs are *not* identifiable in terms of *demographics*.

P4: Social hubs are *extroverts*.

P5: In comparing the opinion leadership and the social hub scales, the opinion leadership scale is a better predictor of the *likelihood* of engaging in WOM, while the social hub scale is a better predictor of the *number* of people told.

Method and Topline Results—Study One

Six final questions were determined to best represent the social hub construct:

1. I very much enjoy learning new things about different people. (5-point scale ranging from *strongly disagree* to *strongly agree*)
2. I very much enjoy meeting new people.
3. Compared to other people, I am very friendly.
4. I go out of my way to introduce people to each other.
5. I enjoy participating in small talk.
6. Compared to other people, I have (*far fewer* to *far more*) friends and acquaintances.

These final questions were incorporated into a large online survey commissioned by a "Fortune 50" firm. Compensation in the form of a modest cash sweepstakes encouraged participation and 6,530 members of a paneling firm completed the survey. The final survey included the above questions, the opinion leadership and market maven scales (Childers 1986, Feick and Price 1987), as well as Gladwell's exercise and several other trait items.

For the social hub scale questions, Cronbach's alpha of .85 indicates appropriate internal validity. Principle component analysis established discriminant validity as well as correlations with the market maven ($r=.38$), and opinion leader components (at $r=.20-.22$, $p<.001$ for all).

A second potential method of identifying social hubs adapted from Gladwell (2001) was also considered. For this method, 100 randomly generated surnames from a local telephone book were listed in the survey, and subjects were asked, "From this list of 100 names, please check those that are shared by someone you know." The dependent variable was the total number of names recognized by each subject. Results ranged from zero to 87, with a mean of 12.0.

The correlation between the scale questions and the name recognition exercise is significant due to the large sample size ($p<.001$), but the effect size is marginal ($r=.18$). Of the three elements comprising the literary definition of social hubs, both the scale questions and the name recognition exercise address the first element. The second element is directly addressed with the scale while it is not addressed by the name recognition exercise, providing some support for proposition 1.

Proposition 2, that the social hub construct is positively correlated with the opinion leader and market maven constructs, was established via principle component analysis and component correlations.

Most demographic and media habit indicators have low correlations with the scale and the name recognition exercise and do not warrant serious consideration as indicators of this new construct. However results indicate that the social hub scale is correlated with the psychographic constructs of *extroversion* ($r=.52$) and *altruism*, the third element of the literary definition ($r=.39$, $p<.001$ for both). Given these analyses, it is concluded that the social hub scale is successful in establishing the first four propositions.

Method and Results—Second Study

An invitation to participate in this experiment was posted on a website for members of a university subject pool. Subjects who completed the experiment ($N=179$) were mailed a five-dollar money order.

At the beginning of the survey, a restaurant consumption scenario was described. Subjects were then asked how likely they would be to tell someone about this restaurant and how many people would you tell, followed by the social hub and opinion leadership scale questions.

To address proposition 5, low, medium, and high segments were created for each of the two scales, with medium defined as being within one standard deviation of the mean. Considering the dependent variable of the *number* of people you would tell, high social hubs would tell significantly more people ($+3.3$, $p=.003$) than low social hubs. However, this difference is not significant for opinion leaders. Therefore, proposition 5 is supported.

Summary

The objective of this research was to identify social hubs. Based on the literary definition, results indicate that a new six-item unidimensional scale is a viable method of identifying social hubs and that social hubs are correlated with but sufficiently distinct from opinion leaders and market mavens.

The value of social hubs in the consumer network was highlighted with the social hub scale being established as a superior

predictor of the number of people told about a consumption experience. This result exemplifies the significance of these social hubs in the marketplace, who can ultimately provide marketers with access to many consumers.

The Interaction between Order of Elicitation and Event Controllability on the Self-Positivity Bias

Chien-Huang Lin, National Central University
Ying-Ching Lin, National Chi Nan University
Priya Raghurir, University of California at Berkeley¹

ABSTRACT

This paper studies the underlying reason behind the self-positivity bias. As events perceived to be controllable implicate self-esteem more so than less controllable ones, they are more prone to self-positivity effects. On the other hand, as less controllable events do not implicate self-esteem, only when the order-of-elicitation cues comparative (versus absolute) judgments about the self, does the self-positivity effect emerge. When information about "self" is asked first, the bias is attenuated, but when others' estimates are elicited prior to self-estimates, the bias re-emerges even for uncontrollable events. Implications for health marketing are offered.

Across a range of domains, people judge that they are less at risk of a negative event than the general population: "self-positivity" (Perloff and Fetzer 1986), and have a greater likelihood of a positive event occurring than the average person: "unrealistic optimism" (Weinstein 1980). Consumer researchers are increasingly examining self-positivity effects in people's perceptions of own risk in contexts ranging from AIDS (Raghurir and Menon 1998) and breast cancer (Luce and Kahn 1999) to Hepatitis C (Menon, Block and Ramanathan 2002) and depression (Keller, Lipkus, and Rimer 2002). As reducing the self-positivity bias can favorably affect preventative action, an important consumer welfare goal is to reduce the self-positivity bias.

Prior research has shown mixed effects regarding key moderators of the self-positivity bias: the perceived controllability of the event, and contextual cues (Helweg-Larsen and Shepperd 2001). Specifically, while the bias has been found to be strong for events perceived to be controllable, there are mixed results for events that are perceived to be uncontrollable (Harris 1996). Context effects, such as order-of-elicitation, have been found by some researchers who demonstrated a stronger self-positivity bias when estimates of an average person were elicited prior to self-estimates (Hoorens and Buunk 1993), though this effect was difficult to replicate (Otten and van der Pligt 1996).

This paper examines the interactive effects of order-of-elicitation of self- and other- estimates of risk, and perceived controllability of an event, on the self-positivity bias. As events perceived to be controllable implicate self-esteem more so than less controllable ones, they are more prone to self-positivity effects (Weinstein 1980, Lin, Lin, and Raghurir 2003). On the other hand, we argue that as less controllable events do not implicate self-esteem, only when the order-of-elicitation cues comparative (versus absolute) judgments about the self, does the self-positivity effect emerge. When information about "self" is asked first, the bias is attenuated, but when others' estimates are elicited prior to self-estimates, the bias re-emerges even for uncontrollable events. This is because the "other-first" order condition, changes the default "self as standard" to an artificial "other as standard." When the standard of comparison is an "other" person, then even though the events are not within an individual's control (and do not implicate self-esteem), the process of comparison leads to self-enhancement, and the re-emergence of the self-positivity bias. This paper reconciles conflicting findings

regarding controllability, and order-of-elicitation and suggests that the underlying cause of self-positivity is to enhance self-esteem. Implications for health marketing are offered.

THEORETICAL FRAMEWORK

Self-Positivity Bias. The tendency for self-enhancement is well documented in the domain of positive and negative events (Weinstein 1980), and, has, in fact shown to serve a functional purpose (Taylor and Brown 1988). There is ample evidence that people underestimate their own health risks as compared to the risks they attribute to others and this leads to unsafe health-related behaviors (Lin et al. 2003, Menon et al. 2002, Perloff and Fetzer 1986, Raghurir and Menon 1998).

H1: The Self-Positivity Bias: Estimates for self will be higher than those of others for positive events and lower than those of others for negative events.

The Moderating Effect of Perceived Controllability. Weinstein (1980) conjectured that "the greater the perceived controllability of a negative event, the greater the tendency for people to believe that their own chances are less than average; the greater the perceived controllability of a positive event, the greater the tendency for people to believe that their own chances are greater than average" (p. 808). This is because people should strategically use the mechanism of believing that they are less at risk than others, if they can attribute this lower risk to their own actions. Therefore, the more controllable that an event is perceived to be the more possible it is that self-positivity beliefs will improve a person's self-esteem. Weinstein (1980) showed that in the domain of negative events, the more controllable the event, the greater the bias (Harris 1996; Helweg-Larsen and Shepperd 2001). However, this relationship was not found for positively valenced events, and the evidence linking controllability and the optimism bias for positive events remains mixed (Harris 1996). It is possible that this may be due to differences in controllability in the events used to test positive and negative events (with negative events perceived to be more controllable, due to an overall optimism bias). In this study, we examine the effect of controllability for positive and negative events and predict:

H2: The self-positivity bias will be stronger the more controllable an event.

Order Effects. Order-of-elicitation is a well-researched contextual cue in behavioral frequency and attitude judgments. One of the routes through which order affects judgments is that responses to a prior question are used to construct a later judgment particularly when people do not have well-formed memory-based information that they may use instead (Raghurir and Johar 1999). Prior literature has found inconsistent effects of order on the self-positivity bias. Hoorens and Buunk (1993) found that the bias was stronger when others' estimates were elicited first,² while Perloff and Fetzer (1986) did not.³

²Alcoholism, AIDS, heart attack, cancer, and suicide.

³Hypertension, cancer, heart attack, alcoholism, divorce, venereal disease, and being mugged; no self-positivity effect for car accident, nervous breakdown, and diabetes.

¹This research was funded through the National Science Council of Taiwan awarded to the first author.

In an attempt to explain these inconsistent effects, Otten and van der Pligt (1996) suggested that these effects are due to whether the “self” or the “other” is used as a comparison standard. They argue that the self is a habitual reference point with a rich representation and unique features. Eliciting others’ estimates prior to self-estimates leads to an “others as standard” perspective, and cues comparative processing: *i.e.*, self-estimates reflect estimates relative to others. On the other hand, eliciting self-estimates prior to others’ estimates leads to the “self as standard” perspective where judgments about oneself are based on absolute judgments of risk. Consistent with this argument, they show that the self-positivity bias is greater when comparative estimates are elicited directly (*e.g.*, “How much are you at risk compared to an average person?”) rather than indirectly (*e.g.*, elicitation of separate estimates of risk for an individual and an other person). They found evidence for order effects with indirect comparisons (Study 1), but not when relative estimates were elicited (Study 2). In a similar vein, Raghurir and Menon (1998) also showed that when contextual cues increased the salience of memory-based information about oneself (similar to the use of self as standard), the self-positivity bias was attenuated.

We now suggest that perceived controllability moderates the effect of order. We propose that when events are perceived to be controllable, individuals are motivated to enhance their self-esteem irrespective of the order-of-elicitation, and therefore, the self-positivity bias will be robust. When events are less controllable, however, the self-positivity bias should be contingent on the order of elicitation of self-other risk estimates. It may not be present when people are using the “self as standard”—*i.e.*, when self-estimates are elicited prior to others’ estimates. Self-positivity would be stronger when people make comparative judgments: when the “other person” is a standard of reference, *i.e.*, when others’ estimates are elicited prior to self-estimates.

- H3: Order will not affect the self-positivity bias for controllable events, but for less controllable events, the self-positivity bias will be stronger when others’ estimates are elicited prior to self-estimates.

STUDY METHOD

Study Participants. Six hundred and twenty one undergraduate students from Taiwan participated in this study. They were assigned at random to one of the eight between-subjects conditions. Due to partial non-response, the usable sample size was 606 (Males=330, females=276).

Design: We used a 4 (target person: self=S, same-sex best friend=F, average undergraduate=UG, and average person=AP) x 2 (event outcome: positive vs. negative) x 2 (degree of controllability: Low vs. high) x 2 (order: Self first, Average person first) mixed design, with the target person manipulated within-subjects, and the remaining factors manipulated between subjects. The four events were chosen on the basis of a pilot test ($n=40$) that showed that marriage and divorce were perceived to be more controllable than getting cancer and winning the lottery. In the “self first” condition, subjects rated their own risk followed by F, UG and AP (as in Raghurir and Menon, 1998). In the “average person first” condition, the order was reversed.

Study Procedure. Participants were assigned at random to one of the 8 (4 events x 2 order) conditions. After a brief introduction to the study, stating that it was related to prospects of life events among undergraduates, participants estimated the likelihood of an event occurring in the future from 0 to 100 for each of the four targets: S, F, UG and AP.

Manipulation Checks. Each individual rated the similarity of the 3 different targets from 0 to 100, with higher numbers indicating

greater similarity. Perceived controllability was measured using a 7-point rating scale (Not at all/ Very under my control). The questionnaire ended with a range of demographic and other questions, after which participants were debriefed, thanked, and dismissed.

RESULTS

Manipulation Checks-Similarity. Overall, the friend was rated as most similar to oneself ($M=50.39$), followed by the UG ($M=43.34$), with the AP rated the least similar ($M=37.43$; target effect: $F(2, 1208)=99.427, p<0.001$). The 3 (target other) x 2 (order of elicitation) repeated-measures ANOVA revealed a main effect of order ($F(1, 604)=11.517, p<0.001$), while the interaction effect was not significant ($p>0.1$). Given the significant order effect, we confirmed that the manipulation was significant in both order conditions (both p 's <0.01).

Controllability. As desired, getting divorced was perceived to be more controllable than getting cancer in the domain of negative events ($M_s=4.97$ vs. 3.91 ; $F=(1, 304)=7.88, p<0.0001$), and having a happy marriage was perceived to be more controllable than winning a lottery in the domain of positive events ($M_s=4.83$ vs. 1.9 ; $F=(1, 298)=3.00, p<0.0001$).

Overall Analysis. We used a 4 (target person) x 2 (event outcome) x 2 (degree of controllability) x 2 (order) ANOVA to test our hypotheses. Complete ANOVA results are provided in Table 1. Predicted effects are analyzed below. As per H1, there was an overall main effect of target person ($F(3, 1797)=8.04, p<0.0001$). The effect of target interacted with degree of controllability ($F(3, 1797)=23.17, p<0.001$) as predicted by H2. A significant 3-way interaction between target, valence and controllability, suggests that the self-positivity bias may be different for each of the four events ($F(3, 1797)=42.40, p<0.001$). Finally, as predicted by H3, this three-way interaction was itself contingent on the order in which judgments were elicited ($F(3, 1797)=5.37, p<0.01$). Means, by condition, are presented in Table 2, and depicted graphically in Figure 1. Below, we analyze the means to test H1-H3.

H1 predicted that estimates for negative (positive) events would be lowest (highest) for one’s self, while H2 predicted that this pattern would be stronger for the more controllable events of “happy marriage” and “divorce” and weaker for the less controllable events of “cancer” and “lottery.” Given the target x valence x controllability interaction, we examine the pattern of self-positivity for each of the four events.

Happy Marriage. The main effect of target was significant for estimates of a happy marriage ($F(3, 152)=66.11, p<0.001$). These were the highest for one’s self ($M=71.59$), and were followed by one’s best friend ($M=63.67$), UG ($M=54.32$), with the lowest estimate for AP ($M=48.74$, all means significantly different from each other at $p<0.05$).

Divorce. Similarly, estimates for divorce were the lowest for one’s self ($M=24.73$), and were followed by the three other targets ($M_F=29.48, M_{AP}=39.25, M_{UG}=44.43$, all means different from each other at $p<0.05$; $F(3, 152)=33.96, p<0.001$).

Cancer. Mean estimates for contracting cancer were lowest for one’s friend ($M=20.69$). These estimates were significantly lower than the other three estimates: ($M_S=25.44, M_{UG}=26.17, M_{AP}=34.78$; target: $F(3, 149)=24.02, p<0.001$). AP estimates were higher than the other three estimates, but F and UG estimates were not different from each other.

Lottery. The only event where self-positivity was not observed was the lowest perceived control event: winning a lottery. Estimates for winning a lottery were no different for one’s friend ($M=14.76$), oneself ($M=15.88$) and UG ($M=18.11$), which were all

lower than the AP's estimates ($M=24.50$; $p's < 0.05$: Target: $F(3, 142)=4.99$, $p < 0.01$), reflecting self-negativity.

To summarize, as predicted by H2, for the two controllable events, we observed patterns of self-positivity (H1), but these patterns were weaker for the less controllable events. For "contracting cancer," we observed self-positivity only against unknown targets. For "winning the lottery," we found no evidence for self-positivity. The reason for this is analyzed *post hoc* below.

H3: Order Effects. H3 argued that order effects would emerge for uncontrollable event with the self-positivity effects stronger when other estimates were elicited first. This is because eliciting others' estimates changes the default "self as standard" judgment process where judgments are based on absolute estimates of risk, to an "other as standard" process, where judgments are based on relative judgments of risk. To test H3, we conducted 4 (target) x 2 (order) ANOVAs for each of the four events. Means for both order conditions across the four targets for each of the four events are provided in Table 2, and followed by ANOVA results. These results show a straight replication of self-positivity in both the order conditions for the two controllable behaviors (Target effect: $F(3, 459)=45.23$ and 65.73 for "divorce" and "happy marriage" respectively, both $p's < 0.01$, also see Figure 1). Self-estimates do not differ as a function of the order in which they are elicited ($M_s=25.42$ and

24.03 for "divorce" and 72.96 and 70.28 for "happy marriage" in the self-first and other-first conditions respectively; see Figure 1). They reflect positivity versus the UG and AP (both contrasts are significant for negative and positive events in both order conditions, $p's < .05$). Importantly, order-of-elicitation does not interact with the target factor, suggesting that the strength and direction of self-positivity does not differ depending on the order in which estimates are elicited.

On the other hand, for the less controllable events, a complex pattern emerges. As predicted by H3, the main effect of target, while significant, is contingent on order (interaction $F(3, 459)=4.76$ and 4.21 for "cancer" and "winning the lottery" respectively, both $p's < 0.01$). The first estimate elicited is the same in the two order conditions, irrespective of whether it is an estimate for one's self or for the AP (cancer $M=35.27$ vs. 31.13 and Lottery $M=15.59$ vs. 15.88 for self versus AP respectively). For "cancer," self-estimates are significantly higher when they are elicited first: the "self as standard" condition ($M=35.27$) versus last when the "other" is a standard of reference ($M=16.35$). This eliminates the self-positivity bias in the self-first condition where estimates are based on absolute rather than comparative judgments of risk.

Post Hoc Analysis of Lottery. As a self-negativity effect was not predicted for the positive-uncontrollable behavior ("winning

the lottery”), we examined whether this effect was contingent on an individual’s absolute level of self-estimate. To assess this possibility, we did a median split of people’s self-estimates for winning the lottery. Half ($n=73$) of the respondents reported a 0 likelihood of winning the lottery, whereas the other half ($n=72$), reported a mean self-likelihood=31.99. A 4 (target) x 2 (order) x 2 (self-estimate: low/ high) ANOVA revealed a three-way interaction ($F(3, 423)=3.08, p < .05$). Those individuals who estimated their own likelihood of winning the lottery as 0, showed self-negativity effects irrespective of whether the self-estimates were elicited first

($M_s=7.84, 18.34, \text{ and } 35.21$ for F, UG, and AP respectively, all means significantly different from each other at $p < .05$) or whether self-estimates were elicited last ($M_s=5.64, 8.70, \text{ and } 11.66$ for F, UG, and AP respectively, with estimates for UG directionally different from F and AP, but other means different at $p < .05$).

On the other hand, those who estimated that they had a non-zero likelihood of winning the lottery, were prone to self-positivity effects when other estimates were asked first: the “other as standard” condition cuing comparative judgments ($M_s=44.72, 19.18, 15.00, \text{ and } 23.32$ for S, F, UG, and AP respectively, with self

FIGURE 1

Study 1 Results: Order of elicitation (Self First or Self Last) affects self judgments only for less controllable events (Lottery Data is shown for those who estimated non-zero probability of winning)

estimates higher than those of the remaining three targets at $p < .05$). However, when self-estimates were elicited first (“self as standard”), estimates did not differ across the four targets ($M_s = 25.21, 25.22, 28.43, \text{ and } 30.55$ for S, F, UG, and AP respectively). Note how the self-positivity pattern is stronger when other estimates are elicited first (“other as standard”), similar to the results for cancer (see Figure 1, for the means for those who estimated a non-zero probability of winning the lottery).

DISCUSSION

To summarize, results replicate the self-positivity bias in the domain of controllable events for both positive and negative events. Manipulations of the order in which estimates were elicited showed that in the high-controllability events, the bias was robust to order-of-elicitation. However, when events are less controllable, then respondents are less likely to show self-positivity, unless their frame of reference is “other focused,” leading to comparative judgments.

Theoretical Contributions. A primary contribution of this paper is to demonstrate that under conditions where individuals are motivated to maintain or enhance their self-esteem (controllable events), self-estimates of likelihood are obdurate for both negative and positive events. A parsimonious explanation for the pattern of results is that self-positivity is a strategic device that people use to maintain or enhance their self-esteem.

The relationship between perceived controllability and self-positivity bias may have important theoretical and practical implication (Harris 1996). Self-positivity due to perceived controllability may be psychologically advantageous, promoting positive mental health (Taylor and Brown 1988). On the other hand, exaggerated control perceptions, may themselves have negative consequences

(Skinner 1995), such as complacency, rather than effective goal-relevant behavior (Weinstein 1989). Either way, the propensity to perceive events to be controllable may make it one of the more pervasive causes of optimistic bias. This suggests that the bias may be related to the illusion of control and over-confidence, an area we offer for future research. Practically, it may be difficult to successfully challenge optimistic expectations rooted in powerfully held individual’s control beliefs, even when it is desirable to do so (Harris 1996).

Are Self or Other Estimates more tensile? Prior literature has shown that self-perceptions of risk are more amenable to change than perceptions of others’ risk as a function of contextual cues, such as the accessibility of AIDS-related behaviors (Raghubir and Menon 1998), and the number and type of Hepatitis C behaviors presented in an advertisement (Menon et al. 2002). Our study found that for less controllable events, self-judgments, when elicited first were similar to other-judgments when those were elicited first and, were accordingly, different from self-estimates when those were elicited last. Our results show that self-estimates were more tensile than others’ estimates. Identifying the conditions under which self-estimates are robust, and others-estimates are tensile are offered as an area for future research.

Cross-Cultural Issues. Cross-cultural variations in self-positivity have been noted. This paper replicated the self-positivity bias in a country with a “collectivist” orientation: Taiwan (Hofstede 1990), suggesting that even if it is lower for people from a collectivist orientation (relative to an individualistic orientation), it remains significant. Heine and Lehman (1995) showed that the belief that positive events are more likely to happen to one’s self (relative to one’s peer) was significantly reduced for Japanese relative to Canadian individuals. Similarly, Chang (1996) found that across

multiple measures, Chinese individuals were more pessimistic than were their American peers. However, Sedikides, Gaertner, and Toguchi (2003) have recently suggested that self-positivity may be a universal phenomenon, but the domain in which it is seen may differ for those from individualistic versus collectivistic cultures.

Similarity Bias. Prior literature shows that people have a tendency to project information about themselves onto others because of the operation of the false consensus bias (Hoch 1988; Perloff and Brickman 1982). This leads them to believe that others behave in ways similar to themselves (Menon, Raghurib, and Schwarz 1995). Although previous research on the self-positivity bias has found a similarity bias, the findings of self-positivity bias between self and close friend (or parent and siblings) are mixed (Helweg-Larsen and Shepperd 2001). Perloff and Fetzer (1986) found subjects perceived a specific target (their closest friend, sibling, or same-sex parent) as equally invulnerable as themselves. However, others have found the self-positivity bias with respect to one's best friend (Menon et. al. 2002, Raghurib and Menon 1998). Perloff and Fetzer (1986) argue that when predictions were being made for vague targets (*i.e.*, the average undergraduate student), respondents chose a person who fit their stereotype of someone to whom the given event typically happens. This suggests that the bias could be stronger when there is an unknown (versus known) target used as a comparison other.

We found that while, on the whole, judgments were more positive for an other person the more similar the other person was to oneself, there were some divergences from this linear ordering. For example, the self-positivity bias in the divorce condition was not entirely inversely related to the similarity of another person to oneself. A possible explanation for our results was that our study was conducted with a sample from a collectivist country (Taiwan) where there exist strong cultural inhibitions against expressing a negative thought against a known and similar other person in one's peer group (Heine and Lehman 1995). However, alternative explanations involving cognitive factors (such as the presence of memory-based information about the best friend) are possible. Delineating the targets relative to which self-positivity will occur is an interesting area for future research.

Implications for Consumer Welfare. The self-positivity bias occurs for both positive and negative events (Weinstein 1980). If the self-positivity bias operates for low chance outcomes, such as winning a lottery, such people may consider themselves as "the lucky ones," overestimate the likelihood of pleasant outcomes and be more likely to over-spend on these products. Further, to the extent people have exaggerated views of their own invulnerability or positivity, they may be less likely to effectively deal with the occurrence of negative events, and the non-occurrence of positive ones. Self-positivity biases in personal risk perceptions are important because they may hinder efforts to promote risk-reducing behaviors (Raghurib and Menon, 1998, Menon et al. 2002). Our results suggest that making the self-as-standard along with highlighting the low controllability of an event can help attenuate the self-positivity bias.

SPECIAL SESSION SUMMARY

The Impact on Preferences of Consumer Access to Information In Online Shopping Environments

Donna L. Hoffman, Vanderbilt University

SESSION OVERVIEW

The Internet makes available numerous information sources that consumers may draw on as they search for information and construct choices about commercial offerings. These information sources include online product reviews (either by peers or experts), and uncensored in-depth product information on a variety of Web sites, among many other sources.

Recently, consumer behavior researchers have begun a close examination of how certain characteristics of the different information sources consumers may access in online shopping environments impact consumer behavior. For example, scholars have investigated the role of electronic recommendation agents on preference construction (Häubl and Trifts 2000) and how consumer control over the flow of information online affects decision quality (Ariely 2000). It has also been demonstrated that compelling online experiences are created through information that strikes the right balance between engagement and effort (Novak, Hoffman, and Yung 2000). Other research has investigated the mechanisms by which Web site backgrounds influence product choice (Mandel and Johnson (2002), and the conditions under which online information interruptions may increase online activity (Xia and Sudharshan 2002). Turning the question around, Moon (2000) examined the factors that influence consumers to reveal information about themselves in online environments.

In this special session, three papers utilized rich theoretical frameworks to examine the impact on consumer preferences of specific information characteristics available in online shopping environments.

The paper by *Hoffman, Novak, and Wan* examined the impact of various information cues of online product reviews on consumer preference in an online retailing environment. In a series of online experiments, they manipulated consumer mindset, consumer purchasing goals, reviewer characteristics, and review characteristics. Results suggested that processing goals differentially affect the interaction between product review description and cue congruency.

Gershoff, Mukherjee and Mukhopadhyay argued that fundamental differences in depth and richness of preference structures for that which consumers love compared to hate or rate neutrally leads to differences in perceived diagnosticity of revealed preferences. Two of their studies showed that loved alternatives are perceived as more diagnostic than hated, and hated more than neutral, for agent prediction of own and others' future ratings and informativeness of tastes. A third study revealed that a prospective agent who agrees with a consumer on loved compared to hated, and hated compared to neutral alternatives, is more preferred, perceived as more similar, and less likely to have agreed by chance.

The last paper in the session was by *Trifts and Häubl*. They investigated under what conditions a vendor, such as an online shopping site, can benefit (most strongly) from providing direct access to uncensored information about its competitors' offerings. Specifically, they examined the effects of facilitating such access on consumer preference for the firm at varying levels of the ambiguity of the information environment and of consumer search cost. The results of two experiments suggested that providing access to competitor information enhances both perceived trustworthiness and consumer preference for the firm, and that these

effects increase in magnitude as ambiguity increases and as the cost of search rises.

The session concluded with moderated discussion led by *Pat West*.

SESSION ABSTRACTS

"The Impact of Online Product Review Characteristics on Consumer Preferences"

Donna L. Hoffman, Vanderbilt University

Thomas P. Novak, Vanderbilt University

Fang Wan, Vanderbilt University

To date, most research on online recommendations has focused on the computer algorithms underlying recommendations (e.g., Ansari et al. 2000); or the impact of recommender system on consumers' search effort and decision quality (Häubl & Trifts 2000; Lynch & Ariely 2000;). However, little research has examined the impact of human-generated recommendations, such as peer reviews, on consumers' preferences. Such reviews comprise an important component of the online consumer decision making process. For example, forty-four percent of respondents in a Bizrate.com survey consulted opinion sites prior to making a purchase and fifty-nine percent reported that consumer-generated reviews were more valuable than expert reviews (Piller 1999).

Even a cursory examination of peer generated product reviews on Internet retailing or opinion forum sites such as Amazon.com or ePinions.com, respectively, make clear that online product reviews contain complex information cues made further complex by the consumer's ability to manipulate the information. Thus, reviews include information about not only the product, but also the reviewer (expertise, credibility, popularity), and the review itself (review valence).

Further adding to the complexity, some of these information cues are unique to the online environment. For example, Web sites usually provide consumers with rankings of the reviewers based on characteristics such as the number of reviews each has written; consumers also have ready access to previous reviews and can search review databases by reviewer or other variables. Additionally, consumers can easily access the number of Web site users who trusted a particular reviewer and determine how useful a particular product review was to other web users. Unlike word-of-mouth in traditional formats, online product review systems enable consumers to track the historical reviewing record of a particular reviewer and group evaluations according to how other consumers perceive and evaluate a certain product review or reviewer simultaneously. Despite the wide appeal of online product reviews, in applied commercial settings, the assemblage of these complex and unique information cues has been largely ad hoc and online managers have little understanding of the impact of various cues on consumer behavior.

This research attempts to address these issues by constructing a series of studies that systematically investigate the impact of combinations of these cues on product preference and related consumer behavior outcomes in an online retailing environment.

Research on the effects of source characteristics (Petty & Cacioppo, 1986) and cue congruence (Chaiken & Maheswaran 1994; Maheswaran et al. 1992;) motivates our examination of the

joint impact of multiple source cues on consumer preference. Because previous research has found that consumers' shopping experiences may be utilitarian or hedonic (Chandon, Wansink & Laurent 2000; Mano & Oliver 1993) and product information can be similarly categorized as hedonic/emotion-laden utilitarian, we examined how hedonic/utilitarian processing goals, together with a hedonic/utilitarian production review affected the impact of source cue congruence on preference.

We hypothesize that when consumers are primed to adopt a hedonic processing goal and product information is hedonic, they will be more likely to process the information in an experiential style (Chen and Chaiken 1999; Epstein 1994). In this mode, individuals rely on simple "heuristics" or feelings regarding the stimuli to derive their judgments. Thus, we expect that compared to positive information, negative or incongruent information will disrupt the process of relying on "heuristics" and confront consumers with inconsistent information to resolve. Such disruption and confrontation will lead to more effortful information processing.

However, when consumers are primed to adopt a utilitarian processing goal and presented with utilitarian product information, they will be more likely to engage in "systematic processing," (Chen and Chaiken 1999). This mode of processing (cf. Epstein's (1994) rational system, Petty and Cacioppo's (1986) central route of processing, and Garcia-Marques and Mackie's (2001) analytical processing) involves careful attention to the specifics of the situation and the explicit use of a criterion or rule to make judgments (Garcia-Marques and Mackie, 2001). This bottom-up systematic mode of processing is controllable, productive, deliberative and relatively slow. Therefore, positive source cues are not necessarily favored over negative or incongruent cues, as we expect when product information and processing goals are hedonic congruent. On the contrary, consumers in this mode are more likely to pay more attention to the review itself than to source cues.

We designed an interactive experiment in an online environment that allowed us to test these and related theories. In the first study, we examined how 1) mindset priming (experiential vs. rational); 2) purchasing goal (hedonic vs. utilitarian); 3) product review descriptions (hedonic vs. utilitarian); and 4) reviewer/rating cue congruence (positive cues, negative cues, mixed-incongruent-cues) affected consumer preference ratings, evaluations of review and reviewer influence, involvement, processing mode, mood, Internet demographics, and a series of response latencies for each phase of the experiment.

The reviewer/rating cue congruence factor incorporated three different combinations of six source cues that mirrored those commonly found in Internet retailing and opinion Web sites. Four of the cues were reviewer cues: 1) number of reviews written (many/few), 2) reviewer expertise in the product category (expert/non-expert), 3) number of consumers who trusted the reviewer (many/few), and 4) usefulness of review as rated by other consumers (high/low). The remaining two cues were rating cues: 5) reviewer's rating (high/low), and 6) average of all reviewer ratings (high/low). Levels for Reviewer the consistency between his/her rating of the product and the average rating of other reviewers (inconsistent/consistent).

We constructed the three levels of the reviewer/rating reviews by assembling the six source cues as follows: level 1) congruency across cue domain (cues 1-4 positive; cues 5-6 positive); level 2) incongruity across cue domain, but congruity within cue domain (cues 1-4 negative; cues 5-6 positive); level 3) incongruity among reviewer cues (positive), incongruity within rating cues (different combinations for cues 1-4; cue 5 positive; cue 6 negative).

As an illustration from the large number of significant findings, results from the first study suggest that processing goal affects

the interaction between product review description and cue congruency. For respondents with a utilitarian processing goal, the particular review description did not affect cue congruence. That is, regardless of the product review, respondents with utilitarian processing goals made less positive product evaluations in incongruent cue conditions than in congruent cue conditions.

Interestingly, the results are more complex for respondents primed with a hedonic goal. For these consumers, how the review was framed did affect the impact of cue congruence. When the review was framed hedonically (consistent with their processing goal), incongruent source cues still negatively affected product evaluations compared to congruent cues. However, when the review description was utilitarian (inconsistent with processing goal), only negative source cues affected product evaluations negatively.

"Loves, Hates, and In-Betweens: The Role of Preference Structures in Agent Choice"

Andrew D. Gershoff, Columbia University

Ashesh Mukherjee, McGill University

Anirban Mukhopadhyay, Columbia University

Prior to making product choices, consumers often go online to consider the advice of agents, who may be either professional critics (e.g., citysearch.com) or lay people (e.g., all-reviews.com). Since agents often provide contradictory advice, consumers must evaluate which agent is more likely to share their tastes and preferences. Previous research suggests that consumers use information about past opinion agreement between themselves and prospective agents as an important cue for agent choice. Recent work by Gershoff, Mukherjee, and Mukhopadhyay (2003) extended this result by showing that not all past agreements are weighted equally. Instead, agreement on extreme-rated alternatives was found to be perceived as more diagnostic than more moderately rated alternatives (the extremity effect) and agreement on extreme positive alternatives was found to be perceived as more diagnostic than agreement on extreme negative alternatives (the positivity effect). These results are particularly interesting in light of prior research that suggests negative word-of-mouth information is generally perceived to be more diagnostic than positive (Herr, Kardes, and Kim 1991).

The present research examines the underpinnings of these extremity and positivity effects. Drawing on research on positivity and negativity effects (Ahluwalia 2002; Skowronski and Carlson 1987) and recent studies on learning and memory for preferences (Herr and Page 2003; Hoeffler, Areilly, and West 2003), it is argued that extremity and positivity effects in diagnosticity of preferences arise from a fundamental difference in the depth and richness of positive and negative aspects of individuals' preference structures, whereby people know more about alternatives they love (and the reasons why they love them), than those that they hate or are indifferent about and perceive loved compared to hated or neutral alternatives as more informative about their own and others' underlying preferences. Consequently, consumers choose, are more confident in the abilities of, and see themselves as more similar to, agents who match them on their extreme positive opinions than those who match their extreme negative or moderate opinions.

These hypotheses were tested in a series of three completed studies. Study 1 examined perceptions of consumers' loved, hated, and neutrally rated alternatives as informative to others for understanding their preferences and predicting future ratings. Using five point scales (1-star to 5-stars), two hundred subjects rated fifty posters from an Internet site. Then, depending on condition, they were shown three of their hated (1-star), neutral (3-star), or loved (5-star) posters and told that another person would use these to predict the subject's ratings for a new set of posters. A fourth condition allowed subjects to choose posters of any rating level to

show the potential agent. Consistent with hypotheses, subjects rated greater confidence in the agent's ability to predict their ratings in the new set, and greater informativeness about their own preferences in the loved compared to hated, and hated compared to neutral conditions. Additional analysis favors the argument that subjects' perceive loved alternatives as more informative because they provide information about underlying preference structure and not because they are more diagnostic due to base-rate frequency.

Study two examined consumers' perceptions of the degree to which another's loved, hated, and neutrally rated alternatives affects confidence in their ability to predict the other's ratings for future alternatives and informativeness about underlying preferences. Ninety subjects were assigned to one of three conditions and shown only three posters that another individual (from Study 1) had rated either as loved, hated, or neutral. Subjects provided estimates of ability to predict the other's ratings and the degree to which the three posters were informative about the other's preferences. Consistent with the hypotheses confidence in predicting others' ratings was greatest in the loved, compared to hated or neutral conditions. Informativeness about the other's underlying preferences was similarly greater in the loved compared to hated, and greater in the hated compared to neutral conditions.

Study three was a with-in subjects design that examined consumers' perceptions of the degree to which agreements and disagreements between a consumer and a prospective agent on loved, hated, and neutrally rated alternatives influences confidence in the prospective agent, ratings of the informativeness of the agreement or disagreement, and knowledge about the prospective agent's preferences and tastes in the category. Sixty subjects used an on-line interactive tool that had four phases of data collection. In the first phase, subjects provided lists of movies they rated as 1-star, 3-stars, and 5-stars. In the second phase, subjects made a series of choices between two prospective agents who each provided their own ratings (1, 3, or 5 stars) for one of the movies the subject had provided (in the first phase). Agent choices were presented in random order and manipulated in a full-factorial design such that subjects made thirty-six pair-wise choices representing all possible combinations of 1, 3, and 5 star agreements and disagreements between the agent and the subject. In the third phase, prospective agents, described as having given 1, 3, or 5 star ratings to one of the movies that the subject had given a rating of 1, 3, or 5 stars, were sequentially presented to the subjects. All nine possible combinations of agent and subject ratings were provided in random order. Subjects rated each agent in terms of ability to act on the subject's behalf, perceived similarity, and inferences about the prospective agent's underlying preference structure. A final phase collected subjects beliefs about the percentage of others in the population who agreed with their ratings of each movie they provided in phase one.

Consistent with the hypotheses, agreement on loved alternatives was preferred in both choice and preference measures to agreement on hated or agreement on neutral ratings. Subjects rated their similarity in tastes with a prospective agent to be greater when the agent loved the same movie as the subject than when the agent hated the same movie as the subject. Further, subjects rated that they were more likely to love the same movies as the agent when there was agreement on a loved film, compared to their ratings that they were likely to hate the same movies as the agent when there was agreement on a hated film. Finally, subjects rated that it was more likely that the future agreements between the subject and the agent would be due to chance when there was agreement on a hated compared to a loved movie. As in study one, analysis of subjects' base rate expectations of agreement for loved versus hated movies rules out an alternative explanation for perceived diagnosticity

based on inferences about base-rate agreement for loved versus hated alternatives.

“The Effects of Facilitating Access to Competitor Information on Consumer Preference”

Valerie Trifts, Dalhousie University

Gerald Häubl, University of Alberta

From a consumer perspective, an important advantage of internet-based shopping environments relative to traditional retail settings is the drastically reduced cost of search for information about market offerings (Bakos 1997; Häubl and Trifts 2000). Low search costs in electronic environments may also benefit vendors in that this provides them with the opportunity to observe, record, and process—in an automated fashion—aspects of their competitors' product offerings. The potential for firms to use this information to strengthen customer relationships is an emerging research area. This paper identifies conditions under which it may be beneficial for a firm to facilitate access to *uncensored* information about its competitors' offerings.

We develop a model of the processes through which the facilitation of access to competitor information influences consumer preferences, both by affecting the perceived attractiveness of the firm's offerings relative to those of its competitors, and by enhancing the trustworthiness of the firm. In addition, we examine how such an action on the part of a vendor influences preference through its effect on consumer information search. We adopt a signaling framework (Spence 1974), and incorporate prior research on trust (Morgan and Hunt 1994) and attribution theory (Jones and Davis 1965; Kelly 1973) as a basis for theorizing about how consumers perceive, interpret, and respond to a firm's act of facilitating access to information about its own competitors.

Recent work by Trifts and Häubl (2003) provides preliminary evidence of the possibility that a retailer's act of providing access to uncensored competitor price information may result in enhanced preference for that vendor, especially if the latter's prices are neither clearly superior nor obviously inferior to those of its competitors. Furthermore, these initial results suggest that the positive effect of facilitating access to competitor's prices on consumer preference is mediated by the perceived trustworthiness of the retailer.

In the present paper, we investigate under what conditions the facilitation of access to competitor information—about price and quality attributes—tends to be most beneficial to a firm. Specifically, we examine how the proposed effects of facilitating such access on consumer preference vary as a function of (1) the degree of ambiguity of the information environment (Muthukrishnan 1995) and (2) the cost of obtaining information about competitors' offerings directly from these vendors (Moorthy, Ratchford, and Talukdar 1997). Two experiments were conducted using a simulated internet shopping environment. In both studies, subjects were asked to shop for vacation packages at a number of online travel sites.

In Experiment 1, we examined the effects of facilitating access to uncensored competitor information on consumer preference at different levels of ambiguity of the information environment. In a 2⁴ full-factorial mixed design,¹ facilitation of access was manipulated within subjects, where one of the two focal travel agents facilitated access to competitor information (“FC-yes”) and one did not (“FC-no”). Ambiguity was manipulated between subjects. In the *low-ambiguity* condition, the FC-yes and the FC-no site offered vacation packages for *identical* resorts at each destination, and the

¹Two of the four factors were between-subjects control factors pertaining to different aspects of stimulus presentation order.

packages were described in great detail. In the *high-ambiguity* condition, the *FC-yes* and *FC-no* travel agents offered packages for *different* resorts, and only resort names and prices were provided. This manipulation of ambiguity addressed two key aspects of information ambiguity, completeness and the comparability. After a practice task, subjects were asked to choose, for each of four destinations, the vacation package offered by one of the competing travel sites.

Our key prediction is that the positive effect of facilitating access to information about competitors' offerings is stronger when the ambiguity of the information environment is high rather than low. In addition, we propose the process hypothesis that, as the information environment becomes more ambiguous, consumers' choice of travel site is affected more by their perception of the vendors' trustworthiness, and less by their assessment of the attractiveness of the sites' offerings. The results of Experiment 1 provide support for both of these hypotheses. First, even when the *FC-yes* travel agent's vacation package was objectively inferior to that of its *FC-no* competitor, a significant portion of subjects chose the *FC-yes* site, but the latter's choice share was significantly greater when ambiguity was high (about 25%) than when ambiguity was low (about 5%). In addition, a significant interaction effect between perceived trustworthiness of the *FC-yes* firm and the level of ambiguity on relative site preference suggests that a vendor's trustworthiness is a stronger mediator of the effect of providing access to competitor information on consumer choice when ambiguity is high rather than low.

Experiment 2 focused on the role of consumer search cost in conjunction with the facilitation of access to competitor information, and on the effects of these two factors on the extent of consumers' independent information search and on relative vendor preference. We used a 3 x 2² full-factorial between-subjects design.² Participants were asked to evaluate a travel site, relative to its competitors, that facilitated access to (1) all competitors ("*FC-yes/high*"), (2) one competitor ("*FC-yes/low*"), or (3) no competitor ("*FC-no*"). In the *low-search-cost* condition, the experimenter's page contained direct links to descriptions of the relevant travel packages offered by all competitors. In the *high-search-cost* condition, the experimenter's page provided links to the different competitors' search-query pages, from which subjects had to re-enter the search criteria in order to obtain the description of a specific travel package offered by a particular firm. Our key hypothesis here is that, by facilitating direct access to uncensored information about its competitors' product offerings, a firm reduces the need for consumers to obtain this information elsewhere and is, thus, perceived by consumers as a more useful source of market information. Preliminary analyses suggest that the facilitation of access to competitor information does in fact result in less search and in greater preference for the firm facilitating such access. Further analyses will reveal whether these effects are contingent upon the continued provision of access to competitor information, or whether the effects may persist into subsequent shopping encounters in which the retailer no longer facilitates such access.

ROUNDTABLE
**Using Qualitative Data Analysis-Part II: Issues in Representations
Suggestions for Positioning Interpretivist Consumer Research**

Craig J. Thompson, University of Wisconsin-Madison

A roundtable session on qualitative consumer research methods, organized by Eric Arnould and Melanie Wallendorf, provided the inspiration for this note. As the discussion unfolded, the question of how to position interpretivist consumption research for journal submission, most especially to the *Journal of Consumer Research*, came to loom large.

The standard answer to this question is “always remember you are not studying context X but some broader theoretical issue that is manifested in context X.” The point being that interpretivist researchers, particularly less experienced ones, often become overly wedded to the details of their research context and, hence, their analyses suffer from being too descriptive, too particularistic, and lacking in theoretical abstraction. While the spirit of this advice is right on the money, it does not acknowledge that in fact, a certain kind of contextual framing can (and does) work exceedingly well. Conversely, the rhetorical emphasis on “theoretical positioning” is too vague on a very key question—what kind of theory? As I now see it, interpretivist papers published in *JCR* (as well as related journals like *Journal of Marketing*, *Journal of Public Policy & Marketing*, *Journal of Retailing*, *Consumption, Markets & Culture*) are organized around one of three different positioning strategies. They are discussed below.

High theory positioning

These papers engage a significant theoretical debate about consumption issues that is playing out in another related source field (i.e., sociology, anthropology, media/cultural studies) and then build a case for the debate’s relevance to the *JCR* audience. This positioning is the high-risk and high effort strategy. To succeed, an author has to become very well-versed in this core debate and its unique theoretical history and then translate (and adapt) the key issues to the *JCR* literature. Pragmatically, papers positioned this way can be a very hard sell because some reviewers will not be up on the core debate (and will demand much more immediate *JCR* relevance) while others will push the authors to make an original contribution to the source field. In other words, here is your rock and here is your hard place.

This cautionary tale aside, a high theory positioning strategy can sometimes work quite well. Doug Holt’s (1998) article “Does Cultural Capital Structure American Consumption,” drew from a theoretical debate underway in sociology. However, this article also demonstrated that this sociological perspective could revitalize consumer research on class and consumption. Consumer researchers, from across paradigms, are using ideas drawn from that paper. As a few other examples, Belk, Wallendorf, and Sherry (1990) and Firat and Venkatesh (1995) respectively won *Journal of Consumer Research* articles of the year with papers positioned along high theory lines.

In sum, strategy 1 is probably the toughest road to publication and, with rare exceptions, it certainly is not the strategy young scholars should adopt for their dissertations or journal submissions. On the plus side, an analysis following a high theory path can foster considerable intellectual growth, it can generate a plethora of ideas for future research, and when it all comes together really well, a pathbreaking article can result. At some point, I think writing a paper of this type is a worthwhile challenge but it is probably best treated as a down stream intellectual project.

Theory-driven categorical positioning

This positioning strategy tends to get lost in the standard advice of “remember you are not studying a context but a larger theoretical question.” This oversight is consequential because this second strategy is a straightforward and highly accessible approach (for both readers and writers). It has a much higher probability of success than strategy 1.

A lot of very rigorous and quite influential interpretivist consumer research has focused on broad categories of consumption phenomenon such as servicescapes, brand communities, brand relationships, subcultures of consumption, gift giving, etc. None of these domains are explanatory theories or even models per se. They describe a general category of phenomenon (i.e., there are many different brand communities, different kinds of servicescapes etc). You can mine these areas and develop a stream around them. For example, gift giving has generated a considerable amount of research that explores a nexus of psychological, social, and cultural dynamics related to these ritualized acts of consumption (see Belk and Coon 1993; Fisher and Arnold 1990; Joy 2001; Otnes, Lowery, and Kim 1993; Mick and DeMoss 1990; Ruth, Otnes, & Brunel 1999; Sherry 1983; Wooten 2000).

However, this positioning is still very much theoretical in nature. For example, if you take up the topic of gift giving, you must also become familiar with an expansive and extensive cross-disciplinary literature that has theorized its various dimensions and your analysis must forge theoretical linkages to these canonical studies. Let’s take the case of brand communities (Muniz and O’Guinn 2000; McAlexander, Schouten and Koenig 2002). A researcher does not simply observe a variety of websites that are devoted to a particular brand—like Saab or Apple—and “see” a brand community. Rather, he/she must invoke theoretical knowledge to recognize an underlying commonality. In the case of brand community, the parallel phenomenon is fan communities, which have been studied extensively in the media studies literature. In a brand community, the brand functions in the role that a celebrity, musical group, movie, or television show serves for fan communities by providing a common point of interest and social linkage among a broad swath of consumers.

This kind of theoretical transfer is an excellent way to develop relatively novel marketing and consumer behavior concepts (e.g., brand communities) that can still be linked to a substantial body of theory. Such theoretical linkages can offer new perspectives on important theoretical questions (i.e. what is the nature of consumer-brand relationships?; how do communities emerge in a postmodern consumer society?) and they have the potential to resonate with a broader readership; factors which usually equate to a high impact article.

The set-up for articles positioned in this manner is very clean. You first make a case that this category of consumption is worth researching because it represents a socio-culturally significant practice (e.g., gift-giving) or it reveals a latent cultural tension or a nascent cultural trend (e.g., Rob Kozinet’s (2002) ethnography of the Burning Man festival) or that it is a likely place to discover something new and important about consumer motivations, choices, and experiences (see Celsi, Rose, and Leigh 1993; Price and Arnould 1993). You can invoke some combination of the three rationales and it does not hurt if your categorical phenomenon has

economic significance. Next, you make the case that your specific case is a good example of the category (i.e. river rafting is a good example of the extended service encounter; skydiving is a good example of high-risk leisure consumption). [This justification should be fairly self-evident; if not, rethink your general category].

After the set-up, you develop a systematic and nuanced interpretation using concepts most often drawn from sociology, anthropology, and social psychology, many of which may have already been applied in other *JCR* studies. In this positioning, a theoretical concept like ritual or cultural capital is simply a tool of explication. Reviewers sometimes get confused on this point. I have seen situations where an author uses a construct like ritual as an analytic tool and a reviewer will say, “oh, we already know about rituals” or “what is your contribution to the vast literature on rituals?” If you are aware of the distinction between a high theory contribution (i.e., we are using this consumption setting to create a general theory of ritual) versus a categorical positioning (i.e., we are using ritual to explicate something interesting about this broad class of consumption phenomenon), you can easily circumvent such objections.

Finally, the paper needs to end on a strong note that cashes out the key implications of its findings and offers some kind of compelling theoretical pay-off.

Arnould and Price’s (1993) “River Magic: Extraordinary Experiences and the Extended Service Encounter” is an excellent example of a theory-driven, categorical positioning strategy. Their positioning was two-fold: extraordinary experiences are an interesting and important class of consumption experiences and, second, that many kinds of extended service encounter (an important economic category) seek to deliver them. Then, Arnould and Price (1993) theoretically unpacked a specific kind of magical extended service encounter—river rafting—using the anthropological concepts of liminality, ritual, rites of passage, and communitas. Finally, they delivered a theoretical pay-off by arguing that, contra existing theory, consumers’ satisfaction with the extended service encounter had little to do with their initial expectations; rather the drivers of satisfaction emerge through consumption experiences. Bingo, we have a very well-received and imminently readable *JCR* paper.

As a segue into the third positioning strategy, please note that it would have been possible, for Arnould and Price, using *their same data*, to have turned their article on its head. Arnould and Price’s (1993) main story could have been that the dominant theoretical explanation of customer satisfaction needed to be revised in a substantive way (a point derivable from prior studies suggesting gaps in the dominant theoretical view) and that the extended service encounter is a good categorical context for developing this new perspective. This alternative positioning strategy is one that Fournier and Mick (1999) developed with much skill (and success) using longitudinal data on consumers’ experiences with technology.

To clarify, I am *not* saying that Arnould and Price (1993) should have positioned their paper around satisfaction. If Arnould and Price had not been as adept at building a case for the CB relevance of river rafting/extended service encounter, however, they would have probably gotten editorial pressure to significantly reposition the paper. More generally, reviewers tend to either reject outright or demand a major repositioning (typically classed as a risky revision) whenever authors do not build a convincing case for the significance of their research domain. The critique usually says something like, “the implications you have buried in the discussion are really the important story but these ideas do not seem well integrated into the paper and they need to be pushed much further. So, lead off with these concluding points and redo the lit review and analysis to further enrich your new starting premises.”

At that point, you may face a choice (depending on the editor’s predilections). Do I seek to strengthen the case for the relevance of my categorical context and find a way to make the analysis seem more insightful and interesting or do I invest the effort needed to radically reposition the paper? I believe the answer to this question lies in positioning strategy #3.

Reconceptualizing Marketing’s core theoretical constructs

Customer satisfaction, brand equity, advertising persuasiveness, customer relation management, consumer lifestyles are some of marketing’s core concerns and each has a specific body of theory to explain them. These theories may have been originally borrowed from psychology and other fields but they have been developed and thoroughly integrated into the marketing canon. Some of the most highly cited and award-winning papers in the interpretivist literature have used qualitative data to develop a novel experiential or cultural perspective on these chestnut constructs (Fournier 1998; Holt 1997; Mick and Buhl 1992; Ritson and Elliott 1999). This kind of theoretical positioning tends to be a much easier sell to reviewers and to be embraced by a broader swath of readers than the high theory approach (strategy one) but it can pose some pitfalls which probably would not arise with a theory-driven categorical positioning (strategy 2).

For one thing, you really need to do your homework on the mainstream theoretical construct. This positioning strategy will inevitably invoke critical concerns that your argument is based upon a theoretical strawman. So, be very careful to recognize the sophistication and nuances of the core marketing theory being engaged and, second, the kinds of domains where it is most (and least) applicable. Per this latter point, the least contentious way to challenge an established theory is to make a sound case that it systematically ignores some important aspects of a given phenomenon be it satisfaction (Fournier and Mick 1999) or brand loyalty (see Fournier 1998) or consumer value systems (Holt 1997; Thompson and Troester 2002). Although I find the “blind researchers and the elephant” allegory philosophically problematic, the rhetorical claim that an established theory is not wrong only incomplete tends to invoke less strident counter arguing.

Now let’s assume you have submitted a paper positioned via strategy #2 (i.e., theory-driven categorical positioning) and the reviews come back suggesting a massive repositioning and reanalysis. If the proposed new positioning points you toward a chestnut marketing issue, revising along those lines could well be the most efficacious means to negotiate the review process and there is a reasonable chance that your overall disciplinary impact will be increased.

Alternatively, let’s say, you are undertaking a study (or dissertation) that has been designed around a strategy #2 and, during the write-up, you realize that your findings have a lot to say about some marketing chestnut. Under that scenario, I suggest you seriously consider turning the paper (or dissertation) on its head. An immediate benefit is that your perceived marketing relevance and (personal marketability) will go way up. Once again, your path to publication is also likely to become less arduous and the disciplinary impact of the study may well be enhanced. The down side is that you will have to do a lot of rewriting (your whole lit review might have to change) and your analysis will likely have to be reworked considerably to systematically model the how, when, and why aspects of the new focal questions.

If the project is a dissertation, odds are you will not have the time to undertake such a massive transformation. So, write up the project as designed and get your degree. You can undertake the inversion when you start converting the dissertation into a journal article.

Thanks much for reading through this and I hope you found some value in it.

SPECIAL SESSION SUMMARY

Understanding the Evaluation of Future Events: The Impact of Psychological Characteristics Both of the Events and of the Evaluators

Jane E.J. Ebert, University of Minnesota

SESSION OVERVIEW

Most decisions consumers make have some form of time component, such as choosing between a cheeseburger (to satisfy a short-term craving) or a granola bar (in line with their long-term diet choice), deciding whether to pay for the gym monthly or yearly, buying financial investment products with delayed returns, or deciding how frequently to visit the dentist to ensure healthy teeth into old age. Intertemporal choice research helps us understand consumer behavior in such decisions. Most mainstream research in this area has focused on measuring the rates at which people tend to discount the future. However, in recent years a renewed interest in understanding the psychological processes underlying discounting has developed (e.g. Liberman & Trope, 1998; Metcalfe & Mischel, 1999; Ebert, 2001; Frederick, Loewenstein and O'Donoghue, 2002). The papers in this session contribute novel work of this type focusing on psychological characteristics of the events to be evaluated (paper 1), of the evaluators themselves (paper 3) and on the interplay between the two (paper 2). In addition, each of these papers does much to help contextualize and provide external validity for this area of research both by the stimuli and methods used (e.g., using behavioral measures and manipulations based on everyday situations) and in the concepts examined, (i.e., the feasibility, desirability and motivational impact of future rewards and important individual differences such as IQ and impatience).

EXTENDED ABSTRACTS

“Value From Highlighting Time-Appropriate Outcomes”

Nidhi Agrawal and Yaacov Trope, New York University

Suppose you were to buy a product and you find an option that is both desirable and feasible. How can the value of this dominant option change as a function of time? We draw on Construal Level Theory (CLT) to suggest that time can influence the value of the dominant option depending on the aspects emphasized in the decision making process. We contend that emphasizing temporally appropriate (vs. inappropriate) aspects of the event in decision-making will enhance (vs. decrease) the value of the choice.

Construal level theory (CLT) suggests that peoples' mental representation of future events changes as a function of temporal distance (Trope and Liberman 2002). As temporal distance increases, the events are more likely to be represented in terms of super-ordinate goals focusing on desirability aspects of an event rather than sub-ordinate dimensions like means and the feasibility of reaching a desired end-state. Hence, in the distant future, desirability concerns are primary whereas feasibility concerns play a secondary role. In the near future, feasibility concerns are primary where as desirability concerns take on a secondary role (Liberman and Trope 1998).

We suggest that when people emphasize time appropriate aspects in the decision process, they associate higher value with their choice. When making a choice in the distant future, emphasizing desirability aspects in the decision making process, will enhance value, since desirability aspects are primary concerns in the distant future. Emphasizing feasibility concerns, which are secondary in the distant future, will decrease the value of the chosen option, even if the option were a dominant choice. When making a choice in the near future context, feasibility concerns are primary and

highlighting these primary feasibility concerns should result in increased value. On the other hand, highlighting desirability concerns that are secondary in the near future should decrease the value that is associated with the option. In sum, people should value their choice more when they rely on temporally appropriate aspects in their decision-making. In three studies, we find that emphasizing time appropriate dimensions enhances the value, whereas emphasizing time inappropriate dimensions dilutes the value associated with the choice.

In study 1, we primed participants to emphasize either desirability or feasibility related information in their decision-making. The participants then chose one out of three alternatives, to be available either in the near or distant future. All participants chose the one dominant alternative and then were asked to evaluate it. Our results show that participants valued their choice more in the distant future when they emphasized desirability rather than feasibility. Participants, who made the choice in a near future context, associated greater value with their choice when they emphasized feasibility rather desirability.

In studies 2 and 3, we primed participants to be in either a “Why” or a “How” mindset. “Why” mindsets direct attention towards desirability concerns where as “How” mindsets draw attention towards feasibility. Participants then made choices in the near or distant future context. The choice set up was such that all participants chose the one dominant alternative and were then asked to evaluate their chosen option. We find that participants who made a choice in the distant future context valued their choice more when they paid attention to desirability rather than feasibility. On the other hand, participants who made a choice in the near future context valued their choice more when they focused on feasibility rather than desirability.

“The Motivational Force of Future Rewards: Differences between Explicit and Implicit Valuations for Future and Uncertain Rewards”

*Jane E.J. Ebert, University of Minnesota
Drazen Prelec, MIT*

In many decisions consumers make, they appear to place much more value on short-term than on long-term desires (i.e., they show high discounting of the future). They choose unhealthy foods and skip a session at the gym despite resolutions to eat healthily and exercise regularly. They procrastinate at work, invest insufficiently or fail to take preventative health measures, like visiting the dentist regularly.

The reasons for such pervasive myopia in consumers' lives are only partially understood. We know that immediate concerns or desires (e.g., eating a cheeseburger) can exercise a uniquely powerful hold on people's attention (Mischel & Baker, 1975) and are

especially potent when visceral needs are heightened (e.g., the person is hungry). While this pull of the present can account for much discounting, studies without an immediate option still show high discounting, demonstrating a lack of attraction or “motivational force” of the future. Psychologically, this lack of motivational force of the future is less well understood, but is possibly largely explained by a perception of the future as relatively “unreal” relative to the present. Early researchers suggested that people perceive the distant future as remote, pallid, and uncertain, relative to a more arousing, vivid and predictable near future (Rae, 1834; Böhm-Bawerk, 1889), and recent empirical evidence shows that temporally distant events are indeed construed more abstractly than are proximal events (Liberman and Trope, 1998).

Conventional measures of consumers’ discount rates seem to correspond with consumers’ myopic behaviors. Ask people to choose between a reward of \$100 now and \$120 in a year and most will choose the current reward. This choice implies a discount rate of at least 20%—surprisingly high compared to typical rates of return on invested money of, say, 1 to 8%. However, even though such discount rate estimates are high, we suspect that these “explicitly” obtained estimates might be *underestimates* of discount rates “implicitly” implied by consumers’ behaviors.

The distinction between such implicit and explicit discount rates hinges on whether an intertemporal tradeoff that is logically present in a decision is also psychologically the focal point of attention. For example, a choice between \$100 now and \$120 in one year’s time forces attention on both present and future options, i.e., on the intertemporal trade-off. In contrast, a decision, e.g., to go to a restaurant this evening, also logically involves an intertemporal trade-off, because if the money is spent tonight than some other bit of future consumption will have to be sacrificed. Here, however, the focus is only on the present event. The future event is, at best, peripheral in attention for the decision. The lack of attention to the future in many decisions such as this is likely to be augmented by the “unreal” or uncertain nature of the future. We suspect that this lack of attention to the future in many real behaviors and decisions might account in large part for the low motivational force of the future. However, conventional explicit measures, that compel some attention to the future, seem unlikely to fully capture this lack of motivational force. Thus we expect implicit discount rates to be considerably higher than explicit discount rates.

It may be difficult to design a measure to capture value due to lack of motivational force. In our first study we attempt to do this, i.e., to obtain an implicit rate of discounting based on the motivational force of the future. In addition we test our hypothesis that our obtained implicit discount rates will be higher than more conventionally obtained explicit rates.

In a second study we attempt to compare the motivational force of a future reward with that of an uncertain one. Finding a similar difference between explicit and implicit valuations for both future rewards and for uncertain rewards would fit with research suggesting that temporally distant and uncertain events may be psychologically similar (e.g., Prelec & Loewenstein, 1991; Keren & Roelofsma, 1995), where temporal distance and uncertainty may each convey a sense of psychological distance (Ekman & Lundberg, 1971).

In line with our hypothesis we find that implicit valuations are considerably smaller (and discount rates considerably larger) than are explicit valuations (and discount rates) for both temporally distant and for uncertain rewards. Moreover, while explicit valuations for future and uncertain rewards differed, implicit valuations of future and uncertain rewards were more similar to each other. These results have several implications. They suggest: 1) that it may be possible to obtain valuations of rewards that capture the motiva-

tional force of a reward; 2) that conventional explicit discount rates for future rewards may underestimate discount rates implied by actual behavior, at least where behavior is motivationally based; and 3) these results are consistent with research suggesting future and uncertain events may be psychologically similar in some respects (here similar in motivational force, while less similar in more cognitive evaluations).

Study details

In study 1, 171 participants worked for as long as they wished on a tedious task (counting the instances of a 5-letter series in other syntax) in return for a reward for perfect accuracy. They completed two such tasks: the first (baseline) task offered an immediate reward of \$2 for a correct answer; the second task (experimental) offered a reward that varied according to one of five experimental conditions: 3 “calibration” conditions (Immediate \$2, Immediate \$10 and Immediate \$25) and two future reward conditions (Far \$25 and Very far \$25). Immediate rewards were given to participants immediately after the session, while Far and Very Far rewards were to be mailed in 3 and 12 months time respectively. In addition, participants in the Far and Very Far conditions provided their present value of either \$25 cash in 3 months or \$25 in 12 months (respectively) as a measure of explicit discounting. We compared participants implicit and explicit “present values” for the future rewards by comparing the time actually spent on the task with an estimate of time spent corresponding to their explicit value (estimated using a regression based on participants’ values of times spent in the calibration conditions). There were significant differences for both future reward conditions, with a particularly strong effect for the 12 month delayed reward, where the actual time spent was less than that estimated based on participants’ explicit present values. These and other analyses suggest that implicit discount rates obtained based on participants’ behavior, and reflecting the motivational force of a future event, are much greater than discount rates obtained explicitly.

Study 2 was identical, except that the conditions were: 3 calibration conditions (Immediate \$1, Immediate \$10, Immediate \$25) and 3 experimental conditions (\$25 in 12 months, a 10% chance of \$25, and a 60% chance of \$25). The results were very similar to those in study 1. The actual time spent for all three experimental conditions was considerably less than that estimated based on the same participants’ explicit values.

“Intelligence and Discounting”

Shane Frederick, MIT

Considerable evidence has suggested a link between cognitive ability and the discount rate applied to future rewards. For example, Mischel and colleagues have found that willingness to delay gratification increases with both age and intelligence, and that it predicts subsequent academic achievement. (See, e.g. Mischel & Metzner, 1962). The relation between IQ and discounting is also suggested by the finding that consumers with high income have lower imputed discount rates than consumers with low income (if one further assumes the well established, albeit modest, correlation between income and IQ).

However, the reasons for the relation between IQ and discounting are unclear. Some have postulated that those with low discount rates become smarter (e.g. by foregoing fun events to spend time studying), while others have postulated that the effects can be explained by differences in cognitive representations (smarter people are better able to imagine future outcomes and those outcomes are thereby endowed with a sufficient sense of reality to support a preference for a larger, but delayed reward). Others have postulated that people of higher IQ live in more benign environments and are, correspondingly, more confident that future rewards will actually be delivered. Still others have speculated that smarter people can better summon the “will” to override impulses to settle for the smaller more immediate reward.

In a series of studies involving college students, I measure the relation between IQ (as measured by a 12 item test), and various hypothetical and real indices of discounting, including choices between smaller proximate rewards and larger delayed rewards, willingness to wait (in days) to receive a discount on a high definition television set, and willingness to pay (in dollars) to accelerate airline travel or the shipping of a desired book. By many (but not all) of these measures, students with higher cognitive ability are more patient (their imputed discount rates are lower).

Cognitive ability, however, is just one factor that affects impatience levels. Thus, I contrast the specific effects of cognitive ability with other moderators of impatience, including experimental manipulations, where impatience is temporarily induced in some respondents by asking them to wait for a desired event (e.g. the scratching off a lottery ticket or the opening of a bag of candy). For the dependent variables that were shared across studies, I compare and contrast the differences in effects between temporary experimentally manipulated impatience levels and “stable” or “inherent” (i.e. IQ related) impatience levels. I also show that while IQ is positively correlated with behavioral measures of patience (e.g. whether one prefers \$400 in ten years over \$100 now) it is *not* correlated with self expressed measures of patience (e.g. the degree to which respondents endorse the statement “I am more patient than other people my age”). Indeed, by such “self-report” measures of patience, smarter respondents are somewhat more *impatient*.

SPECIAL SESSION SUMMARY

Implicit Measures of Consumer Judgments and Choice

Andrew A. Mitchell, University of Toronto

SESSION OVERVIEW

Traditionally, consumer behavior research has characterized consumers as deliberate decision makers and has tended to neglect the role of nonconscious or automatic processes on judgment and choice (Bargh, 2002). An important challenge in consumer research is to develop a greater understanding of the relation between conscious and unconscious processes in the consumer environment. While consumer researchers are familiar with the concept of implicit attitudes, this session was assembled with the goal of explicitly examining both the theoretical and applied issues concerning the use of implicit measures of attitudes in consumer research.

The first paper by Dominika Maison, Anthony Greenwald and Ralph Bruin reported the results of two studies designed to examine the relation between implicit and explicit measures of consumer ethnocentrism. Consumer ethnocentrism (CE) is defined as conscious preference of own country products compared to foreign products (Watson & Wright, 2000; Verlegh & Steenkamp, 1999). The results of two studies showed that on explicit measures subjects preferred foreign products, but on implicit measures they preferred Polish products. Moreover, people who had weaker explicit preference for foreign products had stronger implicit preference for Polish products, which can produce dissociation between implicit and explicit attitudes.

In "The Relation between Implicit and Explicit Attitudes and Spontaneous Choice," Melanie Dempsey and Andrew Mitchell examine the predictability of implicit attitudes in a spontaneous choice situation. Implicit attitudes toward two fictitious brands of pens were created using a conditioning task in which participants are unaware of the contingency relationships between the CS (target pens) and the US (affective stimuli). Conflicting explicit attitudes were also created based on beliefs about the attributes of the pens. They find that participants who had formed a strong implicit attitude toward a fictitious brand of pen and were not instructed to form an explicit attitude were more likely to choose pen associated with the implicit attitude. They also find support for their hypothesis that implicit attitudes are correlated with intuitive or affective processing of information.

Alternative perspectives of implicit attitudes and their relation with explicit attitudes is focus of the third paper "Alternative Theoretical Positions on Implicit Attitudes." Paul Herr, Andrew Mitchell and Melanie Dempsey provide insight into the theoretical basis of implicit attitudes and discuss three conceptual views of implicit attitudes. The first position discussed is based on a context independent view of implicit attitudes. In this view, implicit attitudes are the "true" attitude, while explicit attitudes are subject to context effects. The second position is a dual model of attitudes in which different evaluations of the same attitude object exist in memory (e.g., Wilson et al., 2000). The third theoretical perspective of implicit attitudes draws on the work from dual information processing theory (e.g., Epstein, 1994; Sloman, 1996; Smith & DeCoster, 1999). The parallels between this body of research and dissociations between implicit and explicit attitudes were discussed.

Whereas there is a long history of consumer research on explicit attitudes, implicit attitudes have only recently received attention. Together these papers show that theoretical and empirical research on implicit attitudes is of great importance to understand-

ing the impact of environmental stimuli on consumer attitudes and behavior.

"Implicit Consumer Ethnocentrism—An Example of Dissociation between Explicit and Implicit Preference"

Dominika Maison, University of Warsaw

Anthony G. Greenwald, University of Washington

Ralph H. Bruin, Medical Data Management Corp

Consumer ethnocentrism (CE) is defined as a conscious preference of own country products compared to foreign products (Watson & Wright, 2000; Verlegh & Steenkamp, 1999). CE can have different backgrounds: a) cognitive—when people believe that products produced in their own country are better ("Our products have better quality"); b) affective—when people have a positive affective reaction toward own country products ("I love American products"); c) ideological (normative)—when people believe that it is appropriate to purchase products manufactured in their home country ("It is better for the American economy to buy American products").

CE is observed in many countries. However, in economically developed countries consumers have stronger preferences toward own country products than in under-developed countries. It is explained that in under-developed countries people often have experience with poorer quality of their own country's products compared to foreign brands. This situation can lead to dissociation between implicit and explicit attitudes and it can produce internal conflict between automatic preference based on emotions and rational judgment based on observation and experience.

The goal of two studies was to explore explicit and implicit preferences toward foreign vs. local products and their relation to behavior. In the first study we measured attitude toward Polish vs. foreign brands of cigarettes (Polish cigarettes are considered to have lower quality than foreign brands). Participants (102 college students; 37 smoking; 65 not smoking) participated in an IAT study (Greenwald, McGhee & Schwartz, 1998) where stimuli were names of Polish (e.g. Sobieskie, Carmen) vs. Western cigarettes brands (e.g. Marlboro, Camel), and completed a questionnaire about their opinion about different brands of products. On explicit measures (questionnaire), subjects preferred foreign brands, but on implicit measures (IAT) they preferred Polish cigarettes. This dissociation was stronger among non-smokers than among smokers. However even though smokers smoked foreign brands and preferred foreign brands (explicit measure), the implicit measurements showed a slight preference for Polish brands.

The second study investigated implicit consumer ethnocentrism toward multiple product categories. In seeking to understand CE, we explored its relation toward explicit consumer ethnocentrism (measured by CATESCALE, Shimp & Sharma, 1987), explicit preference of Polish vs. foreign products, and quality perception of Polish products. Participants (97 college students) completed an IAT task, where stimuli were Polish vs. foreign brand names in different product categories, and filled in two questionnaires. The first questionnaire was administered before the IAT task; it concerned explicit attitudes toward brands and products. The second questionnaire (CATECALE) was completed after the IAT test. The results showed a pattern similar to that obtained in the first study: on explicit measures subjects preferred foreign products, but on implicit measures they preferred Polish products. Furthermore,

subjects who had weaker explicit preferences for foreign products had stronger implicit preferences for Polish products. No relation was observed between implicit consumer ethnocentrism (IAT) and explicit ethnocentrism as measured by the CATESCALE.

“The Relation between Implicit and Explicit Attitudes and Spontaneous Choice”

Melanie A. Dempsey, University of Toronto

Andrew A. Mitchell, University of Toronto

The recent surge of interest in implicit social cognition has been accompanied by an increase in the use of indirect or implicit attitude measures (e.g., Fazio et al., 1986; Greenwald et al., 1998; Nosek & Banaji, 2001). But as Bargh (2002) and others have noted, the consumer behavior field has not directed a great deal of attention to the substantial role of nonconscious processes in consumer judgment and behavior or under what conditions it may influence behavior. The present research was designed to address this void. We examine the effect of implicit attitudes that develop from a conditioning procedure on subsequent choice behavior when participants are presented with conflicting product attribute information.

Olson & Fazio (2001) have developed a conditioning procedure in which attitudinal conditioning effects are found on implicit attitude measures. The appeal of this procedure is that subjects are exposed to the CS and US in a manner more consistent with real life advertising (paired together). In our studies we borrowed the procedure as outlined in Olson & Fazio (2001) with slight modifications. The target conditioned stimulus consisted of two fictitious brands of pens and the filler images were additional fictitious products that undergraduates would be familiar with (e.g., deodorant, sunglasses, and toothpaste). The objective of the first two preliminary studies was to replicate previous findings using fictitious brands of consumer products. We found a main effect of target valence, where the pen that had been paired with positive images was rated more positively than the pen that had been paired with negative images on implicit attitude measures (IAT; Greenwald et al., 1998).

After the target pens had been conditioned, participants were presented with attribute information for both brands of pens in the form of print advertisements that were written to contradict the earlier formed valence. The instructions for evaluating the ads were written to encourage some subjects to form an attitude on-line (at the time the judgment relevant information was presented), while others were not expected to form an attitude at the time of exposure to the attribute information (memory condition) (Hastie & Park; 1986). Subsequently, subjects were required to choose between the two fictitious brands of pens. We found that those participants who were not instructed to form an attitude toward a brand during exposure to product information were more likely to choose the positively conditioned pen over the pen described by the more positive attributes. If we assume a majority of advertising is processed by consumers under low levels of involvement, then our finding has important consumer behavior implications.

We also investigated the hypothesis that lower order perceptual associations such as affect or feelings generated may influence attitudes measured by implicit measures. Epstein's cognitive-experiential self-theory (CEST; 1994) suggests that people adapt to their environments through one of two conceptual systems—the preconscious/experiential or the conscious/rational. Whereas the experiential system makes connections through associations, the rational system does so through logical considerations. According to CEST, information processed in the experiential mode is affective in nature. If implicit attitudes are more susceptible to affective or emotional influences, then there may be reliable differences in the

tendency for individuals to form implicit attitudes. We administered the affective orientation scale developed by Booth-Butterfield & Booth-Butterfield (1990) as a measure of individual difference in reliance on emotions/feelings versus logic/facts in decision-making. The results show that implicit attitudes (IAT and evaluative priming) were stronger for participants who scored higher in affective orientation, supporting our prediction.

This present research makes important contributions to the literature. This is the first study to our knowledge that demonstrates that implicit preferences towards a product can persist in the face of conflicting information and influence choice behavior. Additionally, we provide preliminary evidence that implicit measures of attitude tap a database of knowledge that is affective in nature.

“Alternative Theoretical Positions on Implicit Attitudes”

Paul M. Herr, University of Colorado

Andrew A. Mitchell, University of Toronto

Melanie A. Dempsey, University of Toronto

There has been considerable interest recently in implicit measures of social cognition (e.g., Greenwald & Banaji, 1995). Much of this interest has focused on the measurement of implicit attitudes. It has been argued that these measures of attitude allow researchers to learn more about attitudes by gaining access to the unconscious mind (Banaji, 2001). While a variety of different procedures have been used for measuring implicit attitudes, most research has been conducted using one of two different procedures (Fazio & Olson, 2003). The first is an evaluative priming task which assesses the automatic activation of attitudes from memory and was proposed by Fazio, Sanbonmatsu, Powell and Kardes (1986). The second is the Implicit Association Test (IAT) which was developed by Greenwald et al. (1998). The evaluative priming task assesses what is automatically activated from memory upon presentation of the attitude object whereas the IAT assesses the strength of association between an attitude object and an attribute dimension. Both procedures use response times to measure implicit attitudes and both yield information about a person's attitude not yielded by conventional self-report measures.

While there are important methodological differences in the two approaches, here we would like to focus on alternative conceptual views of implicit attitudes and their relationship to explicit attitudes. Basically, there seems to be three positions each with minor variations. The first position is that implicit attitudes are the “true” attitudes, while explicit attitudes are constructed and are subject to context effects. This has been the underlying view of most of the research on stereotypes. An individual's implicit attitude is their true attitude toward a stereotype, while the explicit attitude represents a politically correct attitude. The argument supporting implicit attitude measures as reflecting the true attitude was that individuals could not “fake” them. This view suggests that both implicit and explicit measures of attitude tap a single construct. Self-reported attitudes are a combination of the implicit attitude and self-presentation.

The second position was put forth by Wilson et al. (2000) who argue for the independence of implicit and explicit attitudes. They propose a dual model of attitudes in which different evaluations of the same attitude object may exist simultaneously in memory. According to this model when an individual has more than one evaluation of the same attitude object, one is activated automatically upon presentation of the stimulus (implicit attitude) and the other requires motivation or capacity to retrieve (explicit attitude). They suggest that when an individual changes their attitude, under some conditions the original attitude is not replaced but remains in memory and can be activated automatically.

The final position draws on models which propose a dual theory of information processing (e.g., Epstein, 1994; Sloman, 1996; Smith & DeCoster, 1999). While there are conceptual differences in these models, they all propose that information is processed through either an associative/experiential mode or one that is rational or rule-based. Associative processing is quick, intuitive and relies on associations that are more perceptual or affective in nature. The rational or rule-based system is conscious, analytical, primarily verbal, and relatively affect-free. There are obvious parallels between these modes of processing and implicit and explicit attitudes.

Currently, dissociations between implicitly and explicitly measured attitudes toward the same attitude object have been predominately explained by either self-presentation concerns or unreliable implicit measures. We argue that the third position holds promise for investigating implicit attitudes in the consumer domain. Smith & DeCoster (1999) suggest that the two processing modes (associative and rule-based) tap separate databases representing knowledge in two distinct formats. While the researchers discuss the implications of their model for explaining dissociations in a number of domains (e.g., implicit/explicit memory), we believe that applying model of dual information processing to consumers' implicit and explicit attitudes would be insightful. Different evaluations (explicit and implicit attitudes) toward an attitude object might develop simultaneously based on the two systems processing different kinds of information or experience associated with the target object. Implicit attitudes may be more influenced by lower order perceptual associations, whereas explicit attitudes are based on higher order beliefs. According to Epstein (1994), features associated with the experiential system are more concrete and affective in nature because information processed in the experiential route rely more on feelings generated. Therefore we should not be surprised to find explicit and implicit attitudes dissociated even in areas where demand characteristics are not believed to play a role. Understanding the role of perceptual processes on consumers' implicit attitudes is an important and fruitful area for future research.

SPECIAL SESSION SUMMARY

Consuming Television: Connectedness and Community in Broadcast Media

Hope Jensen Schau, Temple University
Cristel A. Russell, San Diego State University

SESSION OVERVIEW

The concept of consumers developing relationships with brands has been well-documented in consumer research. Seminal work on this topic established that brands can serve as active relationship partners and serve as a basis for various types of consumer-brand relationships (Fournier 1998). Work evolving from this perspective has shown that such consumer-brand relationships also serve as the basis for the formation of brand communities, a fabric of relationships based on personal connections to specific brands (Muñiz and O'Guinn 2001; McAlexander, Schouten, and Koenig 2002). Additionally, it has been shown that there is a reciprocal relationship between consumers and brands. More specifically, not only do consumers seek interpersonal relationships that reinforce their relationships with brands, but they may develop self-brand connections as a means of affiliating themselves with reference groups (Escalas and Bettman, 2003).

This session contributes to extant research by applying the concept of consumer-brand relationships to the context of the television consumption. While it has been proposed that consumers form relationships with TV programs and the characters in those programs (Russell and Puto 1999), research in this session examines this proposition in greater depth. Expanding our knowledge of television audiences beyond Nielsen aggregate analysis to the level of individual consumers and program-related communities of viewers, this session taps into consumer motivations and socialization, consumption stories, and the extension and creation of the TV program as a brand experience.

Cristel Russell and Andrew Norman presented a study on the relationship between program consumption and social interaction. Within the social network of a sorority house, they examine the interplay of the consumption of and connectedness to TV programs and interpersonal relationships. Mary Wolfenbarger and Hope Jensen Schau demonstrated the manner in which *The Simpsons* viewers bond in online communities through subversively explicating American notions of hyper-commercialization and commodity fetishism. Among active *The Simpsons* fans the brand experience is intricately informed by cultural critique, often including parodies of marketing and consumer behavior. Hope Jensen Schau and Albert M. Muñiz, Jr. examined a particular consumer-generated subtext of the former television series *Xena: Warrior Princess* to find how proponents of mainstream and subtext interpretations interact and impact the *Xena* brand. They find the *Xena* community is held together by a delicate dance of ambiguity that supports multiple interpretations of the relationship between Xena and Gabrielle. Finally, Mary C. Gilly, as the discussant, provided a critical perspective on the notion of connectivity as a specific consumption experience and discussed its potential in advancing our understanding of consumer behavior.

EXTENDED ABSTRACTS

"Exploring the Relationship between Television Program Connectedness and Social Network Dynamics."

Cristel A. Russell, San Diego State University

Andrew T. Norman, Drake University

This presentation focused on the socialization process that occurs around the viewing of a television series. We investigated

this phenomenon by exploring brand communities that form around specific television programs. Watching television may be one of the most common social consumption events. Television has been referred to as a "lubricant to interpersonal communications" (Lee and Lee 1995). In particular, favorite TV programs are often watched regularly by groups of individuals and may serve as social bonds to others. Viewers might watch certain TV programs merely for their social utility (Morley 1980), providing a topic of discussion with other viewers during or after the airing of a program (Rubin and Perse 1987). Because of their recurrence, TV series may become ritualized events and extend beyond the mere watching experience, with preparation and follow-up activities (Russell and Puto 1999). Subcultures of consumption sometimes develop around television programs, with their rituals, paraphernalia, and participation in collective activities such as fan groups, conventions, and on the Internet (Kozinets 2001, Fiske 1992; Lewis 1991).

Research on subcultures of consumption and brand communities (McAlexander, Schouten, and Koenig 2002) suggests that a strong bond between a person and a TV program and its characters may serve as the basis for interpersonal interaction and social cohesion. Empirical evidence shows that, as an individual becomes more connected with a given show, she/he will not only have a greater opportunity for social interaction around the program, but will also be more likely to seek out interactions with other viewers of the same program (Russell, Norman and Heckler 2004). Russell and Puto (1999) also emphasized the social embeddedness of the television experience and the importance of relationships within the community of viewers. Not only may viewers develop relationships with their programs, and even para-social relationships with the characters in the programs, but they may also use the TV program as a way to develop or maintain social relationships with other viewers (Frenzen & Davis, 1990).

The horizontal embeddedness of TV consumption and its relationship to previous research on connectedness was the focus of this research project. We reported the results of a study conducted with 28 college females living in a sorority house. These individuals reportedly gathered together at least once a week to watch a TV series, thereby providing us an opportunity to study TV consumption and connectedness in a real and relatively "close" social network of TV consumers. We administered an extensive survey to the participants. After providing information regarding their own personal history with the TV show, the respondents indicated their level of connectedness to the selected program as well as to another TV show of their choice. They also completed an extensive set of measures assessing the strength of their ties with each other sorority member and the level of their interpersonal interaction related to TV programming with each other sorority member.

Much like other studies conducted in fraternity or sorority houses (Reingen, Foster, Brown, and Seidman 1984; Ward and Reingen 1990), our findings provided a unique view of a well-defined subculture which represents a microcosm of television consumption as a whole. While all the respondents reported watching the show, the degree to which they connected to it varied. Within the complex social network of the sorority, we were able to identify pods of viewers of equivalent connectedness and levels similar patterns of TV-related interactions. Opinion leaders also became apparent loci of influence on other sorority members.

**“Bonding through Cultural Subversion: Consumers’
Connectedness with the *The Simpsons*”**

Mary Finley Wolfinbarger, California State University Long
Beach

Hope Jensen Schau, Temple University

The television program, *The Simpsons*, is one of the longest running sitcoms in television history. Initially airing as short comedic sketches in a cartoon format on the Tracey Ullman Show in 1987, the show has earned both harsh criticism for its portrayal of a decidedly dysfunctional American family and alternatively praise for being the most “realistic” show on television (Rapping 1992) and the best television program of the century (Time 1999). Throughout 300+ episodes, *The Simpsons* has remained an “edgy” program, challenging the boundaries and norms of American popular culture and actively parodying the hyper-commercialization and commodity fetishism of Western, specifically American societies. So enduringly popular is the show that, Simpson-isms, like Homer’s “D’oh!” and Mr. Burns’ “Excellent” creep into the common parlance of American speech and are decoded with agility by viewers and nonviewers alike. Additionally, there is a proliferation of show images, screen savers, sound bites, avatars, and cellular phone ring tones associated with the show and theme song. In opposition to the fickle nature of most television trends, books declaring Homer Simpson to be an epic hero with his own philosophy (“The Philosophy of D’oh!”) and definitive show episode guides continue to be produced and sold (Mulhauser 2001).

Although the program has special appeal to the “jaded” mindsets of Generation X and Y (McClellan 1992) the show has a strong and growing multi-generational fan base. In syndication, *The Simpsons* enjoys an expanded audience as younger children are exposed to the early episodes and international markets air the program to fresh viewers. So, what accounts for its popularity and why are the characters and plotlines resonating with consumers? This research examines the subversive nature of the plots and characters of *The Simpsons* and more specifically addresses the consumer response to, identification with, and overall connectedness to (Russell, Norman and Heckler 2004) the program and its characters as a playful enactment of subversion, particularly in reference to the behavior of marketers and consumers.

With the expansion of internet access, broadband options, and consumer adoption of these technologies, an enormous amount of consumer-generated commentary exists online regarding *The Simpsons*. Active and resilient online communities revolving around the show, its characters, setting, and plots exist in several languages (English, Spanish, German, French, Swedish, etc.) and are hosted on resources in multiple countries. This enhanced consumer interaction provides insight beyond the aggregate data Nielsen can provide on audiences, to actual individual consumer interaction with all aspects of the program. Similar to recent consumer research on *Star Trek*, this study focuses on the online fan interactions and on the program content that serves as stimulus (Kozinets 2001). Noting an obvious selection bias, those who engage in *The Simpsons’* communities online are highly involved consumers, but also are likely to reflect resonating themes of connectedness across a vast array of more casual consumers (Schlosser 2003).

Treating *The Simpsons* as a phenomenon, this research regards the program as a brand (complete with its own nearly inexhaustible list of licensed merchandise), its fan communities as brand communities (Muñiz and O’Guinn 2001), and the fan sites inspired by the show as acts of consumption (Schau and Gilly 2003). Through analysis of the episodes, the official website (www.thesimpsons.com), two independent English language discussion boards where fans frequently interact with each other

regarding episode content, and personal websites containing *The Simpsons’* content, we find that the identification with, and connectedness to, the show revolve around the theme of subversive commentary that nevertheless often affirms traditional values and embraces the status quo, warts and all. The show and fan discussions serve as cathartic platforms for both serious, pointed critiques and affectionate acceptance of the tensions inherent in American values and norms.

The program content is itself a critical resource in understanding consumer and marketer behavior. Episodes of *The Simpsons* contain humorous, highly commercialized depictions of social contexts and distinctly marketing-oriented themes. For example, each episode includes Maggie getting run over the price scanner at the grocery store; Krusty the Clown actively marketing low quality merchandise bearing his image and seeking to bypass parental decision makers; and Duff beer’s promotional efforts pervade plotlines (“Duffman never dies, only the actors who play him”). In fact, even the godly Ned Flanders has owned a niche market store for left-handed appliances (the Leftorium) promoted by Homer’s word-of-mouth campaign; as well, Ned briefly operated an ill-fated religious theme park in tribute to his deceased spouse, Maude. All participants in the marketing system are routinely parodied, including big business (the Springfield Nuclear Power Plant), smaller businesses (the Kwik-E-Mart and Moe’s Bar), consumers (e.g. Marge buying 15 pounds of Nutmeg to save money at the local discounter), consumer movements (e.g. Marge’s crusade against “Big Sugar”), marketing researchers (e.g. Springfield Elementary is covertly taken over to provide continuous feedback to a toy manufacturer) and advertisers (e.g. Itchy and Scratchy’s violent ad for a cereal branded as “Stabby-Ohs”).

Consumer reactions to the program reflect the fact that the sarcastic and critical stance of the program resonates with viewers who easily recite the episode content, incorporate it into their belief structures and ideology (Cantor 1999), and engage in prolonged discussions and debates surrounding program content and peer commentary. Initial findings reveal that while the show is a cartoon, consumers tune in and interact with it on a deeper socio-cultural and political level; for example, the statement “*Life Imitates Bart*” in postings serves as a signal that daily news and events prove the relevance of *The Simpsons*. Thus, Springfield and its inhabitants are stand-ins for the world consumers occupy in real life and the issues presented in the program become vehicles for larger social dialog. Participants are at times competitive, with each post seeking to be more clever and creative than previous posts to a discussion. Our analysis finds that these dialogs, like the show itself, critically explicate American social norms, including norms of business and consumer behavior, and are both subversive and affectionate. In fact, we argue that enjoyable subversion is the dominant consumer motivation for active participation in the online brand community.

**“If You Can’t Find It, Create It: An Analysis of Consumer
Engagement with *Xena: Warrior Princess* and the Creation of
Consumer-generated Subtext”**

Hope Jensen Schau, Temple University

Albert M. Muñiz, Jr., DePaul University

With an absence of strong, female action heroines and a dearth of lesbian themed programming in mainstream American media, it is not surprising that a resourceful consumer group would reinvent a show to accommodate both. Although similar in intent to the reframing of *Ikea* (Ritson, Elliott and Eccles 1996), the execution is considerably more subtle and durable for *Xena*. We find that fans of the television show *Xena: Warrior Princess* reframe the characters *Xena* and *Gabrielle* and the show’s plots to suit their needs.

Noteworthy is that the program ceased production in June 2001, yet enjoys a dynamic consumer-driven community both online and offline.

Treating the program as the research focal point (Kozinets 2002), the interactions of the fan base factions as evidence of a thriving brand community (Muñiz and O'Guinn 2001), and the fan websites as acts of consumption (Schau and Gilly 2003), this research tackles the tension between corporate and consumer control (Kates 1997) of the *Xena* brand. Specifically, we examine the birth and persistence of a community devoted to an interpretive reading of *Xena: Warrior Princess* as a lesbian love story between the medieval, heroic Xena and her omni-present, ever-cheerful sidekick and scribe, Gabrielle. Moreover, we investigate the impact this community has on the perception of the *Xena* brand by the mainstream fan base.

The lesbian subtext is not merely a reinterpretation of the literal plot and characters, but includes fan-written fiction (short stories and novellas), teleplays (consumer-written episodes fans wish had been produced), manipulated and enhanced photographic images of the characters engaged in romantic and lustful behaviors, animated renditions of consumer-imagined character interactions, and discussion threads revolving around these consumer-generated texts and pictures. Although no official endorsement exists from the studio, the actress who played Xena, Lucy Lawless, has publicly acknowledged, albeit with ambiguous acceptance, the lesbian subtext as "one possible way to interpret the show." It is also believed that the writers in very subtle ways gave fodder to the subtext through ambiguous scripting and directing. Our research suggests that it is this complex dance of ambiguity that keeps the factions in check and the *Xena* brand alive and strong, unfettered by potentially damaging, homophobic rejoinders.

The data for this project are culled from: 1) the television show content, 2) the mainstream brand community (defined as the official discussion board, personal websites, webring and offline conventions), the subtext community (as manifested online and offline). Both researchers have examined episodes of the show, the official online websites, fan websites, and the discussion threads associated with the subtext. The first author attended a large Xena convention in the East Coast region of United States to further witness the community interaction offline, the tension between the factions, and the impact of the divergent interpretations on the *Xena* phenomenon. The motivation of this project was to determine how mainstream consumers cope with the subtext and how the subtext impacts the *Xena* brand. Recognizing that consumers can and do form active relationships with brands (Fournier 1998), we analyze how the same characters (Xena and Gabrielle) can sustain such divergent interpretations of their feelings, intent and behavior, while maintaining core, universal identity attributes (heroic, honorable, empathetic).

Initial findings reveal the subtext is tacitly acknowledged by the mainstream community as a titillating piece of *Xena* trivia, but is not seriously endorsed or validated by mainstream *Xena* fans. Consumer-generated commentary from both *Xena* camps indicates that this ambiguity allows discrepant interpretations and loci of connectedness (Russell, Norman and Heckler 2004) to co-exist and protects the brand from lesbian associations commingling with their heterosexual viewer segment. Similar to research on the Apple's discontinued PDA, the Newton (Muñiz and Schau 2002), we assert that the fact that the program is a discontinued product (no new shows are being made) aids in the maintenance of the subtext because the corporate interpretation yields to consumer-driven, consumer-controlled dialogs. In essence, the studio does not contribute to the debate in any form, allowing the factions to create

equally authentic interpretations because neither is formally deemed inauthentic by the *Xena* studio, cast, writers or producers. Had the show continued, perhaps the *Xena* producers would have been forced to take a formal stance on the subtext issue, potentially invalidating one faction and alienating consumers; thankfully the authentication never took place. Through maintaining an open text approach to *Xena*, both consumer factions can claim equal validity, hence Xena enjoys an expanded fan base.

Exploring the Architecture of Contemporary American Foodways

Elizabeth C. Hirschman, Rutgers University
Nicole Carscadden, Rutgers University
Lindsay Fleischauer, Rutgers University
Martin Hasak, Rutgers University
Melissa Mitchell, Rutgers University

INTRODUCTION

“Food, at the base of civilization, contains deep, multi-layered meanings. Since it is such a strong component and shaper of identity whether on the level of family, community, ethnicity, class, religion, region, or other entity, food is deeply enmeshed in a collective as well as an individual sense of identity. Whether unprocessed or minimally processed foods (wheat, cooking oil), industrially manufactured items (Coca-Cola or Gerber baby food), or hand-made creations (tamales, holiday cookies), people imbue particular foods with meaning and emotion, regardless of whether they are involved in its production or merely its consumption. How and why these foods accrue special meaning—what makes them unique to particular groups of people—can vary widely: method of preparation, long-held tradition, particular ‘flavour principles,’ perception of purity, religious or political significance, signification of wealth or status, or any combination of factors.”

Bentley (2001)

Food has been studied as an anthropological classifier, signifier and identifier from the 1960’s onward (Balfet 1975; Douglas 1970, 1982, 1984; Levi-Strauss 1970, 1973, 1978). And even prior to that, food consumption and food preparation served as objects of study for economists and historians (Lucia 1963; Potter 1954; Simoons 1961). From this body of inquiry it has become clear that food and foodways play an important role in signifying various forms of social order (Bourdieu 1979). For example, seating arrangements, table manners, the utensils used to prepare, serve and consume food, as well as the actual foods eaten, can serve as rhetorical indicators of familial membership, age and gender statuses, socio-economic position and ethnic affiliation (see e.g., Burnett 1968; Counihan and Kaplan 1998; Lewis 1989; Merrell 1985; Wallendorf and Arnould 1991).

Foodstuffs further serve as hierarchical continua of social prestige and power; with access to certain foods (e.g., meat) or drinks (e.g., wine) being reserved for those occupying certain levels of power and privilege (e.g., Barthes 1970; Bourdieu 1979; Korsmeyer 1999; Mintz 1986; Warde 1997). Finally, food and foodways have also been scientized—recast as nutrients, calories, lipids, carbohydrates, proteins and vitamins—a modernist effort to legitimate their study and quantify their utility to society (e.g., Barnes and Shapin 1979; Caplan 1997; Kamminga and Cunningham 1995; Macintosh 1996; McCollum and Simmons 1929; Simmons 1929).

PURPOSE

Our present purpose is to explore these bases of food meaning in an exploratory and modest way among contemporary Americans. In particular, we are interested in the naturalized categories and hierarchies that are currently present in American society. Thus, we do not focus on food consumption micro-cultures (e.g., Thompson and Troester 2002) or on specific food consumption events (e.g., Wallendorf and Arnould 1991). Rather we are looking for culturally resonant categories and labeling devices that are used by consumers to ‘make sense’ of food.

METHOD

For this exploratory phase of our research, depth interviews were conducted with five men and four women ranging in age from 17 to 45. Participants were from the Working, Lower Middle and Upper Middle social classes. Ethnicities included Italian, Latino and Irish, although all were from second, third or beyond generations. These informants, therefore, would not be able to reflect variations in food classifications among, say, African-Americans, Muslim-Americans, Korean-Americans or persons who had recently immigrated to the United States. Interviews were conducted at the participant’s home, under conditions of informed consent and anonymity, and were audiotaped. Interview length ranged from 45 minutes to two hours and topics ranged across a variety of food practices/norms. Interview format differed slightly from traditional depth/phenomenological techniques (see Thompson and Troester 2002) in that we did not have participants recount specific food consumption events as a means of eliciting their individualized narratives. Rather, because our focus was upon macro-cultural categorization schema, we would introduce an organizing concept suggested by prior research on food (e.g., male/female foods) and have the participants comment on it by expressing their personal experiences with and exemplars of the category. As will be discussed in the Analysis section, this approach proved to be fruitful.

INTERPRETIVE ANALYSIS

Following standard interpretive procedure for depth interviews, each transcript was read several times; as the readings progressed, categorical commonalities regarding foodways were detected and noted in marginal commentary. Ultimately, individual passages were identified and matched to an overarching structure of categorization “nodes.” We viewed this overarching structure as a preliminary version of the architecture of American foodways; that is, as a culturally grounded model that represents the interrelated meanings that foodways have for American consumers. This preliminary model is shown in Figure 1; and the discussion below addresses each major aspect of it.

Non-hierarchical Cultural Distinctions

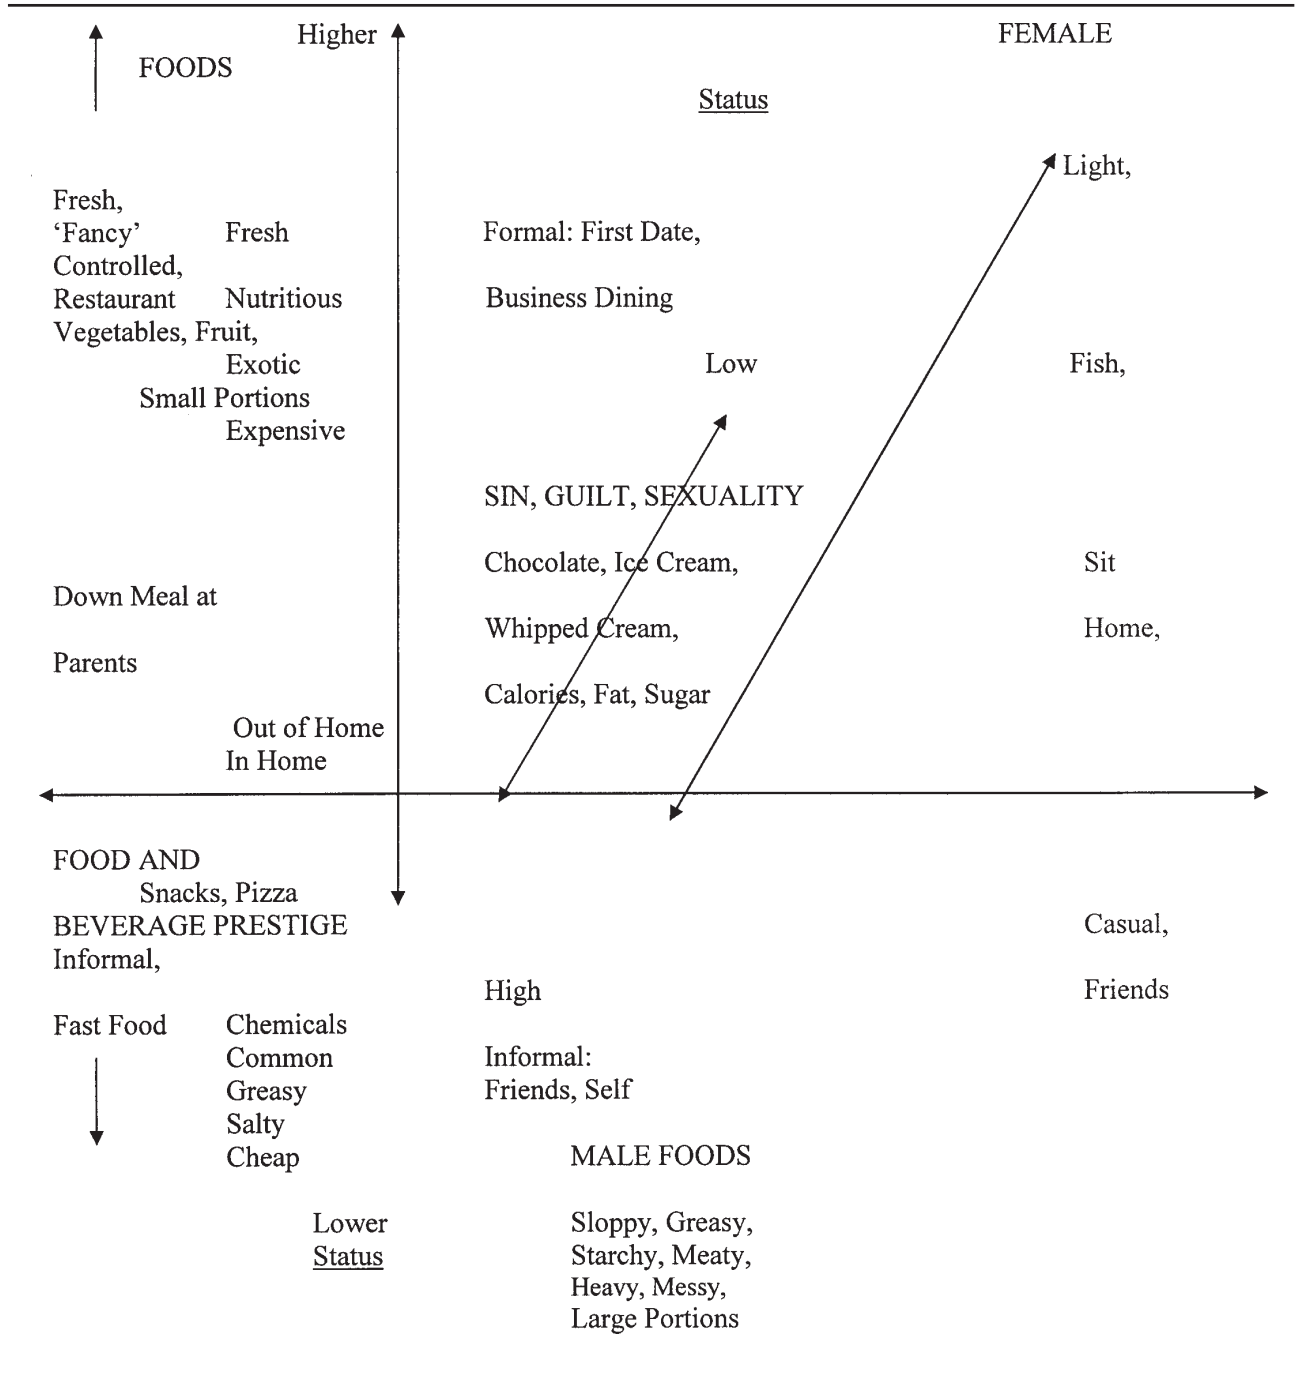

Although parts of our architectural rendering are hierarchical continua (e.g., social class), others are not, and we will address these uni-level dichotomies first.

In-Home/Out-of-Home

One important uni-level distinction consumers made was between eating food *in their homes* versus eating food *outside of their homes*; outside areas could include special events, e.g., weddings, picnics, restaurant meals, or common events such as snacks eaten ‘on the run.’ Cross-cutting this basic In/Out dichotomy were modifiers/contextualizers such as Formal or Informal, Necessity or Pleasure, Snack or Full Meal, and Cheap or Expensive.

For example, for some informants, *every* meal eaten out of the home was special, because it happened so rarely:

FIGURE 1
The Architecture of American Foodways: An Exploratory Model

“I can probably count the times I’ve gone out to eat. More so now; I’ve gone out to eat at restaurants now; but when I was growing up [it was] always a home cooked meal.... We never went to restaurants” (Angela).

“When I go out to eat, I think of food as enjoyment, yeah. For the most part at home it’s pretty much a necessity.... Almost every time I eat out it’s for enjoyment, unless it’s like work-related” (Nick).

Messy, Sloppy vs. Controlled

Our participants dichotomized sharply between food consumed outside the home with friends versus food consumed outside with co-workers, dates or bosses. With friends with whom they felt comfortable and at ease, eating ‘outside’ was frequently an opportunity for feasting, rowdiness, sloppy table manners and release from norms of self-control. Diets, concerns about the nutritional quality of the food and etiquette about food portions, messiness or ‘becoming dirty’ were abandoned.

“We eat whatever we want. When me and Gina go out we usually order an appetizer and split it; something like nachos; it doesn’t matter. It could be messy, gross food” (Joellen).

“This is really bad, but... something fried and disgusting like mozzarella sticks; maybe chicken caesar salads we eat a lot, or bagels....” (Lena).

Frank, below, cites several norms governing ‘eating out’ with male friends at a sports event:

F: Yeah, it depends... like tailgating a game you gotta have subs [submarine sandwiches].

I: What kind of subs?

F: Whatever you want, whatever your preference is. You gotta have beer usually.

I: What kind of beer?

F: Cheap, American, domestic beer.

I: Really.

F: In cans. (Laughs.)

I: Not imported?

F: Not imported.

I: And not bottles?

F: Not bottles, it’s not for a tailgate. I guess you could have bottles.

I: Bottles are okay?

F: Yeah, bottles are okay, but if it was me I would get cans.

I: It’s got to be cheap?

F: It’s got to be cheap, especially at a football game.... Like Monday night football, or the Super Bowl, you get chicken wings.

I: What about for a regular season game.

F: The same thing. Not baseball though.

I: Basketball?

F: No.

I: Hockey?

F: Nope, maybe like pizza is universal for all sports [and] chicken wings.

I: I thought chicken wings was only football.

F: No, it’s primarily football, but like I guess you eat the same things as long as you’re going to the game, what kind of game—it doesn’t really matter.

I: You eat the same things as when you’re at the game? Tonight’s football game? You’re at the stadium.

F: Tonight’s football game? I’d get a sub. We’d hang outside for a little while, have a sub, drink a couple of beers.

I: And when you’re in a stadium, do you get any food?

F: No, no I don’t get any food.

I: Why not?

F: For one it’s the price. I refuse to pay the price in the stadium.

I: What’s the price in the stadium?

F: Last time I think it was a hot dog was \$5.25, something like that. I’m not paying that.

I: Would you drink a beer in the stadium?

F: I refuse to pay those prices too. But sometimes you need a beer, and you make a compromise with yourself, but [I’m] definitely not going there and buying beers if I can avoid it.

I: And you mentioned pizza, that goes for all sports?

F: Yeah, definitely, that’s more universal than chicken wings.

Conversely, “eating out” with first dates, co-workers and superiors was described as restrictive. Etiquette was strictly observed, small portions of “clean,” easy to eat food were consumed, and food was not touched or handled. Sauces or gravies that might

splatter or create a “mess” were avoided; as was alcohol, lest one lose self-control.

“If you’re with your boss, you’ll probably tend to watch what you say and try to eat a certain way and look professional” (Lena).

“If I was with someone I just started dating, it would be different than with a [long-term] boyfriend... it wouldn’t be anything messy.... If it was someone I hardly knew, girl or guy, I would be more cautious. I wouldn’t order spaghetti or even a salad; salads are kind of messy. I would be more likely to have coffee after dinner instead of chocolate cake.... I would try to order something more tasteful or classy. I probably wouldn’t eat it all.... I would try to eat slower, not talk with my mouth full, not make a mess of my plate....” (Joellen).

I would not get anything I had to touch with my fingers or hands. I would probably get chicken or seafood. I wouldn’t eat pasta or anything messy... [I’d get] something that would be very easy for me to eat” (Nick).

Food at Home

Food prepared at home was usually described by our participants as “thrown together,” “easy,” “just to eat something,” “simple” and frequently “sloppy.” Those who often ate at home by themselves tended to eat ‘snack’ foods, which they described as ready-made (microwave meals), sandwiches or even cereal (for dinner). Television often served as a companion for these meals. As one informant put it: “When the tv is on, I’m *not* eating alone.” Another described the tv accompaniment to his at-home meals as being “like a beverage.”

A secondary classificatory device for at-home dining was “sitting down” to a “full meal.” This was used to reference a multi-course meal, served to multiple family members and served at the “appropriate” mealtime. Underlying this was the iconic image of a large family, gathered around a dining table, eating and talking together over an extended period of time. Usually the mother of the family would prepare the meal, often using ‘favorite’ or ‘traditional’ recipes. Among our participants, such sitdown-full-meals were the exception, rather than the norm; but they were idealized as a ‘good’ way to eat or the ‘right’ way to eat (see also Wallendorf and Arnould 1991).

“I miss sitting down at meals, like on Sunday which was always a big meal.... We don’t even do that anymore because we are so spread out all over the place. I miss those big meals, just talking with everybody. Eating on the run sucks.... Every night [at] 6 o’clock we used to sit down. We all knew that was dinnertime; for an hour [from] 6 to 7. Now everybody eats 3, 4, 5, 8, 10, whenever they get in from doing something” (Angelina).

FOOD QUALITY/NUTRITION HIERARCHIES

As depicted in Figure One, there was consonance between the hierarchical continua of food quality, as associated with socioeconomic status, and cultural notions of sound nutrition, especially when nutrition was cast as embodying scientized food notions such as the proportion of carbohydrates, lipids and proteins in one’s diet, food freshness, and the presence/absence of preservatives, sodium, and sugars in foodstuffs (see also Thompson and Troester 2002). In general, our participants saw social class positively correlated with nutrition, such that “affluent” or “upper class” persons ate more nutritious or ‘healthier’ foods. However, this correlation was not

perfect or comprehensive. Upper class persons were also seen as eating more exotic or unusual foods, such as caviar, which were not viewed as being nutritious/healthy. However, the correlation at the lower end of the continua did seem to approach both 100% and complete comprehension, in that poorer/lower class persons were consistently seen as eating poor quality, non-nutritious foods.

More specifically, as will be documented through excerpts below, our informants associated higher levels of protein, red meat, seafood, and fresh vegetable consumption with higher levels of affluence. Conversely poorer consumers were characterized as eating foods that were salty, greasy, filling, starchy, carbohydrate-laden, processed with chemicals and preservatives, high in calories, low in nutrition, and available as “fast food” or as “snacks.”

“Upper class food is food that’s not greasy; food that’s like fresh, and probably expensive. Lower class food is like fast food or just thrown together... just not healthy” (Sean).

“What are some high status foods?”

“Caviar. It shows that you have money. It’s probably gross and doesn’t even taste good, but it’s expensive. Low-budget foods are stuff like Ramen noodles that cost like 10 cents per package. Usually low-status foods are ones that are really bad for you.... They are filled with salt, and MSG and crap. Macaroni and cheese in a box where it’s filled with chemicals. Filet mignon would be a higher-status food. Some restaurants have duck or other weird stuff on the menu; that would be a more expensive restaurant” (Joellen).

“Honey Dijon [mustard]. Grey Poupon [mustard]. If you go to a fancy restaurant, they will use a fancy name for chicken.... It goes hand-in-hand with price. Steak and prime rib would be higher class, and lower class would be hamburgers” (Erwin).

“Well, I think rich people generally have fresher food, food that would be harder to get or cost more money to get absolutely fresh, especially a lot of fresh produce like salad. All the extras would be included in the salad too, stuff like fancy olives and mushrooms. I could see a lot of fresh fruit too and not just oranges and the typical stuff you see but the more exotic stuff like kiwis and, umm, pineapples.... Probably more seafood also which is, well some of it is healthy, some of it is having a lot cholesterol, but anyway I think you would see more of that.... At a poor person’s house, I could see there being a lot of the “fillers” like pasta and bread and more fattening types of food. Something where they (the poor people) could feed a lot of them for the money, pasta goes a long way, rice goes a long way...” (Joni).

As Orlove (1994) notes, in many cultures higher status is associated with the consumption of protein-rich foods, especially ‘red’ meats, whereas bread, grains and other carbohydrate-rich foods are equated with lower status (and see also Barthes 1970).

GENDER AND SEXUALITY/FERTILITY

Scholliers (2001) describes his family’s concern that he rejected eating red meat as a child in Belgium, noting that his father likely viewed it as a rejection of masculinity. And analogously, our informants easily classified foods into masculine and feminine categories. Associated with males and maleness were foods such as meat, especially beef muscle, starches such as potatoes, fats and fried foods, sandwiches (especially large, cumbersome ones), and alcohol, particularly beer and distilled liquors. Men were also

viewed as eating larger portions of food, usually in a sloppy, messy and out-of-control manner. They were deemed to be more frequent patrons of “fast food” restaurants and “junk food” snacks. The eating habits of adult males were often equated with those of children or even animals: dirty, sloppy, hand-to-mouth, out of control.

Conversely, our participants described women’s typical foods as “white/light” meat (e.g., chicken, especially breast filets, fish), leafy vegetables, often eaten uncooked as in a salad, and fresh fruits. Women and girls were characterized as using proper utensils to eat their food, avoiding making a mess or getting “dirty” from spattered food, and maintaining better control over the size of bites and overall portions of the foods they consumed. Clearly, these food stereotypes echo widespread gender categorization schemas (see e.g., Counihan and Kaplan 1998).

Erwin, when asked about what foods a man and woman might like to eat, responded:

“Steak and beer is always for men. I’m not sure for women.... [Maybe] chicken. It’s not messy and it’s not heavy.... A girl doesn’t want to get messy on a first date.”

Frank gave a similar response:

“I think a prime example of a guy food is steak. Meat and potatoes.... [For women] something vegetarian.”

I.: “What about a woman eating a steak?”

F: “I think that’s cool, it’s very cool. I’m proud of a girl that can eat [steak].... That’s the kind of girl you’ve got to marry.”

As did Sean:

“Guys drink beer; girls drink wine. Guys [eat] steak, girls [eat] seafood.”

The women to whom we spoke presented the same gender characterizations:

“Well guys definitely tend to drink beer more than girls do and maybe they tend to eat more hamburgers and like steak. I think that guys tend to eat more than girls” (Lena).

“Probably guys would go for the red meats and stuff like that. Girls are more chicken eaters.... Pasta eaters.... I always envision guys eating sandwiches. Like big, huge sandwiches... and girls are more like vegetables and fruits.... My dad would always have a steak. At least twice a week my mom would make steaks for him. And my sister and me... would eat chicken, vegetables... where my father and brother would eat steaks and bread” (Joellen)

These metaphoric equivalences of course echo the gender norms that pervade most of American culture. Women are deemed lighter, more genteel, more fragile than men, therefore requiring less aggressive fare. Men, viewed as warriors and laborers, are believed to require the strength and body mass provided by muscle meats and starches (see e.g., Counihan and Kaplan 1998; Lakoff 1987; Orlove 1997).

Fertility/Sexuality

Related to these gendered food categories are beliefs about fertility and sexuality that are also linked to particular foods. Given Americans’ conflicted feelings about their sexuality, most of our informants mixed notions of sexuality with not only concepts of

gender, but also with feelings of sin, guilt and indulgence/pleasure. Like food, sexuality tempts us to consume “the forbidden,” to abandon self-control. In particular, chocolate was seen as an aphrodisiac for women. Fruits – sweet, juicy and fed from hand to mouth – were also characterized as sexual stimulants. And whipped cream, requiring licking and filled with fat and sugar, was viewed as a sexual metaphor.

“Chocolate covered strawberries you can actually feed to somebody and that’s always fun.... Champagne and wine....” (Sean).

“Strawberries, champagne, wine, whipped cream, ice cream.... They’re sweet, they taste good and, of course, with champagne you get a little tipsy” (Lena).

“Ice cream, hot fudge, chocolate covered strawberries.... Stuff that melts” (Angela).

“Grapes could be sexual.... I’ve seen scenes where people are laying naked eating grapes, or the woman is feeding the man grapes....” (Joni).

“I think most of fruit... juicy fruits or just very ripe fruits like strawberries or peaches... soft type foods... chocolate... and things that are very sweet” (Nick).

From prior discussion, we can see that most of these associations are with “feminine” foods that either represent the female body (e.g., peaches) or represent reproduction/fertility (grapes). Americans’ notions of sinfulness and sexuality are seen in “bad but delicious” foods such as chocolate, ice cream and whipped cream.

DISCUSSION AND CONCLUSIONS

The present exploratory study has outlined some of the architecture underlying American food beliefs and practices. Clearly, this effort is quite preliminary and much more detailed excavation of American foodways is required. Shown in our tentative model but left unaddressed in this brief report are such category schema as food *seasonality*, both in content and preparation. For example, summer is not only associated with the availability of fresh fruits and vegetables, but also with outdoor meal preparation and consumption (picnics, hiking, grilling). Conversely, winter may be culturally associated with heavier foods, such as stews, casseroles, pastries, potatoes that create a sense of warmth, fullness and security. Notably, several feast-days, such as Christmas, Thanksgiving and New Years occur in the winter time and may have ancient roots in human concerns about maintaining sufficient food supplies to survive the barrenness of winter.

Also unexplored at present are consumers’ perceptions of food *ethnicity*, for example which foods are associated with particular racial and religious subcultures? How does this association influence how they are prepared, when they are consumed and who eats them?

With regard to ethnicity, foods can have positive and negative cultural associations that group members must deal with. For example, consuming watermelon and fried chicken is incorporated into negative stereotypes about African-Americans. Conversely, some groups have seen ethnically-identified foods ‘slip-away’ from being associated with a given ethnicity and become circulated in the wider culture; examples would include bagels, pita bread, sushi and salsa.

We also were not able to attend to issues of food taboos and segregation. Why are some foods, e.g., wine, coffee, not served to

American children when they are permitted in other cultures? Why are foods typically eaten in a given order, e.g., salad, meat and starch, sweet dessert? Are there social taboos that operate to prevent specific genders from eating given foods (e.g., females and raw beef)? Food marketers have had to deal with some of these restrictions when attempting to broaden the usage of particular items. For example, efforts (largely unsuccessful) were made to re-position orange juice as an all-day (not just breakfast) beverage. Iced tea has been more successfully re-positioned as a men’s beverage, by emphasizing its ‘briskness’ (=potency). Males still seem hesitant to accept salads as ‘meals’ however, and are likely more stigmatized if vegetarian, than are women.

And finally, we did not address iconic American foods, such as Coca Cola, McDonalds, Pizza Hut, potato chips, hot dogs and corn-on-the-cob, which may represent nonculinary cultural constructs such as democracy, materialism, leisure and modernity. Identifying the deeper aspects of American culture embodied in our foodstuffs (as seen both by Americans and non-Americans) would be a useful avenue to comprehending our national image. Why are we the Fast Food Nation? And, what does this signify? Why has the term ‘McDonaldization’ come into play in cultural discourse? What are the positive and negative meanings of Coca Cola as an icon of America? Obviously, there is an enormous terrain of food meaning available for exploration by consumer researchers, which we have not touched upon in the present effort.

Despite these omissions, however, we believe that the initial mapping shown in Figure One may be of benefit to consumer researchers, especially in the area of gender studies. For example, our model suggests that “fancy restaurants” and sit down dinners at home may both be seen as somewhat more feminine, due to elements of self control and formality. Conversely, snacking and fast food dining seem to both evoke maleness, because they are seen as inherently dirty, messy, uncontrolled and somewhat ‘bad for you.’ Read in this way, sexual foods may also evoke aspects of maleness because they represent a loss of control, eating with hands, high caloric content and messiness.

We hope this initial effort is helpful and may stimulate additional inquiry into this under-studied area.

Extreme Foods: Expanding the Boundaries of Taste

Ann Veeck, Western Michigan University

EXTENDED ABSTRACT

The purpose of this paper is to explore variations in individuals' food preferences as examined through an analysis of people's encounters with new and unusual food. The theoretical foundation of this study is the omnivore's paradox (Fischler 1980, 1988; Rozin 1976), which juxtaposes the attraction and distrust with which human beings (and other omnivores) approach new foods. The main thesis of the "omnivore's paradox" is that the survival of omnivores depends on a predisposition to seek novelty and variety (neophilia), juxtaposed with a natural distrust of the unfamiliar (neophobia). In an evolving world, the durability of a species depends on its ability to adapt to the changes in its environment. Still, at the same time, the omnivorous creature must operate caution as it samples new options, taking care not to introduce harmful or poisonous substances into its system.

In the U.S. today we are exposed to an unprecedented variety of food, due to agricultural and commercial innovations, improved transportation and distribution systems, and global trade. According to Rozin (1999), we currently know very little about how people acquire food preferences. Individuals are born into a culture of biological and cultural tastes, and while socialization surely plays an important role in the acquisition of tastes, the correlation between the food preferences of parents and their adult offspring has been shown to be surprisingly low (Rozin 1991). The phenomenon by which consumers enlist tactics to protect themselves and their families from unsafe food in the face of an environment of increasing food choice has been called "strategies of confidence" (Sellerberg 1991) or "coping strategies" (Beardsworth and Keil 1997). These analyses provide important insight in addressing how consumers evaluate the safety hazards of unknown foods in the face of food risks, such as GM foods and Mad Cow Disease. However, in addition to food safety, there are surely other dimensions that consumers evaluate when encountering new and unusual food items that are also important to recognize.

The main focus of this study is the experiences of consumers with new and unusual foods. Data for this study were analyzed from transcripts of 250 face-to-face interviews. The semi-structured interviews were conducted by trained undergraduate students of a large midwestern public university, with the aid of an interview guide. The interview transcripts were systematically analyzed, and the findings of the research were organized around three central questions that emerged from the depth interviews. How do consumers define "extreme" foods? What are the meanings that consumers derive from eating or avoiding "extreme" foods? Under what conditions are consumers most likely to sample "extreme" foods, and how do consumers characterize these experiences?

The findings show that the list of foods that U. S. consumers consider to be "extreme" is highly individualistic, but commonly includes endangered animals, animals that are viewed as pets, game, animal organs, raw meat, spicy foods, and odd food combinations. While the demarcation of edible and nonedible is too diverse and idiosyncratic to provide easy categorization, bipolar characteristics that seem to aid consumers in classifying foods according to edibility include familiar/nonfamiliar, safe/unsafe, and bland/spicy. How consumers approach food that they consider unusual depends on individual evaluations and characteristics as informed by social forces. In particular, the meanings derived by experiences with unusual foods are influenced by the degree to which the consumers view the tasting of new foods as an adventure,

the extent to which the consumer can feel safe ingesting the food, and the raw emotions evoked by the encounters with the food.

An individual characteristic that appears to be of paramount importance in every encounter with new foods is the extent to which a consumer is a neophilic who embraces novel food items or a neophobic who avoids unknown foods. The findings seem to indicate that this characteristic is more of a dichotomous trait than one of gradation, as most respondents readily self-classified themselves into one of the two extreme positions of "willing to try anything" or "picky." Neophilic consumers are more likely to view unusual foods in a positive light and to embrace situations involving new foods as "adventures." Neophobic consumers, on the other hand, view unfamiliar foods with disgust and purposely avoid events in which they might be expected to taste unusual foods.

The findings also shed light on conditions that result in changes in food tastes. The contexts in which consumers are most likely to encounter and sample new foods includes incidents involving travel, while dining in trusted restaurants, and during social events in which the consumer feels pressure to conform. As Fischler would predict, encounters with new food often involve an evaluation of food safety. Still, many experiences with novel foods occur in situations in which food safety anxieties must yield to more pressing concerns. In fact, as the findings show, many experiences in which people find themselves consuming unusual foods actually occur by accident. As such, the food preferences that people form from birth are altered and amended as they live out their lives while engaged in social relationships with others. Altogether, this study underscores the influence of psycho-social forces on food tastes, with neophilic/neophobic tendencies and the formation, maintenance, and alterations of identities and relationships informing encounters with novel foods.

Consumer Trust and Distrust in the Food System: Some Implications for the Debates on Food Biotechnologies

Ahmet Ekici, Bilkent University

ABSTRACT

Biotechnology is considered to be one of the most influential revolutions, one far greater in its potential societal consequences than the computer, electronic or atomic revolutions. As with most revolutions, the public's view on the risks and benefits of the technology is divided. However, most scholars agree that public trust in social institutions and in the food system would be a central issue to understanding public attitudes toward the risks and benefits of food biotechnologies. To date, the nature of such trust has received little systematic empirical attention. This study provides a detailed look at consumer trust and distrust in social institutions and in food safety system. Theoretical significance and practical (public policy) implications of the findings are also discussed.

INTRODUCTION

The broad objective of the study is to investigate consumers' trust and distrust in the food system with respect to food safety and food biotechnologies (a.k.a. Genetically Modified Foods). Trust in the food system is considered to be a central issue for biotechnology debate; however, we do not know the nature and components of this trust and how it affects consumers' view of the food safety. Further, studies to date (both in food and other contexts) have investigated consumers' views on one institution at a time and in isolation. For example, some studies focus only on one institution such as a regulatory agency (e.g. Lazarus 1991; McGarity 1986) or universities (e.g. Rampton and Stauber 2001). Others studied a number of institutions (e.g. government, military, schools) in the same study and basically reported the degree of public trust in these institutions. No specific attempt was made to understand consumer perceptions of the interplays among various institutions that form the system. In other words, past research provides a detailed account of trust for one or more institutions (e.g. how trust in these institutions has changed over time) but does not explain, for example, how consumers' trust and distrust in various institutions may interact with each other and collectively contribute to beliefs about the trustworthiness of the "system." As a result, we do not know how individuals' positive and negative views and expectations of various components of a food system interact within the system to result in an overall view of the system. These knowledge gaps inhibit a complete understanding of the consumers' view of the food system with respect to biotechnology. This, in turn, may hamper any communication efforts for healthy public debate and resulting public policies.

Social scientists have argued that Americans' trust in social institutions has deteriorated over the last a few decades. More specifically, studies have reported that most Americans do not trust the government and governmental agencies (Epstein 1998), manufacturers and other big businesses (Bernstein 2000), universities (Rampton and Stauber 2001), science and scientists (Maddox 1995), etc. At the same time, it has been the common view among the authors in the popular press (e.g. Kilman 1999), and in the academic community (e.g. Hoban 1998; Mokhiber and Weissman 1999) that when it comes to views of biotechnology in general and genetically modified foods (GMF) in particular, most Americans are not concerned (i.e. they feel safe) about the food they purchase because they tend to trust their food supply (system). These views, however, may suggest a contradiction because as mentioned above, Americans, over the last a few decades, have become distrustful of various institutions including the government, manufacturers, me-

dia, etc. It appears that the issue of what American consumers' trust/distrust in the food supply (safety) system really means is not clear and perhaps underexamined. As a result, this study aims to answer questions such as can the food system be trusted, what does that trust/distrust mean, and how is that trust/distrust related to the components of the system. More specifically, the study asks is it possible that while individual components of a system (e.g. government, manufacturers, scientific community within the food system) cannot be trusted, the system as a whole can be? Is it possible that consumers feel their food is safe while they are suspicious about various actions of regulatory agencies, manufacturers, and scientists?

REVIEW OF RELEVANT LITERATURE AND OBJECTIVE OF THE STUDY

Most studies on institutional and system trust have been carried out in sociology and political sciences. These studies have focused on citizen views of such institutions as media (e.g. Sperling 1997), big corporations (Bernstein 2000), science (e.g. Maddox 1995) and the government and governmental agencies (e.g. Rose and Mishler 1997). A Common characteristic of these studies is that they mostly report trust in a particular target (e.g. politicians or media) instead of taking a broader approach to study public trust and distrust. In order to understand consumer trust in the food system, one should investigate consumers' views of various institutions in the food system through a holistic approach. However, most research conducted with regard to institutional trust has either dealt with views of a particular institution (e.g. Abbott and Dalton 1999; Lazarus 1991; McGarity 1986; Renn and Levine 1991) or dealt with multiple institutions (in isolation) with no specific attempt to understand citizens' perceptions of the interactions between institutions (see Rose and Mishler 1997; World Values Survey 1984, 1993). Even though these studies provide in-depth understanding of the views about one particular institution, they fail to account for the complexities and the challenges that are associated with social systems.

Other studies have examined citizen views of various institutions within a country (e.g. Rose et al. 1997; World Values Survey 1984, 1993). The main objective in these studies was to monitor the changes in public confidence in various public and private institutions (e.g. police, legal system, armed forces, parliament, civil service, the church, major companies, and press). They provided detailed understanding about the impact of these changes on the overall performance of the studied countries. However, these studies reveal little information regarding how individuals' views of various institutions interact and/or how such interactions determine individuals' overall views of a particular system (such as the food system). Institutional trust studies (when they deal with individuals' views of various institutions in a system in a holistic manner) have the potential to provide detailed understanding of policy problems and their potential solutions. Through a holistic approach, one can look at individuals' views of various institutions and institutional interactions in complex systems of the society (e.g. the food system) and understand how trust and distrust are distributed and managed among these various institutions within the system.

Based on these points, in summary, the specific objectives of this study are to study consumer trust and distrust the food system, to understand the impact of the interactions between social institu-

tions (perceived by consumers) on consumers' trust and distrust in the food system, and to question the relationship between individuals' trust/distrust in the system and their beliefs about food safety. Public policy implications of the findings will also be included in the discussion of the findings. In this study (analysis), as identified by the informants, key institutions of the food system include government (food related regulatory agencies), food manufacturers, farmers, scientific community, consumer groups, and media.

METHODOLOGY AND METHODS

The research design used in this study is an adoptive and emergent one. In other words, the design unfolds as fieldwork unfolds and the emergent nature of the design affects decisions regarding sampling, data collection and analysis. Our design involved a two-stage data collection process. The first stage involved seven depth-interviews with consumers in a Midwestern state on their knowledge, beliefs and attitudes toward issues surrounding GMF. For the first study conducted in 2000, we sampled relatively educated consumers because at this time both academic and popular press noted consumers' awareness of GMF was very limited (Kilman 1999). By 2002 consumer awareness of GMF had increased from 12% in 2000 to over 70% largely due to the Starlink[®] corn fiasco and debates on stem-cell research. Therefore, our emergent theoretical perspective on factors that influence beliefs and behaviors related to GMF drove sampling decisions for the second stage. We sought to include informants with diverse orientations to GMF based around underlying differences in family stage, health concerns, social and political beliefs. The second stage involved 10 depth interviews focused on uncovering consumers' trust in the quality and safety of their food and whether and how that is related to GMF and institutions they identify as playing a role in food safety.

Data analysis was a process of gradual induction. Analysis of textual data proceeded through two distinct stages of iteration: intra-text and inter-text (Arnold and Fischer 1994; Thompson 1997). Intra-text analysis asks a set of questions to identify the codes and categories of the findings. Once codes and categories

have been identified, the researcher uses inter-textual analysis to look for patterns of relationships within different interviews (Thompson 1997). Thus, intra-text analysis addresses the extent to which general themes are shared by different respondents, and patterns of difference.

FINDINGS

Our findings are intended to illustrate the range of beliefs and behaviors associated with food safety in general and GMF in particular among U.S. Midwestern consumers. Thus, our intent is not to generalize to the American public. Table 1 provides a summary of the types of informants who rely (or not) trust and distrust for food safety. As can be seen in Table 1, many informants look at a "system" for food safety. Some of them (two columns on the right) trust the system, and some of them (first column on the left) distrust the system. However, as can be seen in Table 1, not all of the informants rely on a "system" to ensure the safety of the food. For some informants, trust in one institution (e.g. the watchdog or a high authority) can be sufficient to feel safe about the food. Similarly, for some respondents, distrust in one institution would be sufficient to feel unsafe about the food supply. In addition, some informants do not rely on trust/distrust when they think about food safety. They have other ways to ensure the safety of the food they eat. The remainder of this section will discuss various types of consumers summarized in Table 1.

Column 1: Distrust-Reinforcing Properties of the Food System (Perceived Negative Synergetic Interactions between Social Institutions)

Analysis of the data suggests that there are mainly two types of interactions that are perceived to be distrust reinforcing. Among the six social institutions that are most commonly recognized by the informants, only three institutions are mentioned to have negative (distrust-reinforcing) interactions: the government, the scientific community, and the food industry, the industry being in the center of all the negative synergies identified in the study. It is also observed that rhetoric used by the informants changes when they

speak about a negative interaction that involves the industry. The words such as “big business” and “lobbyists” are used very often to describe the industry.

A distrust building interaction between the scientific community and industry comes from the belief that scientists are increasingly being hired and funded by “big business. This, in turn, concerns Pam, a housewife, and mother of two, whose husband is a scientist/researcher in a state university. She knows through her husband how researchers in universities are increasing relying on the industry-backed “soft money” and that (as she indicates in below lengthy excerpt) concerns her as far as the safety of the food supply goes.

You know, I see...research, um...from, uh...major universities, um...research...I'd say...funded by major companies, but you'd kind of have to be careful about, well it's, uh...especially the research that is, um...performed by specific companies for their own good. I think that some of those could be skewed. Um,...so, you know, you kind of have to keep your eye on things, but, you know, I'm somewhat concerned about the, um...current trend of, um...big business and um...uh...commodity boards. Um...these groups funding research at the Universities rather than the scientists at the University getting funding from the University for pure research. Because, again, I think that uh...that limits, um...the objectivity of the researchers, um...getting money from people who are in the various industries, um...also can limit what research is done. Um...so if a scientist has a great idea for...for research that might end up harming some particular industry depending on how the research comes out. Um...what's to say he's able to get, uh...will be able to get a particular commodity board or um...company to provide funding for him to do that, uh...if there's a possibility that it could harm their, um...productivity. That just isn't happening much any more. And, uh...I think that can very much color the research that is done. And that's definitely a concern...in terms of the safety... I think that...that's a biggie. And, I think that...and I think I'm very much in a minority about this. I think most people don't really care what funding the research is coming from.

The next excerpt is from an interview with Kyle. He describes a more complex interaction that involves the government, food industry, and the scientific community and creates concerns in his perception of the safety of food. Even though there are regulations in places, he believes these food-related regulations are at times set by “listening to the industry lobbyists” instead of listening to scientists. He sees such interactions between government agencies and industry as a part of the current economic and political system that “intellectually pisses him off.”

I don't think the industry is...is...is purposely violating regulations and I...I...I don't think that the regulations aren't being followed. I think the...in...some cases the regulations just aren't strong enough. And, um...regulations aren't strict enough and part of the problem stems from the system in terms of how the regulations are...are established in the first place. You know...such as the...the use of hormones and anti-biotics. That's really a...a...a scientific and...and...policy question. But, the science is out there that...uh...that says that the hormones and the anti-biotics are a long term problem for humans. That it's a policy problem. So, in terms of who sets the...establishes the regulations...um...they are not establishing permanent regulations...in terms of how much anti-

biotics can be used or where even anti-biotics can be used. They're not listening, uh...to...to the scientists or...or reading the scientific information that says, yes, anti-biotics fed to cattle will wind up in our system and can be a problem...The industry that raises the cattle is a big industry and they...and they do have tremendous lobbying power. So, it...really it's not economics, it's politics. They have tremendous lobbying power and...they...ironically, it's the industry that's being regulated, but the industry in part establishes the regulations...When I think about how the system works...you know...it...uh...I'm upset by it. On a day in and day out basis it...it doesn't disturb me. I...on an intellectual basis it pisses me off. But, then that's the way the system works in terms of regulation of...of...how regulations are...are set up for...for...how other things...whether it be cars or...uh...pollution levels or...uh medicine. The...the regulations...regulation process is intended to protect us, but on the other hand it's compromised by...what the pressures that those particular industries apply on the regulators.

It appears that lobbying attempts of the food industry (though they are legal) have created enough disturbances among some of the informants to make them distrust the food safety system. Kyle and other respondents who are described in this section expect some components of the system (particularly government and the food industry) to act in a responsible manner. As recently noted by Nestle (2002) “Our...system must balance the rights of individuals and groups against the rights of society as a whole, and it requires elected officials to listen to groups demanding self interested actions. What concerns us... is the differential ability of food companies to obtain laws and rules that act in their favor at the expense of public health” (p. 96).

Column 2: Distrust A Particular Institution

This section deals with respondents who believe that the food supply (through conventional food system) is unsafe largely due to their perception that one major component of the system is incompetent to ensure the safety of the food. In most cases, government (regulatory agencies, politicians) is considered to be the source of their distrust in the food supply. Respondents usually make reference to the political and economic system as the source of their distrust. One important observation about these informants is that, in the presence of such distrust, the informants assume more responsibility (take more control) over their food supply and use strategies such as buying from co-ops, organic food stores, and growing their own produce and some dairy products.

Larry, an organic food consumer-informant, who is also a vegetarian, shows a great deal of suspicion when it comes to his feelings toward the conventional food system. Even though he thinks that most foods are safe to eat (to the extent that they won't kill people), he feels entering a grocery store is like entering a lottery and buying food in grocery stores can be very risky. He is particularly suspicious about meat products. Though he is a vegetarian he thinks those who buy meat in groceries are “guinea pigs” or test animals.

I think...I think it's (the food) primarily, mostly safe. In terms that it's not going to make you die or give you a horrible illness, but, um...when you walk into the grocery store one of my gut feelings is that I'm entering a lottery. Um...kind of a...gambling situation because...especially if you buy meat in a grocery store...I mean what...you always hear about these stories where a certain amount of meat gets recalled...because it was tainted with something. Or, there's an illness on certain foods

and they had to pull it off the shelves...nobody really else buys it. But, if you're the person that bought or if you're the person...the first one, or one of many that...uh...is the...the...guinea pig...or the test animal to...to start that process of saying there's a problem with this meat. It needs to get recalled. You know, so, you could be the one.

Susan shares the Larry's view in that she sees government policies and their consequences as the main source of her concern for the safety of food supply. She believes that government has let food production and processing businesses to get so big that the government can not control these businesses effectively anymore. She believes that once a powerful watchdog has become weak, it cannot oversee these big operations anymore. As a result, it does not matter for her if government (USDA) tries to assure her about the food safety. She, therefore, elects to take more responsibility in making sure about the safety of her food.

I mean just like the USDA's so-called overview of chicken production, I mean, you're probably aware now, we have to be so careful we cook our chicken thoroughly, you know. Well, if you look at how some of these chicken producers kill chickens, gut them, you know, there's all the waste, there's all the excrement. They dump the carcasses in a tank of water. No wonder we've got bacterial contamination of our chickens (laughing). And there not being cleaned, the exception is we've been buying the "Smart Chicken" which is produced here in Tecumseh, NE...The USDA has a really hard job (now). This is a big country, there's so much stuff coming in that they have to be aware of and concerned about and it's easy for me to be a critic, but um, it is the USDA's fault. They let things get bigger and bigger and out of control. I don't think it would matter any more if the USDA assured me that something was O.K...any more than if the grocery store assured me. Cause...I just don't see how they can do all the things that they're supposed to do.

Column 4: Trust A Particular Institution

This section deals with informants who believe that their food is basically safe because they believe that one component of the food safety system performs its duties sufficiently and (if necessary) would catch the mistakes made by others in the system. Barbara, for example, mentions that she would trust the decisions made by the government agencies if labeling is not offered for GMF products. She believes, if labeling is not mandatory, products must be safe and consumers would not need to know the genetic modification characteristics of these products. She further believes that even though some aspects of the food system (e.g. the food scientists) do "scary" things, she doesn't feel scared because she is confident that FDA would not allow any dangerous products to be put on the grocery shelves.

Well, I suppose it (labeling of GMF products) would be depending on how concerned you are. A lot of people would be and a lot of people would. I guess I am basically pretty trusting that they are not giving us the things that we shouldn't have. I think we have to use our best judgment and hope. I would not go to the grocery store and buy something that I know it is not safe... I think that, umm, I trust the Food and Drug Administration most of the time (laughs) and I think we have to have faith in what is happening. I know there are things happening in food and science labs, scary things. I try not to worry about whether there are negative things. I think, thanks to FDA, I don't have to (laughs).

Jenny is also a nurse but she is in her early thirties. She takes the statements made by higher authorities very seriously. In fact, she has more confidence in consuming particular food products if, for example, USDA endorses it. She has enough trust in governmental authorities that she feels she doesn't have to worry about listening (trusting) other sources for food safety.

Well, you know, maybe because I worked at the public health and I have worked in health for long time, if the government came out, or the surgeon general came out and USDA came out and say "you know people you have been eating this genetically modified food for the past X years and its fine, its healthy, its great for you," then I would probably be very comfortable with it... I think, you've got to trust something or somebody, you know people at the higher up, you don't have to trust everyone, or even think about it. You know surgeon general or a higher authority comes out and says "it is fine, there is nothing wrong, we have been doing it for the past X years," then I probably, personally would have more confidence in it.

Column 5: Trust-Reinforcing Properties of the Food System (Perceived Positive Synergetic Interactions between Social Institutions)

In this section, we will discuss the informants' view of the interactions between some of the social institutions in the food system. Some of these interactions are perceived to be trust-reinforcing in that consumers see them working together in order to provide consumers with safer, higher quality, and more efficient food supply. One of the informants, Amanda, is explaining how she feels safer about the food supply today than in the past due to the interactions between some of the social institutions, namely, science/technology, manufacturing, and the government. For example, she has trust in the "food processing business" because technology has advanced and impacted how they (businesses) are doing their job in treating food products. She also makes reference to government suggesting that due to the technological developments government is better able to ensure the safety of the food supply:

...Our technology is so advanced over the years that, you know, people tend to trust more that they're doing things better than before. You know, things are just getting better. Um...with...

I: When you say trust more to them. Who are they? Can you talk about them?

I think we're taking about businesses as well as government because I'm thinking of, you know, all the companies that are in the food processing business or in the food producing business, um...that, I probably have more trust then just because technology has advanced that, um...you know, that has to be impacted. You know, things have to be. I'm trying to think of what I've seen happen over the years since I was a kid, um...just things that you...are obvious signs that is has advanced and uh...probably for me it's seeing things like, um...what I've, again, I hate to say it, but what you'd watch on the media about, uh...how they're treating foods or how they're working on growing things more effectively or they're working sure our meats are, you know, safer...things like this. I guess I'm...I can't be in all of the places...So, I'm believing and hoping that their technology is true and they have just continued to grow in that area, and government is using these

technologies to check things, keep things under control. That's my hope.

In other cases, informants see the close relationships between big food manufacturers and the government as trust reinforcing. April perceives big manufacturers' foods as being safer due to a closer look on their operations by the government. She compares government scrutiny on a big manufacturer versus a small one, and concludes that interaction between big companies and government would make her feel better about the safety of the food offered by these big companies.

I sort of think that this is just a perception of mine that bigger the company the more watchdog the government towards that company. Like Oscar Mayer because they produce so much deli meat that FDA or whoever looks at the way they process the meat and whether their employees are wearing gloves all the time, whether what they do when something fall on the floor. I sort of think that those government regulators would be more regulating these big companies than Joe Black on the street who makes turkeys in umm slaughters them and sells to you. He doesn't have good safety and health regulations because no one enforces that for him.

Column 6: Offsetting Properties of the Food System (Consumers' Use of Balancing Strategies)

In this section, we explain the informants' use of "balancing" strategies among various social institutions in the food system to assess the safety of the food they eat. Due to page limitations this section is built around only one of the informants, Nina, who provides a very elaborate picture of strategies she uses to assess food safety. This section begins with reporting her trust in food manufacturers. She trusts the fact that big food manufacturers would provide higher quality and safer products because they have access to higher quality ingredients. Their suppliers (farmers for instance) would want to give the best of their products to these big manufacturers in order to keep their business. Further, she specifically indicates that she trusts the packaging and labeling practices of such big manufacturers due to their long time presence in the marketplace. This, according to her, in turn, generates a sense of competence that leads her to believe that these big manufacturers can be trusted.

Well, I have to say, I might have a brand bias. I mean, I do have a tendency to trust products by companies like Procter and Gamble. I feel that they are in the business long enough that if they are going to package cereal, they know how to do it, they know how to label, and therefore, they are experienced enough to accurately say what the ingredients are. This is for the accuracy of information disclosed. As far as the food quality and safety goes, I have tendency to believe that big big big businesses like PG sort of get first bites of the products, that they are more likely to get better grain, the better beans, you know, they might just have better access to umm better products that make up their final product. Whereas a smaller company or generic company might be buying cheaper products. If I am selling beans to PG, and it is every year with great quantities, I would tend to give my better product to PG. So, from the producer position, there might be bias to get better product to PG, so that's one point... And so, PG's product will be safer and higher quality.

Even though Nina indicates trust in the big manufacturers such as Procter and Gamble, she feels that (she is suspicious that) these

companies could also do anything (including potentially health damaging food practices) to stay profitable because people running these companies sometimes can be very "greedy." She believes the greedy managers might not care about the safety and welfare of the consumers as they didn't care about welfare of their employees at Enron.

I think that on the one hand P&G for example want to support their name and therefore have good quality product. But if they could cleverly inject green dye in green beans and make them look better, umm, and hide it, fool the consumer. And it may not be important for them if that green dye is not good for consumers in the long run. They have to take care their profits first, right (laughing) Look at Enron, right, they...who cares about their employees? So, right, They might not care about consumers? There are people that are very greedy and I guess greed is a...is a very big problem.

When food manufacturers cannot be counted on to bring safe products to consumers, Nina finds comfort in believing that farmers (small or big scale operators) will, to some extent, buffer the bad intentions of greedy food manufacturers. She trusts the farmers to set their priorities in favor of the consumers by "drawing the line at some point" when manufacturers try to push farmers to use potentially unsafe food practices. The source of her trust is the belief that farmers (unlike manufacturers) have a greater attachment to land, and therefore, they care more about the food (and consumers) than manufacturers.

I think, the nice thing about farmers is that, I think they want to increase yield but I think they are less likely, because they are close to the production, this is their product and I think most farmers have some, umm, there is reason why they are in that business, you know, there is some tie to the land, between them and the product they produce. Whatever that tie might be different than going to a factory and producing, you know, car parts. So, I think that for that reason farmers, even those who are in very big business, umm still are going to have a greater alignment to consumer interest than other (food) manufacturers. So, I think the farmers also will protect consumer interest and care about our safety to some extent...the manufacturer might try to push farmer beyond what they want to do, umm, but I think farmers would draw the line at some point.

However, according to Nina, in some cases, farmers are not as reliable in following food safety rules set by authorities as one might think. She doesn't believe that farmers would "degrade" the quality of the products or jeopardize the safety of the consumers intentionally; however, they may not be willing to follow the recommendations of the government because of financial pressures or convenience reasons. In fact, the farmers wouldn't voluntarily follow crucial rules (e.g. crop rotation) if there were no enforcement. In this case, the source of her distrust in farmers comes from farmers' lack of knowledge of safety issues and their unwillingness to follow the rules. In such cases (when farmers cannot be counted on ensuring the safety of the food supply) she relies on the government to "do the testing," "educate the farmers," and "enforce all the necessary rules" to protect consumers from any unsafe food. Her parents who have a small farm in the Midwest had to pay over \$10,000 in fines the year they didn't follow crop-rotation rules properly. Since then she says all farmers in the place her parents live follow the rules very carefully. From this first hand experience, she knows and trusts the government to enforce the planting rules on farmers when they are unwilling to do that.

Nina believes that government can ensure the safety of the food supply not only by controlling the farmers' practices but also setting standards for food/biological scientists who are working for the food industry. As detailed in below excerpt, she believes that scientific community (except some university-research) cannot be completely counted on to bring safe and quality products on the market because their objectives are to increase yields and the profitability of the industry for which they are working for. Through the end of the excerpt she suggests another "layer of scrutiny" that makes her feel better about the safety of the food when she is distrustful of the food-related scientific community; she feels safer in consuming food products that are exported to other countries since the these foods must also pass the safety and quality standards set by these countries.

I think scientists, too, have competing motives. So some scientists are probably trying to improve the quality of the food. Some scientists are probably trying to improve the quality of our soil. But there are other scientists who are employed by big business umm who might somehow trying to increase yield without concerns about the quality and safety, you know, humanity. And not much attention to quality and safety issues. So, and then for the industry, so if you were working for the cattleman or the dairyman, you might be trying to produce bigger cows. That might be your objective. How do we get more meat per cow? Umm, therefore, your sole objective might be really narrow. But, again I think there is government regulation that at least caps that in somewhere, you know (laughs), that there's got to be some standard out there, I assume, there is a standard out there of meat quality, beef quality and safety. Particularly on exports! Umm, because, there is something we haven't talked about it is that we focus so much about the US government, but foods that are put out there for export, I think that adds all other layer of scrutiny. And probably unfriendly scrutiny. So the Canadians are going to be very critical to some American beef because it is competing with Canadian beef. And the same is true for beef between United States and Europe. You know, the things that forces us, or umm, the structures that protects the beef industry, same structures that Europeans have in placed to protect their own beef industries, and therefore, they are going to be scrutinizing our meat.

Even though one believes that government can offset many of the food safety problems created by farmers, the scientific community, and the food industry, the informants' trust in the government is not endless. In fact Nina, in some areas, distrusts the government agencies' ability to ensure the safety of consumers. She is very suspicious about government overseeing powerful industries (such as the beef industry). It is noted earlier how she trusts government to make sure farmers are following the rules. She also owns a small store where she (among other things) breaks bulks of cheese and sells. She mentioned during our interview how government officials are checking her scale regularly to make sure she is measuring cheese right. That kind of "attention to detail" makes her trust the government in food safety. However, she also believes that government is not willing to do similar enforcements to powerful industries such as the beef industry. She believes the government is highly affected by these industries' lobbying efforts and such influences can very well jeopardize the safety of the food for consumers. For example, consumers may be fed with meat that has highly dangerous amounts of steroids in it.

I have to say, that am very suspicious of our government may be with beef industry. I think it is very powerful. Umm, the exportation of things like beef might be area in which there might less scrutiny. You know, because you want to remain competitive internationally, and so yeah, I think that there are some areas I would think that government is not that strict...I think that on the one hand, government is going to make sure that if I buy a package of cheese, that is eight ounces. They try to regulate that. On the other hand, if I buy meat, there might be dangerous amounts of steroids in it because that might enhance business and make American cows competitive with Canadian cows. Umm, yeah there might be steroids in it that make us all sick but government may not willing to see this.

When government cannot be trusted, the informants still do not feel helpless. In fact, Nina for example believes consumer action groups are potentially "the best insurance" for food safety when big business and even the government cannot be counted on, or as she puts, "get out of wag." The source of her trust in the consumer groups comes from the belief that these groups do not have competing objectives (but all the other components of the food system, farmers, scientific community, manufacturers, and government have competing objectives) The sole objective of the consumer groups is to "protect consumers" and they perform their job without expecting any funding from the industry.

I think consumer action groups probably are someways the best insurance. I remember in the past some complains about beef sold at McDonald's. It seems to me that if a high profile place like McDonald's is selling some problem meat, that you might have consumer actions response for that. Umm, some type of consumer watchdog comes in and breaks in the chain. I think, consumer action is extremely important and they are the mechanism that ensure that neither big business nor big government gets out of wag. So. I think they are very important. And not even being active, but just being latently being present probably puts pressure on chains like McDonald's, as consumer are coming and purchase goods. I think that they are big pressure. Probably more on business then on government actually. Because I am to some extent distrustful of government, umm, I think that government has competing set of goals. On the one hand consumer protection on the other hand is sale of exports. Whereas, I think consumer protection groups, their entire focus and objective and agenda is to provide consumer protection. So they are less susceptible to competing interests.

Column 3: Food Safety beyond Trust and Distrust

So far, it is argued in this paper that consumer beliefs about food safety are closely related to their trust and distrust in various food related institutions. However, not all of the informants rely on trust or distrust in institutions/system to ensure the safety of the food they consume. George, for example, accepts the fact that food cannot be completely made sure to be safe. In other words, neither government, farmers, manufacturers, nor scientists can guarantee the safety of food completely. George's view does not necessarily mean that he distrusts these institutions that are a part of the food safety system. Instead, he uses a different strategy to minimize the risks posed by potentially harmful food products: he basically tries to serve a varied diet to his family and avoids overconsuming a particular food product. This way, he doesn't "worry about consuming unsafe food."

Yeah...yeah...food in general...no, I usually don't worry about it being...uh...um...being...safe or...or...I don't...I don't worry about consuming unsafe food. Let's put it that way. I mean I...intellectually, I understand that that can happen...and, um...but...I feel that...that I eat such a varied diet and that I serve...we try to serve, you know, our family such a varied diet that they're not going to overconsume any one particular product which would...uh...if it was tainted that it would effect their health. Obviously, then you know, you can these occasional problems such as Salmonella or E. coli in meats and there, you know, we just try to be as...as careful as we can when we prepare and uh...cook the meats. But, in terms of, um...uh...any kind of packaged food or...or canned or bottled food, I...I...intellectually, I...I know that occasionally there can be problems...uh, but I...I just don't have that forefront of my mind.

Tyson is another informant for whom trusting/distrusting food system or its components is not a very important consideration for thinking about food safety. In other words, he doesn't consider trust/distrust as bases for making judgments about food safety; rather, he sees trust as given component of purchasing and consuming food. He believes he has no other choice, but to purchase food that is offered to him in the stores. He relies on his three decades food purchasing experience in making food decisions, he knows that food can be unsafe and "something could be wrong with the food", but he elects to not to think about it.

That something could be in fact wrong with the food. That something could be in the can or the package...but you do (buy) it anyway. Cause it's the only choice I have.... I don't grow my own food and I don't grow my own cows and I don't, you know... HyVee or Super Saver or I don't eat. So, basically that's the system that delivers me all my food and I don't have a lot of options to it. And so, yeah...I mean even if I am concerned about it, ultimately...being kind of pragmatic, what am I going to do if I don't want... You go with it and you know within that because that's the system that delivers my food.

DISCUSSION

In the beginning of this paper we asked: is it possible that while individual components of a system cannot be trusted, the system as a whole can? In other words, is it possible that consumers feel safe about the food they eat while they, according to many studies, distrust various institutions that are responsible for bringing them "safe" food? It appears that consumers use a number of different mental models to reason with the GMF in particular and food safety in general. The findings suggested that one explanation for this question would be the view that consumers recognize a system of food safety with various individual components (social institutions) working in a "system-like" manner to balance the weakness of each other. We framed this type of mental model of consumers as "offsetting properties of the system." In order words, the data suggest that it is true that consumers may, at times, distrust the activities of various social institutions. However, perhaps more importantly, they see interactions between their trust and distrust in various institutions, for example, trust in farmers in one issue offsets the distrust consumers have for manufacturers. These kinds of balancing strategies, in turn, appear to make the informants feel safer about their food supply. Research in systems suggests that properties of each element of the set have an effect on the properties of the set taken as a whole (Ackoff 1974; Gharajedaghi and Ackoff 1986). Similarly, as suggested in this paper, properties such as

consumer trust and distrust in each element (social institution) may affect consumer trust in the food system.

A second consumer model that may explain this question is "trust reinforcing properties of the system." In a systems view, interactions between the components of the system can create synergies that are greater than the utility of each component (Ackoff 1974). The data suggest that when consumers see positive interactions between the component institutions (e.g. between the government and science and manufacturers) they may have a greater confidence in the food supply system. These perceived interactions create positive synergies and resulting positive attitudes and beliefs toward the food system. We believe that the formation of the system trust through this second (interaction) model can also be considered as a potential problem for public policy researchers. It can be argued that in situations where the respondents trust the system, they may consciously suppress their distrust in various institutions. In such cases, although trust expressed by the informants in the system typically is rational and grounded in some experience it can be misattributed at times, and existing foundations for distrust can be discounted or ignored. In other words, it may be possible to argue that, even though consumers distrust some institutions, they may overgeneralize trust in food system. The rich sociological tradition of research on white color crime points to the role of "overgeneralized" trust as a necessary precondition for the undermonitoring of trusted employees that leads to possible deception, fraud, and embezzlement (Granovetter 1985; Shapiro 1990). This case points out the difficulties encountered where broad (generalized) trust or distrust emerges and where countervailing facets that support the contrary view is suppressed. Future research can examine the extent to which misattribution of institutional distrust and overgeneralization of the system trust can explain the difference.

Our study also suggests that a single institution may be sufficient to feel safe about the whole food supply (strong watchdog model). In all of our cases that fit into this model, government appeared to be the "sufficient" watchdog. As suggested in the literature "creating institutions that help secure trustworthiness thus helps to support or induce trust" (Hardin 1996, p.28). Sztompka (1999) notes, for example, that "it is easier to trust business partners to deliver the goods, if there is an enforceable contract signed by them at the public notary's office; it is easier trust fellow musicians in the orchestra not to botch the tune, because of a towering presence of the 'maestro' who will enforce good performance if needed..." There are numerous institutions within the food system and it may be easier to trust them if there is an institution oversees the others. Research has suggested that informants trust the government because the government "enforce rules," "have sufficient regulations," "oversees industry," "enforce recalls," etc.

We also have two consumer models in which the informants feel unsafe about the food supply because they distrust the system or one of its components. Similar to the discussion on system trust through perceived positive synergetic interactions, we believe, system distrust through the consumers' perceptions of negative synergetic interactions is an important public policy problem. Even though some informants (e.g. Pam and Terri) are identified as having distrust in the system, these informants, too, trust some aspects of the social institution in the food system. In situations where the respondents distrust the system, they may summarily dismiss the evidence of possible trustworthiness of some institutions in the system. In this case, although distrust expressed by the informants in the food system (e.g. Pam, Kyle, and Terri) has empirical foundations and is justifiable, this may lead to the summary dismissal or reinterpretation of the evidence of actual

trustworthiness of some specific institutions. From this point, benevolent or altruistic conduct by the target of distrust (specific institutions) may be viewed as further evidence of manipulativeness, an attempt at impression management, and so forth. Importantly, objective evidence of trustworthiness can be misattributed and summarily dismissed, and ultimately, the potential benefits (efficiencies and savings) associated with trust relations can be lost.

Implications for Public Policy Debates on GMF: Some of the broad public policy implications of the study has been offered in the preceding section. Now, we would like to conclude this paper with a few specific implications on GMF policy debates. The main biotechnology debates are over the novelty of modern genetic engineering, debate over pre-release testing, debate over labeling, constitutional debate, and debate over transparency (public information). In addition, there are two fundamental debates that shape the current regulatory regimes on agriculture biotechnology applications: debate over substantial equivalence doctrine and debate over the precautionary principle.¹

Perhaps the most important implication for public policy of GMF comes from the finding that, as opposed to the existing views, the relationship between consumer trust/distrust in the food system and their beliefs about the safety of GMF may not be strong. For example, those who trust the system (e.g. Amanda) can still strongly demand labeling for GMF for many other reasons such as ecological, moral, and ethical reasons. At the same time, a respondent who distrusts the system (e.g. Pam) would not have health/safety related concerns with GMF.

Our study also suggest the importance of designing public policies by distinguishing between health related and other social, economic, ecological and moral concerns consumers have about GMF. Thus, regulatory agencies should broaden their scope of what is a reasonable regulatory regime for GMF. Our findings suggest there is not a complete failure of trust among the informants as regards regulatory agencies' dealings with GMF and other food safety issues. This is in contrast to findings in other countries and consistent with previous quantitative results. However, we find consumers favor a precautionary principle rather than a substantial equivalence doctrine as a foundation for regulating GMF, primarily because of non-food safety issues associated with GMF. The substantial equivalence doctrine was adopted by the US, Canada, and Japan following the OECD-Edinburgh Conference. However, currently the US is the only country that still relies on this doctrine to regulate GMF. EU has always been skeptical, and recently both Canada and Japan have decided to reexamine and change their underlying foundation for regulating GMF.

Finally, our study suggested that informants see "industry" as the key player in their perceptions of negative synergetic interactions (distrust reinforcing properties) among the components of the system. At the same time, some informants see government as very important component of their confidence in the food safety system. As a result, we suggest that that public education programs (a component of the transparency debate) should be prepared and run by governmental outlets (e.g. NPR or PBS). A relatively successful example of this suggestion was executed about two years ago. "Frontline" and "Nova" combined their efforts to produce *Harvest of Fear* aired on PBS in the fall of 2000, incidentally during the most intense days of the Starlink[®]-corn fiasco. According to the critics, the program was "a better presentation of the controversy surround-

ing biotechnologies" and applauded even by the opponents of the biotechnologies (McCullum 2001)

In addition, more research should be funded by the federal government. As one of our respondents (Pam) suggested, she would like to see more research be done through "independent academicians" who are purely funded by the federal government. Independent academic research sponsored by the federal government is an essential component of a protective regulatory system. Unfortunately, the federal agencies that fund scientific research are not the agencies that need it for regulatory purposes. Of the three agencies with primary responsibilities for regulating GM foods, only USDA has a significant program for supporting academic research, and as Gutterman (2000) argued, the USDA is devoted primarily to developing new applications of biotechnology, not to discovering the adverse health and environmental effects of the products of the new technologies. We believe that, in order to boost consumer trust in the scientific communities, the US Congress, for example, should create a separate program through the EPA to fund research on the potential environmental effects of GM crops and animals. As suggested in this paper, it is possible that such interactions between government and scientific communities (consumer perceptions of positive synergetic interactions) can also boost trust in the system.

How Do Consumers Solve Value Conflicts in Food Choices? An Empirical Description and Points for Theory-building

Harri T. Luomala, University of Vaasa
Pirjo Laaksonen, University of Vaasa
Hanna Leipämaa, University of Vaasa

ABSTRACT

In this paper, the value conflicts that consumers may experience while making food choices are addressed. On the basis of a literature review, there may exist several food-related value conflicts including novelty vs. tradition, health vs. indulgence, economy vs. extravagancy, convenience vs. care, technology vs. nature, and others vs. self. The key empirical issue of this study was how individuals phenomenologically experience these different food-related value conflicts. Our empirical data was qualitative and consisted of collages and interviews. Our data suggests that the most common food-related value conflicts are those between convenience and care and between health and indulgence. These two conflict experiences are described and analyzed in depth. The paper concludes by showing the relevance of attribution and balance theories in moving consumer research toward conceptualizing value conflicts in food choices.

Consumer choices are a common yet complex research phenomenon. Especially, in the case of food, consumers encounter multiple choices on the daily basis. In itself, food and eating are by their nature dynamic phenomena full of changing psychological, social, cultural and economic meanings. Connors, Bisogni, Sobal, and Devine (2001, p. 189) have illustrated this inherent dynamism and complexity in food choices and eating.

“The abundance and variety of foods from which to choose is extensive. Social changes such as the increased participation of women in the work force lead to reduced time available for food selection and meal preparation, which further complicates food choice. Contemporary consumers have fears and conflicts involving food and health, and social norms about food and meal composition that guided previous generations appear to be eroding, leaving people with a lack of structure related to food and eating behavior.”

For the majority of the consumers, food is involving in one way or another. For instance, in their study comparing food-related lifestyle segments in France, Germany, UK, and Denmark, Brunso, Grunert, and Bredahl (1996) found that Germany had the largest segment of uninvolved consumers which was still smaller than one-fourth of the consumers studied. This implies that consumers associate a variety of values with food. Values are often seen as synonymous with goals (especially general ones) which are receiving more attention from consumer researchers. For example, Bagozzi and Dholakia (1999) stress that “we know little about what consumption goals are, how they are represented in memory, how they come about and change, or how they are pursued and achieved.” According to Martins and Pliner (1998), people seek sensory enjoyment, economy, health, convenience, emotional experiences, familiarity, novelty, and ways of impressing others from their food choices. A natural consequence of this multitude of food-related values is that sometimes value conflicts arise. The conflicts happen when “values are contrasted with each other and juggled according to their significance for a particular food choice” (Furst, Connors, Bisogni, Sobal, and Winter-Falk 1996, p. 257).

It is exactly these conflicts in food choices we are interested in our paper. How usual is it that consumers experience value conflicts when choosing what to buy for food? What kinds of value conflicts are most common? Under what circumstances do the conflicts emerge? How do consumers solve these value conflicts? These are questions we try to answer in our research. On the basis of the preceding discussion we set three objectives for our paper. First, to review the existing literature concerning food choices in order to identify the nature of potential value conflicts. Second, to empirically explore the extent and nature of the value conflicts consumers face in their everyday lives. Third, to offer conceptual ways and ideas to advance theorizing about value conflicts in food choices. Not so long ago Steenkamp (1996, p. 16) stated that “consumer behavior with respect to foods has not attracted much systematic attention by consumer behavior researchers.” The situation has improved since then, mainly thanks to the Danish research program and group MAPP. In line with this development, we hope to contribute to food consumption research by giving both theoretical and empirical attention to a poorly-researched phenomenon in order to provide building blocks for food-consumption theory generally.

The rest of the paper is structured as follows. In the next section we consult the psychological, sociological and cultural literatures concerning food choices to review the repertoire of potential value conflicts. In the third section we briefly describe the method and data we used. The results of a qualitative pilot study are reported next. Lastly, we introduce two theories that can be harnessed to forward the conceptualization of value conflicts in food choices.

WHAT KIND OF VALUE CONFLICTS THERE MIGHT EXIST IN FOOD CHOICES?

We decided to organize the following discussion according to juxtapositions found in Warde (1997), Ekström and Askegaard (2000), and Mäkelä (2002). These juxtapositions include novelty vs. tradition, health vs. indulgence, economy vs. extravagancy, convenience vs. care, technology vs. nature, and others vs. self.

Novelty vs. Tradition

There exist consumers who consistently want to try out new products, brands, services and experiences. This kind of food consumers can be called either novelty seekers or variety seekers, but, by the same token, there are persons who can be classified as food neophobics (Lähteenmäki and Arvola 2001). They are afraid of new elements in food. In many societies, being open to new thoughts and ideas is valued. Food manufacturers and marketers are continuously bringing new products and brands to markets. Distant ethnic cuisines are introduced and gaining ever-increasing popularity. Magazines offer food recipes that are claimed to be new in one way or another. On the other hand, tradition has become appreciated again. One of the millennium trends identified by Shore and Cooper (1999) was labeled as “origins.” Sometimes traditional food dishes conjure up nostalgia, which has received attention in consumer research lately (e.g. Summers, Johnson, and McColl-Kennedy 2001). Tradition in food choices may be preferred because it creates a sense of security, continuity, and social togetherness. Particularly

on special occasions (e.g. when having foreigners as guests or at Christmas) conventional dishes and foodways are important to many consumers.

Health vs. Indulgence

On the level of values, people in many countries state that health is one of the most important things for them. Especially in Western societies increasing preoccupation with the health effects of modern food can be seen (Caplan, 1997). Government authorities are “preaching” the importance of the food-choice-health linkage and provide norms to guide citizens in making healthy food choices. Food manufacturers and marketers try to capitalize on this trend by offering new foodstuffs and drinks that are supposed to have positive impact on health (so-called functional and/or organic foods). Ironically, the increased health-consciousness has generated anxiety in consumers too. People have started to ask questions such as What can be safely eaten? and Who should I listen to? (Ekström and Askegaard, 2000). However, even the most devoted health grazers do have their weak moments of relapse. Food is one of the most fundamental sources of hedonic experiences in human life. It is not uncommon for people to give themselves permission to indulge in delicious food every now and then (e.g. on holiday or on weekend). Mood experiences have been shown to heighten gourmandizing and excessive drinking (Luomala and Laaksonen, 1999). Perhaps the most gruesome example of these opposite forces at work is the situation in which the self-indulgent relapse is regretted and self-punishment follows in the form of food abstinence and increased physical exercise.

Economy vs. Extravagancy

In every country there is a group of consumers who are very price-conscious. Thrift has been a virtue in many countries (Warde, 1997). Economical emphasis manifests itself in many ways in food choices. Many consumers seek low prices especially on weekdays. Large quantities of dishes that are easy to prepare may be cooked for economy and convenience. Many consumers are reluctant to throw away food that is left. The leftovers are preserved in the fridge for later use. The “conservative” lifestyle segment found in Brunso et al.’s (1996) study is likely to behave like this. As an echo of the wartime, children are still often asked to “empty their plates.” Although the monetary resources of households have a direct bearing on how much and what food is consumed (Ritson and Petrovici, 2001), even households with moderate or low income are on certain festive occasions extravagant. Extravagancy may mean that there is plenty of something, or that food is basically the same as usual but is done using higher quality ingredients, or that food (or food items) is a rarity. For example, food and wine connoisseurs often want to impress others by offering exceptional wines and exotic dishes (cf. Martins and Pliner, 1998). On these occasions extravagancy becomes a statement of social status, and appreciation of the generous sophistication might be expected.

Convenience vs. Care

It is a general belief that life has become more and more hectic. For some consumers (e.g. career women with children) time is a more valuable resource than money. This has created a natural demand for convenience foods (fully or partially prepared foods, take-away meals, eating in restaurants). According to Candel (2001), a person who seeks convenience in meal preparation is not involved with food products, is not a variety seeker, does not enjoy cooking, and has a heavy burden of obligatory activities. Food provision (planning, shopping, preparing) is still very much of women’s responsibility (Ekström, 1991). Caring diligently that the

husband and the children get enough good and healthy food is a part of the stereotypical picture of a “proper housewife”. Care materializes when a woman puts a lot of effort and time into preparation and esthetic serving of food to please her spouse and/or children. Contentment may be felt after role-congruent behavior, but not being able to meet the norms, for example by resorting to convenience foods, may also create feelings of shame and guilt.

Technology vs. Nature

One of the millennium trends uncovered by Shore and Cooper (1999) was transformism. They state (1999, p. 43) that: “Advances in science and genetics have created the biological foundation for the belief in ‘new self’. ... Scientifically-based pharmaceutical, health and beauty products, nutraceuticals, new fabrics and leading edge products are among the categories likely to respond to this trend.” While many American consumers believe that genetic modification of food will result in more healthy and higher quality food, the public reaction in Europe has been much more negative and reserved (Nelson, 2001). For instance, Danish and Swedish consumers in Ekström and Askegaard’s (2000) study used words such as artificial, synthetic, and unnatural to describe genetically modified food. It seems that for some consumers the naturalness of food has become an important choice criterion (the case of organic food products) (Kantanen, 2002). In Scandinavia especially, “technological” food are associated with danger and “natural” food with safety.

Others vs. Self

Here, by “others” we mean both widely-impacting and long-term consequences of food choices for the mankind (e.g. ethicality) and social aspects of eating. Food choices can be seen as moral and ethical utterances which make food also a societal and political issue. People have in addition to their personal welfare started to think about the welfare of other people, animals, and the globe (Mäkelä, 2002). According to Shore and Cooper (1999, p. 42), “attention will turn to family unity, bonds of love and sharing, and the importance of maintaining family ties” (the so-called “unification” trend of the millennium). Planning, preparing, and enjoying food have always had a role in maintaining and developing social relationships. On the other hand, there is a discussion concerning the individualization of societies. For example, Valentine and Gordon (2000, p. 196) assert that “the 21st century ‘consumer’ is a ‘subject’ that continually constructs identities for itself by entering into the process of consumption.” An illustration of expressing one’s individuality by very specific food choices is vegetarians and food connoisseurs (cf. Ekström and Askegaard, 2000).

The value conflicts listed here and summarized in Table 1 arise mainly from sociological research which emphasizes society as a level of analysis. Is it so that consumers also experience these value conflicts at the individual level and if they do, how do they experience them? This is what we wish to find out in the empirical part.

METHOD AND DATA

As the aim was to identify consumers’ potential value conflicts in food choices, two different kinds of qualitative research methods were used to gather the data. First, seven focus group interviews (in the summer of 2001) and after that ten personal interviews (in the spring of 2002) were performed. To supplement interviewing, the collage technique was also used. Visual methods are useful when there is a need to reveal deep and latent thoughts, attitudes and feelings related to a research topic (see e.g. Lieber, 1997; Sack, 1998; Zaltman, 1996). The data was originally gathered for analyz-

TABLE 1
Summary of food-related value conflicts

Value conflict	Key meaning
novelty vs. tradition	The tension between an individual's perceived pressures of favoring the new and unknown (e.g. distant ethnic cuisenes) and the known and "correct" in foods and eating (e.g. a Christmas turkey).
health vs. indulgence	The tension between an individual's perceived pressures of favoring the healthy (e.g. low fat yogurt) and the pleasurable in foods and eating (e.g. a butter-baked cream cake).
economy vs. extravagancy	The tension between an individual's perceived pressures of favoring the economy (e.g. use of leftovers) and the luxurious in foods and eating (e.g. caviar with champagne).
convenience vs. care	The tension between an individual's perceived pressures of favoring the ease and save of time (e.g. take-away-food) and the effort and use of time in foods and eating (e.g. preparing a gourmet dinner for the family).
technology vs. nature	The tension between an individual's perceived pressures of favoring the advancement (e.g. vitaminized orange juice) and the naturalness in foods and eating (e.g. organic pork meat).
others vs. self	The tension between an individual's perceived pressures of favoring the other-centeredness (e.g. a family meal on Sundays or buying bananas whose farmers are properly compensated for) and the self-centeredness in foods and eating (e.g. a wine and cheese connoisseur giving him/herself a treat).

ing the relationship between the consumer and food. The value conflicts in food choices, per se, were not the primary focus when the data was gathered. So, here the data is more or less of secondary in nature.

Altogether, 48 interviewees participated in the interviews (38 in focus groups and 10 in personal interviews). They were chosen purposively so that they formed as rich and versatile a sample as possible. There were 29 women and 19 men and their ages varied between 17 and 67. In focus groups the participants were asked to create freely a collage with pictures and words given (170 pictures to each) from a topic "Food and me". After that each participant described his/her collage to the rest of the group. In personal interviews participants were asked to create "Food and me" - collage in their homes within one week. Pictures were allowed to be chosen freely from newspapers and magazines, except pictures describing food. This restriction was given in order to encourage the participants to use pictures as *metaphors* describing their relation to food. The participants were then interviewed personally mainly on the basis of Zaltman Metaphor Elicitation Technique, which is developed for helping revealing consumers' internal state of mind (Zaltman, 1996, p. 13). All the focus groups and personal interviews were recorded and transcribed carefully afterwards.

To reiterate, the data consisted of both verbal and visual material. In order to reveal consumers' food-related value conflicts, the transcribed interview tapes were read through several times analyzing the collages at the same time. All the food-related value conflicts that emerged were marked and summed up in order to form a general picture of the magnitude of different conflicts. Special attention was paid to examining how participants felt the conflict, how it was explained and solved and in what context it emerged. Reliability of the analysis was safeguarded by having three coders independently identifying the conflicts in the transcripts and collages.

FINDINGS

Table 2 reports the frequencies of the value conflicts in food consumption as identified by the three different coders of the data.

As can be seen from the table, all of the food-related value conflicts could be identified in the data, although there are differences in the magnitudes of the value conflicts. Next, we will phenomenologically explore the two most common value conflicts in food choices, which include the convenience-care conflict and the health-indulgence conflict. The potential reasons for some of the differences in coder frequencies are tackled at the end of this section.

Convenience vs. Care

On the basis of our data it seems that many informants felt the need to defend their use of convenience foods and highlighted the occasions on which they put a lot of effort and time into preparing and serving food. Convenience meant using semiprocessed food-stuffs, preparing "easy foods", and serving snacks. Reasons that justified the use of convenience foods included lack of time on weekdays (mainly work), household obligations, hobbies, and eating alone. On the other hand, care was often associated with gourmet food and food that is prepared all way through and with esthetics in serving and laying the table. Weekends and festive occasions seemed to evoke care (e.g. window-dressing when having guests over) in food preparation and eating. Also family gatherings and social interaction often induced care. The narratives below illustrate some of the points made here.

"And then the food what we have on weekdays. We don't put that much effort into laying the table, we throw the plates on the table. We are busy, we don't have the time for it. And tired too, especially now when we have the baby. We have clearly reduced this, and when preparing food for myself I try to quickly do something when I'm alone with the baby, gourmet food is out of the question then." (female, 26, social worker)

"I do homely food and offer vegetables, but not every day. I cook the dishes my children want me to cook, but I also sometimes buy convenience foods for them. You cannot be perfect every day." (female, 36, secretary)

TABLE 2
Frequencies of different value conflicts in food consumption by coders

Value conflict	Coder 1	Coder 2	Coder 3	Mean
novelty vs. tradition	18	9	17	14
health vs. indulgence	25	15	29	23
economy vs. extravagancy	8	10	11	9.7
convenience vs. care	34	23	23	26.7
technology vs. nature	3	4	3	3.3
others vs. self	13	11	17	13.7

“These wine bottles are here because they tell that in our family wine is a part of a good meal. These beautifully laid tables imply that when we invite guests over we have a habit of making food to its perfection and put a lot of effort into serving and table decoration. Then we eat peacefully and without any sense of hurriedness.” (female, 31, forewoman)

Health vs. Indulgence

It was usual for informants to recognize the importance of healthy eating. It seems that food and health education has been internalized to a great degree, because many informants used words such as “regularity”, “balance”, and “manysidedness”. Also food that was wholly made at home (possibility of controlling what is put into food) and the domestic origin of foodstuffs were often taken as signs of healthiness. For some informants, digressing from the healthy diet caused feelings of guilt and anxiety (one informant even punished herself after “not playing by the rules”). Even the most health-oriented informants agreed that hedonism and self-indulgence are an essential part of their “foodworlds”. Indulgence is ok, if there is some permission for it and it is temporary (many informants were aware of the unhealthiness that goes with food treats). Weather, accomplishments, weekends, festive occasions, mood states can act as permission givers for indulgence. Food hedonism may be focused (e.g. gulping down huge amounts of Mövenpick ice-cream) or comprehensive (e.g. gourmet food made of the very best ingredients, extravagance in laying the table and decorating the dining space). The following three narratives shed some light on the issues discussed above.

“Nowadays, it is so that chocolate is a delicacy I often cannot resist. And then we eat a lot of Italian food, even though I have many domestic foods in my collage. This picture of a slim, skinny and healthy woman, it’s the ideal, but I feel that I am this little chubby elephant, who, nevertheless, is happy, even though its measures are not what they are supposed to be.” (female, 27, architect)

“I have used contradictory words in my collage: impulsive, prudent and rational on the other hand, emotional and careless on the other. It is just so, my mood states greatly influence my eating and even my shopping behavior. Sometimes I think that I should skip eating buns and cakes... There are no days that are exactly the same. It depends how I feel.” (female, 23, student)

“On weekdays we try to have healthy food, but at weekends we give ourselves a permission to relapse. Eating goodies while reading or watching movies are examples of relapses. And

grilling sausages in the fireplace... I don’t know, but we will always come up with an excuse for eating better and more expensive stuff.” (female, 26, construction engineer)

An important observation was that the experiences of food-related value conflicts were not always in terms of the antinomies that emerged from the literature review. For example, the other pole for convenience was in some cases indulgence (“convenience foods taste bad”), economy (“convenience foods are not inexpensive”), or health (“convenience foods are unhealthy”) and not care. Similarly, the other pole for health was sometimes convenience (“healthy foods require effort in purchasing and preparation”), economy (“healthy foods are expensive”), or technology (“healthy foods are genetically modified”) instead of indulgence. It is likely that this is a valid explanation for the differences in frequencies that can be seen in Table 2. One coder may have classified a convenience-indulgence value conflict as belonging to the convenience-care category while the second coder may have classified this conflict as belonging to the health-indulgence category. This issue needs attention in future research.

DISCUSSION: TOWARDS CONCEPTUALIZING VALUE CONFLICTS IN FOOD CHOICES

In this section we describe how two different theories could be harnessed to advance conceptualization of value conflicts in food choices. These two theories are the attribution theory and the balance theory.

Attribution Theory

The origins of attribution theory can be seen in Kelley’s (1967) work (Weiner 2000, p. 382). However, the most prominent developer of the attribution theory as it now stands is Bernard Weiner. Here we briefly introduce the theory, apply it in the context of food-related value conflicts, and make a couple of claims that should be addressed in future research.

The guiding principle of attribution theory is that individuals search for understanding, seeking to discover why an event (especially if it is negative or controversial) has occurred. Inasmuch as the potential list of causes is considerable within any motivational domain, and because the specific causes differ between domains, it is essential to create a classification scheme or a taxonomy of causes. (Weiner 1982, pp. 185-186) Weiner (1982) identifies three causal dimensions: locus of control, stability, and controllability. Later he (2000) emphasizes the relevance of the last two in the consumer behavior context. According to this thinking, the basic ways of explaining different outcomes are: stable-controllable attribution, stable-uncontrollable attribution, unstable-controllable attribution, and unstable-uncontrollable attribution.

FIGURE 1
Unbalanced states in the person-food product-food value triad.

What do then these basic attributions mean in the context of food-related value conflicts? We illustrate these basic attributions by using examples from our data. A value conflict (health vs. indulgence) may arise when a person who has a hedonistic orientation toward food, buys or eats something that is healthy (and by his/her standards often tastes bad). A case of the stable-controllable attribution can be seen when this person believes that hedonism is not just self-indulgence, it is abstinence too: without abstinence or “suffering” there cannot be real eating pleasure. This is one way to resolve the value conflict.

According to our empirical data the convenience-care value conflict may be generated when an individual sees himself/herself as caring about the quality and appearance of food, but buys semiprocessed foodstuffs and uses them in preparing meals (which can be regarded as unhealthy or even dangerous). An example of stable-uncontrollable attribution is when this kind of care-oriented person explains his/her “deviant” behavior as reflecting the current work situation: “my life is so busy nowadays that I cannot follow my principles all the time.” This was one explanation for the convenience-care value conflict that emerged from the data.

It seems that unstable attributions are more common. For instance, when a person, who normally favors organic foods and ingredients, buys and eats technologically engineered food, technology-nature value conflict may be witnessed. An example of an unstable-controllable explanation for this value conflict is a situation in which an organic food favorer has invited guests who are known to like or for medical reasons need technologically engineered food. To illustrate, the guests may be older people with increased risk of heart disease. The hostess, who normally buys “natural” food, may think that “my husband’s parents have high cholesterol levels so this time I buy a box of cholesterol-reducing margarine for everyone to use”. The premeditation of this decision makes it a controllable explanation.

Finally, the unstable-uncontrollable attribution can be illustrated by looking at the economy-extravagancy value conflict. A price-conscious consumer may temporarily give up his/her economic principle due to, say, a negative mood state. For example, a person may after a stressing work week (that was caused by uncontrollable factors) want to give himself/herself a treat by buying filet and red wine instead of the usual minced meat and milk. In other words, the existence of the negative mood gives the permission for the person to behave extravagantly, against the norm that may be long-established and personal. Stories like this were not difficult to find in the data.

We hope that these examples have shown that attribution theory is a viable candidate when the food-related value conflicts need conceptual foundations. Our observations give rise to at least two intriguing questions. First, do certain attributions (e.g. un-

stable-uncontrollable) outnumber the rest? Second, to what extent does the “content” of the attributions vary across different food-related value conflicts? The next step is to increase the formalization of the attribution theory account of food-related value conflicts and of the empirical and analytical approaches to treating food choice-related attributions (cf. e.g. Stratton and Bromley 1999).

Balance Theory

Balance theory considers relations among elements a person perceives as belonging together. These relations may be for dyads, triads, or more complex cases, but all relations are seen from the perceiver’s subjective viewpoint. Two types of relations between separate entities are identified: unit and sentiment relations. A unit relation exists when one entity is seen as belonging to or being a part of the other entity. A sentiment relation exists when two entities are linked because one has expressed a preference or dislike for the other. The theory specifies that people desire relations among entities to be harmonious, or balanced. If they are not, a state of tension will result until perceptions are changed and balance is restored. (Solomon, Bamossy, and Askegaard 1999; Woodside and Chebat 2001).

In the present research context, the entities involved in the relations could logically be person-food product-food value. The existence of food-related value conflict implies the existence of imbalance. On the basis of Woodside and Chebat (2001), there exist three different kinds of unbalanced states in the case of triads. Figure 1 depicts these three potential unbalanced states in the person-food product-food value triad. The first triad illustrates the health-indulgence value conflict, the second triad the economy-extravagancy value conflict, and the third the novelty-tradition value conflict.

The unbalanced state in the first triad is a case where a person values health, but also likes chocolate which is unhealthy. According to the balance theory, there are three principal ways to achieve a harmonious state of being. First, the person somehow manages to turn his/her liking for chocolate into dislike. Second, the person reevaluates his/her values and reaches a conclusion that health is not important to him/her. Third, the person stops considering chocolate as unhealthy.

The second triad presents the unbalanced state in which the person values economy, but does not like porridge, which is an inexpensive food. The principal ways of resolving this food-related value conflict are the following. First, the person develops a taste for porridge. Second, the person relaxes his/her demands on the value of economy. Third, the person changes his/her view concerning porridge as an economic choice.

The last triad tackles the unbalanced state in which the person does not think highly of traditions, but likes pea soup which is a very

traditional dish in certain countries. Once again, there are three ways to dispel the tension. First, the person stops liking pea soup. Second, the person, for some reason or other, starts to appreciate traditions (e.g. as growing old). Third, the person does not any longer associate pea soup with tradition.

The discussion above raises many interesting questions. In re-establishing the balanced state, which ways are the most logical and feasible and thus dominate. Describing how the process of regaining the balanced state goes about in the case of different food-related value conflicts is another intriguing issue. Beyond triads, more complicated constellations of entities and unit and sentiment relations involved in food choices and consumption should be analyzed (e.g. family food choice and consumption processes). Another promising future research theme is to examine how the changes in perception of different relations can occur. For instance, is it possible to develop a chocolate that is perceived as healthy or a porridge that is perceived as a delicious treat? Should this be done by really changing the product or just by creating a new image for the product? Generally, going analytically through different food-related value conflicts in the case of different food products from the viewpoint of balance theory may produce novel ideas for food product development and marketing.

We conclude with a few words concerning the relationship between the attribution theory and the balance theory. As we see it, the attribution theory can be used to analyze the causal origins of consumers' food-related value conflict experiences, while the balance theory is useful in understanding how consumers resolve the value conflicts they perceive to exist in food choices. In other words, these theories supplement each other; they can be used to investigate different aspects of the same phenomenon. Furthermore, it would be intriguing to combine these theoretical accounts to scrutinize whether different attributions (e.g. external vs. internal) lead to a selection of certain type of balance regain strategy. The integration of the attribution and balance theories offers a fruitful point of departure for developing many new and interesting research questions for future studies.

SPECIAL SESSION SUMMARY

Consumer Decision Strategies Under Conflict

Kristine R. Ehrich, The University of Texas at Austin

SESSION OVERVIEW

The three papers in this session address decision strategies that people use when they are confronted with different types of conflict. When consumers are faced with purchase decisions, some type of conflict is inherent. Options that present the most positive attributes also may naturally contain negative elements. For instance, the designer sweater may also pose a challenge to the budget; the beautiful table you'd like may have been made with wood from an endangered rainforest, etc. How do consumers cope with these sorts of conflicts? These three papers suggest that consumers utilize cognitive coping skills to protect themselves from the affect inherent in the conflict. The papers address a coping strategy at each of the three levels of the decision process. Meloy and Russo's paper shows that, when available, decision framing can make a big difference. By reframing the decision task to be compatible with the valence of the options, consumers experience less conflict and have more confidence in their decision. Ehrich and Irwin's paper shows that, when faced with a decision they cannot reframe, consumers will implicitly and explicitly avoid information that has the potential to cause conflict. Finally, Mukhopadhyay and Johar's paper shows that, if the attribute information cannot be avoided, consumers will engage in complex justification strategies aimed at reducing the conflict.

In the first paper, Meloy and Russo showed the importance of decision framing in choices between negative and positive options. When people are asked to choose among negative options ("burdens") or to reject positive options ("benefits"), they experience negative consequences, such as conflict, confusion, and lowered confidence. On the other hand, when they are asked to reject negative options or choose among positive options, they cope much better, affectively and cognitively. Note, of course, that the framing of the task does not change the informational content of the decision. Thus, this work suggests that decision conflict may be avoided by reframing the question to be compatible with the valence of the options.

Reframing of the situation is not always possible because the options themselves may contain both positive and negative elements. In the second paper, Ehrich and Irwin showed that, in this situation, consumers avoid having to use information that causes conflict. It was found that consumers willingly used the conflict causing information when it was presented to them prior to a choice task, but would specifically avoid requesting the information if they were told it was available. Ironically, they discovered that these findings are especially true for respondents who value the attribute that is causing the conflict (that is, respondents who are experiencing increased conflict). For example, people who were very concerned about the protection of endangered rainforests would avoid information about the source of the wood used to make a desk while consumers who felt that child labor was something to be highly concerned about avoided information about the labor conditions in the plants that manufactured cell phones on which they were deciding. Consumers were found to avoid the information explicitly (by not asking for the attribute information) and implicitly (by forgetting or misremembering) the attribute information.

The third paper, by Mukhopadhyay and Johar, consumers are faced with decisions with full attribute information that cannot be reframed. How do they cope with decision conflict in this situation? In several studies, the authors show that decision justification plays

a large role. When consumers can justify their decisions, they experience less conflict and emotion. Note that these justifications are coping mechanisms, not (necessarily) earmarks for actual utility maximization strategies. For instance, the justifications become especially necessary when the conflict has been primed by a previous related conflict that did not lead to purchase.

Discussion leader, Baba Shiv, did a great job of tying the three papers together while noting the importance of studying how conflict impacts the strategies that consumers use in their decision making. He also answered audience questions and discussed future research directions for this area of consumer research.

"Conflict and Framing: Selecting versus Rejecting in Binary Choice"

Margaret G. Meloy, The Pennsylvania State University

J. Edward Russo, Cornell University

We examine information processing differences under instructions to select versus reject in binary choice. Although the experimental evidence provides support for previously hypothesized causes for select-reject differences, many of the predicted relationships were reversed when the decision alternatives were undesirable rather than attractive. Selecting one of two negative options or rejecting one of two positives resulted in a more disrupted process and greater conflict. In these incompatible cases, individuals were less certain of their choice, less extreme in their attribute evaluations, and less likely to distort attribute information. Verbal protocols revealed that task re-framing was common to reduce decision conflict and increase compatibility.

"Willful Ignorance in the Face of Conflict: The Avoidance of Ethical Attribute Information"

Kristine R. Ehrich, The University of Texas at Austin

Julie R. Irwin, The University of Texas at Austin

We find that, when presented with the possibility of finding attribute information that conflicts with personal goals, in this case behaving ethically, consumers are likely to avoid this information; however, if presented with a full-information analysis, they will use it in their decision making. This avoidance of information is especially strong for those consumers who value this information and are therefore at an increased level of conflict. In two follow-up studies, we find that consumers who were asked to recall attribute information are likely to either forget the conflict-causing attribute value or to misremember the attribute as being more favorable than it actually was.

"When Desire Conflicts with Willpower: The Role of Justification in a Theory of Unintended Purchase"

Anirban Mukhopadhyay, Columbia University

Gita V. Johar, Columbia University

Consumers spend substantial proportions of their expenditures on products they had not intended to buy. Correspondingly, marketers spend billions of dollars trying to influence purchase incidence. What determines whether consumers give in to such temptations, or hold back from them? Research in this area typically looks either at compulsive consumption, i.e., behaviors of people who chronically succumb to purchase temptations (e.g. O'Guinn and Faber 1989), or at impulsive behavior not necessarily in purchase contexts (e.g. Shiv and Fedorikhin 1999). This paper

addresses the question of how consumers respond to unintended purchase opportunities, and how a decision to either buy or not buy can affect responses to subsequent tempting offers. Distinct from the majority of research on self-control, it builds on the insight that purchase consists of the two related but independent activities of spending and acquisition, and proposes a conceptual model specific to situations of unintended purchase. This model suggests that exposure to an unintended purchase opportunity may simultaneously cue the two goals of acquisition and not spending. These goals may be in conflict under some conditions, and this conflict may be resolved through a search for reasons, and the relative justifiability of the two options available to the consumer, buy or not buy.

We present three studies based on scenarios where participants see tempting products on sale while waiting at a mall. A goal of not spending money unnecessarily was always salient. The products used were extensively pre-tested to be equally attractive, and were from two categories, books and software. Each purchase occasion was disguised as a choice between two similar offers within the same category and a no-choice option. The dependent variable whether either of the two offers was chosen as opposed to not buying anything. Building on Wertenbroch (1998), virtue products were defined as *any* products that deliver long-term value, but are relatively less valuable in the short term, such as science books and instructional software. Vice products, on the other hand, were defined as those that offer greater value in the short term than they do in the long term (e.g. thriller books and computer games), and stimuli were pre-tested to suit these definitions.

Experiment 1 studied responses to single unintended purchase opportunities, and found that under a low need to justify the purchase decision, proportions of subjects deciding to buy was the same across virtues and vices (approximately 50% as per the baseline propensity to buy established in a pilot study). However, under a high need to justify, the proportion choosing to buy vices dropped, while choice proportions for virtues remained unchanged. This demonstrates that under a high need to justify the purchase decision, vices are more difficult to justify buying than virtues. Analysis of thought protocols supported this contention.

Experiments 2 and 3 extended the investigation to an intertemporal domain. Theoretically, encountering a second unintended purchase opportunity while the first decision is still accessible in memory should have two effects. First, since both goals—acquisition and not spending—have recently been invoked, conflict should be greater at Time T2, and this should lead to a relatively high need to justify. This would imply that virtues would be easier to justify buying at T2. Moreover, if a second purchase opportunity is encountered while the reasons for the first decision are accessible, then behavior is likely to be consistent with these reasons. Hence the justifiability of buying at T2 should be driven by the nature of the decision at T1 as well as the nature of the product at T2, and the higher this justifiability (highest for T1 Buy T2 Virtue, lowest for T1 No buy T2 Vice, and intermediate otherwise), the higher the purchase likelihood. However, this need not always be the case. Specifically, those respondents who had not bought at T1, and have the reasons for their restraint made more accessible, may self-reward with a vice.

Experiment 2 was a 2 x 2 x 2 between-subjects design, where subjects were made to go through the decision process twice (at different purchase opportunities within the same scenario). After being exposed to an offer at T1 (product category: books, vices only), they were told whether they bought or not, and were asked to generate reasons to support this decision. Then, after a filler task, they were asked to recall these reasons (or not—this was the accessibility manipulation). Then at T2 they saw another offer

(product category: software), which was either a virtue or a vice. We found that under a baseline accessibility of reasons for the T1 decision (no recall condition), purchase likelihood decreased monotonically with justifiability. This was also the case in the heightened accessibility condition, except for the critical case of respondents who had not bought at T1 and were presented with a vice. In this case, normally the lowest justifiability of buying at T2, purchase likelihood was the highest.

The aim of Experiment 3 was to allow the decision at T1 to occur naturalistically, instead of being forced, and also to allow the product at T1 to be either a virtue or a vice, to investigate switching or balancing hypotheses. Similar to Experiment 2, after being exposed to an offer at Time T1 (category: books, virtue or vice), respondents chose to buy or not. We treated this response at T1 as a measured variable. Then at Time T2 they saw another offer (category: software), which could again be virtue or vice. As before, purchase likelihood decreased with justifiability of buying at T2. However, the nature of the product at T1 had no effect on the decision at T2, thereby refuting balancing explanations in favor of the proposed justification model.

In sum, this research contributes to the literature on consumer self-control, by demonstrating how conflict between desire and willpower plays out in purchase situations where consumers had not originally intended to buy. The study of purchase incidence over time is an important problem, and, across experiments, the justification model explains the observed patterns better than competing theories.

Outraged Consumers: What Lights Their Fire?

Nada Nasr Bechwati, Bentley College
Maureen Morrin, Rutgers University

EXTENDED ABSTRACT

It seems like outraged consumers are everywhere. They become furious when their flights are cancelled, their telephone bills contain unexpected charges, or the line they must wait in for service is excessively long (Brady, 2000; Appelman, 2001). Considerable research has examined consumer responses to low to moderate levels of dissatisfaction. Researchers have also reported the existence of outraged and highly frustrated consumers who want to get back at firms (Blodgett et al., 1997; Oliver, 1989; Richins, 1983). However, little research has examined in depth the segment of consumers so highly frustrated that they seek to exact revenge on firms or brands. Initial research in this area has documented extreme, and possibly harmful, consumer feelings and behaviors resulting from a consumer desire for vengeance (see, e.g., Nasr and Morrin, in press). In the present paper, we try to better understand the affective experiences of outraged consumers. We particularly focus on what pushes these consumers over the edge, i.e., the main drivers of their outrage.

Two studies designed to better understand the psychological mechanisms underlying the vengeful behavior of outraged consumers are reported in this paper. Study 1 is exploratory in nature and consists of a content analysis of messages posted on the web by highly frustrated consumers who express a need to "get back" at firms. After detailed analysis of the themes emerging from the web content analysis, we designed a laboratory experiment to investigate, in a more controlled setting, one of the major factors that appeared to be involved in consumers' desire for vengeance against firms, namely, perceptions of justice.

A non-structured content analysis of 29 web messages located through the Google search engine, revealed four major themes, namely (1) trust violation, (2) rude treatment, (3) feelings of disappointment and helplessness, and (4) the urge to disseminate negative experiences. Consumers became outraged when they felt that firms violated their trust by breaking promises that firms had made initially (e.g., in its advertisements), or in the redress stage, i.e., in the process of handling their complaints. Rude employees were frequently reported in the messages. Such rude treatment by customer service personnel was received with surprise on the part of the consumers who expected to be treated with courtesy. Consumers, particularly those in the redress stage, expect not only courtesy, but feel that an apology is due. Faced with a firm that did not meet their expectations, customers felt disappointed and in a state of disbelief. Their bad experiences were perceived as painful to them. A general feeling of helplessness, i.e., inability to make any useful steps further, was reported. In terms of behavioral response, consumers felt an urge to disseminate their negative experience and considered it something they had to do. Others went further in an attempt to warn consumers about bad firm practices.

The four themes emerging from the content analysis are in line with previous research in the fields of vengeance and consumer dissatisfaction. Researchers have identified trust violation as a main antecedent to vengeance (see, e.g., Bies & Tripp, 1996). This theme is also in line with literature on satisfaction/dissatisfaction where, according to the expectations paradigm, breaking a promise is one form of negative disconfirmation, a main reason for dissatisfaction (Oliver, 1989). Although product/service failures were not necessarily due to employees' incompetence or mistakes, mistreatment by employees seemed to inflame the problem. The importance of personal interactions has been noted in previous research address-

ing the redress stage (Blodgett et al., 1993). In studying complaint behavior, Richins (1983) pointed to the absence of a firm's apology as an incentive to spread negative word-of-mouth.

Feelings of helplessness are an interesting finding as they appear to be qualitatively different than negative emotions experienced by dissatisfied consumers and previously reported by researchers (see, e.g., Westbrook and Oliver, 1991). Researchers in the area of vengeance have reported that feelings of helplessness and the absence of an alternate system to restore order was a main antecedent of vengeful actions (Gould, 2000). This feeling of helplessness has been used to explain the widespread behavior of vengeful activities in societies lacking active judicial systems (Waldmann, 2001). A similar line of reasoning could explain why so many instances of consumer revenge seem to be directed towards large, market-dominant, and highly powerful firms, such as Nike or Microsoft. It is unclear whether participants disseminated information for the good of other consumers, i.e. to help them, or for the bad of the perpetrator firm, i.e., to hurt the firm, or both. Previous studies on negative word-of-mouth behavior have pointed to consumers' eagerness to share their negative experiences, at times even with complete strangers (Richins, 1983; TARP, 1986).

Study 2 focuses on the redress stage and was designed to address the following questions: (1) is it possible to avoid consumers' retaliatory behavior by allowing for a better experience at the redress stage, and (2) what makes a redress stage successful in offsetting the vengeful effects of the initial problem? To address these questions, we draw on perceived justice theory. Two aspects of perceived justice, interactive and distributive, were examined as possible psychological triggers to vengeance. Distributive justice is concerned with the perceived fairness of the tangible outcome, e.g., credit for excess billing charges. Interactional justice is the perceived fairness of the manner in which individuals were treated throughout the conflict resolution process, e.g., courtesy of employees handling the complaint.

Results of a 2 X 2 between-subjects laboratory experiment showed that the tangible outcome of a complaint, i.e., perception of distributive justice, is a significant determinant of the feeling of desire for vengeance. However, it takes a perception of bad personal treatment, i.e., low interactive injustice, for consumers to behave sub-optimally or with revenge. In effect, the strong feelings of vengeance led to reactive switching behavior in cases of negative tangible outcomes. However, those feelings were not converted into a proactive response unless the consumer was also treated rudely. In fact, acting vengefully, i.e., proactively, came as a result of bad personal treatment regardless of the tangible outcome of the dispute.

Eating Guilt: Measurement and Relevance to Consumer Behavior

Ajay Sukhdial, Oklahoma State University
David M. Boush, University of Oregon

EXTENDED ABSTRACT

Introduction

Few areas of consumer behavior rival the importance of eating. Americans spend over \$750 billion each year for food, nearly 15 percent of total expenditures (U.S. Department of Commerce 2001). Moreover, eating in most cultures is strongly associated with morality in that most religions have normative beliefs about what to eat, when to eat, and how much to eat. The historical connection between morality and eating has received renewed attention recently (Rozin 1999), perhaps because of growing health problems associated with over-eating. Over the past few decades, obesity has increased dramatically in developed countries such as the U.S. contributing to a variety of negative health conditions (Must et al. 1999). Some have referred to this trend as an obesity epidemic, and have warned that strategies for weight control need to receive a greater public health priority (Mokdad et al. 1999).

This paper measures eating guilt and tests a model of its antecedents and consequences using structural equations. The model test serves both to assess the validity of the scale and to provide substantive insights regarding the role of guilt in consumer behavior. Despite extensive research into the role of guilt in eating disorders, guilt about food has not been widely studied relative to food consumption in a healthy population.

The Concept of Guilt

Huhmann and Brotherton (1997) define consumer guilt "as an emotional state involving penitence, remorse, self-blame, and self-punishment experienced after committing a violation or contemplating a future violation of internalized standards of proper behavior." Thus, guilt can occur because one did something which violated one's standards (guilt by commission) or because one failed to do something consistent with one's standards (guilt by omission). In addition, central to the concept of guilt is the idea of alleviating guilt via making reparations for one's transgressions. Guilt inducing messages can be effectively used to motivate consumers to make reparations for their transgressions by consuming certain products.

Measuring Eating Guilt

Statements designed as guilt indicators were generated from the literature by the authors. A pool of 40 such items was reviewed by a panel of marketing doctoral students and reduced to 13 based on ambiguity and redundancy. A sample of 267 student respondents was asked to indicate their level of agreement/disagreement on 6-point scales where 1=strongly disagree and 6=strongly agree (sample item: I often feel guilty about overeating at meals). Using these data, the 13-item scale was reduced to six items based on exploratory factor analysis and evaluation of Cronbach's alpha. The exploratory factor analysis resulted in a two-factor solution that explained over 74% of the variance in the data. Cronbach's alpha for the scale was .85. This appropriateness of this two-factor scale for eating guilt was then confirmed via confirmatory factor analysis. Consistent with theoretical conceptualizations, scale items reflect guilt by omission (not doing what one feels one *should* do) and guilt by commission (doing what one *should not* do). Respondents in the main study which tested a structural model involving eating guilt were 79 male and 87 female students at a large Midwestern university.

Tests of Relationships in the model

The model hypothesized eating guilt as a central mediating variable. Hypothesized antecedents of eating guilt were concern for appearance and concern for healthy food. Consequences of guilt were making reparations, the physical appearance component of self esteem and preoccupation with health. An explicitly affective component of guilt based on a modified version of the Harder and Lewis (1987) Personal Feelings Questionnaire was used to measure eating guilt-evoked feelings.

Tests of the model indicate factorial invariance between males and females in the measurement of latent variables. That is, the measurement items load similarly on the latent variables for males and females. Also, all scales to measure the independent and dependent variables showed a factor structure consistent with theory and acceptable levels of coefficient alpha. Cronbach's alpha for the eating guilt scale was .85.

Consistent with theory, guilt leads both males and females to make reparations (i.e., by exercising or eating less at the next meal). Guilt also seems to lead both men and women to a preoccupation with health. The negative feelings associated with guilt strongly mediate the effect of guilt on self-esteem for both males and females. That is, guilt as measured by statements incorporating both cognitive evaluations and feelings had no direct effect on physical appearance self-esteem. One plausible interpretation of the mediating role of these strong negative feelings is that people also have very strong feelings about their physical appearance. Once the strongest feelings surrounding guilt have been accounted for, the less affective component of guilt has little effect on self-esteem.

Interesting gender differences also emerged in this study. Women were more apt than men to feel guilty if they were concerned with their appearance, and men tended to feel more eating guilt if they were more concerned with healthy food.

The Effect of Irrelevant Information on Consumer Irritation and Attitudes: The Moderating Role of Need to Evaluate

Abhijit Biswas, Wayne State University
Sweta Chaturvedi Thota, James Madison University

EXTENDED ABSTRACT

Past research has investigated the effect of irrelevant information related to the advertised product on consumers' beliefs in the product's ability to deliver the desired benefit. The results suggest that irrelevant product information systematically weakens consumers' beliefs that the product will provide the desired benefit. An interesting question that follows is if the impact of brand related irrelevant information is considerable to the extent it may systematically weaken the impact of diagnostic information, then what would be the impact of non-brand related irrelevant information, as it is likely to be in the context of cross-selling? Is the impact of such irrelevant information negative to the extent that it causes irritation in consumers? Since irritation can have negative consequences, does such irrelevant information lead to negative reactions toward the focal product as well as the advertiser? The above questions assume importance when—in an attempt to make additional sales—advertisers and salespeople frequently expose consumers to a substantial amount of information that may be irrelevant to the product under consideration.

The current paper explores consumers' reactions to information that is irrelevant to the product offering itself, as is likely to happen in a cross-selling context. We posit that consumers are likely to be more irritated when they are exposed to descriptions and offers of products that are completely unrelated to the focal product (i.e., highly irrelevant information) than when these products are viewed as complementary to the focal product (i.e., less irrelevant information).

Based on excitation transfer theory and recency effects, it is suggested that the irritation elicited as a result of exposure to information that is not relevant to the focal product may negatively affect consumers' attitudes toward the advertiser, the focal brand, and their purchase intentions. We further posit consumer irritation will be elicited in different degrees in consumers who differ in their propensity to evaluate information. In other words, the individual level variable—need to evaluate—will moderate the elicitation of irritation in consumers and its subsequent transfer to attitudes towards the advertiser and the advertised focal brand.

A 2 (nature of irrelevant information: highly irrelevant vs. less irrelevant) X 2 (need to evaluate: high vs. low) between-subjects design was used to test the proposed hypotheses. Seventy-two undergraduate students received course credit for participating in the experiment. Out of these, twenty-eight students were males and forty-four were females. The subjects were randomly assigned to the two conditions related to the nature of information: highly irrelevant vs. less irrelevant. Need to evaluate was a measured variable. The subjects completed a questionnaire which contained a scenario. The subjects were asked to imagine that they had called the toll-free number in the ad for the abdominal exerciser and were in a conversation with a sales representative. The scenarios contained information that varied in its degree of irrelevance—highly irrelevant vs. less irrelevant.

The results of this study show support for the moderating influence of consumers' need to evaluate. Specifically, it was found that highly irrelevant information leads to higher levels of irritation and the effect is greater for consumers with a high need to evaluate than for consumers with a low need to evaluate. Consequently, consumers with a high need to evaluate displayed lower attitudes

toward the advertiser and the focal brand, as well as lower intentions to purchase the focal brand compared to consumers with low need to evaluate. Finally as hypothesized, irritation is seen to completely mediate the effects of irrelevant information and need to evaluate on consumers' attitudes toward the advertiser, the focal brand and their intentions to purchase.

Our study supports the excitation transfer theory in that consumers' negative feelings such as irritation may be transferred to their subsequent judgments. This is because residual arousal, such as feelings of irritation from preceding emotional experiences or behaviors, may be carried over to subsequent experiences or behaviors. In addition, recency effects may also explain our findings. Since consumers were exposed to irrelevant information immediately before forming judgments of the advertiser and the advertised brand, it may be argued that this irrelevant information was more salient in the minds of the consumers. Overall, our findings suggest that irritation, an under-researched construct in marketing, may have serious and undesirable implications for consumer attitudes. Thus, it becomes critical to identify the causes of irritation in consumers from a theoretical as well as managerial point of view. Knowledge of factors that irritate consumers is critical since consumers are often exposed to cross-selling situations.

From a managerial point of view, our findings may be deemed as disturbing and problematic for advertisers or marketers involved in cross-selling. Our findings assume importance especially because advertisers and salespersons often attempt to increase their overall sales by offering products which may not be related to the focal product or to each other, thus increasing the likelihood of a negative response from the consumer. In addition, since our results indicate that the high need to evaluate individuals show higher irritation levels and unfavorable attitudes toward the advertiser, the focal brand, and intentions to purchase products, it is suggested here that advertisers and the researchers may consider need to evaluate and other such individual level variables to understand the differences in cognitive and affective processing.

A Grounded Typology of Consumer Coping Strategies Within the Context of Infertility Treatment

Eileen Fischer, York University

Cele C. Otnes, University of Illinois at Urbana-Champaign

Linda Tuncay, University of Illinois at Urbana-Champaign

EXTENDED ABSTRACT

In recent years, researchers in consumer behavior have increasingly recognized that people may encounter significant obstacles when attempting to achieve goals related to consumption. One research stream demonstrating the salience of this topic focuses on understanding the coping strategies consumers employ when they experience and attempt to manage negative or mixed emotions in a variety of consumer contexts. Coping has been defined as “a multidimensional set of cognitions and behaviors called upon to help the person manage or tolerate the demands imposed by chronic or acute stressors.” (Eckenrode, 1991, p.3).

In contrast to studies that examine how individuals cope with consumption challenges during difficult life stages of their life cycles, this paper focuses on how consumers cope as they use marketplace choices to help them *progress* to a desired stage in the life cycle—parenthood. Although 90% of childless married couples say they would like to have children, infertility affects one in six married couples in the U.S. (May, 1995). Moreover, consumers now spend an around \$2 billion a year on infertility services, and the average costs of “Assisted Reproductive Technology” treatments such as insemination and in vitro fertilization range from \$4,000 to \$11,000 per attempt (De Witt, 1993), with most procedures not covered by insurance. While demand for infertility treatments has skyrocketed, and while these services are typically emotionally charged, prolonged, and extremely costly, to date few scholars in consumer behavior have explored this context.

One instrument that is well known in psychology, and that was designed to capture the cognitive and behavioral coping strategies used in stressful situations, is the “Ways of Coping” survey. Folkman et al. (1986) applied this survey to their study of a variety of stressful situations, and factor analysis revealed people used eight distinct coping strategies. Our research on infertility has led us to believe these strategies are neither mutually exclusive nor collectively exhaustive. Specifically, as we consulted both our naturalistic data and the literature on coping, we honed the following research questions:

1. How relevant are the eight coping strategies identified by Folkman et al. (1986) in consumers’ own descriptions of their infertility experiences?
2. What other types of coping strategies (if any) do consumers employ in the context of seeking infertility treatment?

We explored these questions by conducting in-depth personal interviews with 20 women and 3 men experiencing infertility in the U.S. and Canada from May 2002 until February 2003. Informants ranged in age from 28–47 years, were from a variety of geographic locations, represented a variety of socioeconomic backgrounds, and were mostly white. Three researchers (two professors and a graduate student) read all of the interviews several times for familiarity. Each author was then primarily responsible for rigorously coding one third of the interviews for the presence of the eight coping strategies identified by Folkman et al. (1986), assigning their informants’ coping strategies to one of eight categories, or

creating and naming emergent categories if none of these *a priori* strategies were descriptive of our informants’ coping behavior.

Our findings reveal that the Folkman et al. typology is somewhat useful in interpreting the coping strategies used by consumers when they manage the stress they incur when being treated for infertility. Moreover, we find there are four categories of stressors that are relevant within this context: impediments to achieving the goal of becoming a parent, emotions, information uncertainty, and failure (interim and terminal). Our other findings include: 1) the absence of the escape/avoidance coping strategy as described by Folkman, et al. in our text; 2) the fact that taking responsibility for one’s infertility emerged not as a coping strategy but as a stressor, and 3) the emergence of several distinct strategies under the umbrella of the general strategies described by Folkman et al. Examples with respect to the latter point include various types of painful problem solving, such as active problem solving, leadership, simultaneous problem solving and acquiring and deploying resources. Our findings demonstrate the value of a grounded-theory approach to understanding coping, and call for creation of more discerning measures of coping within a high-stress context where failure rather than success may be the norm.

Consumer Evaluation of Multiple Internal Reference Prices

Miyuri Shirai, Yokohama National University

ABSTRACT

This study aims to understand the consumers' general view of each of multiple IRPs in terms of importance and usage propensity for price judgments, the effort devoted to its formation, and whether its adoption is universal through all product categories and brands. Findings are as follows. First, in terms of importance, usage propensity, and effort, a normal price is highly evaluated and the highest-observed and lowest-acceptable prices less so. Second, the normal and expected prices are likely to be used over many product categories, whereas the lowest-acceptable price is not. Third, purchased price is likely to be used over many brands, whereas reservation price is not.

INTRODUCTION

An internal reference price (IRP) is known to have a multidimensional nature. That is, IRP has multiple operational definitions even though the conceptual definition of IRP is clearly defined. Winer (1988) presented eight common IRPs and organized them into five prices: fair, reservation, lowest acceptable, expected, and perceived. Although IRPs have been a focus of marketing research in the past, most have examined the importance of IRPs in consumers' purchase decisions (for an early review, see Kalyanaram and Winer 1995), explored promotional tools that affected IRPs (e.g., Folks and Wheat 1995; Kalwani and Yim 1992; Lichtenstein and Bearden 1989), or measured the accuracy of IRPs (e.g., Helgeson and Beatty 1987; Mazumdar and Monroe 1990). Consequently, the operationalization of IRPs has been unrestrained and various actions have been adopted. Previous studies that measured several IRPs found that some levels were fairly similar (e.g., Bearden et al. 1992; Diamond and Campbell 1989; Folkes and Wheat 1985). Nevertheless, each IRP is conceptually different and consumers are likely to use them differently depending on product type, consumer characteristics or purchase occasions. Therefore, investigations on the multidimensional nature of an IRP are needed, especially on the type of IRP used, factors that affect its adoption, and the perceived difference of each IRP.

As mentioned above, this topic has attracted the attention of few researchers. However, research on the topic recently has increased. Chandrashekar and Jagpal (1995) presented the first study of this and demonstrated that consumers used IRPs (fair, reservation, normal, and lowest prices seen) independently to evaluate an offered price, instead of combining them into an overall unitized IRP prior to making an evaluation. Then, Chandrashekar (2001) extended the study of Chandrashekar and Jagpal and showed that this non-unitized process was used regardless of the level of product involvement. However, product involvement affected the number and types of IRPs utilized; while high-involvement consumers used only reservation price, low-involvement consumers used fair and normal prices as IRPs. Klein and Ogleshorpe (1987) classified multiple IRPs into three categories that were not mutually exclusive: aspirational, market, and historical IRPs. The aspirational IRP was based on consciously established goals or targets for price, the market IRP on the perceptions of price levels in the marketplace, and the historical IRP on consumers' purchase experience. By following this classification, Vaidyanathan et al. (2000) investigated the effects of aspirational IRP (AIRP) and market IRP (MIRP) on deal attitude and purchase intention. The AIRP was operationalized by fair and reservation prices and MIRP by lowest market and normal prices. They showed that consumer

use of AIRP and MIRP depended on the level of consumer confidence in IRP estimates and on the type of consumer response. When price uncertainty was low, AIRP influenced purchase intention and MIRP deal attitude. However, when price uncertainty was high, only AIRP influenced deal attitude and no IRPs were regarded in forming purchase intention. Subsequently, Vaidyanathan and Muehling (1999) derived theoretically that AIRP was more likely to be used when product knowledge was low, but price consciousness high, whereas MIRP was more likely to be used when both product knowledge and price consciousness were high. Furthermore, Vaidyanathan and Aggarwal (2001) demonstrated that AIRP was used when product involvement was low and MIRP when it was high. Finally, Shirai (2003) investigated the number and types of IRPs utilized for products that differed in perceived price expensiveness and product involvement. The number of IRPs utilized was found to increase as perceived price expensiveness and product involvement increased. While normal and expected prices were commonly used among the products, fair, reservation, lowest-acceptable, and average-observed prices were used when perceived price expensiveness and product involvement were high, and purchased price was used when they were low. Also, Shirai showed that combinations of multiple IRPs utilized were similar, but the most important IRP varied among consumers.

The above studies have targeted just one or only a few product categories; therefore, their findings have not yet reached generalization. Accordingly, some of the findings are not consistent. In particular, the results provided by Chandrashekar (2001), Vaidyanathan and Aggarwal (2001) and Shirai (2003) seem to contradict each other in terms of consumer use of reservation and fair prices. Chandrashekar showed that reservation price was used when purchase involvement was high and a fair price when it was low. In Vaidyanathan and Aggarwal's study, both prices were used when product involvement was low. However, Shirai showed that both prices were used when it was high. These studies, however, differed in the type of product involvement and the product category they focused on. While the first two studies looked at the involvement within a product category (running shoes in Chandrashekar and coffeemakers in Vaidyanathan and Aggarwal), Shirai looked at the involvement among different product categories (personal computers, cellular phones, and shampoo). Thus, further investigations are necessary, especially on the type of IRPs utilized for different product categories and in respect of consumer characteristics.

Given that consumer use of IRP for price judgments is changeable, some questions arise regarding how consumers basically think of each IRP without assuming particular purchase situations by specifying a product category, brand, contest, or shopping purpose. Do consumers really perceive each IRP differently? If so, on what aspect, do they differ? This study aimed to find some answers to those questions. More specifically, instead of focusing on particular product categories, this study aimed to investigate consumers' general views toward various IRPs in terms of importance and usage propensity for price judgments, and the effort devoted to its formation. Our interest in elucidating the perceived effort devoted to the formation of IRPs was motivated by Vaidyanathan and Aggarwal (2001). They assumed that MIRP was more data driven and more analytic than AIRP so that consumers who use MIRP are considered to have high product involvement. Since they did not examine this view empirically, whether the

TABLE 1
Mean Value of Each IRP

	Importance	Usage propensity	Involvement	Category specific	Brand specific
FP	5.698	4.377	4.302	4.887	4.528

PP	5.585	5.453	3.868	4.189	3.887

formation of MIRP actually required more effort than AIRP is not clarified. Accordingly, we investigated this and also whether consumers felt that the use of each IRP depended on product category or on brand. The latter enabled us to see whether consumers were likely to use each of the IRPs in price judgments of most product categories or most brands.

METHOD

Data were collected from 53 undergraduate student subjects by a survey questionnaire. Prior to participation in the survey, the subjects were briefed about the concept of IRP and given a specific description of nine operational IRPs: fair price (FP), reservation price (RP), lowest-acceptable price (LAP), lowest-observed price (LOP), highest-observed price (HOP), average-observed price (AOP), normal price (NP), expected price (EP), and purchased price (PP). These IRPs have appeared in previous research. Based on the Klein and Oglethorpe (1987) classification, FP, RP, LAP, and EP may be categorized as AIRP and LOP, HOP, AOP, and NP as MIRP. PP is historical IRP; however, and it is likely to be related to both AIRP and MIRP as noted by Vaidyanathan et al. (2000, p.181).

Then a questionnaire was distributed to subjects and these five questions were asked for each IRPs:

- Q1: "In general, do you think that this price is necessary in evaluating the validity of an offered price?"
- Q2: "In general, do you consider this price when evaluating the validity of an offered price?"
- Q3: "Suppose that you use this price to evaluate the validity of an offered price. Do you think that it takes some time and effort for you to decide how much this price should be?"
- Q4: "Do you think that whether to use this price for your price judgments depends on product category? That is, you might not use this price for all product categories?"
- Q5: "Do you think that whether to use this price for your price judgments depends on brand? That is, you might not use this price for all brands?"

Q1 measured the perceived importance of each IRP for price judgments, Q2 whether each IRP is commonly used in price judgments, Q3 the level of involvement devoted toward each IRP, and Q4 and Q5 whether the use of the price is universal throughout product categories or brands. Hereinafter, Q1 is referred to as the

"importance" feature, Q2 as "usage-propensity", Q3 as "involvement", Q4 as "category-specific", and Q5 as "brand-specific". This design can be considered as a single, nine-level within-subjects experimental design. Each IRP was again described specifically. The order of presenting these IRPs was alternated. Subjects were asked to answer each question on a seven-point scale anchored by "1=Not at all" and "7=Very Much". Subjects also rated their level of price consciousness and importance of price in purchase decisions on a five-point scale.

RESULTS

Before examining individual repeated-measures of ANOVA on each measure of five features (importance, usage propensity, involvement, category-specific, and brand-specific), we carried out a one-way MANOVA using IRP type (nine different IRPs) as dependent variables. The MANOVA revealed an overall significant effect of IRP type ($Wilk's\lambda=.53, F=7.83, p<.0001$). Therefore, follow up ANOVAs were performed for each of the five features. The mean values of the nine IRPs for each feature are presented in Table 1. Table 1 shows that each feature varied among the nine IRPs.

With regard to the importance of price judgments (Q1), ANOVA demonstrated that some of the nine IRPs differed significantly ($F(8, 468)=14.58, p<.0001$). Also, the following results were found by Tukey test. First, the importance of NP was significantly more than RP, LAP, LOP, HOP, and PP. Second, the importance of FP, AOP, EP, and PP was significantly more than LAP and HOP. Third, the importance of HOP was significantly less than FP, RP, LOP, AOP, NP, and PP. Lastly, the importance of LAP was significantly less than FP, LOP, AOP, and PP. These results indicated that in particular, the need for price judgments was relatively high for NP and low for HOP. Also, the results indicated that in terms of the level of importance as IRP, it was inappropriate to classify IRPs as MIRP or AIRP since each member IRP in the same category had a different level. Within the AIRP category, some IRPs were perceived to be more important than others (e.g., EP vs. LAP; FP vs. LAP). Also, within the MIRP category, some IRPs were perceived to be more important than others (e.g., NP vs. HOP; AOP vs. HOP).

Regarding the usage-propensity for price judgments (Q2), the ANOVA revealed that some of the nine IRPs differed significantly ($F(8, 468)=15.58, p<.0001$). Also, Tukey tests indicated the following: first, NP and EP were used significantly more than FP, LAP, and HOP. Second, HOP was used significantly less than RP,

LOP, AOP, NP, EP, and PP. Third, LAP was used significantly less than RP, LOP, AOP, and PP. Lastly, FP was used significantly less than LOP, AOP, and PP. These results indicated that in particular, the usage propensity for price judgments was relatively high for NP and EP and low for HOP and LAP. Also, similar to the importance feature, these results indicated that in terms of the usage level of IRPs, it was inappropriate to classify IRPs as MIRP or AIRP since each member IRP in the same category had a different level (e.g., EP vs. FP for AIRP and NP vs. HOP for MIRP).

ANOVA revealed that some of the nine IRPs differed significantly in the involvement devoted to its formation (Q3; $F(8, 468)=3.0, p<.01$). Tukey tests showed that the involvement with HOP was significantly less than AOP and NP, and that of LAP was significantly less than NP. These results indicated that in particular, the time and effort spent on deciding the level of NP was relatively high and HOP and LAP was relatively low. Furthermore, these results indicated that even within MIRP, the level of effort spent in forming each IRP tended to be different (e.g., NP vs. HOP).

Whether the use for price judgments depended on product category was shown to vary among the nine IRPs (Q4; $F(8, 468)=8.8, p<.0001$). Tukey tests indicated that the extent of NP and EP were significantly less than FP, RP, LAP, and LOP. Also, the extent of LAP was found to be significantly more than HOP, AOP, and PP. These results indicated that NP and EP were likely to be used on many product categories, whereas the use of LAP was likely to be limited to certain product categories. Also, these results indicated that it was inappropriate to classify IRPs as MIRP or AIRP when considering the product-specific feature, since each member IRP had a different level although they were in the same category (e.g., RP vs. EP for AIRP and LOP vs. NP for MIRP).

Whether the use for price judgments depended on the brand was shown to vary among the nine IRPs (Q5; $F(8, 468)=2.78, p<.01$). According to Tukey tests, the extent of RP was significantly more than AOP and PP. These results indicated that PP was likely to be used on many brands, whereas the use of RP was likely to be limited to certain brands.

We additionally note that there was not a strong, but positive correlation between the importance and usage-propensity features ($r=0.62, p<.0001$), between the importance and involvement features ($r=0.4, p<.0001$), between the usage-propensity and involvement features ($r=0.39, p<.0001$), and between the category-specific and brand-specific features ($r=0.5, p<.0001$). These indicate that the IRPs that consumers tend to use are the ones they think are necessary to judge an offered price. Moreover, the IRPs used for certain product categories had a tendency to be used for certain brands.

DISCUSSION

This paper has presented findings regarding how consumers generally perceive each of multiple operational IRPs without considering any specific purchase situations such as product category, brand, context, and shopping purpose. More specifically, this study investigated consumers' general view toward each IRP in terms of the following features: importance and usage propensity for price judgments, effort devoted to its formation, and whether the use of each IRP for price judgments depended on product category or brand. Since consumer use of IRP is affected by many factors, we thought it was important to understand their basic views, before hypothesizing certain purchase situations.

The results obtained from a survey done by questionnaire examining nine IRPs (fair, reservation, lowest-acceptable, lowest-observed, highest-observed, average-observed, normal, expected, and purchased prices) indicated that some IRPs were perceived

quite differently on the five features. In terms of importance, usage propensity, and effort, normal price was evaluated highly and highest-observed and lowest-acceptable prices were evaluated relatively less. Moreover, normal and expected prices were likely to be used on many product categories, while lowest-acceptable price was likely to be used on particular product categories. Further, purchase price was likely to be used on many brands, while reservation price was likely to be used only on certain brands. Consequently, it is inappropriate to treat each IRP similarly when directly measuring consumers' IRP or when planning to affect consumers' IRP at a desired level by using marketing tools. Also, further development of theories that explain consumer use of multiple IRPs is definitely needed.

Inferred Transaction Value: A Key to Understanding the Effects of Price Bundling

Roger Heeler, York University
Nguyen, Adam, York University

EXTENDED ABSTRACT

This paper examines a common marketing tactic called price bundling, defined as the practice of marketing multiple products and/or services at a bundle price (Johnson, Herrmann, and Bauer 1999). Examples include the purchase of a car where the basic model and options are bundled into a package or the purchase of a skiing pass good for multiple days. Behavioral research on price bundling has traditionally viewed the psychological impact of price bundling in separation from, and as violation of, its economic logic (Prelec and Loewenstein 1998; Soman and Gourville 2001). This frame overlooks the possibility that some of the psychological impact of price bundling may be driven by its economic logic.

This paper proposes and tests a psychological impact of price bundling that is derived from its economic logic. We call it the inferred transaction value (hereafter, ITV) effect. It has become a popular belief that bundles typically involve a discount (Estelami 1999; Yadav and Monroe 1994). Since prior beliefs can drive perception and judgment (Abba, Broniarczyk, Shimp, and Urbany 1994), consumers may infer a bundle saving or transaction value (Thaler 1985) when being presented with a bundled offer even in the absence of explicit information about bundle savings. And because signal of a deal is sufficient to generate consumer reaction (Inman, McAlister, and Hoyer 1990), this ITV should enhance consumer evaluation, and hence purchase likelihood, of the bundle offer.

The ITV hypothesis offers new insights into the direction and mechanism of the psychological impact of price bundling. The dominant perspective in the literature relies on mental accounting's loss aggregation principle (Thaler 1985) to explain pre purchased bundle effects, e.g., the impact of price bundling on consumer perceptions of an offer (Stremersch and Tellis 2002). Assuming that price information is coded as a relative loss, Johnson, Herrmann, and Bauer (1999) suggested that price bundling enhances consumers' evaluations because consumers perceive a single loss as less punishing than multiple losses. We believe that this assumption is inconsistent with mental accounting theory. According to this theory, the cost of good is treated as losses or gains when being evaluated against a reference point, e.g., in cases of a price change (Mazumdar and Jun, 1993), but the price of a product in and by itself is unlikely to be coded as a loss. As Thaler (1985) suggested, "... the cost of the good is *not* treated as a loss. Given the steepness of the loss function near the reference point it is hedonically insufficient to code cost as loss" (p. 205). Therefore, we argue that it is the ITV, rather than the lost aggregation effect, that accounts for Johnson et al's (1999) empirical findings about the positive impact of price bundling on consumer perception of the offer. This implies that, contrary to the convention, the positive impact of price bundling may not be universal, because price bundling may not always produce ITV.

The ITV hypothesis can also explain the impact of price bundling on post-purchased consumption behavior. Soman et al (2001) proposed the transaction-decoupling hypothesis, which holds that price bundling further decouples the sunk cost of the bundle from its benefits, thereby reducing the likelihood of consuming the entire bundle. The ITV effect provides another mechanism for this effect. Specifically, the inferred bundle saving may reduce the perceived sunk cost of the bundle itself. While the two hypotheses are complementary, the inferred transaction cost hypothesis has the advantage of being able to account for both pre and

post purchased bundle effects, which to date have been two relatively unrelated areas of research on price bundling.

We conducted three lab studies to test the ITV hypothesis. In study one respondents were presented with a bundled (unbundled) offer and then asked to indicate how much they think the total price of an equivalent unbundled (bundled) offer would have been. As a triangulation, respondents provided open-ended rationales for their response. As expected, respondents presented with the bundled (unbundled) offer believed that an equivalent unbundled (bundled) offer would have been 10.2% more expensive (6.9% cheaper) than the original offer. In study 2, three automobile offers were presented; the first two were identical to the bundled and unbundled offers in Johnson et al's (1999), while the third was a bundle offer in which the ITV was excluded (by indicating that the price of an equivalent unbundled offer would have been the same). Consumer preference for the bundle versus unbundled offer was reversed as ITV was removed: Once ITV was removed respondents' evaluation of the bundled offer drops significantly (from 5.08 to 4.48, $p < .05$), to a level even lower than that of the unbundled offer. Study 3 modified the skiing scenario employed in Soman et al's (2001). Respondents imagined that they had bought separate individual one-day tickets (unbundled condition), and then indicated how much they think the total price would be for a/ single ski pass (bundled condition), and b/ a set of tickets (semibundled condition). As expected, respondents believed the bundled offer would have been 20.6% cheaper than the unbundled offer, and the semibundled purchase would have been 14.4% cheaper than the unbundled purchase.

Overall, these studies provided strong evidence that the ITV effect is robust in both product and service bundling contexts and can provide alternative explanations for the results found by Johnson et al (1999) and Soman et al (2001). Study 2 also provided some evidence that it is the ITV, rather than the loss aggregation effect, that accounts for the positive impact of price bundling on consumer perception of the bundle offer. This finding has important theoretical and practical implications. Because price bundling, or more generally, price integration, may not always produce ITV, this tactic may not always enhance consumer perception of the offer, and thus, contrary to the convention (Stremersch et al 2002), is not always an optimal tactic for firms. For example, because integrating base price and surcharge into one inclusive price does not involve any inferred discount, it may be better to partition price information to take advantage of the heuristic effect (Mortwitz, Green, and Johnson 1998).

Did You Hear What My Friend Paid! Examining the Consequences of Social Comparisons of Prices

David Ackerman, California State University, Northridge
Lars Perner, San Diego State University

ABSTRACT

This paper examines the impact of social comparisons of prices. It considers the effects of price comparisons on consumers when they get a better bargain and when they pay more. This study finds that satisfaction with both the store and the product purchased are lower when consumers pay more than others. Findings also suggest that prices consumers are willing to pay more easily go down than up, where as perceptions of prices stores normally charge stay the same or even increase.

Does it matter to consumers what others pay for products? Consumers have ample opportunities to find special bargains in retail stores, even though bargaining is not as common in the United States as it is in some societies. This means that different consumers often end up paying very different prices for similar products and services. Hagglng and internet bidding are examples of contexts in which the pricing for the sale of products varies considerably by customer (Heun 2001). Although electronic forums allow for increasingly sophisticated methods to set profit maximizing prices for each customer, many of these types of transactions still take place in the traditional retail environment. University and medical fees are often based on willingness and or ability to pay for a particular service. Even for consumer products in which direct negotiation of prices is not possible, prices may vary quite a bit depending on the retailer and the location.

One way in which consumers can find out about differences in prices is through social comparisons. Social influence can be a source of informational influence on purchases. Information from friends or peers is sought by consumers to make purchases, especially for symbolic products (Midgely 1983). Information passed along by others can also be a one factor in facilitating fads (Bikchandani, Hershleifer and Welch 1998). Specifically, price information can also be shared among consumers (e.g., Feick and Price 1987). Sharing of price information can have an impact on the effectiveness of targeted promotions (Feinberg, Krishna, and Zhang 2002).

This paper is an exploratory study examining the impact of social comparisons of prices. It considers the effects of price comparisons on consumers when they get a better bargain and when they pay more. It examines the consequences for satisfaction with the product and the retailer and product repurchase intentions. It also looks at the impact of appraisals on and the emotional reactions to the price comparison process.

Price Comparisons and Satisfaction

Comparisons with consumers who purchased the same product at a cheaper price can lead to dissatisfaction with a previously satisfactory purchase. These are social comparisons that can lower the reference price so that a consumer can become dissatisfied even when everything about the product they just purchased remains the same. An early study, Brickman and Campbell (1971), identified social comparison as potentially the most potent influence to raise comparison standards and create dissatisfaction. They found that this comparison increases standards that can result in a negative discrepancy with the performance of the existing product. Social comparisons of prices paid for a product should do the same.

A link between social comparisons and dissatisfaction with income has already been identified. Management studies have indicated that the pay of referent others can be an important part of pay dissatisfaction (Scholl et al. 1987). Martin (1981) suggested relative deprivation as an important construct to explain dissatisfaction with pay. More recently, Sweeney, McFarlin and Inderridien (1990) tested relative deprivation across a variety of contexts and found it to be an important predictor of pay satisfaction. Dissatisfaction regarding differences in pay involves appraisals of inequity and injustice (Martin 1981). Would these same appraisals be made if the entity of comparison was the outflow of money as part of a cost rather than the inflow of income?

Unfavorable social comparisons can lead to dissatisfaction even without these negative appraisals. Richins (1991) found that idealized images of women in advertising can invite unfavorable comparisons with the self. These comparisons led to raised comparison standards and to dissatisfaction with the self.

Impact on Satisfaction. These findings can be applied to price comparisons. When consumers compare prices with a friend who has paid a lower price, they should feel less satisfied with the store where they bought the product than when they compare with friends who paid a higher price.

Price Comparisons and Reference prices

A consumer's *internal reference price*, or the price that he or she would expect to be charged for a given product in a given situation, is a standard which has been closely examined in the marketing literature (e.g. Kalwani and Yim 1992). Consumers are further exposed to *external* reference prices, or cues in the external environment such as prices suggested by merchants in order to influence the consumer's evaluation of an offering price. Consumers' evaluation of prices are influenced both by internal reference prices and by external reference prices (Rajendran and Tellis 1994).

Typically, a relatively high external reference price is provided so that the target price is "contrasted"—that is, seen as a bargain. For example, a sign or advertisement may compare a sale price to the "regular" price, that of a competing brand, the price of the same brand in a different store, the "manufacturer's suggested retail price," or an "original" price. There are limits to the credulity of the consumer, but Urbany, Bearden and Weilbaker (1988) and Lichtenstein and Bearden (1989) show that even "implausibly high" external reference prices tend to increase internal expectations. By contrast, Yadav and Seiders (1998) suggest that the respective impact of new high and low price stimuli is quite asymmetric. Their results found that price expectations of consumers knowledgeable about a product category were influenced significantly more by prices that were below their established reference price levels.

Impact on Internal Reference Prices. Internal reference prices may be influenced downward by external sources of comparison. When a consumer compares prices paid for a product with bargain prices paid by another, this lower price forms the anchor by which other prices are judged. Thus, exposure to lower prices paid by others can lead to lowering of consumers' internal reference prices for that product category. Similarly, under some circumstances consumers may also raise their internal reference prices by com-

parison to the external reference prices of others that paid more (cf. Urbany, et al. 1988).

Social Comparisons and Emotions

Social comparisons can elicit quite a range of emotional responses. They can result in a reduction of closeness with the comparison other (Pleban and Tesser 1981), disparagement of the comparison other (Achee, Tesser, and Pilkington 1994), anxiety (Tesser and Collins 1988) or jealousy (DeSteno and Salovey 1996). They can also be mixed with positive emotions such as happiness (Ackerman, MacInnis and Folkes 2000).

Impact on Emotions. Within the context of pricing, Feinberg, Krishna, and Zhang (2002) present experimental data to suggest consumers loyal to a firm felt “envy” when special pricing is made available to potential “switchers” currently served by other firms. When consumers compare with friends who have found cheaper prices for the same product they are likely to feel envy, anxiety and even anger. By contrast, when they compare with friends who have paid more for the same product they should feel positive feelings such as happiness, gratefulness and even pride.

METHOD

The research required a method that would allow us to explore and compare reference prices, product and store satisfaction, emotions and appraisals when the comparison was with a more expensive price for the same product and when it was with a cheaper price. To facilitate the comparison and to control for individual differences in emotionality, appraisal biases, and optimistic vs. pessimistic tendencies, we used a within-subjects design. Fifty-five undergraduate business students served as respondents. All who agreed to participate completed the task.

Procedure

Subjects were asked to remember and describe in detail two experiences involving the social comparisons of prices (cf. Roseman, Antoniou and Jose 1990; Smith and Ellsworth 1987). In one condition, subjects were asked to describe a time when they purchased a product and then soon after discovered a friend who had found the same product for a much cheaper price. In another condition, subjects were asked to describe a time when their friend purchased a product and soon after discovered that they (the subject) had found the same product for a much cheaper price. The order in which the reports were generated was randomized.

In each of the conditions, respondents were asked to fill out a survey with various measures of satisfaction, appraisals, emotional responses and assessments of reference price. Responses were paired by subjects’ mothers’ birth dates. The two reports were separated by 45 minutes of filler activity.

Clothing was mentioned most frequently by subjects in both conditions ($M_{\text{selfbargain}}=24$, $M_{\text{otherbargain}}=18$). Entertainment ($M_{\text{selfbargain}}=8$) and electronics equipment ($M_{\text{selfbargain}}=6$) were the second and third most frequently mentioned in the condition in which subjects bought at the cheaper price, hereafter referred to as the *self-bargain condition*. Communications equipment ($M_{\text{selfbargain}}=9$) and entertainment ($M_{\text{selfbargain}}=6$) were the second and third most frequently mentioned in the condition in the other person bought at the cheaper price, hereafter referred to as the *other-bargain condition*.

Measures

Social Comparison Emotions. A modified version of the emotion inventories of Burke and Edell (1989) and Richins (1997) was used to measure emotions elicited by a social comparison of products. Fifteen emotions, ten negative and five positive, were

measured were measured with single item measures and then clustered using factor analysis. Correlation and factor analyses revealed three groups of negative emotions and one group of positive emotions. Regret, loss and envy loaded on one factor ($M=1.38$, $a=.94$), anger frustration and stress loaded on second factor ($M=1.75$, $a=.91$), happiness, enjoyment and exhilaration loaded on a third factor that represented a sort of general state of happiness ($M=4.83$, $a=.90$), shame, humiliation and hate loaded on a fourth ($M=1.48$, $a=.95$) and gratefulness and pride loaded on a fifth factor that represented both internally and externally attributed positive feelings about an outcome ($M=3.96$, $a=.74$).¹

Appraisals. Twenty-one items, each using a seven-point agree-disagree Likert scale, were used to indicate the various appraisal dimensions. The scale was derived from Lazarus’ (1991) appraisal components and modified by a review of the reference price (Biswas, Pullig, Yagci and Dwane 2002; Janiszewski and Lichtenstein 1999; Schindler 1998; Lichtenstein and Bearden 1989), social comparison (Tesser 1990; Tesser and Collins 1988) and relative deprivation (Sweeney, McFarlin and Inderrieden 1991; Martin 1981) literatures.

Seven subscales were identified through factor analysis. The first measures whether subjects felt they could *undo what happened* ($M=5.48$, $a=.86$), while the second assesses how much subjects *cared about what happened* ($M=4.36$, $a=.92$). The third assesses how *good* the outcome was for the subject ($M=3.00$, $a=.94$). The fourth component measured perceived *unfairness* of the situation ($M=3.89$, $a=.97$). The fifth component, assesses the degree to which the situation *affected self-esteem* ($M=2.84$, $a=.97$). The sixth component measures the degree of *responsibility* subjects felt for the outcome of the situation ($M=4.61$, $a=.94$). A higher number indicates higher self-blame. The seventh assesses the degree of *control* subjects felt they had over the outcome of the situation ($M=4.56$, $a=.83$).

Prices for the product were measured by open-ended questions asking how much was paid by subjects and their friends. Five items were used to assess reference prices (cf. Lichtenstein & Bearden 1989). The first 3 items measured the prices that consumers would really want to pay for a product. One item asked subjects what a fair price for the product would be. A second item asked subjects what was the lowest price by which they thought the product could be obtained. The third item asked subjects what they expect to pay if they bought the item again. The fourth and fifth items measured what subjects perceived to be price norms for a product. The fourth item asked subjects what they felt the store where they purchased normally charges for the product. The fifth item asked subjects the same question about the store where the other person bought.²

Satisfaction for the product ($M=4.93$, $\alpha=.98$) and with the store ($M=3.96$, $\alpha=.97$) were measured using a three-item, seven-point, likert scale. Desire to repurchase the product ($M=3.91$, $\alpha=.87$) and to repurchase at the same store ($M=3.72$, $\alpha=.97$) were also measured using a three-item, seven-point likert scale. Both scales were anchored by “strongly disagree” and “extremely agree.” A lower number indicates disagreement.

Manipulation Checks. Open-ended questioning revealed that in every case the price for the self in the self-bargain condition was lower than the friend’s price and the price for the self in the other-bargain condition was higher than the friend’s price. There were no

¹This scale was used to compare differences in the same emotion between conditions.

²Given the variability in prices, a loglinear transformation was done. Since the results using the transformed data were very similar, the raw data was used for analysis.

TABLE 1
Means for Negative and Positive Emotion Conditions

Scale	Mean for "Self Bargain"	Mean for "Other Bargain"	t (54)
Emotion Measures:			
Regret	1.38	2.74	-5.80**
Anger	1.75	3.13	-5.03**
Happiness	4.83	2.20	7.58**

significant differences between the cheaper price in the self-bargain condition and the cheaper price in the other-bargain condition ($M_{\text{selfbargain}}=126$, $M_{\text{otherbargain}}=162$, $t(54)=1.13$, $p=.27$). Similarly, there were no significant differences between the more expensive price in the other-bargain condition and the more expensive price in the self-bargain condition ($M_{\text{selfbargain}}=191$, $M_{\text{otherbargain}}=226$, $t(54)=1.18$, $p=.24$).

RESULTS

Comparisons between the emotions, satisfaction, repurchase intentions and appraisals for consumers in the self-bargain and other-bargain emotions conditions were done by paired sample t-tests. We also examined the difference between prices paid by subjects and what was considered a fair price, the lowest price they felt they could obtain the product and what they would pay again. Lastly, we analyzed the relationship of appraisals to satisfaction with the product, store and repurchase intentions by regression analysis.

Table 1 reveals clear differences between the "self-bargain" and "other-bargain" social comparison of price conditions (see Table 1). Consumers reported feeling happier and more proud in the "self-bargain" vs. the "other-bargain" social comparison of price situations, and reported feeling more regret, frustration and shame in "other-bargain" situations. "Other-bargain" social comparisons of prices were also associated with less satisfaction with the product, the store, as well as lesser desire to repurchase the product and to purchase again at the same store. In both the "self-bargain" and the "other-bargain" conditions, satisfaction was lower with the store than with the product.

Within conditions, happiness and envy were the most intensely experienced emotions. However, happiness was a more intensely experienced emotion in the "self-bargain" condition. In the "other bargain" condition, anger and regret were the two strongest emotions. Of these two, frustration was the marginally more intensely experienced emotion.

Social comparisons of prices also differed in the appraisal of situations in which the subjects or the friend, respectively, got the bargain Table 1 shows that consumers tended to appraise "other-bargain" situations as more unfair than "self-bargain" situations, and tended to appraise the "self bargain" situation as one for which outcomes were more desirable, and which had a greater impact on self esteem. On the other hand, subjects appraised "other-bargain" (vs. "self-bargain") situations as more easily undone.

The change in reference prices held by subjects was examined by a series of paired t-tests. Table 2 shows that reference prices more often differed from what the subjects paid when subjects compared with others who purchased at a lower price, than when they compared with those who purchased at a higher price. In the self-bargain condition, there was no significant difference between the price subjects paid and their perceptions of the fair price, the lowest price or the price that subjects expected to pay again. The price subjects paid was significantly lower than perceptions of the price normally charged both where subjects and where the other person bought.

By contrast, in the other-bargain condition, the results are the opposite. The price paid by subjects was significantly higher than either the "fair" price, the lowest price or the price subjects expected to pay again. It was not significantly different than the price

TABLE 2
Changes in Reference Prices

Self-bargain Condition:

t-value diff from self	Self Price	Reference Price	Other Price	t-value diff from other

normally charged either by the store where subjects or where the other person bought the product.

Differences in reference prices paid by the other person compared with the other revealed a similar pattern. In the self-bargain condition, the price paid by the other person was significantly higher than the fair price, the lowest price, the price subjects expected to pay again or the price normally charged at the store where the subject purchased the product. In the other-bargain condition, the price paid by the other person was significantly higher than the lowest price for the product and significantly lower than the price normally charged at stores where either the subject or the other person made the purchase.

Further insight into the reaction from social comparisons of prices is gleaned from regressions of appraisals on satisfaction and repurchase intentions (see Table 3). Dissatisfaction with a product from a social comparison of prices is evoked in response to

situations in which subjects feel there is unfairness. These results show that dissatisfaction with the store evoked from social comparison of possessions is driven by situations appraised as undesirable and having an impact on self-esteem. Desire to repurchase the product evoked from social comparison of prices is driven by situations appraised as being those that subjects do not care about and had an impact on self-esteem. Lastly, desire to repurchase at the same store is evoked when the outcome is appraised as being desirable and when it impacts self esteem. The remaining relationships between appraisals and satisfaction and desire to repurchase were insignificant, though some might gain significance with a larger sample size and greater power.

DISCUSSION

There was a fairly big difference in satisfaction and repurchase intentions between the comparisons in which subjects paid the

lower price and those in which their friend paid the lower price. Consumers were much less satisfied and much less likely to repurchase when they discovered that their friends had purchased at a lower price than when they found they got a better price. These comparisons affected satisfaction and repurchase intentions not just with the store but also with the product. Even though the products themselves were not at fault, they also seemed to be tainted by the situation.

Satisfaction and repurchase intentions were lower for the store than for the product in both conditions. To the extent that shoppers believe that stores have the ultimate control over prices charged, it is quite surprising that subjects evaluated the store less favorably than the product even when they actually get a nice deal. It is not clear what drives this outcome. The answer may lie in attributions for the store's pricing and promotional decisions. Alternatively, the formation of satisfaction with stores and products may involve different processes or may be influenced by different considerations. Future research needs to address the robustness and causes of this phenomenon.

Another key finding of this study is that there is an asymmetry of reference price change. When measuring what consumers were really willing to pay, reference prices only changed when consumers encountered lower prices. Exposure to higher prices in comparisons had no effect. Consumers seem to believe that the "real" price is not some higher price but always the lowest price in a situation. This price was even lower than the lowest observed price in one case. The perceived lowest price was significantly lower than that

which their friends paid in the "other bargain" condition. Perhaps the frustration felt at having paid more than another could have led subjects to feel that an even better price lay hidden somewhere else. Although internal references seem to eventually follow increased market prices, Assimilation-Contrast Theory and Range Theory (Janiszewski and Lichtenstein 1999) both suggest that numerous exposures to a price higher than the expected range may be needed before the new and higher price levels are accepted. By contrast, a single exposure to a low price indicates that it is feasible for a retailer to offer such a price at a profit.

The exceptions to this pattern are consumers' perceptions of the price normally charged at stores. In this case, consumers' reference prices were more influenced upward than downward. This was especially true in the other-bargain condition. Consumers may be attempting to preserve or enhance their evaluation of themselves as shoppers by maintaining or adjusting their comparison standards upward. When consumers pay the lower price, their "normal price" should be significantly higher, otherwise they would not be smart shoppers. When friends pay a lower price, subjects' reference prices should be equal to the higher prices that they paid; otherwise they would appear to be poor shoppers.

The results of this study suggest that there is a direct relationship between appraisals of fairness and product satisfaction but not with store satisfaction. These appraisals of fairness seem to be a factor in the spread of dissatisfaction with the store to the product. Just finding out a friend paid a lower price for the same product can make consumers upset at the store. If they feel cheated as well, they may

blame all parties in the process. Satisfaction with and desire to repurchase at the store depend heavily on overall happiness with the outcome and how much the price comparison affected self-esteem. Subjects may have had to feel that the higher prices paid were unfair before they became dissatisfied with the product as well. On the other hand, mere unhappiness with the store is enough to lower satisfaction, perhaps since it is the store that sets the price. Desire to repurchase the product was only impacted by how much subjects cared about what happened. The less they cared, more willing they were to purchase again.

This study also found that consumers feel a great deal of happiness and positive feelings about the outcome when they find a great deal. These were the strongest emotions felt in either condition. Pride is elicited by a good outcome for which people feel they are responsible (Lazarus 1991; Smith and Ellsworth 1987). Both of these appraisals were found to be associated with the “self-bargain” condition in this study. This finding also has support in past research that has found shopping—and especially successful shopping—can be quite an enjoyable experience (Schindler 1998; Babin et al. 1994; Holbrook and Hirschman 1982). This study adds that finding a good bargain, and perhaps feeling proud about being a smart shopper, is an important factor in the pleasure of shopping.

Similarly, consumers feel a mixture of anger and regret when they discover they have paid a higher price than a friend. Subjects perceived the situation in the “other bargain condition” as unfair so that it is natural that they felt angry. Since responsibility felt by subjects for the outcome was equally strong in both conditions, a bad outcome should naturally elicit regret.

Nevertheless, our study is admittedly exploratory. We placed no restrictions on the context under which the social comparison of price took place, so the emotions elicited by these types of comparisons could vary widely depending on where they took place and what type of product was involved. Further, memory biases may have influenced the sort of experiences that subjects recalled.

IMPLICATIONS AND DIRECTIONS FOR FUTURE RESEARCH

An examination of social comparisons of prices may help explain the dynamics of any context in which prices are not fixed, which includes not just dynamic pricing and bargaining but almost any retail market. The implications are serious for marketers that charge different prices to different customers. Consumers will be angry and will not be likely to shop at the same store. Manufacturers also need to be careful about pricing policies of distributors since customers will hold the products accountable for the pricing policies of the stores. Future research might address the dynamics by which consumers judge the extent to which manufacturers, intermediaries, and retailers, respectively, are responsible for retail prices and their fluctuations.

On the other hand, shopping for the best price seems to be a source of great pleasure for customers. Finding a better bargain elicited strong feelings of happiness and positive feelings regarding the outcome. This contradicts the popular opinion that consumers do not like to price comparison shop. Perhaps future research could look at the conditions in which consumers do and do not like to comparison shop. Further, additional research might address the question as to how much consumers learn from friends who receive better deals and whether such an appreciation for such learning may curtail resentment. The present research involved a comparison with bargains obtained with friends toward which subjects likely had considerable good will. Future research might address whether bargains received by strangers are resented more.

The Influence of Price Difference and Equity Sensitivity on Customer Satisfaction in a Dynamic Pricing Environment

Susan K. Harmon, Middle Tennessee State University
David A. Foote, Middle Tennessee State University

ABSTRACT

This study investigates consumer reactions to a dynamic pricing situation. The results show that satisfaction with a transaction is impacted by knowledge of the price others paid for the same product. Participants who got a better deal than a comparative other rated their satisfaction higher than those who got a worse deal. The magnitude of the price difference mattered only when the deal was worse, resulting in satisfaction for the higher priced item being lower than for the lower priced item. Counter to our expectations, the Equity Sensitivity Index did not provide any significant explanation of price satisfaction.

Price promotion, a very popular tactic for increasing sales volume, immerses consumers in a sea of coupons, volume discounts, rebates, preferred customer discounts, holiday sales, and countless other forms of marketing. Because firms employ so many varieties of price promotion, many of which are available only to certain individuals or groups, different customers are often charged different net prices (Martins and Monroe, 1994). As a result, different customers may pay different prices even when buying the same item at the same time from the same seller.

As long as customers do not have the opportunity to compare transactions with other customers, judgments of fairness occur largely as a result of the buyer-seller relationship and the buyer's preconceived ideas regarding a fair price (referred to as *internal reference price*) for a particular item, based on perceived product quality and buyer sacrifice (Martins and Monroe, 1994). However, when consumers can "compare notes" about their transactions, decisions about what is fair take on a sizeable relative component as well (Monroe and Petroschius, 1981). That is, consumers' expectation that they should pay relatively equal net prices for what they purchase becomes a significant factor in their decisions about fair price.

Consumers evaluate their [potential] transactions in part by assessing transaction utility, the difference between the perceived fair price and the actual price of the item (Thaler, 1985). In determining an internal reference price, consumers take into account the motives of the firm (e.g., passing on costs vs. exploiting consumers) and an intuitive sense of what the price should be based on the conditions of the specific transaction and the prevailing conditions of similar transactions (Campbell, 1999).

Price differences in a traditional 'brick and mortar' setting are frequently obvious, as in the case of a grocery store where the reduced price for customers with a bonus card is clearly marked in close proximity to the higher price for customers without a bonus card. Reduced prices and rates for various groups are openly advertised in signage and media. Because the advertising identifies the type of discount and the group(s) receiving the discounted prices, consumers have information with which they can justify price differences based on their understanding of the benefits and sacrifices associated with membership in that group(s).

In contrast, Internet technology makes it possible for two consumers to access the same web site at the same time and get different prices on identical items, and to do so in virtual isolation from other consumers. This particular aspect of technology enables sellers to simultaneously offer a wide variety of prices to different individuals or groups without publicizing any information that can

be used as justification for priced differences by other individuals or groups.

Still, Internet consumers do compare transactions, though perhaps more deliberately and with fewer others. However, in the case of Internet transactions, the absence of justifying information substantially complicates the challenge of preventing perceptions of unfairness. Preventing such perceptions is critical because perceived unfairness in pricing leads to reduced intentions to buy (Campbell, 1999), an outcome exactly opposite that desired. Thus, understanding the process and outcomes of transaction comparisons becomes essential to successful pricing strategies. We believe the concept of equity sensitivity provides important insight into understanding this aspect of consumer behavior.

EQUITY SENSITIVITY

Adams' (1963) equity theory, a precursor of equity sensitivity, offers a fairly simplistic view of social exchange in which people: (a) tend to seek equitable relationships; (b) compare their own outcomes and inputs to the perceived outcomes and inputs of others; (c) experience distress when they perceive themselves to be in a situation of inequity; and (d) attempt to restore equity in those situations. According to this theory, people share a universal preference that their outcome/input ratio be equal to that of a comparison other. The distress experienced in inequity situations occurs regardless of whether the inequity results from being over-rewarded (the individual's outcomes are higher in relation to inputs than the comparison other's) or under-rewarded (the individual's outcomes are lower in relation to inputs than the comparison other's). Adams (1965) also noted that if the magnitude of inequity is the same for both the over-reward and under-reward situations, the felt distress will be greater in the under-reward situation.

Building on studies suggesting that individuals differ in their assessment of what constitutes inequity (e.g., Carroll & Dittrich, 1978; Tornow, 1971), Huseman, Hatfield, and Miles (1985, 1987) developed the concept of *equity sensitivity* as a more complex way of explaining the dynamics of equity perceptions. Equity sensitivity addresses varying perceptions of inequity among individuals by positing that individuals vary in their preferences when comparing their own outcome/input ratios to those of referent others.

As originally set forth by Huseman et al. (1985, 1987), equity sensitivity identified three equity preferences. First, *equity sensitives* exhibit classic equity theory preferences. They seek equity in their own outcomes and inputs, and prefer net outcomes equal to those of referent others. Second, *entitleds* prefer that their outcomes exceed their inputs. They prefer to get more from a relationship than they give to it, and that their net outcomes are greater than those of referent others. Third, *benevolents*, conceptually opposite from entitleds, prefer to have their inputs exceed their outcomes. They prefer to give more to a relationship than they get from it, and that their own outcome/input ratios are less than those of comparison others (i.e., their net outcome is less than that of referent others).

Researchers have used equity theory to illuminate a number of marketing issues, such as consumer expectations of service (Clow, Kurtz, and Ozment, 1998), business-to-business marketing (Patterson, Johnson, and Spreng, 1997; Boyd and Bhat 1998), customer complaints (Lapidus and Pinkerton, 1995), fairness in

pricing (Martins and Monroe, 1994), satisfaction with merchants and products (Oliver and Swan, 1989), and buyer-seller exchange (Huppertz, Arenson, and Evans, 1978). We believe equity sensitivity offers an expanded framework beyond that of equity theory in which to understand relationships in marketing; however, to date we have found no applications of equity sensitivity in marketing research. Our purpose in conducting this study is two-fold: first, to introduce equity sensitivity as a means of explaining customer satisfaction in a dynamic pricing environment; and second, to examine perceptions of fairness in Internet pricing.

EQUITY SENSITIVITY AND PRICE

Based on earlier studies discussed and on equity theory, we believe that consumers take into account the price paid by others when evaluating their satisfaction with the transaction.

H1: Consumers will indicate higher levels of satisfaction when they get a better deal (pay less) relative to a comparison other than they will when they get the worse deal (pay more), even though the price paid is less than a published price for the item.

Carrell and Dittrich (1978) identified a number of general, internal individual factors, such as social and religious values, intelligence, and gender that influence equity perceptions. In the case of online transactions, we believe that consumers' familiarity with the Internet will moderate their evaluations of the transaction. If a consumer gets a worse deal he may attribute it to his lower Internet skills and as such may evidence less dissatisfaction than someone who gets a worse deal but who believes he has strong Internet skills. We would expect those with greater Internet familiarity are likely to have higher expectations regarding their own ability to find the better deal when purchasing online. Therefore:

- H2a: On a worse deal, those who have greater familiarity with the Internet will be less satisfied with the transaction.
H2b: On a better deal, those who have less familiarity with the Internet will be more satisfied with the transaction.

There is also evidence of external factors that influence equity perceptions. Huppertz et al. (1978) found that perceptions of inequity were greater for high cost items than for low cost items. That is, in situations where the prices of both a high cost item and a low cost item were substantially more than expected, individuals' perceptions of inequity were significantly stronger for the high cost item than for the low cost item.

Inequity magnitude may be another related external factor. We noted earlier that the reactions of parties in an inequitable exchange are proportional to the magnitude of the inequity perceived (Adams, 1965). In other words, a greater perceived difference in compared inputs/outcomes should result in stronger feelings of distress or guilt than does a lesser perceived difference. Also, as previously stated, the intensity of the distress felt by the disadvantaged party (i.e., the one who got the worse deal) should be greater than the intensity of the guilt felt by the advantaged party (the one who got the better deal). Thus we expect that:

- H3a: Consumers' evaluations of the transaction will be more negative if they paid more for the airline ticket (\$150 price difference from comparison other) than if they paid more for the book (\$10 price difference).
H3b: Consumers' evaluations of the transaction will be more positive if they paid less for the airline ticket (\$150

difference) than if they paid less for the book (\$10 difference).

Equity Sensitives

These reactions illustrate classical equity theory responses to situations of inequity and, as such, should be typical of equity sensitives. If equity sensitives do not pay the same price for a product or service as does a comparison other, we can expect their satisfaction level to decrease as price magnitude increases. In addition, even though they prefer situations of equity, because the inequity of a given situation will produce more intense reactions for the disadvantaged party than for the advantaged party, we can expect equity sensitives to experience higher levels of satisfaction (i.e., a less negative reaction) when advantaged than when disadvantaged. However, because individuals differ in their sensitivity to inequity, we should expect the reactions of entitleds and benevolents to differ from each other and from those of equity sensitives in important ways. Unfortunately, very little empirical work has been done in this area to date.

Entitleds

Huseman et al. (1987:225) described entitleds as persons for whom "distress would occur if they were not 'getting a better deal' than their comparison other." In other words, they want to get more for their money than their comparison other got, or to pay less for the same product or service than did their comparison other. If price magnitude is also a factor, as we propose it is, then these preferences should be stronger for high cost items than for low cost items, or when their advantage in percentage of price difference is larger.

Benevolents

Conceptually opposite from entitleds in their preferences, benevolents are typically more satisfied with situations in which they give more to a relationship than they get from it, and when their own net outcome is less than a comparison other's net outcome. Considering price magnitude as a factor, benevolents' reactions may exhibit a similar intensity to that of entitleds in that their preferences should also be stronger for high cost items than for low cost items, and for larger percentage of price differences, as we hypothesized above. Consequently, we suggest equity sensitivity will influence consumers' response to a better or worse deal relative to a comparison other. Specifically:

- H4a: On a better deal, those with the highest level of entitlement will be most positive in their evaluations of the transaction.
H4b: On a worse deal, those with the highest level of entitlement will be most negative in their evaluations of the transaction.

METHOD

This study used a 2 (product- airplane ticket or book) x 2 (price-paid more or paid less) between subjects experimental design. The products were chosen because each has a fairly lengthy and significant history of online sales. We developed four scenarios that described various on-line purchase transactions followed by an encounter with another purchaser of the identical item. The four scenarios described: 1) a high-cost item (airplane ticket) that the respondent paid more for than the other purchaser (\$300 vs. \$150); 2) a high-cost item (airplane ticket) that the respondent paid less for than the other purchaser (\$150 vs. \$300); 3) a low-cost item (book) that the respondent paid more for than the other purchaser (\$25 vs. \$15); and 4) a low-cost item (book) that the respondent paid less for

I am satisfied with the price I paid
The price I paid was good given time I spent searching online
The online (book/travel) industry sites are fair in their pricing
The Internet allows me to find the best price
What I paid was a fair price
Cronbach's $\alpha = .90$

than the other purchaser (\$15 vs. \$25). In all scenarios the price paid by the respondent was less than a published price for the item. Each respondent received only one of the four scenarios.

Subjects were given a scenario to read and were asked to complete a questionnaire. The survey asked respondents to rate their satisfaction with the transaction, their perception of fairness regarding the price they paid, and their evaluation of the value/risk of purchasing online. Because this is a study of online pricing judgments, we also included nine items to measure respondents' experience and familiarity with the Internet. Equity sensitivity was measured using the Equity Sensitivity Instrument (ESI) developed by Huseman et al. (1985, 1987).

A pilot study with 60 undergraduate and graduate management students had the respondents read the scenario and complete a short survey. After students completed the survey, we solicited their comments on the scenarios and the survey questions. Based on this feedback, we made minor modifications to the survey and to the scenarios.

The actual study consisted of two separate sampling plans. First, students in a large Southern state university were contacted during a business class and asked to participate. The 351 (186 male, 163 female, 2 did not indicate gender) students who chose to participate received one of the four scenarios, randomly distributed, along with the survey items, which they read and completed during class.

Second, as part of a project in a marketing research class, students were asked to recruit a non-student sample to complete the survey. Each student was asked to recruit ten respondents who met the following qualifications: at least 25 years old, non-students, and a balance of men and women. Again, the participants each received one of the four scenarios, randomly distributed, along with the survey items, which they completed and returned to the marketing research students. In addition, the non-student respondents were asked to provide a contact number for follow-up verification. We contacted about 20 percent of the respondents to verify participation and that the proper procedure was followed. Additionally, the marketing research students were required to read and sign an acknowledgement of the following statement: "I have read the above information, followed the guidelines for administering the survey and to the best of my ability completed this process in line with established professional research procedures. All of the surveys represent the opinions of the participants. I have not in any way unduly influenced their participation or responses." Of the 201 respondents, 95 were male and 106 were female.

RESULTS

The student sample did not differ significantly from the sample of the general public on any measure; therefore, the results reported represent the combined sample. Eight items were developed to measure consumers' evaluation of their purchase. These eight items were subjected to a reliability analysis that showed a Cronbach's alpha of .76. While this is sufficient for an initial scale, further examination revealed two items that had very low (below .30) item-to-total correlations. Removing these two items ("The other person probably spent more time searching online than I did" and "The deal I got was not worth the risk of buying online") resulted in a substantially improved Cronbach's alpha of .90. Table 1 shows the items that were summed to get a measure of Purchase Evaluation for further analysis.

We had hypothesized that the respondent's perception of his skill at using the Internet would impact satisfaction with the deal he got. As shown in Table 2, the nine items measuring Internet aptitude generated a Cronbach's alpha reliability rating of .81. These items were summed for each respondent to create a new variable, Internet Skill.

An analysis of variance was run with "Purchase Evaluation" as the dependent variable, product (airline ticket/book), price paid (more/less), Internet skill (low/high), and Equity Sensitivity (entitled/equity sensitive/benevolent) as factors. The design is unbalanced since each cell in the model does not contain the same number of cases.

Both product and price had significant main effects ($p = .000$) as well as two-way interaction effects ($p = .000$). Figure 1 shows respondents were more favorable in their price evaluations when they paid less for the product than a comparison other than they were when they paid more, supporting Hypothesis 1. When the price paid was higher than a comparison other, the size of the price difference was significant, with price satisfaction for the book (\$10 price difference, 1.67 times higher than other price) higher than for the airline ticket (\$150 price difference, 2 times higher), thus supporting H3a. However, there was no significant difference between products when the price paid was lower, failing to support Hypothesis 3b. Future research might investigate whether this satisfaction difference would hold if the absolute value were greater but the relative difference were less (for example if the ticket had been \$50 higher or 1.34 times the comparison other, while the book was \$10 higher or 1.67 times the comparison other). As seen in Table 3, the Equity Sensitivity Index was not a significant covariant with satisfaction, failing to support Hypotheses 4a and 4b. Internet

TABLE 2
Internet Skill

I enjoy using the Internet.
I am not at all familiar with the Internet (R)
Others ask me how to find things online.
It takes me longer to find things online than it does my friends. (R)
I am often frustrated in attempting to navigate the Internet. (R)
I only visit the same few sites anytime I am online. (R)
I am confident purchasing items online.
I find the Internet very useful in finding information I need.
When looking for a product online, I usually visit several sites.
Cronbach's $\alpha = .81$

(R) Indicates item was reverse-scored.

skill did have a significant main effect on satisfaction; however, correlations between satisfaction and Internet skill were positive regardless of whether the respondent got a better or worse deal. This was counter to hypotheses 2a and b. Although the main effects for price, product and Internet skill were statistically significant, the effect size for product and Internet skill were relatively small, with the partial Eta squared showing each accounted for less than 4% of the overall (effect + error) variance.

DISCUSSION

Consistent with earlier studies and with equity theory, this study demonstrates that consumer satisfaction with a transaction is impacted by knowledge of the price others paid for the same product. Participants who got a better deal than a comparative other rated their satisfaction higher than those who got a worse deal. When getting a better deal, the magnitude of the difference did not seem to matter, but when the deal was worse satisfaction for the higher priced item with \$150 difference (airline ticket) was lower than for the lower priced item with a \$10 difference (book). Since both the absolute and relative value of the differences was higher for the airline ticket, we don't know if the dissatisfaction was driven more by the absolute value of the difference or by the relative value of the difference. Future research is needed to explore the threshold of impact in comparing prices with others.

As the Internet facilitates dynamic pricing and companies have more opportunities for finely targeted pricing they must recognize that consumers have greater access to quick price comparisons online. While pre-purchase comparisons may guide consumer choice (as companies have known for years), post-purchase comparisons may impact consumers' satisfaction. Companies cannot control the word-of-mouth comparisons of prices, nor the accessibility of price comparisons on others' web sites; however, a company with consistently low prices may want to consider providing price comparisons on their web site to highlight the price advantage over the competition and reinforce consumers' choices. Furthermore, companies must recognize that segmented pricing has the potential to lead to dissatisfied consumers.

Counter to our expectations, the Equity Sensitivity Instrument did not provide any significant predictive power for price satisfaction. A possible explanation for this result is that the artificiality of scenarios failed to completely engage participants' emotions and may have resulted in evaluations that differ from what they would be in real life situations.

It is reassuring to note that the evaluations of the transaction did not vary between the student sample and the sample of the general public. Academic researchers are often torn by the conflicting goals of conducting research in a timely and cost effective manner (which can be most readily done using student samples) while ensuring that the research results are generalizable to the broader public (typically requiring a non-student sample). Yet this study suggests there may be occasions when results from a student sample may not differ significantly from results from a non-student sample.

While Internet skill showed statistically significant main and interaction effects on participant satisfaction with price, from a practical point of view the impact was minimal as shown by the low partial Eta squared values.

SPECIAL SESSION SUMMARY

Automatic Effects: The Consequences of Construct Accessibility for Behavior, Self-regulation, and Information Processing

S. Christian Wheeler, Stanford University

SESSION OVERVIEW

A rapidly burgeoning body of research indicates that the activation of constructs such as traits, stereotypes, and goals can affect subsequent judgment and behavior (see Dijksterhuis and Bargh 2001; Wheeler and Petty 2001, for reviews). For example, individuals primed with the elderly stereotype subsequently walk more slowly, consistent with the stereotype that elderly individuals are slow (Bargh, Chen, and Burrows 1996). Similarly, individuals primed with the African-American stereotype subsequently perform more poorly on a standardized math test, consistent with the stereotype of Black academic underperformance (Wheeler, Jarvis, and Petty 1999). The papers in this session examined automatic processes in consumer behavior contexts and provided evidence for strong automatic components in the direction and instigation of behavior. This research supports the notion that both chronic and situational sources of activation can lead to automatic behavioral change, and that automatic behavior can potentially be driven by multiple different mechanisms.

The first paper, by Fitzsimons, Chartrand, and Fitzsimons, demonstrated that anthropomorphized objects like animals and brands can nonconsciously shape behavior in ways consistent with the traits associated with the objects. Across the three studies, the authors provided evidence that anthropomorphized objects can activate traits much like stereotyped individuals can, and once these traits are activated, they can influence behavior automatically. The third study used a delay paradigm to show that the resulting behavior was driven by automatically activated goal components that have increasing effects over time.

The second paper, by Ramanathan and Menon, decomposed the automatic and controlled components of impulsive and prudent behavior across individuals who have the goals chronically or situationally accessible. This research suggests that both impulsivity and prudence can be automatically directed, but that the strength of these automatic motivations may differ. The automatic prudence goals of non-impulsive people are considerably stronger than their conscious indulgence goals, whereas the automatic indulgence goals of impulsive people are stronger than conscious control goals, but much less so. The authors suggested that these patterns are due to the relative frequency of goal activation and behavior.

The third paper, by Wheeler, DeMarree, and Petty, provided evidence that primed traits and stereotypes can influence information processing as though they were self-descriptive. Using a schema-matching persuasion paradigm, they demonstrated that individuals engaged in greater elaboration of messages matching primed traits and stereotypes, much as has been shown for chronically held, self-endorsed schemata. A second study showed that the effect was larger among low self-monitors, consistent with the notion that effects were driven by changes in the active self-concept.

The discussion was led by Chris Janiszewski, who highlighted similarities and differences across the papers and provided insightful directions for future research.

LONG ABSTRACTS

“Automatic Effects of Exposure to Anthropomorphized Objects on Behavior”

Gráinne M. Fitzsimons, New York University

Tanya L. Chartrand, Ohio State University

Gavan J. Fitzsimons, University of Pennsylvania

The social environment can automatically activate in individuals goals and motives, emotions and mood, evaluations, cognitions, judgments, relational schemas, and stereotypes. These constructs can in turn influence behavior outside of an individual's awareness, intent, and control. Thus, the automatic influence of the environment on behavior can be mediated by many different motivational, cognitive, and affective constructs. The present research focuses on the route involving automatic stereotype activation.

In particular, research has shown that the presence of an individual from a stereotyped group can automatically activate the corresponding stereotype (Devine 1989). This in turn leads the perceiver to behave in a stereotype-consistent fashion (Dijksterhuis and Bargh 2001). In the laboratory, researchers subliminally or supraliminally prime (i.e., activate outside of awareness) an individual with a stereotype (e.g., African-Americans), and then show the primed individual to behave in line with the content of that stereotype (e.g., act hostilely).

Thus far, research has centered on stereotypes dealing with human beings—racial, gender, and other group-based stereotypes. But we also have stereotypes concerning anthropomorphized objects (Aaker 1997). Can these stereotypes also become automatically activated and then guide behavior? The current research used a priming methodology to determine whether exposure to anthropomorphized objects can nonconsciously guide behavior.

In a first study, we examined one type of anthropomorphized object that is near and dear to many people's hearts: pets. We first conducted a pilot study in which we asked participants what the stereotype they had of cats and dogs was. Results indicated that dogs are stereotyped as being 'loyal' much more than cats. We therefore hypothesized that people primed with dogs would behave more loyally than would people primed with cats.

To test this hypothesis, participants were supraliminally primed with photographs of either cats, dogs, or neutral objects. Participants then completed a loyalty measure, consisting of scenarios describing friends' transgressions, and questions about how loyally participants would respond. As predicted, participants primed with dogs responded more loyally to friends' transgressions than did control participants or cat-primed participants.

In a second study, we examined another type of anthropomorphized object: brand names. Individuals often attribute human-like qualities to brand names (Aaker 1997). We focused on a brand that had a strong stereotype associated with it. Specifically, the brand 'Apple' has been shown to connote creativity more than does the brand 'IBM' (Aaker 1997). We therefore hypothesized that people primed with Apple logos would perform more creatively than would people primed with IBM logos.

Participants were subliminally primed with either Apple logos, IBM logos, or pattern masks while completing a computerized

vigilance task. All participants then completed a creativity task—the ‘Unusual Uses Task’, in which they were asked to generate as many unusual uses as possible for a brick. Trained coders rated the uses for their creativity. Dependent measures included the total number of uses generated and creativity ratings.

As predicted, Apple-primed participants outperformed control and IBM-primed participants on the creativity task: Apple-primed participants generated more uses overall and received higher creativity ratings than did control or IBM-primed participants. Participants did not differ on self-reported motivation or interest in the task, suggesting that the effects of the brand logos on behavior were nonconscious. Importantly, participants also reported no awareness of the primes.

We conducted a third study to examine whether the stereotype influenced behavior in a nonconscious, direct stereotype-behavior fashion, or whether there was a motivational component involved. Did individuals primed with the Apple logo want to be more creative? Perceptual priming effects are known to diminish in strength after a short delay. In contrast, motivational priming effects continue—and even increase—after a delay (Bargh et al. 2001).

Thus, a follow-up study replicated Study 2 and also examined the results after a 5-minute delay between the prime and the creativity measure. Students attending two separate lectures were subliminally primed with either Apple or IBM logos while allegedly doing a computerized vigilance task projected at the front of the lecture hall. Half of participants completed the Unusual Uses Task immediately; half did so after a 5-min delay.

The pattern of data for the No Delay condition replicated the findings of Study 2: Apple-primed participants were more creative than IBM-primed. In the Delay condition, Apple-primed participants became significantly more creative than they were in the No Delay condition. As suggested by Bargh et al. (2001), priming effects that increase over time may be motivational—rather than perceptual—in nature.

These studies use priming procedures to demonstrate that perceiving anthropomorphized objects can elicit automatic stereotype-behavior effects in the same fashion as does perceiving humans. In addition, there appears to be a motivational component involved, such that individuals, upon being primed, take on a goal to act in a stereotype-consistent fashion.

“Decomposing Automatic and Conscious Components of Self-Control and Indulgence”

*Suresh Ramanathan University of Chicago
Geeta Menon, New York University*

Studies on self-control and impulsive behavior have long debated the extent to which impulsive behavior is driven by spontaneous affective or goal-driven processes (e.g., Rook 1987; Shiv and Fedorikhin 1999, 2002; Ramanathan and Menon 2002). Many studies have argued that impulsive behavior is characterized by the simultaneous experience of spontaneous desire and will-power (e.g., Hoch and Loewenstein 1991). Implicit in this notion is that only urges are automatic while self-control is a conscious process. Recent work by Fishbach, Friedman and Kruglanski (2002) suggests that temptations are capable of activating higher-order self-control goals automatically. Fishbach (2003) goes on to argue that self-control goals may be chronically accessible and hence the idea that will-power is conscious may not necessarily hold true.

Recognizing that any behavior is likely to have both conscious and non-conscious components, we propose a Process Decomposition Model based on the work by Jacoby (1991) and Fitzsimons and

Williams (2000). We disentangle the extent to which impulsive behavior is determined by automatic hedonic goals among impulsives and as a corollary, the extent to which prudent behavior is determined by automatic prudence goals among non-impulsives. Our model assumes that impulsive people engage in indulgences on the basis of some combination of automatic and conscious processes. Similarly, we assume that non-impulsive people choose to be prudent as a result of both automatic and conscious processes. Based on the theory of the PDP model, we enhance or diminish the conscious components by priming people with the consonant or the dissonant goal. Thus, impulsive people might experience a magnification of a hedonic urge when they are primed with the hedonic goal while they may experience a diminution of the conscious hedonic urge when they are primed with the opposite prudence goal. Similarly, non-impulsives were primed with a hedonic goal in order to reduce their conscious component of control while they were primed with the prudence goal in order to magnify the conscious component of control. In addition, respondents were placed either under high or low cognitive load. The load conditions were fully crossed with the priming conditions. Subsequent to the priming/load manipulation, respondents were taken to a second room where they were left alone for two minutes with a tray filled with cookies with a cover story that these cookies were from a departmental meeting that ended just a few minutes ago. Unknown to the respondents, a hidden video camera recorded whether they picked up a cookie or not. The dependent measure was the percent of people who picked up (or did not pick up) a cookie.

Based on the process decomposition procedure, one can construct a set of four equations for the four conditions such that a) the conscious component is either magnified or reduced and b) the same occurs either under full cognitive resources or under diminished resources. These equations are constructed separately for impulsive and non-impulsive people. By solving these equations, we can determine the relation between the conscious and automatic components of behavior. Our results show that while the automatic urge to indulge oneself is about two and a half times as strong as the conscious control component for impulsive people, the automatic urge to exercise control is about seven times as strong as the conscious urge to indulge oneself for non-impulsive people.

We conclude that non-impulsive people have a stronger automatic element of self-control because their pattern of exercising control is more reliable and frequent. Their likelihood of succumbing to temptation is less likely due to the fact that they probably hold a stronger motive to be prudent. On the other hand, impulsive people have a relatively weak automatic element of indulgence because their behavior is not as reliably and frequently engaged in—the notion that there is some fight between desire and will-power indicates that there may be times when the latter wins out, hence reducing the reliability of the behavior.

“The Role of the Self in Prime-to-Behavior Effects”

*S. Christian Wheeler, Stanford University
Kenneth G. DeMarree, Ohio State University
Richard E. Petty, Ohio State University*

Research on prime-to-behavior effects has shown that the situational activation of selected mental contents can reliably influence judgment and behavior. Typically, these effects occur in an assimilative direction, although contrast occasionally occurs (Dijksterhuis et al. 1998). That is, individuals in whom a trait or stereotype is made salient typically behave more similar to the stereotype. For example, college participants walk more slowly when primed with an elderly stereotype (Bargh, Chen, and Burrows 1996). One account for these effects is ideomotor activation (Car-

penter 1874; James 1890/1950). According to this account, ideation is sufficient to drive action in the absence of will. When behavioral and procedural constructs become active, either by direct activation or indirect activation (e.g., via trait activation), they can automatically shape action. However, more recently, evidence has suggested that processes related to the self and self-concept may also sometimes play a role (Hull et al. 2002; Wheeler, Jarvis, and Petty 2001; Wheeler and Petty 2001). Based on this evidence, Wheeler and Petty (2001) suggested that stereotype activation effects may sometimes be due to temporarily activating or including content in the working self-concept.

If this is the case, individuals who are primed with a stereotype or trait construct should act as though the prime were part of the self. That is, their judgments and behaviors should resemble those individuals who embody the traits and stereotypes included in the prime. Additionally, however, the effects of the prime should depend on the extent to which individuals rely on their self-characteristics and beliefs to guide behavior. More specifically, self-monitoring is a variable that predicts the extent to which individuals rely on inward cues or outward cues in determining their behavior in a situation (Snyder 1974). The Other-Directedness Subscale of the self-monitoring scale specifically predicts the desire of individuals to modify their behavior to best interact with others in the social environment.

Because low self-monitors' behavior is more consistent with their internal states, they might show high levels of assimilation to the activated prime. Because high self-monitors direct their attention outward and compare themselves more with others, they might show reduced or even reversed effects of the prime. These effects should be particularly pronounced among individuals scoring high or low on the other-directedness subscale of the self-monitoring scale.

To test these hypotheses, we used a self-schema matching paradigm. Research on self-schema matching has shown that individuals who receive persuasive messages matched to an aspect of their self-concepts engage in greater message elaboration than individuals who receive persuasive messages mismatched to their self-concepts (Petty, Wheeler, and Bizer 2000; Wheeler, Petty and Bizer forthcoming). If individuals incorporate primed content into their self-concepts, then they could show increased elaboration in response to messages matching the primed content. The first experiment tested this hypothesis.

Individuals were subtly primed with extraversion or introversion using a sentence-unscrambling task (Srull and Wyer 1979). Following the priming manipulation, they read advertisements for a VCR framed to match introverts or extraverts. Manipulated orthogonally to the message frame was argument quality such that some participants read strong arguments, whereas other participants read weak arguments. Individuals who engage in greater message elaboration exhibit stronger argument quality effects than do individuals who engage in less message elaboration (Petty and Cacioppo 1986). Results indicated that participants engaged in greater elaboration of the message when the message frame matched the primed personality trait (i.e., extraversion or introversion) than when it mismatched the primed personality trait. Hence, participants processed the advertisement as though it were self-relevant when it matched the primed trait.

A second experiment tested whether these effects would be moderated by self-monitoring. In this experiment, white high and low self-monitors were subtly primed with the African-American stereotype or not, using a sentence unscrambling task. They then read an advertisement for a CD player that contained strong or weak arguments. Additionally, the message was framed to match African-Americans or Whites by providing names of rap and R&B

artists or rock artists in the background of the advertisement. Low self-monitors assimilated to the prime. That is, low self-monitors engaged in greater message processing of the African-American framed ad when they had been primed with the African-American stereotype. When low self-monitors were primed with neutral words, they engaged in greater message processing of the White-framed ad. High self-monitors, on the other hand, showed no significant effect of the prime, although they exhibited a slight tendency for contrast in the African-American prime condition.

These results show that primed traits and stereotypes can influence the elaboration and evaluation of persuasive advertisements in prime-consistent ways. That is, individuals in whom traits or stereotypes are temporarily made active act as though they are characterized by the primed content and find the information matching the primed content important and self-relevant. These findings are consistent with the notion that primed content is sometimes incorporated into the self-concept and that the effects of primed material will depend not only on the prime content, but also the characteristics of the prime recipient.

ROUNDTABLE

Olfactory Stimulation and Affect Intensity: Gender Differences in Yielding to the Enticing Aroma of Food?

David J. Moore, University of Michigan

In spite of the competent marketing research already conducted in the area of olfaction (Sprangenberg, et al. 1996; Mitchell, Kahn and Knasko 1995), very little formal research has examined how consumers are influenced when exposed to the aroma of enticing food in a retail service environment (e.g., restaurants). Companies employ a variety of strategies to exploit the sensory arousal capabilities of the savory aroma of food products. According to Krause (1998), the aroma of savory foods is an underutilized marketing tool in the restaurant industry, and restaurants should realize that many foods “impart seductive aromas that entice consumers even before they taste the dish” (Krause 1998, p.2).

Several important questions about the role of olfaction in marketing are yet to be explored. For example:

(a) Does the exposure to an enticing food aroma stimulate an affective response (e.g., desire and craving), which, in turn, stimulates an irresistible desire to consume the product?

(b) What is the role of affect in this process? Most of the research in psychology has focused on the role of the olfactory system in human memory and cognition (Richardson and Zucco 1989; Schab 1991). Other studies have examined how pleasant and unpleasant odors create affective experiences which ultimately function as mechanisms for the retrieval of happy and unhappy memories (Ehrlichman and Halpern 1988). However, what is still not known is the manner in which an olfactory stimulus itself produces a sensory arousal, creates affect, which, in turn, may intensify the consumer’s craving and desire to consume savory foods.

(c) Do individuals differ in the intensity of their response to olfactory sensations? If olfaction stimulates affect, then consumers who manifest high levels of affect intensity in response to olfactory stimulations may indeed show stronger levels of craving and desire when faced with an enticing food temptation. Affect intensity measures the strength with which people respond to emotionally charged stimuli (Larsen 1984). One of the temperamental dimensions of affect intensity is *sensory arousability*– which identifies individuals who are overly sensitive to sensory stimulation such as olfaction. Moore and Homer (2000) tested this notion and found that high affect intensity consumers expressed a significantly higher level of enjoyment for smelling the aroma of freshly baked bread and the fragrance of perfumes.

(d) Is there a gender difference in consumers’ response to olfactory stimulation? Women manifest more intense levels of emotion than men when exposed to emotionally charged stimuli (Diener et al. 1985). Will women respond differently from men when exposed to certain types of olfactory stimulations?

The results of a preliminary study conducted to respond to the research questions listed above was the focus of discussion at the ROUND TABLE. Essentially, this study found that:

- (a) Exposure to olfactory stimulation (the aroma of cinnamon rolls at a Cinnamon store in a local mall) did create significant increases in craving and desire
- (b) Women reported higher intensities of craving for snacks than their male counterparts
- (c) Women experienced high intensities of craving and desire to eat only when exposed to the olfactory stimulation (aroma of cinnamon rolls).
- (d) High Affect Intensity subjects expressed higher levels of craving and desire than their low intensity counterparts.
- (e) Women showed lower levels of ability to resist an eating temptation when the situation was associated with one’s emotions.
- (f) The segment of the affect intensity individuals who were most highly associated with intense craving for snacks (e.g. brownies) was the group who experienced higher levels of negative affect intensity.
- (g) The data seemed to indicate that women were less likely to resist an eating temptation for snacks than their male counterparts. This is also consistent with recent data from the Snack Food Association (SFA) USA.
- (h) Public policy implications: The rise in the frequency of snacking among consumers may be linked to recent increases in life threatening diseases.

SPECIAL SESSION SUMMARY
Advances in the Psychology of Consumer Investment

Rongrong Zhou, HKUST
Michel Tuan Pham, Columbia University

SESSION OVERVIEW

Consumers make important investment decisions throughout their lives. While such decisions were once thought the exclusive province of finance and economics, they also deserve great attention from consumer researchers. First, consumption is intimately related to wealth: consumption requires money, and money is for consumption. No theory of consumption can be complete without an understanding of how consumers manage their wealth. Second, investment decisions typically entail substantial financial stakes and can have important influences on consumers' welfare. Finally, investment decisions are theoretically interesting in their own right. Although one might be tempted to regard them as a special kind of consumption decisions—decisions about financial products as opposed to traditional consumables—it is not clear that investment decisions respond to the same principles as those governing more traditional product decisions. However, despite their importance, surprisingly little consumer research has focused on such investment decisions.

This special session is an attempt to address this void. In the first presentation, Dhar and Kumar (see Dhar and Kumar 2004) analyze individual-level trading data from a brokerage house to investigate how investors' decisions to buy and sell stocks are influenced by short-term past price trends. They used Monte-Carlo simulation to classify individuals in their dataset as "momentum investors" (those who expect continuations of past price increase or decrease) or "contrarian investors" (those who expect reversals of trends). They observed that the two segments showed different responses to reference points such as recent highs and lows in stock prices. They also found that the two segments exhibited differences in term of the disposition effect—a well-established phenomenon whereby investors tend to realize gains too quickly but are reluctant to realize losses. Analyzing the differences in portfolio and trading characteristics of the two segments, they additionally found that momentum investors held less diversified and riskier portfolios and traded more actively than contrarian investors do. They concluded that, overall, contrarian investors appear to be relatively more sophisticated.

In the second presentation, Zhou and Pham examined consumers' investment decisions across different types of financial products from a self-regulation perspective. They argued that investment decisions are largely driven by regulatory systems known as promotion and prevention. Promotion and prevention-focused self-regulation, though both essential to successful investment management, tend to be pursued separately through distinct mental accounts. Furthermore, different financial products are posted to separate mental accounts set up around a promotion versus prevention focus. This in turn leads to systematic differences in the way consumers make decisions about these products. They reported results from four experiments showing that (a) investors are asymmetrically sensitive to potential gains versus potential losses across financial products; (b) investors are differentially risk-seeking with money mentally associated with different financial accounts; and more importantly (3) these effects occurred because investors categorize different financial products in terms of distinct self-regulatory focuses.

At the conclusion of the presentations, John Gourville led the discussion. Besides summarizing the papers and highlighting the

common learning, he put forward interesting questions and issues and offered suggestions on directions of future research in this area.

“Non-Random Walk Down the Main Street: Impact of Price Trends on Trading Decisions of Individual Investors”

Ravi Dhar, Yale University
Alok Kumar, Cornell University

Recent research has examined the systematic deviations from traditional models of rationality to better understand investor behavior in financial markets. Relatively little is known about the psychological motivations that determine decisions about buying and selling stocks for individual investors. In this paper, we analyze the impact of price trends on trading decisions of more than 40,000 households with accounts at a major discount brokerage house and find that buying and selling decisions of investors in our sample are influenced by short-term (less than 3 months) past price trends. Investors that trade on trends can be broadly classified as momentum (positive feedback traders) or contrarian (negative feedback traders). *Ceteris paribus*, momentum investors expect price continuations and hence they buy on an upward trend and sell on a downward trend. Contrarians, on the other hand, expect price reversals and thus they buy on a downward price trend and sell on an upward trend. By comparing the observed distributions of average trend before buys and average trend before sells with the average trend distributions (obtained using Monte Carlo simulations) when investors trade randomly, the null of non-trend motivated random trading is easily rejected (p -value <0.002). Using Monte Carlo simulations again, we examine investor heterogeneity in trading based on prior returns and classify investors into (i) momentum buy (MB), (ii) momentum sell (MS), (iii) contrarian buy (CB) or (iv) contrarian sell (CS) category. The trading behavior of these investor segments shows systematic differences that are persistent across time periods. We find variations in the response of these investor segments to reference points such as recent high and low prices for the traded stock.

Previous research suggests that investors may be reluctant to realize losses (disposition effect or DE) on their investments due to various psychological factors including mental accounting (reluctance to close a mental account at a loss) and regret aversion (reluctance to accept mistakes). The reluctance to realize losses can also result from different expectations about the future prices. Contrarian investors expect trend reversals and so the propensity to hold on to the losers is likely to be stronger for them. Momentum investors, on the other hand, are more likely to realize their losses since they believe that a downward price trend is likely to continue. This suggests that the disposition to hold on to a losing investment is likely to vary across investor segments due to the differences in their expectations about the future price movements. Consistent with differences in expectations, we find that the disposition effect varies across the investor segments. All four investor segments are reluctant to sell losers but the effect is the strongest for contrarian sell investors who expect price reversals and hence show a greater tendency to hold on to the losers. The effect is very weak for momentum sell investors who believe that a downward price trend is likely to continue and hence are more likely to realize their losses. The presence of DE even among momentum investors who expect trend continuation suggests that loss aversion is an important

determinant of disposition effect. However, the variation of DE across momentum and contrarian investor segments suggests that in addition to loss aversion, contrarian expectation is an important determinant of investors' reluctance to sell losers. Analyzing the differences in portfolio and trading characteristics of investor segments, we find that momentum investors hold less diversified and riskier portfolios and they trade more actively. Consequently, they earn lower risk-adjusted portfolio returns in comparison to the contrarian investor segment. The relatively stronger performance of contrarian investors can also be attributed to their "value" focus. Overall, our results suggest that relatively more sophisticated investors exhibit contrarian trading behavior.

"Financial Self-Regulation across Mental Accounts: Implications for Consumer Investment Decisions"

Rongrong Zhou, HKUST

Michel Tuan Pham, Columbia University

We propose that consumers' investment decisions can be usefully studied from a self-regulation perspective (e.g., Carver and Scheier 1998). In particular, consumers' investment decisions are largely driven by generic regulatory systems known as promotion and prevention (Higgins 1998). The promotion system regulates nurturance needs and those motives related to aspiration and accomplishment (i.e., ideals). The prevention system regulates security needs and those motives related to safety and responsibilities (i.e., oughts). Since promotion and prevention-oriented financial self-regulation is difficult to achieve simultaneously, investors tend to perform the two types of self-regulation using separate "mental accounts" (a promotion focus account and a prevention focus account). In addition, consumers post various financial products to these two accounts according to these products' representativeness to the motives and goals defining these accounts (see Brendl et al. 1998). Financial products such as individual stocks and trading accounts tend to be associated with a promotion focus, which emphasizes growth and aspirations. In contrast, financial products such as mutual funds and retirement accounts tend to be associated with a prevention focus, which emphasizes security and protection. This association in turn leads to systematic differences in the way consumers make decisions about these products.

A major correlate of promotion versus prevention is a differential sensitivity to positive versus negative outcomes. The promotion system tends to be more sensitive to positive outcomes (e.g., gains), and the prevention system tends to be more sensitive to negative outcomes (e.g., losses). Therefore, we predict that investment decisions involving financial products tagged with a prevention focus will exhibit a relatively greater sensitivity to potential losses than to potential gains. However, investment decisions involving products tagged with a promotion focus will exhibit a relatively greater sensitivity to potential gains than to potential losses. This prediction is tested in Experiment 1. Results from Experiment 1 reveal that consumer investors evaluating an individual stock held in a trading account were found to be very sensitive to upside potential, but curiously oblivious to downside potential. In contrast, investors evaluating a mutual fund held in a retirement account were found to be very sensitive to downside potential, but oddly insensitive to upside potential.

Another major correlate of promotion versus prevention self-regulation is a different propensity toward risk. In most situations, promotion-focused regulation entails greater risk-taking, whereas prevention-focused regulation entails greater risk aversion. Therefore, we argue that in decisions involving financial products tagged with a promotion focus, consumers should exhibit greater risk-seeking than in decisions involving financial products tagged with a prevention focus. We predict that this difference in risk propensity

will hold even for money that bears only a mental association with promotion versus prevention-focused financial products. In particular, we predict that money to be withdrawn from a prevention-tagged account will be invested more conservatively than money to be withdrawn from a promotion-tagged account. Furthermore, this effect will be amplified when consumers' self-regulation concerns are heightened. These predictions are tested in Experiment 2. Results reveal that respondents whose money was to be withdrawn from a trading account were much more willing to invest in a risky business venture than respondents whose money was to be withdrawn from a retirement account. These differences in risk propensities were accentuated when respondents were encouraged to reflect on their goals, that is, when their self-regulation systems were actively engaged.

Experiments 1 and 2 provided input-output evidence of a relation between certain financial products and investment behavior (in terms of sensitivity to gains and losses and risk propensity). Experiments 3 and 4 provide more process-level evidence that this relation could be due a mental association between certain financial products and distinct regulatory focuses. In experiment 3, it was found that making decisions involving different types of financial products resulted in subsequent unrelated decisions being carried out with distinctive promotion versus prevention orientations. Specifically, respondents who had made decisions about individual stocks in trading accounts were later found to prefer consumer products with promotion-related benefits and favor approach strategies in friendship. In contrast, respondents who had made decisions about mutual funds in retirement accounts were found to prefer products with prevention-related benefits and favor avoidance strategies in friendship. In experiment 4, it was found that the mere priming of a promotion versus prevention focus through tasks that have little to do with financial decision making produced distinct patterns of allocation of money across types of accounts and across types of assets. Specifically, when the unrelated tasks (proofreading and anagrams) were framed in terms of avoiding misses, thus priming a prevention focus, respondents' allocations tended to shift (a) toward the IRA (as opposed to the online trading account) and (b) toward the mutual fund (as opposed to the individual stock). In contrast, when the unrelated tasks were framed in terms of maximizing hits, thus priming a promotion focus, respondents' allocations tended to shift (a) toward the online trading account (as opposed to the IRA) and (b) toward the individual stock (as opposed to the mutual fund).

Taken together, the results show that (a) investors are asymmetrically sensitive to potential gains versus potential losses across financial products; (b) investors are differentially risk-seeking with money mentally associated with different financial accounts; and more importantly (3) these effects occur because investors associate different financial products with distinct self-regulatory focuses. Overall, the findings are consistent with the view that promotion and prevention self-regulation are pursued through separate mental accounts and that consumers post different financial products to these mental accounts set up around different regulatory focuses. As a result, decisions involving these products are carried out with a distinct promotion or prevention orientation.

SPECIAL SESSION SUMMARY

Alternative Decision Processes in Consumption: Personal Rules, Rationales, and Identity Maintenance

On Amir, Yale University

SESSION OVERVIEW

Consumers make many decisions on a daily basis. The outcomes of these decisions have been traditionally taken to reflect consumers' internal states, or preferences. Furthermore, traditional view requires the consumer to attempt to provide an optimal solution for each decision problem. This session describes a different mechanism that drives consumer behavior in various situations. Specifically, consumers are assumed to sometimes follow overarching guidelines (rationales / rules) simply because of the complementarity between the decision problem and a specific guideline they hold. Moreover, consumers sometimes behave in this manner even when it is not in their best interests to do so. This behavior can be characterized by a discrepancy between preferences (expressed) and actions (or predicted actions).

The first paper by Hsee et al (2003) describes three important classes of rationales that are used by consumers to their own disadvantage. In all three cases, consumers focus too much on rationalistic attributes and too little on hedonic attributes because they try to be rational, even when the latter are more discriminatory for their subsequent happiness. Consumers' attempts at acting in a rational way are classified into three categories: In the first, "lay economism," consumers are using economic-like principles (e.g. "maximize economic gains") that are invoked because of the economic nature of the decision problems to make decisions. In the second, "lay scientism," consumers overemphasize objective attributes over affective-subjective ones. Finally, in the third, "lay functionalism," consumers over focus on their primary goal. The paper argues that when following such rationales, consumers may over emphasize unimportant and sometimes wrong attributes of the situation, and thus make suboptimal outcomes.

The second paper by Amir and Ariely takes one such consumption rule and investigates the mechanism by which it operates. Specifically, it is demonstrated that people are not willing to pay more in order to delay a positive experience, even in those particular situations in which they would be happier doing so. Moreover, the more salient the invoking cues for this rationale, or the more salient lawful behavior is, the greater the discrepancy between peoples' preferences and their actions. Finally, the specific reason this rule is invoked, the thought about monetary payment, is demonstrated by showing that willingness to exert effort as opposed to willingness to pay does in fact correspond to expressed preferences.

The third paper by Prelec proposes a model of personal rules. The model assumes that in the presence of a personal rule, a choice becomes a signal of a long-run propensity to behave in a certain way (e.g., to spend money on luxuries, to neglect family life in favor of work, etc.). This raises the stakes on any single decision, because by breaking the rule, a person also lowers their expectations of future adherence to the rule. The paper also explains why rules are in some sense 'designed to be broken,' but not too often.

In sum, this emerging body of research uncovers important mechanisms that guide decision makers in many consumption occasions. These mechanisms suggest that many times consumers behave according to lay principles that stem from experience in other domains, or from cultural or social antecedents. Understanding these processes, where and when they dominate behavior aids in identifying and in understanding situations in which consumers err or behave in specific, previously unpredictable ways.

"Hot Predictions and Cold Choices: Rationalism in Decision Making"

Christopher K. Hsee, Jiao Zhang and Fang Yu, University of Chicago Graduate School of Business

The present research concerns decisions with choice options involving a tradeoff between a relatively rationalist attribute and a relatively hedonistic attribute. Rationalistic attributes are colder (less affective), more objective, easier to be translated into economic calculus, easier to be quantified, or more directly related to the primary function of the activity at hand. In contrast, hedonistic factors are warmer (more affective), more subjective, less easy to be translated into economic calculus, less easy to be quantified, and more directly related to the process of the activity at hand.

Traditional decision theorists assume that when choosing between options that have the same current costs, decision makers analyze which option will deliver the highest expected outcome utility and choose that option. This is a consequentialist utility analysis approach. According to this approach, when people are choosing between choice alternatives for consumption purposes and when the choice alternatives involve a tradeoff between a rationalist attribute and a hedonistic attribute, they should consider these attributes only to the extent that these attributes can help predict the consumption utility of the choice alternatives. In other words, if half of the people are asked to predict which option will produce a greater consumption utility, and half of the people are asked to indicate which option to choose, the responses of the two groups of people should be identical. In other words, there should be no inconsistency between predicted utility and choice.

Built on research on reason-based and rule-based choices, our theory is that there is rationalism among decision makers. Decision makers tend to focus on rationalistic attributes and downplay the importance of hedonistic attributes. Compared to the consequentialist utility analysis, decision makers will assign more weight to rationalistic factors and less weight to hedonistic attributes. In other words, there will be an inconsistency between predicted consumption utility and choice. That is, compared to people's prediction of which option will bring the best consumption utility, people's choice will veer toward the rationalistic-superior and hedonistically-inferior option.

Here is an example: Respondents were asked to choose between two free dinner sets, each consisting of four dinners to be consumed over the next four weekends. One set of dinners decreases in price from week 1 to week 4, but the overall value is slightly higher. The other set of dinners increases in price from week 1 to week 4, but the overall value is slightly lower. Respondents indicated their preference either by making a choice between the two sets of dinners, or by predicting which set they would enjoy more. In predicted enjoyment, most people favored the increasing but lower-total-value series. But in choice, most people chose the decreasing but higher-total-value series.

We have also found similar inconsistencies between predicted experience and willingness-to-pay. We will present other results, covering several representative subcategories of lay rationalism, including the tendency to focus on objective and quantifiable attributes, the tendency to focus on economic calculus, the tendency to focus on the "sum" of temporally-extended events, and the tendency to focus on the functionality of an activity.

We will discuss the significance and potential problems of using decision/WTP/predicted-experience to study rationalistic decisions, and suggest alternative methods. We also review the relevant literature and discuss the relationship between rationalism and decision rules.

Whereas research on affect-driven decisions suggests that people weigh hedonistic factors too much by the consequentialist benchmark, the present research shows that people weigh such factors too little. We conclude with an integrative framework that reconciles these two apparently contradictory models.

“Decisions by Rules:

Disassociation between Preferences and Willingness to Act”

On Amir & Dan Ariely, Massachusetts Institute of Technology

Individuals make many decisions entailing payment or reception of money. Such exchange has been argued to reflect their internal attitudes, utilities or preferences, such that the decisions taken maximize (under a set of constraints) these internal values. For example, if a person schedules a vacation on a date two months into the future instead of a week into the future, all else being equal, it is assumed that this person has an internal state under which the expected pleasure of the later vacation is higher.

However, several streams of research have demonstrated that even predicted actions may be inconsistent with expressed preferences. Such inconsistencies may arise because of the specific context the decision maker encounters (Tversky & Simonson, 1993), the affective characteristics of the decision problem at hand (Fredrick, 2002; Slovic et al, 2002), or the specific elicitation procedure used (Fischhoff, 1991). More recently, researchers have begun uncovering the mechanisms underlying some of these documented inconsistencies. A major driver of such inconsistencies in the realm of consumption was proposed by Prelec (1991) to be the use of rules and morals as opposed to cost-benefit analyses. Prelec focuses on the use of rules in self-control, and identity maintenance. Hsee et al (2003) describe a set of ‘expressed preferences–anticipated action’ inconsistencies and categorizes them into three subgroups of “rationales”—rule like principles that guide behavior, and are sometimes applied even when doing so leads to less preferred outcomes. The current work follows a similar line of thought but instead focuses on one such rule, and attempts to provide detailed evidence for the decision making mechanism itself.

While there is no question that internal states are commonly used as inputs for consumers’ decisions, the main two claims of the current work are that 1) when consumers make decisions, they follow these “moral-like” rules when these are invoked, instead of staying true to their preferences, and that 2) these rules can sometimes be invoked in situations that undermine preference maximization. For example, if the person in the above example will be willing to pay more for the immediate getaway, this will be a preference-willingness-to-pay inconsistency. If the only reason the less preferred vacation was chosen was an unwillingness to pay an equal or greater amount for a delayed positive experience without examining the specific details of this case, the claim that the individual is following a decision rule would be supported.

So why the term “rules”? Unlike preferences these rules are assumed to be general over-arching guidelines for behavior and as such are applied broadly in a legal-like manner—“do or do not do” (hence the term “rules”) (Prelec, 1991). One consequence of their broad application is that there are circumstances in which the rules are not applicable and yet they are applied (again as with many legal systems), resulting in actions that can at times be disassociated from preferences.

Another aspect of these rules is that they have to be learned (while preferences can be either learned or endowed). Some of the

rules are learned from personal experience, while others are based on social, cultural, and moral conventions. Because these rules are learned and are socially constructed they are also not universal and the specific rules that are applied in different circumstances depend on individual, social, and cultural factors.

In order to investigate the mechanism underlying the use of decision rules, the paper focuses on one specific rule of consumption. To do that, one needs to show that behavior follows a systematic pattern that coincides with the “rule” (observe behavior), does not match people’s preferences (measure preferences), and that this happens upon specific rule activation (invocation cue). In fact, it will be argued that money or the act of paying is the cue that invokes this rule, by showing that it is not medium invariant (“paying” with effort does not invoke this rule). Moreover, one must ascertain that the actual mechanism is rule-following-like in nature. This last property can be investigated through the use of priming of rules and lawful behavior, and through personality differences.

The paper attempts a deeper investigation of one particular rule—“One should not pay more for a delayed experience”. Specifically, this rule concerns the assumed advantage of having positive experiences sooner rather than later. This rule implies that delay should not be paid for. Pilot experiment 1 demonstrates that there are at least some desirable experiences (concerts being one of them) that are preferred to be experienced later rather than sooner. This preference for delay is established using both choices and discounted expected future happiness as proxies of preferences. Moreover, in Pilot experiment 2, this preference is shown to correspond to the happiness from anticipation of the positive experience. The postulate that the rule implies that people will not be willing to pay more for a delay they prefer is validated in experiments 1 and 2. Experiments 2 and 3 provide further support for the proposed mechanism by demonstrating that the magnitude of disassociation is related to the saliency level of invoking cues for the specific rule, and to saliency of rule-based behavior in general. Experiment 4 demonstrates that when using a different “payment” method, exerting effort, participants do not exhibit the predicted action–preference inconsistency, but in fact, are very consistent in their preference for the delayed concert. Finally, Experiment 5 demonstrates that individuals that tend to follow rules exhibit a greater disassociation.

Decision mechanisms such as “decisions by rules,” provide a new perspective on the ways in which individuals carry out their decision policies. Decision theorists have largely assumed that people make decisions according to a set of preferences or feelings. Such views imply a search for at least a local optimum, or for a close enough estimate when exact algorithms are too costly (use of heuristics). The current work suggests that this is not always the case—decision makers sometimes do not try to consider the best alternative according to their preferences or feelings, but rather act upon pre-imposed decision-rules that are based on moral or social norms and on behavioral guidelines.

“Personal Rules (Are Meant to be Broken)”

Drazen Prelec, MIT, Sloan School of Management

The paper presents a theoretical model of personal rules. Examples of personal rules are: (1) to do the dishes right after dinner, (2) to decline collision insurance in car rentals, (3) to answer the phone when it rings, (4) to refuse panhandlers (5) to floss before bed, (6) to return purchases that are (even slightly) damaged or spoiled, (7) to decline consulting assignments. Much of our decision-making is governed by application of personal rules rather than utilitarian cost-benefit calculations, as has been argued by Ainslie (1992), Prelec (1991), and Amir and Ariely (2003), among others.

Personal rules seem to arise in situations where a decision between two alternatives is required, but there is a chronic mismatch (or, in extreme cases, an outright incommensurability) between the attributes involved in the decision (Prelec and Herrnstein, 1991). Because of the mismatch, a person is inclined or tempted to do one thing, but yielding to temptation places some larger values at risk. For example, while the benefits of accepting a lucrative consulting assignment are relatively well-defined, the costs of the taking on the assignment are diffuse, hard to evaluate, and experienced indirectly, through lower performance or satisfaction with other activities. This creates a bias in favor of accepting the assignment. The bias can be counteracted by a personal rule against consulting.

A key paradox about most personal rules is that although on the surface they appear to be an all-or-nothing constraint on behavior (e.g., the rule “refuse consulting assignments” means “always refuse consulting assignments”), in practice they are often broken. Even a person with an anti-consulting rule may encounter consulting opportunities that are too good to refuse. To function and be useful a rule doesn’t have to be followed 100% the time. One can have a rule and break it, so it seems.

In this paper, I develop a self-signaling model of personal rules, extending the general self-signaling framework developed by Bodner and Prelec (2001). The general model rests on a distinction between two types of reward (or utility): reward that flows directly from the causal consequences of choice, whether these consequences are immediate or delayed, and diagnostic reward, which is the pleasure or pain derived from learning something positive or negative about one’s own internal state, disposition, ability, or future prospects. People are presumed to be uncertain about where they stand with respect to these broad attributes, which in turn makes their choices diagnostic. For example, taking a drink before noon is diagnostic of alcoholism; hard exercise is diagnostic of health, willpower, perhaps even financial success, and so on. Anticipation of such diagnostic reward, or fear of diagnostic pain promotes self-control and inhibits self-indulgence.

In the original self-signaling model (Bodner and Prelec, 2001), a choice was treated as a signal about an underlying state (e.g.,

virtue). In this paper, I assume that in the presence of a personal rule, choice becomes a signal of a long-run propensity to behave in a certain way (e.g., to spend money on luxuries, to neglect family life in favor of work, etc.). In other words, a rule makes a single decision diagnostic about the chances of achieving or failing with respect to some broader objective. Diagnosticity creates a motivation to follow the rule. However, if the level of temptation becomes too high, the rule will indeed will be broken.

The model makes precise the interplay between the diagnostic value of following a rule, and the likelihood that the rule will indeed be followed on any given occasion. In particular, if a rule is ‘strict’ then breaking the rule on a given occasion provides a strong negative signal, while following provides almost no new information. In contrast, if a rule is ‘lax’, then following the rule provides a strong positive signal, while breaking it is not a big deal.

SPECIAL SESSION SUMMARY

“If I Could Be Like That...”: The Not-So-Harmful Effects of Social Comparisons on Consumers

Naomi Mandel, Arizona State University

SESSION OVERVIEW

First proposed by Festinger (1954), social comparison theory suggests that people have a drive to evaluate their own abilities, and that they satisfy this drive by comparing themselves to others. Much of the existing social comparison research has examined the harmful effects of exposure to thin, beautiful models on female consumers. In contrast, this session presented recent findings suggesting that social comparisons may not always be harmful to consumers, and in some cases may even inspire consumers.

products. Experiment 1 confirmed that exposure to a successful comparison target increased preference for brands such as Lexus and Rolex, but only when both the target and the subject had the same college major. Experiments 2 and 3 examined mediators of these interactive effects, and found that preferences were driven by the impact of such depictions of successes or failures on participants' expected future incomes.

“Idealized Images, Self-Perceptions and Behaviors of Young Women: Explanation via the Third-Person Effect Model”

Fang Wan, Vanderbilt University

William D. Wells, University of Minnesota

Ronald Faber, University of Minnesota

Although research has found that idealized images in media and advertising affect body image and induce eating disorders, knowledge about the manner in which these images operate is incomplete. This study proposed the third person effect as an alternative model of addressing the underlying mechanisms of how idealized images in advertising exert influence on young female consumers. Survey findings suggest that body enhancement behavior is partially driven by perceptions of the reactions of male “others”—most men, male friends or romantic partners. Depth interview data helped explain this conclusion and reveal the complexity of the processes. These findings suggest that the mechanisms through which idealized images affect perceptions, attitudes and behavior are more complex than previously thought.

“Effects of Exposure to Thin Media Images: Evidence of Self-Enhancement Among Restrained Eaters”

Jennifer S. Mills, York University

Janet Polivy, University of Toronto

C. Peter Herman, University of Toronto

Marika Tiggemann, Flinders University

The effects of viewing media-portrayed idealized body images on eating, self-perception, and mood among young women were examined. Study 1 found that dieters rated their ideal and current body sizes as smaller and ate more following exposure to such images. Study 2 found that strengthening thinness attainability beliefs further enhanced the apparent “thin fantasy” demonstrated by dieters following exposure to idealized body images. Study 3 found that when explicit demand characteristics were present, participants reported feeling worse following exposure to thin models. The complexities of the media's role in body dissatisfaction and dieting behavior are discussed.

“Comparisons with the Good Life: Images of Success and the Preference for Luxury Products”

Naomi Mandel, Arizona State University

Petia K. Petrova, Arizona State University

Robert B. Cialdini, Arizona State University

Television shows and magazines have increasingly portrayed “the good life” in America, where everyone is wealthy and successful. This research examines whether a social comparison activated by a news article can impact a consumer's desire for luxury

Consuming Activism: Peace, War, and Consumer Research

A. Fuat Firat, Arizona State University

ABSTRACT

This paper reports an ethnographic study of activists in a current peace movement. Through observations of and extended conversations with twenty-three informants, the researcher attempts to understand the factors that most influence the orientations and behaviors of activist members of a peace alliance. The paper also attempts to provide some discussion on the domain of consumer research and definition of consumption. The claim is made that current definition of consumption and consumer may be limiting our ability to gain insights into the human condition through consumer research.

INTRODUCTION

There is a fast growing literature in consumption activities that are outside the sphere of activities conventionally deemed as consumption, that is, acquisition, use and disposal of goods and services (see, for example, Belk 1991; Holbrook and Hirschman 1982; Roberts, Scammon and Schouten 1988; Schouten and McAlexander 1995). Yet, there have also been concerns as to whether any and all human behavior can be considered as consumption, whether there may still be some utility in delineating a certain set of behaviors to be studied under the rubric of consumption. Is, for example, someone participating in a “meals on wheels” program, where volunteers carry meals to people in need, a consumer in this activity? Yes, s/he is usually driving a car or riding a bicycle to carry the meals and, as such, s/he will even conventionally be considered as a consumer, but is the whole activity in which the car is used consumption; is carrying meals to the needy a consumption activity? Therefore, should such behaviors be the domain of consumer research?

Sociological and anthropological studies have implied that distinctions made between production and consumption depended on the definitional constitution of value in modern economics, but that such constitution of value is debatable (Bataille 1985; Baudrillard 1981; Bourdieu 1984). Based on this literature, it has been argued that distinctions made between production and consumption, producer and consumer are culturally constructed, thus historically contextual and arbitrary (Firat 2000). The conventional content of consumption has further been challenged by studies that expose the “consumptive” nature of performative, anti-market, counter-consumption movements or activism (Kozinets 2002).

The purpose of this paper is to illuminate some of the issues raised above about the nature of consumption and consumer research by studying a group involved in the current “Peace Movement,” an activist movement that proposes peaceful policies to deal with terror acts, as specifically exemplified by the September 11, 2001, attacks in New York and Washington, D.C., and opposes the use of military force as a solution. Some theoretical propositions are advanced in the conclusions.

THE STUDY

This research was performed in a large metropolitan city in southwestern United States. It is an ethnography of contemporary activism. Participant observation was the methodology used in studying an organization of peace activists.

The Organization

The organization studied is a loosely organized alliance without any elected or appointed officials except a treasurer. Around eleven to fourteen different groups are represented by the alliance's

members, but many members participate as individuals, without any group representation. The groups represented include faith and church based organizations, peace organizations, civil rights organizations, and other organizations for varied social causes.

The decisions are made by all who come to the general assembly that meets every other weekend. This body assigns tasks to several ongoing committees and infrequently formed ad-hoc committees. The most central committee is the organizing committee that meets on weekends alternating with the general assembly. Other ongoing committees are the events committee (planning the events to be undertaken by the alliance, such as peace rallies), the education committee (planning the educational programs to be undertaken by the alliance), and the outreach committee (planning the contacts that the alliance decides to make with other organizations). An early media committee was later combined with the events committee.

At each meeting of the general assembly, two people who volunteer to lead the discussions at the next meeting are selected. These two people, along with all who choose to come to the organizing committee meeting, are responsible for putting together the agenda for the next general assembly. The organizing committee discusses what topics need to be on the agenda, organizes tasks that were assigned by the general assembly, hears committee reports, and makes budget allocations for the tasks that have been authorized by the general assembly. Membership in all committees and in the alliance is based upon turning up at the meetings.

The alliance has many ongoing activities. The core of these activities is the varied weekly vigils. One vigil is called “Women in Black” and is an extension of such vigils across the world, where women clad in black and wearing black veils stand silently at a central spot and distribute flyers of information. This vigil takes place on three different days of the week in different parts of the city—the city library and two separate campuses—with participation of different women. The numbers have been changing between six and twenty-five in these vigils.

Another weekly vigil, on two different days of the week at two different major street intersections of the city, is the peace vigil. At these vigils, with numbers changing between nine and forty, signs are held, flyers are distributed to pedestrians and vehicle occupants, peace slogans and songs are voiced. Recently, a third weekly peace vigil that focuses on puppets and street theater has started at a major university campus in town.

The alliance also participates in peace and anti-war rallies, gatherings, marches, and teach-ins that are organized by other organizations, sometimes in partnership with the alliance. It has been active, for example, in the worldwide peace marches organized on February 15, 2003, and March 8, 2003. It was also very active in the 2003 Martin Luther King, Jr., march that had a strong peace contingent and message. It is the local organizer of the global “Candlelight Vigil” that is to take place on March 16, 2003. Two major peace concerts were organized by the alliance in cooperation with student and municipal bodies.

The Informants

The alliance now has several hundred “members” in the city and is part of a peace movement across its state that has thousands of participants. This study has especially focused on twenty-three alliance members, of which thirteen are women and ten are men. While there is no official count of the sex distribution of the alliance's membership, most meetings have a majority of women.

Of these twenty-three members, five are professors (two at community colleges), four represent faith organizations (their employment is unknown to the researcher), two are students, four are small business owners, three are retired, one is semi-retired (working out of the home), one works for the Green Party state organization, one is in construction, and one is a state government employee. The youngest is in her mid-twenties and the oldest in his mid-seventies. The researcher participated in multiple activities with this group of members, although for separate events, and had a chance to converse with them at length many times. None of these conversations were pre-planned, but followed the natural course of sharing experiences and thoughts among co-activists.

A Brief History of the Alliance

The alliance was started when a peace organization in the city called for a meeting of citizens following September 11, 2001. Over one-hundred people turned up for this meeting. An original ad-hoc committee drafted a mission statement for the alliance, which was finalized after several weeks of intense discussions. An original organizing committee developed proposals about how the alliance should be structured and operate, as a result of which the structure and operating procedures described earlier were constituted. Later, an attempt at developing a document for short and long term peaceful alternatives to military actions to represent the alliance's view failed due to extreme disagreements on its content and language.

The alliance has continued and undertaken several effective actions, however, despite the ideological differences among its members. While a few of the most active members have dropped out from general assembly and committee meetings due to these differences and other personal reasons (dissertations, address changes, work changes, etc.), they continue to participate in the major events that the alliance takes part in. Recently, there is an attempt at evaluating the alliance's successes and failures in keeping active members, as well as considerations of its future. With the impending war in the Persian Gulf, there seems to be a greater unity of purpose and a rejuvenation of commitment to working for the alliance among its members.

Numbers that participate in the general assembly have fallen from over one hundred in the early days of the alliance to around thirty to forty, sometimes around twenty, currently. While there are no set officers of the alliance, there have arisen a few very active members who regularly participate in the committees and other meetings and who, thus, have become major players in decisions made and tasks undertaken. These members contribute extended time to the alliance's activities and tasks. Seven of the twenty-three informants this study focused on belong to this category.

An interesting development in the last seven months has been that two of the informant members who stopped coming to the alliance meetings have, together with two other informants, who are active members of the alliance, formed a new group that comes together to organize actions—specifically, rallies and teach-ins—inviting organizations to join in, the alliance being one of them. Once the organized action is done, this group disperses until the next action to be organized. They find this format able to react to events much faster and more effectively. This perception may be validated by the fact that this group was the leader in organizing three very successful events: two marches and one teach-in, all of which attracted unprecedented numbers in the state.

SOME PRELIMINARY OBSERVATIONS

While the alliance has been successful in uniting several peace groups together and enabling them to bring in a growing number of people into the peace movement in the state, it has encountered

difficulties. Specifically, while the numbers of people joining the actions have increased, the number of active members who take on tasks has decreased, putting more pressure for time allocation and effort on fewer members. The reason for this is a fractioning of the members of the alliance.

The most significant fraction among the membership seems to have occurred due to three reasons. One is the relatively slow pace and seeming anarchy in decision making. Related to this is the feeling among some that the heated discussions have sometimes become too aggressive and offensive. Several members voiced their discomfort due to their perceptions that they have been attacked and, at times, verbally abused. Other members have found the “endless” discussions too distracting from actions that need to be taken in view of, what they consider to be, looming issues and impending events, got frustrated with the pace of meetings and decision-making, and have left to work with other organizations.

A second reason for the fraction is the frustrations with what some feel to be a failure to be more inclusive and understanding of the values of varied faith and ethnicity based groups. Several have complained that the general assembly is always on Sundays, a day not convenient for certain faiths to allocate to such activities. Others have complained that Islamic and Jewish values do not get equal acceptance. All members agree that the alliance has not been able, and according to some not sufficiently active, to draw into the alliance and the movement members of African American, Hispanic, and Native American backgrounds. These concerns have created discontent among members who, nevertheless, are still active in the alliance.

The third reason for the fraction has been the relations with anarchist groups that are in the peace movement. During rallies and marches, the anarchist groups are more reluctant to follow discipline and rules. While they have not until now engaged in destructive acts during these events, there have been arrests of members of these groups for offenses such as stepping into the traffic during pedestrian stop lights—when the police force expects the marchers to halt the march—and shouting slogans at the police. While practically no one in the alliance agrees with the anarchists' tactics during the peace events, there is a difference of opinion as to whether they should still be allowed in the events. Three major opinions are voiced: (1) anarchist tactics are in conflict with the “peace” message of the movement and, therefore, they should not be allowed to participate in events organized by the alliance, (2) all who are for peace, regardless of their views and tactics should be included, and (3) we cannot control or police who comes to the events, so we should concentrate on what we do, not on what others do.

This disagreement has caused a very few number of alliance members to stop coming to the events. While this is a recurring argument, specifically following every large event, no clear decision has been made to this date.

FURTHER OBSERVATIONS AND PRELIMINARY INTERPRETATIONS

A purpose of this research was to understand the motivations that led people in the alliance to take the positions they took. Why did some stay in the alliance despite their disappointments while others left? What were the reasons that led to the different behaviors among those that did stay, and what caused those who left to take different paths after leaving the alliance? Do insights into these issues enlighten us about people and consumption? Following are some observations and related interpretations regarding these questions.

From conversations with the informants and discussions in the general assembly and committee meetings, it was possible to discern some differences in the political backgrounds of the alliance

members. One difference that seems to make a significant contribution to the variance in behaviors is the degree of knowledge and analysis with which members came into the alliance. Mediating the effect of this was the political orientation of the member.

Members who came into the alliance with the most articulated analyses and greatest degree of knowledge regarding world affairs tended to have the least patience for the slowness of decision making and organizing actions in the alliance. Of these members, however, some left and some did not. Those who left the alliance were the ones who perceived that the links they already had with political organizations, such as the Democratic and Libertarian parties, or organizations with social or environmental agendas, such as labor unions and ecological groups, were strong. As mentioned, while they continue to participate in marches and other events organized or co-organized by the alliance, a common theme that runs through their justifications for no longer participating in the meetings of the alliance bodies is that they can do more with their time allocated to other activities.

Those with articulated analyses and knowledge who did not have perceived strong links to other organizations have stayed with the alliance meetings—meaning the general assembly and committees, and tasks needed to realize alliance actions. Despite discontent with the pace and perceived inactivity, what keeps these members in the alliance is a shared belief that peace is the most significant purpose to work for in a contemporary world where much danger of terror and violence loom. There are, however, following the threat of a war in Iraq, two differing views among these peace activists. One view is that all effort needs to be put into averting a war in Iraq. A second view is to keep the theme of resolving world's problems through peace central, while opposing war in Iraq.

A second stream of differences is observed based on the alliance members' perceptions of the mainstream media. As a result of differing analyses regarding the nature and role of mainstream media, there are two different approaches to how media ought to be encountered. One approach insists on letter writing campaigns, contacting the media to invite them to the events, and is built on the belief that there is sufficient neutrality in the mainstream media to have an impact and representation.

A second approach to mainstream media is based on the belief that they are basically controlled by corporate economic interests, which are currently heavily represented in the government. According to this view, media's representation of movements, such as the peace movement, will be biased and, while there may be some minimal coverage of the peace movement, the overall tone and accompanying items will be orchestrated to undermine the peace efforts. Two sometimes overlapping proposals regarding how the media should be encountered arises out of this approach. One is to not waste time with the media, but to concentrate peace efforts on actions that will carry the message directly to the masses. The second is to target the media and its role in current political predicaments as part of the peace efforts, to get the media interested in its own interests.

Another significant difference in the members' approach to the alliance, maybe a more interesting factor in exploring consumption, has to do with how the alliance is perceived and what is expected of it. A group of members view the alliance very instrumentally. That is, the alliance and their efforts in it are to achieve certain goals that specifically have to do with the advancement of peace and avoidance of war. They often ask that clear, reachable goals ought to be set that, when achieved, success may be measured by the fact that the alliance would be no longer needed. They are focused on the ends of the process. Another group of members focus on the process. For them the ends are not the only, maybe not even the more important purpose of the alliance. The alliance, its work-

ings, the theater of actions and activities constitute not only means to reach ends, but a way of life, a form of existence and, maybe, a model for a peaceful world.

This distinction in the perceptions of the alliance results in more or less a completely overlapping distinction in strategic orientations to the alliance's actions. Members from the ends focused group tend to concentrate and see greater value in actions that are *confrontational*, in the sense that the messages, signs, etc., of the actions take on the policies of the government and other parties, opposing them and calling for change. Their signs at the rallies will say, for example, "No Blood for Oil," "Drop Bush, Not Bombs," "Regime Change in the USA."

Members from the process focused group, on the other hand, concentrate on and express value in *performative* actions. While they participate in rallies and marches with signs such as "Economy in the Service of the People," "God Does Not Only Bless America," and "Let's Try Preemptive Peace," they prefer actions like teach-ins, silent vigils, and street theater.

DISCUSSION

Clearly, this is research that is ongoing, the activism studied may be, at this very time, in its crucial moments. Events may yet create major turns in the reactions and behaviors that are being studied. However, some preliminary insights may be possible now.

One insight that stands out, specifically in relation to "consumption," is the clear distinction in the orientations of the activists between getting involved in activism for the goal(s) to be achieved versus immersing in activism for the experience. In conversations with the informants it is evident that three groups emerge in this respect. One group of members is the goal-oriented one, for whom the experience of being at the meetings and undertaking tasks is quite a miserable, almost a torturous, necessity. They express feelings of time pressures and usually are the first ones to leave when meetings are over.

A second group cherishes the time spent in meetings, finding these to be satisfying social times. They enjoy dwelling on the issues that arise in the meetings and that require involved discussions. Meetings are something they look forward to, as are the events organized by the alliance, where they look forward to interacting with the participants and to having long conversations with co-activists. In effect, for this group, these meetings and events are not simply means to achieve results, but are part of living and being.

A third group has characteristics of both the first and the second groups above. They appreciate that the alliance exists to achieve some goals, but also consider it to be a part of a (worthy) way of living. For these last two groups, being a member of the alliance is not just something they do, but something that defines who they are and how they choose to live their lives. That is, while for the first group membership in the alliance is not a matter of identity, for the last two groups it certainly is.

Based on the conversations with the informants, it is found that the motives that place the members into these groups include, along with some of the reasons discussed earlier, the member's ideological affiliation. These ideologies are not exclusive of each other, but often overlap, making the analysis more complex. However, some tendencies are discernable. Specifically, the ideologies that are most often voiced among the alliance members are politically (most frequently Marxist and progressive), ecologically, anti-consumption culture, feminist, minority/civil rights, or faith based ideologies.

Among the informants, there are two who almost exclusively espouse a Marxist ideology. Both of these members belong to the first, ends-oriented group, as do the four who exclusively espouse

faith based ideologies. One informant who particularly is an environmentalist with also feminist background, two others with strong anti-consumption culture ideologies with ecological values, and one who has a long civil rights activism history belong to the second group, for whom the participation in the alliance is simply a way of life. The remaining thirteen informants who espouse combinations of post-Marxist/progressive, environmentalist, feminist and minority/civil rights ideologies belong to the third, hybrid group. These informants express, in varying words and degrees, the necessity of life styles, as practiced in and through the alliance, to be models for the goals that are sought to be achieved by the peace movement.

The existence, preferences, and behaviors of the “purely way of life” and hybrid groups, and the actions they tend to prefer, as discussed earlier, seem to support some sociologists’ claims that both the form and meaning of activism has been changing, beginning with the 1960s. Berman calls this the aestheticization of politics (Berman 1989) following theories of the new avant-garde (Bürger 1984), while others see it as a “post-” phenomenon (Cohen 1998; Eschle 2001; Grossberg 1992), or the rise of personal politics (Jamison and Eyerman 1994), or the popularization of theory (McLaughlin 1996). In each case, there is the implication that a transformation from the modern sense of agency and activism that was confrontational and instrumental (Rejai 1973) is taking place. The fact that informants who represented the more modern forms of organized ideologies, political or faith based, especially exhibited an affinity to and preference for this modern sense of activism corresponds with this implication.

In terms of consumption, as Roberts, Scammon and Schouten explore with the craftspeople (1988), what conventionally is deemed as work or productive activity or hobby, and the like, is often an act of “consumption,” whether in terms of one performing the act as a way to “enjoy” life or as a means of “living” life. Hirschman (1983), in pointing to the limits of the marketing concept also had presaged the limits of the clear distinction marketers and consumer researchers were making between consumption and production. Artists’ work is often not simply an act of producing artworks, but a model of and a proposal for consuming/living one’s life. Finally, Firat and Dholakia (1998) have observed a growth in the orientation of consumers globally in terms of approaching all of their life activities as constructing *theaters of consumption*. The activists approaching activism with “purely way of life” or hybrid orientations do indeed seem to be interested in constructing theaters of consumption as a way of living.

CONCLUSION

From the point of view of consumer research, the transformation implied in the trends in activism and agency indicated by sociological studies and supported by these observations of a current peace alliance and its members, further tends to indicate the superficiality of the distinctions made in modern thought in defining consumption as separate or different from other human behaviors. Indeed, as the brief study in this paper shows, living, making life choices, acting for social change, or activism for peace are not only consuming the people involved, for many it is the consumption of life experiences, camaraderie, ideologies, ideas, time, and identities as, simultaneously, these same things that are consumed are being produced. This confusion, therefore, makes it difficult to explore our human condition with constructs that are unrepresentative and illusory. They may, in fact, be blocking our insights.

As consumer research continues to break down the received limitations of what is to be or should be studied, consumer researchers may be well advised to consider breaking ground for a new vocabulary.

Identity, Consumption and Loss: The Impact of Women's Experience of Grief and Mourning on Consumption in Empty Nest Households

Carolyn Folkman Curasi, Georgia State University
Margaret K. Hogg, UMIST
Pauline Maclaran, Leicester Business School

ABSTRACT

In this paper we examine how women use consumption to negotiate the four tasks of grief and mourning, as they experience the loss of children in the empty nest household. From our study we identify the double loss faced by empty-nest mothers: the physical and emotional presence of their child; and the tasks central to the motherhood role: daily maintenance and the production of sociability. We discuss how women use consumption to re-establish emotional connectedness with their children who are physically absent; to reconfigure their mothering tasks in order to maintain the sense of family beyond the empty nest household; and to re-create their sense of self in the life long project of identity formation.

INTRODUCTION

Loss is an important life event that affects women's identities and their patterns of consumption. The empty nest household represents a potentially rich site for researching the dialectic between identity and consumption during periods of transition and loss. In our consumer culture consumption is often used to help negotiate the very difficult life stages including those characterized by separation and loss and the tasks associated with mourning and grieving (Bowlby and Parkes 1970; Kubler-Ross 1969; Worden 1991). Our data illustrates how women's construction of identity and sense of self as mothers undergoes a series of changes as these women confront the stages of 'loss,' experienced as the grief and mourning involved in their children leaving home. We investigate how empty nest women use consumption to help them emotionally re-locate their relationships with their children and to help them refocus and move forward with life (Bowlby and Parkes 1970; Worden 1991, p.10-14). We strive to contribute to the systematic discussion of the dialectic between consumption and the "common elements of loss that are associated with adverse life situations in general" (Murray 2001, p. 219).

We begin with a brief review of the literature on grief, mourning and loss; identity and motherhood; and transition. We then describe our research design and methods; and present the findings. We conclude by discussing how the psycho-social needs of women in empty nest households impact their consumption and market place behavior as their identities evolve in response to changes in their mothering role and their experience of children leaving home.

LITERATURE

Loss, grief and mourning.

As death and its associated emotional, psychological, physical, and economic losses represents one of life's major events, many major role changes and life status transitions can also be understood in terms of loss and the consequences of suffering a loss. These major life status transitions usually force consumers to negotiate a reconfigured or recreated sense of self. Women entering the parental life stage transition of the empty nest household can also be examined from the informants' lived experience of suffering a loss. Thus, women's experience of their children leaving home and its associated impact on women's identities and sense of self can be

understood within the wider literature about grief, loss and mourning (Rosenblatt, Walsh, and Jackson 1976; Worden 1991).

We follow Worden's distinction between *grief* (which "refers to the personal experience of the loss") and *mourning* (as "the process which occurs after a loss") (Worden 1991, p. 34). Grief is characterized by acute and episodic 'pangs' and "the stages of alarm, searching, mitigation, anger and guilt, and gaining a new identity" (Parks 1998, p. 43 cited in Clear and Burggraf 2002, p. 1). "Mourning has four phases: numbing, yearning and searching" (or pining), "disorganization and despair, and reorganization" (Bowlby 1969, 1973, 1980, cited in Clear and Burggraf 2002, p. 1). This is very similar to Worden's (1991) argument that mourning involves the four tasks of: first, accepting the reality of the loss; second, working through the pain of grief and dealing with the feelings; third, adjusting to an environment in which the departed is missing; and fourth, emotionally relocating the departed and moving on with life (Worden, 1991, p. 10-14).

Identity and motherhood.

Children moving out of the home constitute much more than simply the absence of their physical or emotional presence. Our immediate family is a part of our extended self (Belk 1988; James 1890). Not unlike the grieving that accompanies the feelings of self loss experienced during a divorce or with the death of a child or spouse, it seems likely that many women recently in the empty nest stage may also feel a sense of self-loss. Since children are part of a parent's extended self, a child's move out of the house may well be seen as a loss of part of that parent's extended self.

Women's identities as mothers evolve in response to changes in the parent-child relationship, beginning with the arrival of the new baby, and their socialization as mothers (McMahon 1995). Within feminist sociology McMahon (1995) argued that it was important to understand "*what kind of identities*" are produced by the processes of separation, independence and autonomy (McMahon 1995, p. 268). According to McMahon, motherhood allows women to feel they have achieved, "a feminine identity as a loving, caring, responsible person." What was vested in the women's commitment to motherhood was not simply the social identity of being a mother, but also the character of being a caring, patient, responsible adult person; a positively valued character that may be symbolically expressed for many women through motherhood (McMahon 1995).

Surprisingly, there has been very little research on how women's experience and understanding of motherhood changes as they reach the major transition point of their children moving from adolescence to adulthood as symbolized by the empty nest household. The necessity, for instance, of renegotiating relationships of dependence (parent-child) to interdependence (adult-adult) (Berne 1961, Pitman 1982) while still maintaining interconnections and a sense of family and its resulting impact on the consumption behavior of the family has remained poorly understood. This represents a gap in our knowledge about subsequent stages of women's re-socialization as they learn how to mother 'at a distance'; and importantly, how they use consumption to negotiate this transition and the resulting impact of this transition on their market place behavior. The empty nest is an especially interesting stage at this point in

history because it is a life stage that many of the 76 million baby boomers in the U.S. are undergoing, or will undergo during the decade. Further, we are seeing the same phenomena played out in many other developed countries.

Just as importantly, the nature of the empty nest transition is not just about re-defining the mothering role and the child/parent relationship, it also demands re-definition of the parental partnership, the wife/partner role; and often re-negotiation of the equilibrium of the remaining familial relationships (Worden 1991, p. 126). With the continuity of core relationships thus being rendered unstable, many empty nest women seem to experience a dislocation from past relational reference points. In conjunction with such feelings there is then an overriding sense of loss of identity with a concomitant search for new meaning in their lives.

Transitions and Role Status Change

Transitions or liminal phases (Turner 1969) have been described as “a limbo between a past state and a coming one, a period of personal ambiguity, of non-status, and of unanchored identity” and represent valuable sites for exploring the impact of loss on the dialectic between consumption and identity (Schouten 1991, p. 49). Important role transitions generally occur in three stages: separation; transition; and incorporation (Van Gennep 1960). These rites of passage are traditionally associated with major life transitions and events such as birth, marriage and death. The transformation in the mothering role which occurs as children leave home represents a major disruption to their established world and its associated activities, roles, practices and consumption activities that are constitutive of a central part of many women’s identities. These three stages—of separation, transition, and re-incorporation—are therefore very consistent with the role status change of empty nest mothers as their sense of self and identity is reconfigured and adjusted around changes in the enactment of the parental role.

Role status transitions are accompanied by a liminal phase in which the individual holds an ambiguous non-status, and is between two different role statuses, but not firmly grounded in either. In the modern, secular world people often experience liminoid states (cf. Turner 1974) devoid of supportive formal rites of passage” (Schouten, 1991 p.49). Without some type of societal support system firmly in place, consumers attempt to cope with this difficult transition and their ambiguous self-concepts in a myriad of ways. Contemporary consumers who are left to their own devices create their own personal rites of passage which are carried out, at least in part, through symbolic acts of disposition and acquisition of consumer goods. These acts of consumption and disposition allow consumers to utilize products in their role status transitions and in the transformation of their new concept of self. The reconstruction of self that began with separation from the parental role and the end of the original child-parent relationship, is assisted through the disposition of consumer goods and the rituals consumers play out with material objects.

METHOD

After examining relevant literature we began to explore the lived experience of women consumers in empty nest households. We specifically sought to better understand the experiences of women whose children had left the parental home within the last 18 months. We used a feminist perspective and an interpretive research design with two data sets.

The first data set.

Our first data set consisted of twenty-one in-person unstructured interviews with empty nest women whose children had left the

parental home within the last 18 months. The interviews were held in the participants’ own homes and lasted between 30 minutes and two hours, averaging one hour in length and were conducted in Ireland, England and the United States. An informal approach was adopted for the interviews, with the researchers using a broad topic list covering key issues including: changes to daily activities; lifestyle; social networks; consumption patterns; and their role as a mother. We used a purposive approach (Miles and Huberman 1994) to select our sample design, looking for “representativeness by ‘purposefully’ choosing a sample that typifies the population, the theoretical category or the phenomenon to be studied” (McMahon 1995, p. 34). Participants were recruited via friends and acquaintances using a snowball sampling method (Miles and Huberman 1994). The interviews were audio taped and transcribed, resulting in approximately 300 pages of data. Transcribed interviews were read repeatedly by all research team members; themes were identified independently and then discussed amongst the team members. Consensus was reached on each theme discussed in the final manuscript.

The second data set.

The second data set was collected using netnography (Kozinets 2001, 2002) and included participant observation in two online bulletin boards. Our netnographic investigation produced an online data set of over 500 postings to the bulletin boards and also a set of reflexive field notes which represented the written account of the fieldwork conducted in a computer-mediated environment.

We announced on the bulletin boards our presence as researchers interested in the topic of empty nest women, and of our plans to prepare research papers on this topic. Formal observation of the boards lasted for fifteen months, using a mixture of unobtrusive and participant observation. The first board was monitored weekly and more frequently whenever there was a particularly active posting period. New postings usually appeared every day and sometimes there could be up to six postings on the same day. Three hundred and six postings were downloaded for analysis. In addition archival material was also downloaded from this site which produced a further 100 postings for analysis. We monitored the second site for 3 months, and downloaded 95 postings for analysis. We observed that some self selection took place among the members of this second data set, since women having difficulty with this life stage transition are more likely to seek out a site such as these. However, we do not believe this is problematic since we are not suggesting that this is a representative sample. We do believe that the participants in this data set and in our first data set provide insight into the difficulty of this life stage transition for some women.

FINDINGS

Loss in the Empty Nest Stage and the Tasks of Grief and Mourning

“It is a death of sorts... it is the death of life as you know it. Mommy job ending sorta, and you have to grieve” (Online Bulletin Board).

For most of these women their children’s departure potentially represented a double loss: first, the loss of the child, his/her physical and emotional presence and that relationship; and second, the loss of tasks central to the motherhood role: daily maintenance and the production of sociability. The themes of separation, transition and incorporation are interwoven throughout our informants’ stories about the losses they experienced as their children leave home.

Worden (1991)'s four tasks of mourning are also clearly evident as well as the importance of completing these tasks in order to work through this difficult life transition.

Dealing with grief and working through the tasks associated with mourning was clearly evident in our data. Using representative comments, our informants illustrate the many parallels of the losses they felt with those losses described in the literature on grief and mourning. The first task, accepting the reality of the loss (Worden, 1991) was realized by many of our informants, often admitting that this happened before their child even left home. The following woman explains that for her accepting the reality of the loss started during her daughter's senior year in high school:

This year hasn't been bad. It's the second year. The first year was,... (pause) the first year started about Christmas time of her senior year of high school and her graduation of high school and it was just,... (pause) devastating for me. (In-person Interview).

The second task, working through the pain of grief and dealing with the feelings (Worden, 1991) was evident repeatedly, also.

I seem to muddle through for a few days and then something happens to set me back. My daughter came home from college this weekend and it started all over again—remembering how good it was and how awful and lonely it is now. You kid yourself and go about your life as if all is OK until something happens to make you realize it really isn't. (Online Bulletin Board).

The loss associated with the physical and emotional absence of the child was discussed by many:

"Hello to all, Melissa here, one daughter, Sandy, age 19. Sandy married on July 7 and moved to England to live. ...Needless to say—I crashed and burned. It has been 4 months and I am happy to say, I am having some good days, more good days than bad." (Online Bulletin Board).

This woman's description illustrates how she has worked through the pain of grief and expressing her feelings (*I crashed and burned*) and is beginning to adjust to the loss she feels.

There were many examples in our data of the third task, adjusting to an environment in which the departed is missing; (Worden, 1991), although it was met begrudgingly and out of necessity as shown in the following woman's comments:

...and then we took her to school. I cried all the way home. ...I walked in the house and sort of busted up. I cried for days afterwards. I mean, different songs would make me cry. It was terrible! (stresses terrible) And then, with the friends that I had, we sort of commiserated and started doing other things. And in October of last year I got a part time job, (laughter) because I thought, "Okay, I have to do something!" (In-person Interview).

The fourth task, emotionally relocating the departed and moving on with life (Worden, 1991) was also evident in our data. Once women had worked through these very difficult tasks, they often became supportive to others still trying to deal with the pain of this transition. June below provides a succinct overview of her experiences:

My youngest left 5 months ago and just very recently, I'm starting to heal from the pain. I know this doesn't make sense right now and it probably doesn't help you at all, but time has a wonderful way of healing us. I suffered a tremendous loss because being a mother was what I loved best about my life. In fact, I couldn't even imagine a time when all my children would be grown and on their own. But it happens, and the pain for me was excruciating. What has helped me the most is seeing a therapist and learning that it is normal and natural when children grow up and leave. It hurts, but it gets better. I still enjoy a close, loving relationship with all 3 of my grown children. Reach out to friends and professionals for strength to help you through this time. It will pass, I promise, and on the other side you will feel a new freedom and a softer, kinder person inside. Reading this board really helped me and there are others as well on the Internet. If I can offer my friendship, I would be happy to do so. It's important to allow yourself to cry. I cried every day and sometimes more than that for several weeks. It does get better. Please write, if you'd like. I'd like to be here for you if you need me. (Online Bulletin Board).

In describing her loss and subsequent adjustment, another informant talked about how she had found the first six months after her children left very traumatic. Once her children had been away for a while they established a routine for the holidays, and things have become more tolerable. Her relationship with her children has changed and is now more similar to that of adult friends (In person interview) (Berne 1961; Pitman 1982). The next informant also exemplifies the idea of how things have improved over time:

"This year hasn't been bad. It's the second year. The first year was... just devastating for me. ... I mean, I stopped eating. I stopped sleeping.... we took her to school and I thought I was going to die. I cried all the way home. I literally made it from her dorm room to the elevator, which was probably about 6 yards and completely came unglued" (In-person interview).

USING CONSUMPTION TO NEGOTIATE THE PHYSICAL AND EMOTIONAL LOSS

Objects Providing Comfort

Women used consumption in various ways to negotiate these stages of separation and transition in order to cope with the physical and emotional absence of their children. As children moved away from home, they took certain belongings with them that involved strategic decisions about creating an identity in their new lives (Silver 1996). They took many meaningful personal items (CDs, clothes, photographs, duvet covers) and useful items of general furnishing (chairs, televisions, and sometimes even their bed). Some mothers felt the need to substitute for the missing items whenever possible to maintain a home atmosphere. This was particularly true in the case of replaceable items such as furniture and decorations. In this way mothers may keep a child's bedroom almost as if it were a shrine to that child.

"Her room is basically, she left it like it would be when she came back ...She left her room as intact, as if she would be home for the weekends or come for a visit. It's just there and I can walk in at anytime and feel her presence there and know that she is going to be back. And see her school pictures and know as time has gone by those pictures will be taken down and replaced with other pictures of her new found friends and her new life. (In-person Interview).

This informant's comments are particularly interesting since it is unlikely that after graduating from college, her daughter will want to move back into her childhood bedroom. This fantasy of sorts, however, seems to have a therapeutic effect, and by maintaining her daughter's bedroom as it was when her daughter was living at home, this woman has been better able to cope with the empty nest stage of her life.

In the following extract Mary preserves her son's bedroom and his displayed collection of baseball cards and balls. Mary uses his possessions to evoke proud memories of her son's achievements and to provide a physical linkage to him:

Mary: "I still have all the baseball cards up there and the balls that are all signed. And they're still out... And, his flight stuff. He didn't take that 'cause he's not gonna be flying up there.

Interviewer: Is there anything in there, that when you see it you just think about the past?

Mary: A memory? His flight bag is lying up against the wall. And every time I walk by, it's lying up there by the door, and the cats sleep on his bed anyway, and I look at it and think, boy, I'm glad he did that and it was so hard. Because we had to really push him to finish it." (In person Interview).

However, children usually left behind items overtly associated with their childhood such as teddy bears and various childhood collections. As demonstrated above sometimes items left behind can emotionally reconnect the mother with her offspring. Other informants related similar experiences. Sheena, for example, played her son's old cassette tapes as she went about her housework and Mandy wore her son's t-shirts:

"So I might sleep in them [the t-shirts] or work in the yard in them, and little favorites of theirs, old school team t-shirts from where they won something, a championship or something... Every time I put it back on again, I can remember them racing in that t-shirt in a special road race, I can remember them wearing it, getting dirty, washing it for them...there's something warm and comforting about sleeping in them". (In person Interview).

Mandy has appropriated her son's t-shirts to help her with the separation phase. There were many other examples in our data of our informants finding comfort in objects left behind by their children. Similar to the ability of a blanket to provide security to babies as they start the 'separation phase' from their mothers, so adults, too, are often able to feel comfort with a particularly meaningful possession that helps them deal with the liminal 'separation' phase. The role of material objects and their symbolic properties during transition was a common theme found in this data (Belk 1988, 1990; McAlexander et al. 1993; Price, Arnould and Curasi 2000; Silver 1996). This woman, for instance, used her grown children's rooms as a transitional object, that provided her comfort and made her feel closer to her boys who were away at college.

"Basically, as strange as it may seem, when you walk into their rooms, their rooms smell like them, even this one. When you just pick up something, even the odor smells like whichever boy it is. That's a strange thing when you walk into there, you think (sniff), that's them all right." (In-person Interview).

She simply walked into their rooms and sniffed, and she immediately felt the presence of her sons. Another empty nest mom,

discusses how looking through the photo albums that her daughter left behind was comforting:

She has them all at school now but when she doesn't have them at school, when she brings them home in the summer, yes, I'll look at them. When she's not there, I'll go look at them and relive her senior year, because her friends are awesome, and I like watching her change. (In-person Interview).

Finally, the increased consumption of technology, seen in the use of the bulletin board, also represented attempts to re-establish some degree of connectedness to replace the physical and emotional absence of their children. These discussions highlight the pain of working through the grief and also showed the level of social and psychological support offered by the board:

"I've mentioned things on some of these boards that I haven't talked to anyone about, not even my friends, so this is like therapy!!!" (Online Bulletin Board).

"All your postings and suggestions help so much. I hope a year from now we can all return after successfully getting on with our lives, to help others just starting the process" (Online Bulletin Board).

The second aspect of loss was associated with the daily tasks of mothering. In terms of 'caring for' their families women talked about a whole series of production type tasks related to the full nest, such as feeding the family; doing the laundry; taxiing children around. These aspects of mothering largely disappeared with the transition to the empty nest. These mothers regretted the disappearance of the tasks traditionally associated with their mothering role:

"I miss watching her [eldest daughter] perform, singing, and dancing the most...I'm having trouble finding something I enjoy as much as watching her perform. I do plenty of hobbies, church work, and have 3 other girls, but the first one is hard. It seems all the activities I said I would do when I didn't have to drive her around anymore just don't seem to be as inviting as I thought they would." (Online Bulletin Board).

The crucial dialectic between the physical, psychological and emotional aspects of parental love and labor (Rothman 1989 in McMahon 1995) are brought into stark view by the transition to the empty nest. The sense of loss because of the lack of the 'daily maintenance' (i.e. *caring for*) (De Vault 1991) comes through clearly here:

"No one needs me any more. When I get home, John doesn't really need me, you don't think your husband needs you, sort of thing. What with the children leaving, no help with homework and things." (In person interview).

The importance of mother's co-ordination work round meal times to 'do family work' can also be clearly seen. This description reflected the idea of the family as the factory for the family (De Vault 1991):

"I would tend to cook a meal at night, particularly to try and encourage Nick to eat. I would try and get him to come and sit with us but quite often David's not with us either so it's hard. I do though try and cook a meal. Actually we sit down more since we've put this table here in the sitting room. We used to

sit round the breakfast bar in the kitchen or have things on our knees. Emma coming back has put more pressure on in some ways in terms of set meals because she's wanted to know what time food's at so that she can go out" (In-person interview).

Caring for family and caring about family (De Vault 1991) are both captured in this woman's description of feeding her family. She describes the investment of her time and effort in terms of meal preparation ("I do though try and cook a meal") and promoting the social setting for its consumption ("I would try and get him to... sit with us"). She revisits the theme of 'sitting down' two or three times as she describes the physical setting for creating family life. This description shows again the range of coordinating skills (De Vault 1991) required to produce family life via meal times by accommodating everyone's different needs, illustrated here by the informant's catering to one daughter while also recognizing the need to plan around another child's timetable of social activities.

Many women made a deliberate effort to overcome their feelings of loss by searching out new social networks for themselves. Anne works part-time. She has recently taken up golf, an activity she can also enjoy with her husband. This, in turn, has helped her build a new social life, based partly on her husband's social networks and golf; thus she has regenerated her social networks by using bridging social capital. In a similar way, Jean has coped well with the adjustment by re-building her networks around social activities. She has developed her own independent social network:

"Yes, it was an adjustment but I adjusted very well I think. I had activities that I wanted to do. I wanted to pursue playing tennis, which I had just taken up about two years before my daughter graduated. I wanted to be a gardener. I love the outside and having more time to just spend there rather than being a chauffeur, so to speak, to the kids." (In person interview).

Adjusting to living without those who have gone is one of the central tasks of grief and mourning (Worden 1991). Consistent with role identity theory, this was where women with a role in the workplace, in addition to their role in the home, often benefited when they experienced the empty nest (Thoits 1983; White and Edwards 1990). For many women these changes to the pattern of their daily lives produced deep role insecurity. Adjustment was more difficult for those women who had not worked outside the home and they were especially vulnerable to feelings of insecurity at this time. Mandy recalls her feelings as she realized that she was "losing" her kids. Her uncertainty over her new situation is evident:

"I had arranged my life around them, and it was unconscious, actually, but my money, my time, projects that I worked on, I would check their schedules first. So now that they are gone, it's very confusing at times, the emptiness that I think is invigorating, for the most part, most days but then it's the other part about what I didn't do with my life to prepare myself for now." (In person interview) [emphases added].

Having spent so much time and energy developing their children's social capital ("I had arranged my life around them... my money, my time"), suddenly they find that networks held together through children's activities have diminished. Many women neglect their own social networks during their years of child rearing, and thus lacked 'bridging' (Putnam 1995, p.2; Onyx and Bullen 2000) qualities of social capital (Bourdieu 1986, 1987). "One way to learn about the nature of connectedness is to explore its absence..."

(McMahon 1995:138). Consequently, feelings of loss and emptiness were commonly expressed.

With children no longer as accessible as they once were, consumption becomes a bridge to connect parents with their children's new lives, both as a way to communicate more effectively at a distance, and as a way to still share a part of their lives. Consumption is used to re-establish some of the social connectedness which had been disrupted with the departure of their children. Technology, such as mobile phones and computers, enables connectivity across different sites for 'doing mothering'. Many mothers emphasized the role of mobile phones in maintaining vital contact with their offspring. The ownership of a mobile phone (both for children and parents) provides reassurance that, in the event of an emergency, children can always establish immediate contact. This reassurance is not restricted to mothers, children also find it comforting to maintain contact with family and their home environment. One informant related how her daughter's mobile bill had been £2000 (approximately \$3,000 in U.S. dollars) in the first month that she had been away from home. Computers too gain significance at this time, as a way to maintain email communication and to even facilitate a physical presence through the use of a webcam, an item that was recommended for purchase by one bulletin board poster to her friends in the empty nester online community.

One of the key challenges for the empty nest mother is determining how to maintain this sense of family across a wider range of settings beyond the household in the wake of the loss of tasks and activities associated with *caring for* her family. Consumption was employed to meet this challenge of ways of mothering at a distance, and to help work through the tasks of grief and mourning. Changes to rituals around meal times and food consumption in our data supports earlier research (De Vault 1991) about the importance of finding intersections of activities for creating family life. Kathleen's story neatly illustrates the change in family meal time routines. Kathleen related how, when her children were at home, she would dutifully prepare the evening meal every morning before she left for work. She was proud of the fact that she had never relied on any readymade meals, emphasizing the nutritional value of her own home cooking for the children, despite the inconvenience to her in terms of her busy schedule. Kathleen is a good illustration of the sacrificial elements involved in feeding the family (DeVault, 1991) and the importance of the family meal (Miller, 1998). In the empty nest household the consumption scape for feeding the family often moves from the private domain of family mealtimes to the public domain (e.g. *We do go out to eat at least once a week sometimes with the youngest daughter joining us*). Several other informants indicated that they would also spend less time preparing food, and were more willing to eat convenience foods or eat out at restaurants. This seems to mark a change away from the mundane, nurturing type activities that Miller (1998) has shown can be ways to manifest love and devotion in families.

Loss of Part of Extended Self

Mothers in the empty nest household felt the loss of their extended self (Belk 1988). McMahon's (1995) study of new mothers had shown how children were seen as "*constitutive and integrative* of the self in many of the women's self-conceptions" (McMahon 1995, p. 140). The experience of attachment had been central to these women's sense of themselves as mothers (McMahon 1995):

"I've been pondering this a lot lately, trying to get to the core of what I'm feeling. And I think it's this...*the part of me that has been the intense, Mama Bear, hands-on, super-involved,*

watchful mother the past two decades...well, really *isn't needed* to do that *anymore*. There's no need for it, so where does that part of myself go? It's not like there aren't other parts of myself, other parts of my mothering profile even, that aren't alive and well and functioning fine..." (Online Bulletin Board).

This highlights, first of all, the intense sense of responsibility experienced as part of the mothering role (Thompson 1996). "*The intense, Mama Bear, hands-on super-involved, watchful mother the past two decades... really isn't need ...anymore*". Second, this woman recognizes how her mothering role has evolved: "*other parts of my mothering profile... alive and well and functioning fine*". Motherhood does not disappear when children leave home, but experience of motherhood changes dramatically. For our informants, moving from the full nest to the empty nest meant dealing with the fear that being 'without children' would mean being disconnected in some way, not just from their children (and thus experiencing loss in the sense of the physical absence of their children). It also meant confronting a sense of loss of their own feelings of motherhood. What they had to explore, as they worked their way through the tasks of grieving, were the different ways to enact mothering across different sites, often using different types of consumption. As women come to terms with the changes they recognize first that "*I'll always be there as their mother*" (In person interview) and second, that "*you just have to move on*" (in person interview).

CONSUMPTION AND GIFT-GIVING

Consumption as gift-giving becomes an important strategy for negotiating the loss of their identities as "loving, caring, responsible" (McMahon 1995) adults. Mothers use consumption to express love (phone calls, cards, care packages, things for apartment or dorm). The following informant describes how she and her husband express their affection and re-create their new role as long distance parents through tangible gifts to their children who have moved away:

"Daddy sent Mandy tons of M&M's, or m-em's as she always called them. We sent her four boxes in the past three weeks...I sent her a food box, then she got very sick and I sent her a medicine box! Then daddy sent her a dehumidifier. Then the candy. And I know daddy has sent her \$\$'s in there, also!" (Online Bulletin Board).

Notice also the use of brands to reinforce familial connections and memories (Olsen 1995). Another mother illustrates how she uses consumption to traverse this liminal period. She talks about gift-giving and the things she has bought for her daughter:

"*I bought a new rug for her apartment, because we only bought one set and I figured she needed more. ...And I send her care packages. I send her a card, like once a week and in between I think I've sent her two or three care packages, no two. But I have some other things I like to buy for her when I see them, like last time I sent her a care package I sent her a CD and a magnet for her fridge and some jiffin pops... they're like a kool-aidy stuff... just fun stuff... She loves getting real mail! She says e-mail is great fun and she hears from everybody, but... My mom will send her a card occasionally, sometimes with cash involved—she likes those. ...And it's fun for me too.*" (In-person Interview). [emphases added]

Mothers help their children to personalize and appropriate their new living spaces (e.g. *I bought her a rug*). An important

opportunity for expressing love and enacting their new identities as empty nest parents was evident with many of our informants who helped their adult children become more comfortable in their new homes. Informants often made purchases of food and more general household items such as furniture and household decorations. They continued to undertake 'mothering at a distance' by putting together and sending off care packages; boxes of medicines; sweets; and small fun gifts (e.g. "*kool-aidy stuff...just fun stuff*").

DISCUSSION

We can trace themes which relate to the four tasks of mourning and grief (Bowlby and Parkes 1970; Worden 1991) in these women's stories of their experiences of the empty nest household. Worden (1991, p. 10-14) argued that in order to complete the tasks of grief and mourning successfully, it is necessary to actualize the loss; identify and express feelings such as anger, guilt, anxiety, helplessness and sadness; adjust to living without the departed; facilitate emotional relocation of the departed; and provide time to grieve. Further although both of our data sets include informants from at least three countries, the grief, mourning and the associated consumption behaviors revealed were consistent across the data—regardless of the informants' country of residence. We suggest that the experience of the empty nest mother, although unique and nuanced for each individual, appear to be a universal phenomena commonly experienced by women new to the empty nest stage in developed countries.

Accepting the reality of the loss: "The idea of being without children was not experienced simply as an absence but as a *loss*" (McMahon 1995:138), which confirms the themes of mourning and grief (Worden 1991). Women clearly experienced loss across all aspects of their mothering role; and describe it "as a death of sorts" (Empty Nest Bulletin Board). Their stories showed that accepting the reality of the loss was central to allowing them to emotionally re-locate their relationships with their children and move forward with life (Worden 1991, p. 10-14).

Working through the pain of loss. Many of these women's stories show them working through the pain, and especially the feelings of sadness and helplessness. Many women initially felt quite overwhelmed by the loss of children from the family home and they dealt with the initial trauma, grief and pain in a variety of ways, typically played out with consumption behaviors. Some used drugs (e.g. Wellbutrin) to help them cope with the painful emotions; some used established personal social networks as they worked through the experience; some sought solace outside their established social networks (e.g. on bulletin boards). They missed not just the physical and emotional presence of their children, but also they anticipated the loss of their roles as mothers. Role identity theory suggests that, when children leave their parents' home, their departure will be associated with a decrease in parental well being (Thoits 1983; White and Edwards 1990). However, this premise rests on the assumption that launching one's children means that the parent then abandons the parental role. Many scholars reject this premise and believe that once individuals have had children, then they continue to occupy a parental role throughout their lives. Our study supports this as we found evidence that the role of mother evolves and changes, but does not disappear, and we found considerable evidence of how women adapted the tasks of *caring for* and *caring about* (De Vault 1991) so that they re-constituted their identities as 'loving, caring, responsible adults' (Worden 1991).

Adjusting to the environment without the child. Women's understanding of motherhood is altered as they experience the transition to an empty-nest household. This has implications for their changing perspectives of sites for production and consumption in 'doing family work'; and their further re-socialization as

mothers (McMahon 1995) as they adjust to the absence of their children.

As motherhood had symbolized connectedness (McMahon 1995) it was the loss of social connectedness and social capital which was particularly hard to bear. The levels of distress experienced seems to be directly related to the variety and degree of enmeshment of the different role sets and the associated networks that represent the informants' social capital. In the empty nest stage these parents' and children's sets of social capital start to be 'decoupled' and the experience of that decoupling process is more or less painful depending on how 'enmeshed' these sets of networks are; and the centrality of the children's social networks to women's identities and sense of self. As the social networks that had been dependent on children dwindled, many women experienced a concomitant crisis in role identity. Scott (1991) argues that the diversity of networks and their linking to a variety of roles are a major source of self-esteem and that adjustment is easier if not dependent on one role. Thus, one of the major factors to influence the extent of the crisis in role identity associated with adjusting to the environment without the child depends on whether a woman has her own independent social networks that allow her roles outside of her mothering home-based ones. Varied social networks, if independent from those of the children, can offer a stronger support system. These networks may be career, hobby or community-related. For example, several women described the solace they found through their professional activities, their volunteer work, church group, or health club. For others it was a regular coffee morning with friends that had been meeting for many years. This is consistent with other scholars who argue that playing multiple roles in society helps to insulate an individual from emotional threats to a specific role (McAdams 1997).

Emotionally relocating the child and moving on with life. What was vested in the women's commitment to motherhood was not simply the social identity of mother, but the identity of the extended self of the woman. This emphasises the importance not just of relocating their children, but also of the women relocating themselves (Worden 1991) in their new world—and learning to 'mother at a distance' and thus become re-socialized into a different way of mothering.

CONCLUSION

This interpretive study explored how women used consumption to negotiate the transition phase represented by the empty nest household, and their adjustment to new identities; the re-configuration of roles, tasks and networks; and the experience of and response to the disruption of their social and emotional capital. Our study argues that "there is no single meaning or experience of being a mother" (McMahon 1995, p. 263) or of the experiences of grief and mourning suffered following the loss of children from the family home. What happens during periods of transition—as represented by the empty nest household—is a major readjustment of the tasks associated with the mothering role within the life-long project of identity formation, and we can clearly see the psycho-social needs and its respective impact on consumption and market place behaviors. Future research could usefully explore other aspects of consumption linked to experiences of being a woman and mother at a variety of intersections (e.g. race, class, age, sexuality) in relation to different points of transition and the concomitant potential sources of loss, grief and mourning (e.g. children starting school; divorce; death of child or spouse; career break; (re)-starting work).

From Patriotic to Tasteless: Exploring Consumer Reactions to 9/11/2001 Related Advertising

Charles A. McMellon, Hofstra University

Mary Long, Pace University

ABSTRACT

In the weeks following September 11, 2001 marketers responded with a variety of advertising messages directly related to the events of that day. Four categories of advertising emerged from our content analysis of all newspaper advertising in the New York City area: condolence, information, inspirational or patriotic, and commercial. To better understand consumer reactions to these advertisements, we measured Attitude Toward the Ad and recorded consumer reactions. Our results suggest gender differences and a wide variety of attitudes for each category. In addition, consumer comments reflected a bipolar evaluation from deep-seated feelings of patriotism to outright cynicism.

In the days following September 11, 2001, marketers appeared to be concerned about consumers' reactions to their advertising. As a result, some removed all of their advertising from the media, believing it was not a time for commercialism, while others, feeling a need to communicate to consumers about the events, placed advertisements the very next day. Advertisements related to 9/11 first appeared in newspapers, but eventually spread to radio, television, outdoor, the Internet, and direct mail.

The research described here is taken from a larger study consisting of a content analysis of the newspaper advertising related to 9/11. Our analysis of the appeals used in these advertisements suggested four basic types of advertisements: (1) condolence, (2) inspirational or patriotic, (3) informational, and (4) commercial advertising (McMellon and Long 2003). Many of these advertisements used some type of patriotic appeal (e.g., a picture of the U.S. flag), no doubt in the belief that the use of patriotism as part of their message strategy would evoke positive attitudes from consumers. Yet, as Gelb (2002) and others (e.g., Elliott 2001; Garfield 2001) suggest, the combination of commercialism and patriotic appeal may instead evoke negative attitudes in consumers. We could find nothing in the academic literature examining the important subject.

Over 1,400 advertisements referring to 9/11 appeared in the local New York City newspapers in the first month following the attack. Obviously, advertisers felt this was an important issue to address, yet no one to our knowledge has made a systematic study of consumers reactions to these advertisements. As a starting point, we measured attitude toward the ad (Aad) for a variety of 9/11 related advertisements. This is an appropriate measure as attitude toward the ad (Aad) has been widely used over time and has been shown to influence both brand attitudes and purchase intent (MacKenzie and Lutz 1989). In order to further our understanding of consumers' attitudes, we also conducted qualitative research and examined written comments about individual advertisements.

We begin with a discussion of the four types of message appeals reflected in our prior content analysis of 9/11 advertisements. Next, we describe our data collection method. The paper concludes with our analysis and findings.

BACKGROUND

Although the 9/11 related advertising was placed in all types of media, we focus on newspapers, as they appeared to be the dominant outlet for these messages in the New York City area. Because of the characteristics of newspaper advertising—immediacy, cost effectiveness, and short closing times—advertisers were able to respond immediately to the event. Our prior research employing content analysis of newspaper advertisements during

the one-month period after 9/11 suggested four types of message appeals (McMellon and Long 2003). Although more than one type of appeal might appear in any single advertisement causing some confusion in categorization, generally a single message appeal dominated. Descriptions of the four types of message appeals along with examples of representative advertisements follow.

Condolence Advertising

Advertisements categorized as "condolence" tended to be emotional in nature. They used words such as "condolences," "prayers," "sadness," "sympathy," "suffer," and "tragic." In Figure 1, the Emigrant Savings Bank advertisement is representative of a technique that combines sympathy (e.g., "Our deepest sympathies and prayers...") with a patriotic motif. In this case, the use of the words, "God Bless America," with the iconic images of the American flag and the Statue of Liberty provide the patriotic symbolism.

Inspirational or Patriotic Advertising

Meadow (1981) identified this particular type of appeal as communicating pride in America and its values. The advertiser used symbols (e.g., U.S. flags or the colors red, white, and blue) or words (e.g., "United We Stand" or "God Bless America") that were meant to evoke patriotic thoughts and feelings. These advertisements used heroes, rebuilding, and courage as themes in an attempt to elicit feelings of hope or of a defiant American spirit. Advertisements in this category ranged from those that were clearly inspirational or patriotic to those that began to approach commercialism. For example, more than one consumer, when asked to comment on advertising with a patriotic appeal, stated that the name of the firm was too large, thus detracting from the patriotic aspect of the advertisement. In Figure 2, Computer Associates attempts to evoke feelings of patriotism using simple, yet strong imagery and a patriotic slogan.

Informational Advertising

Informational advertisements provided helpful, factual information to consumers. For example, they covered such topics as an announcement that the firm was still open for business, had started a fund for helping victims, or was there to help those who were in distress (e.g., providing assistance to fill out insurance claims forms.) Figure 3 provides information regarding the availability of free flag posters at a local store.

Commercial Advertising

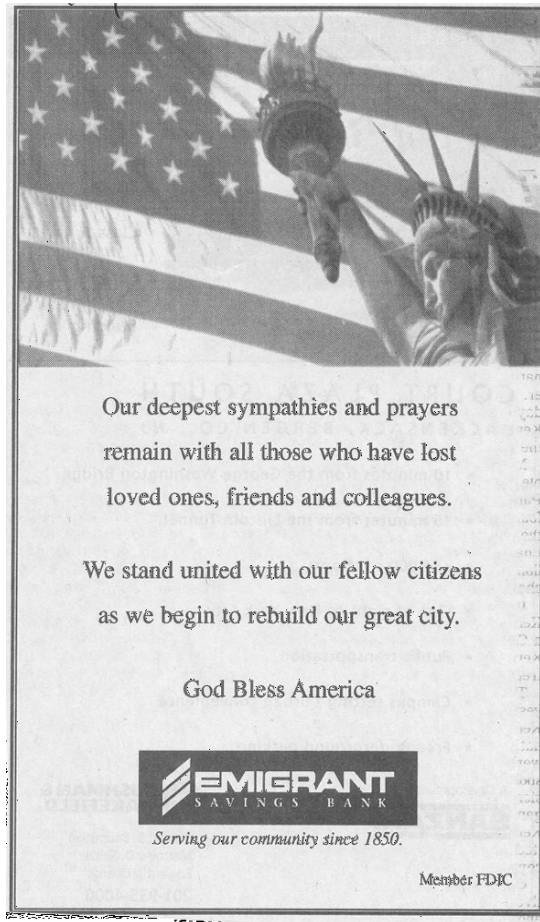

Advertisements categorized as "commercial" looked very much like traditional product or service advertisements, with the exception of an added reference to the events of September 11th. They used various patriotic symbols or phrases along with a strong sales pitch for their products. In Figure 4, Baron's Auto Mall proclaims "God Bless America" followed by "ONLY \$20 DOWN ON EVERY CAR IN STOCK."

CONSUMER ANALYSIS

Measures

In order to understand consumer's reactions to the 9/11 related advertising, two approaches were used: (1) Attitude Toward the Ad (MacKenzie and Lutz 1989) and (2) an open ended question requesting opinions on an exemplar from each category.

The Aad scale used in this study was the 7-point 3-item measure suggested by MacKenzie and Lutz (1989). The three semantic differential items were good/bad, pleasant/unpleasant, and favorable/unfavorable anchored by agree/disagree. An average of the three items served as a measure of the overall evaluation of the advertisement. In addition, consumers were also asked to respond in writing to one open-ended question: "Please describe the advertisement you have just seen in your own words."

Demographic data on age and gender were also collected as these two variables have been shown in the past as possible influences. For example, Han (1988) demonstrated a relationship among age, gender, and patriotic intensity. Patriotic intensity influenced choice. Although age cohorts (e.g. baby boomers, generation X, and the millennial generation) are difficult to categorize because of overlapping, generational attitudes, the use of age groups as a segmentation tool is growing (Tsui 2001). Thus, we suspect that attitudinal measures will differ across gender and age segments.

Data Collection Method

Graduate and undergraduate students from a mid-sized northeastern university were trained to administer the Aad scale and to collect written consumer reactions to the advertisements. The students were asked to collect 10 surveys when home on their Thanksgiving break. This approach provided some geographic dispersion of the sample, although most respondents were in the New York City area. Because of the local nature of much of the 9/11 related advertising, New York City area respondents provided an appropriate sampling frame. Since much of the imagery dealt with U.S. symbolism, non-US citizens were excluded from the study to avoid any potential bias.

Each consumer was questioned about one exemplar from the four shown in this article. A paper and pencil questionnaire was used to collect the Aad measure, a description of the advertisement, and demographic data.

Sample Description

The sample consisted of a wide range of consumers from the New York City area. It included 541 individuals with a mean age of 35, ranging from 11 to 85 years of age. More than half the sample was female (54.7%) while 45.3% was male.

The respondents were segmented into three age groups: 41 plus ($n=136$), 24-40 ($n=228$), and those below the age of 24 ($n=170$). We chose these segments to reflect noted attitudinal differences for each cohort (Tsui 2001). The 41-plus segment includes three groups commonly referred to as the "GI Generation," "Silent Generation," and "Baby Boomers." This conglomerate cohort can be characterized as more conservative and civic minded than younger groups. The 24-40 age group, which includes "Generation X" and "Generation Y," is known to be more cynical and media-savvy, while the 23 and younger group, sometimes called "Millennials," are less affected by media, more accustomed to violence, and have grown up in an affluent environment.

RESULTS

The Aad scale demonstrated high internal consistency ($\alpha=.95$). This was consistent with prior results from MacKenzie and Lutz (1989) who reported an alpha of .90. A principal component analysis extracted one factor containing 90% of the variance.

Analysis of variance was used to examine the effects of gender, type of advertisement, and age cohort on Aad. Table 1 shows that there were significant differences for gender ($F=13.022$, $\text{sig}=.000$) and advertisement type ($F=81.032$, $\text{sig}=.000$), but not

for age cohort ($F=2.122$, $\text{sig}=.121$). There were no interaction effects between any of the variables. Tukey post hoc analysis of the advertisement types suggested attitude differences between the Baron's Auto Mall advertisement and all other types. Attitude differences also existed between the Emigrant Savings Bank and Newsday advertisements. In addition, the mean Aad score for each advertisement suggested that Newsday had the highest positive rating, with Computer Associates and Emigrant Savings Bank less positive and the Baron's advertisement scoring the lowest.

Further examination of the data using one-way ANOVAs revealed that females had directionally more positive attitudes than males for all advertisements (see Table 2). Specifically, these gender differences were significant for the Emigrant Savings Bank ($F=8.464$, $\text{sig}=.004$) and the Computer Associates ($F=5.045$, $\text{sig}=.027$) advertisements.

In order to better understand the underlying reasons behind these attitude scores, we analyzed respondents' written comments about the advertisements. Specifically, we asked them to "Please describe the advertisement you have just seen in your own words." Their comments represented a wide diversity of opinion for each advertisement, evoking both negative and positive comments. Interestingly, the advertisements evoked deep feelings of patriotism among some of the respondents, while eliciting expressions of cynicism from other respondents. For each of the four different types of advertisements, the majority of comments reflected the mean attitude scores (positive or negative) reported in Table 2.

Condolence Advertisement—Emigrant Savings Bank

Emigrant Savings Bank's condolence advertisement evoked a mixed response from consumers. On the positive side such comments as "sincere," "appropriate," "hopeful," "patriotic," and "comforting" were used. The negative comments included "cheap shot," "served no purpose," and "taking advantage."

A 25-year-old female stated: "I think it's an appropriate advertisement as it encourages patriotism and unity at a time of despair and distraught (feelings of hopelessness)"

A 25-year-old female says, "This advertisement is a wonderful way to express sympathy for those who have lost loved ones in the terrible tragedy, while at the same time portraying a sense of hope for the future of our country."

A 22-year-old male negatively states: "I feel offended when people try to cash in on the 9/11 event. Let people rest. Do not use a tragedy to try to make money."

A 60-year-old female suggests her feelings run deeper: "Unfortunately in our society, we forget too fast how quickly life can change. For so many their lives were completely turned upside down that day, never to be the same again. I feel it is a good reminder that we never forget that day or the people who lost loved ones."

On a more cynical note, a 20-year-old male feels that the Emigrant Savings Bank is: "A bank that is being sympathetic for their own needs, not necessarily to be sympathetic."

Patriotic or Inspirational Advertisement—Computer Associates

The Computer Associates advertisement elicited the most consumer comments, both in frequency and detail. However, responses to this patriotic/inspirational advertisement were mixed.

* The lower the mean score, the more positive the Aad.

Compared with the other advertisements, respondents' positive comments reflected more emotional feelings with such words as "very poignant," "patriotic," or "heartfelt." There were also some negative comments ranging in intensity from mild (e.g., "it's feel good advertising") to strong (e.g., "bad taste," or "cheap ploy"). Respondents provided more detailed analysis for this advertisement, perhaps because of the strong imagery. A 27-year-old male digs deep into his inner feelings as he describes the advertisement:

"I think that this advertisement says a lot about the events of 9/11 and it also symbolizes what American stands for. I believe the most powerful aspect of this ad is the silhouette of a woman and child playing. This picture is a true unbiased representation of America. America is the home of the free. This is depicted in the silhouette as the mother and daughter frolicking through the fields. In addition, you can not conclude what race or ethnic background the people are from. The only disturbing part is that there is no man in the image, for some it can represent a lost firefighter or dad. The image also repre-

sents the future of America. From the bright sun in the sky we can ascertain that life will go on and the lost will be watching over us. Overall, in my opinion this ad was created in good taste and is appealing to a broad audience."

Many consumers were also cynical about this advertisement because a corporate advertiser placed it. A 24-year-old female writes:

"The ad is an acknowledgement of the losses suffered as a result of Sept. 11. The statements are moving and powerful. However, it is an ad, and because of this fact, I'm trying to figure out the real motivation behind the statements."

A 26-year-old male plays art director while making his point: "I feel the ad does show some sincerity, but the logo should have been smaller to draw less attention to the organization. The focus should have been more oriented towards the families."

On a less cynical note, a 23-year-old male states: "I feel that it is a good gesture by Computer Associates to place their advertisement. You get the feeling that they truly care about what happened on Sept. 11th."

Informational Advertisement–Newsday

Newsday's informational advertisement evoked few strong comments. Consumers tended to give a more literal explanation of the advertisement. It did not appear to bring forth the same level of emotional response as the other three advertisements. Comments such as "an act of support," "tasteful," "they care," "helping," and "positive" were common. The negative comments were milder than those for the other advertisements. For example, "Newsday wishes to raise its public image." However, some respondents saw more than just the simple message of "free flags" in this advertisement.

An 18-year old female states with a hint of cynicism: "While they want to be perceived as patriotic and compassionate toward the victims, I see that they are only doing this just for the appearance. Although Newsday is providing people with posters, they in return are advertising."

A 33-year-old male cynically states: "I feel that Newsday used the tragedy of 9/11 as a ploy to buy Newsday. It was considerate of the people at Newsday to give away free flags but it was another sales tactic."

Deeper feelings were evoked in a 58-year-old female: "I am very sorry that it took such a great loss of lives and a tragedy that shook the world for us as Americans to display our flag or to sing our national anthem with pride, honor and love of country. President Roosevelt said a chicken in every pot, I say a flag in every window and on every lapel."

Commercial Advertisement–Baron's Auto Mall

Baron's Auto Mall evoked the most negative comments, although this viewpoint was not unanimous. Positive comments such as "well done" and "clearly patriotic" appeared in a few respondents' comments, but as one consumer succinctly stated: "One's patriotism cannot be equated with automobile purchases." Most consumer comments reflected this point of view with such words as "opportunistic," "tasteless," and "offensive." (Our favorite negative comment came from a 21-year-old female who said, "It sucked.") There was also a strong strain of suspicion for any automobile advertisement. As one 50-year-old consumer stated, "...most of the prices shown will have hidden costs—usually if it sounds too good to be true, it most likely is." Interestingly, many consumers did not make any comments, choosing to ignore our request for a description. As shown by the mean ranking of advertisements in Table 2, the Baron's Auto Mall advertisement was rated significantly less positive for Aad than the other three.

A 31-year old male speaks negatively about the advertisement and its cynical reflection of American society: "A poorly laid out advertisement which tries to capitalize on the strong patriotic sentiment in the country, at the moment, in an effort to make money. But that is the American way."

DISCUSSION

One basic assumption about this type of advertising is that it usually works in the best interests of the firm that places the message (Waltzer 1988). Our findings suggest this may not be true for some of the advertising placed after the attack on the World

Trade Center. We found significant differences in attitudes and a wide range of comments from deep-seated feelings of patriotism to cynical observations of commercialism.

The results also suggest that males and females respond differently to this type of advertising. Specifically, in the case of the 9/11 related advertisements, females generally scored higher on a measure of Aad than did males for those appeals that had more emotional content. Significant differences were found for both condolence and patriotic/inspirational types of advertisements (i.e., Emigrant Savings Bank and Computer Associates). Interestingly, there were no significant gender differences for informational or commercial advertisements, which, in our judgment, had less emotional content.

Contrary to what we anticipated, age cohort did not appear to be an influential factor on Aad. However, from our analysis of respondents' comments, it seemed that younger consumers more often expressed skepticism regarding the advertisers' true motivations for placing these messages. On a more positive note, for some consumers these advertisements could also elicit deep emotional feelings of patriotism for the U.S. culture. In summary, our findings suggest that the more commercial in nature the advertisement was perceived to be, the less positive the reaction to the advertisement.

Marketers may have placed some of the advertising for patriotic reasons based on small group behavior patterns (Sherif and Sherif 1953; Hinshelwood 1987), while some of it may have been placed for commercial gain. Either way, there are concerns that these types of ads are exploitive, jingoistic (Elliott 2001; Garfield 2001), or self-serving (Coe 1983; Gelb 2002) and that they will evoke a negative response from consumers. We found this to be true for some respondents. Thus, advertisers should use caution when thinking about placing advertising in response to national events. In particular, for industries or companies, which already suffer from negative consumer perceptions (e.g., auto sales), it is likely that these advertisements will be viewed as self-serving.

Our research suggests that firms walk a fine line between being viewed as sympathetic versus exploitive. Companies that wish to acknowledge a tragic event through advertising should consider how they might counter consumer perceptions of commercialism. The effectiveness of this type of advertising has never been supported in the literature (Coe 1983). The events of September 11, 2001 were horrific to all Americans. Marketers should moderate their urge to communicate personal feelings because, although it may be personally satisfying, it may not be in the best interests of the firm.

A TALE OF TWO 'CITIES'

("It was the worst of times"; "It was worse at times"): Shoppers in Montgomery County, MD and Washington, D.C. during the recent Sniper Attacks

Denver D'Rozario, Howard University

EXTENDED ABSTRACT

I. Introduction:

The string of sniper attacks in the Washington, D.C. area beginning on October 2, 2002 and ending with the capture of two snipers on October 23, 2002, is by now familiar to most in this country (Tucker 2002). Two gunmen terrorized the Washington, D.C. area with their long-range rifle attacks on unsuspecting individuals (Subramanya et al., 2002), while most of them were engaged in some act related to shopping. Before this spree was brought to an end, 10 of these individuals were dead and three seriously wounded (Subramanya et al., 2002). In this article, I shall concentrate on what effect this shooting spree had on various aspects of shopping (e.g., driving to the store) of two samples of residents I surveyed in Montgomery county, MD and Washington, D.C., shortly after the shooting spree ended.

II. Objectives of Study:

More specifically, my intent in this study was to learn whatever I could about the following:

1. How consumers/shoppers in the D.C. area *felt* during the shooting spree,
2. How consumers and consumers/shoppers in the D.C. area *behaved* during the shooting spree,
3. What if anything consumers/shoppers in the D.C. area felt retailers &/or area-governments *could have done* to make them feel more safe during the shooting spree,
4. What, if any, *residual effects* this shooting spree has had on consumers/shoppers in the D.C. area, even after the shooting spree ended, and finally,
5. What *implications* this shooting spree holds for Marketing in general and Retailing in particular.

III. Background:

There is anecdotal evidence to indicate that during the shooting spree, the following were just some of the issues that were understandably, given much attention: (a) victims were mourned (Lew 2002; Purtill 2002b), (b) most people couldn't focus on anything else (see e.g., Stanley 2002), (c) people (Purtill 2002 a & b) and even the Police (Michael 2002) suffered from the stress of living in the sniper's territory, and consequently were given counseling (Abrams 2002; Michael 2002; Rathner 2002), (d) people's lifestyles and outdoor activities were severely hampered (Amato 2002), (e) some prepared to leave the area altogether (Hogan 2002), (f) schools were in a constant stage of siege (Dolinski 2002), and, (g) area retail businesses suffered (Ford & Monroe 2002).

There is anecdotal evidence to indicate that after the shooting spree ended, the following were just some of the issues that were understandably, given much attention: (a) people were thankful to the Police for successfully apprehending the gunmen (Boris 2002), (b) many citizens offered their thanks in prayer that the crisis ended

(Hille 2002), (c) long-canceled/postponed activities were resumed (Spuhler 2002), and (d) others focused on the prosecution of the gunmen (Moore 2003; Johnson 2002; White and Schmidt 2002).

IV. Research Issues:

However, not much, if any attention was given to the following, which was understandable, until now. How did people in the D.C. area shop in this period? If they did not shop in this period, how did they cope with their consumption needs? Did shoppers feel that it should have been the task of Retailers &/or governments to protect them in this period? To answer some of these questions, I conducted a survey shortly after the snipers were caught, of individuals who live, work, go to school and shop in the Washington D.C. area.. I briefly describe this survey next.

V. Methodology:

Questionnaire: The instrument that was used for gathering data in this study was a self-administered questionnaire and was comprised of three sections: (a) in section 1, respondents were queried on how they felt, how they behaved (where they did/did not go, what stores they did/did not shop at, how they traveled to/from stores, how they entered/exited stores, how they behaved in the store), what they felt stores did/did not do to help them shop as normally as possible, what they felt governments did/did not do to help them shop as normally as possible, etc., (b) in section 2, respondents were queried on how they felt about danger and how they assigned blame for this danger in the context of the sniper shooting spree, and (c) in section 3, were some simple demographic questions.

Sample: The first half of this survey was conducted in the first week of November, 2002, amongst the undergraduate students attending a major University in Washington, D.C. (n=72). The second half of this survey (n=52) was conducted at three different points in the Fall of 2002, on three different non-student populations in the D.C. area: (a) 32 questionnaires completed by staff/parents at an elementary school in Potomac, Maryland, (b) 8 questionnaires completed by employees and customers at a gas station in Kensington, Maryland, and (c) 12 questionnaires completed by parishioners of a church in Potomac, Maryland.

VI. Results:

The significant results from this study are too numerous to even attempt to list (let alone explain) in this abstract. Further, many of these findings mask complex subtleties in how different types of individuals react to danger and several of these findings are counter-intuitive.

That having been said, three broad conclusions that can be drawn from this study are as follows: (a) there were some basic similarities in how the two samples used in this study (i.e., D.C.-student-population-based sample versus a Montgomery-county-M.D.-non-student-population-based sample) reacted to the danger from omnipresent sniper attack, (b) however, perhaps more importantly there were several significant differences in how these two populations felt about the sniper-related danger, how they reacted to it as shoppers, who they felt was responsible for their safety and what actions they felt should have been taken (by themselves and

others) to reduce their exposure to this danger, and, (c) the factor structures underlying the shopping-related sentiments of these two populations during the sniper-attack were drastically different.

VII. Marketing Implications:

This study has implications for businesses, but more importantly for retailers, who God forbid should ever find themselves in a similar predicament in the future. They range from obvious, in-store and out-door store-security issues, to merchandise pick-up and delivery issues, all the way to some less obvious findings, such as: (a) various danger-avoidance strategies (e.g., shopping at lesser known, off-the-beaten path type of stores), (b) switching to on-line-shopping-only-during-the-shooting-spree strategies, and (c) store/parking-lot re-design issues, to name just a few.

SPECIAL SESSION SUMMARY

The Adaptive and Less Adaptive Impact of Visceral and Cognitive Facets of Emotional Experience

Laurette Dubé, McGill University

Catherine Cole, University of Iowa

Emotional experiences entail a complex mixture of visceral and expressive reactions, which, combined with conceptual representations of these, guide consumer responses to internal and external events of significance. This special topic session featured recent research that pushes the frontier of our understanding of the adaptive (i.e., contribute to consumer welfare) and non adaptive (i.e., impede consumer welfare) impact of the visceral and cognitive facets of emotional experiences on judgments, decision making and behavior.

In support of the adaptive value of the visceral facets of emotional experience, Cole, Denburg, and Bechara reported results from two studies demonstrating that normal older persons with decision making impairments on a laboratory task that is sensitive to the integrity of the ventromedial prefrontal cortices (VMPC), an area of the brain that is central to emotional processing, were more likely to be deceived by misleading advertising than either normal older adults without such decision making impairments or normal younger adults.

The second presenters, Shiv, Loewenstein, Bechara, Damasio H., Damasio A., reported studies in which normal individuals and patients with bi-lateral lesions in their ventromedial prefrontal cortex (VMPC) engaged in an investment task. The investment task was structured such that the optimal strategy would be to invest in all rounds since the expected value on each round is greater than a dollar. Results were supportive of non adaptive value of emotional experience. Specifically, the authors found that normal individuals deviated more from the optimum than VM-patients, hypothetically because they were reacting emotionally to the outcomes the previous round(s), while VM-patients did not. Normal individuals were probably being negatively affected by memories of emotional experiences in prior investment rounds, becoming more risk-averse if they lost and more risk-seeking if they won, regardless of their knowledge about expected value.

In the third paper, Dubé and Paquet explored the possibility that individual differences in a cognitive facet of emotions, i.e., how emotional experience is conceptually represented in one's mind, modulate the power of emotions in playing their adaptive and less adaptive roles as responsive and guiding devices. Results show that more complex conceptual representation of emotion was tied to a less powerful impact of emotions as a guide for judgments and behavior, regardless of whether the function of these responses was adaptive or not. In addition, individuals whose representation was organized around positive affects, emotions were more powerful predictor of drives, judgments and behaviors than they were in other individuals whose structure of experience was not dominated by positive emotions.

The first discussant, Antoine Bechara, presented a basic neuroscience model of emotions, emphasizing its power and boundaries in terms of its ability to inform consumer research by its description of somatic processes and brain events underlying emotional experience and its impact on judgments, decision making and behavior. He also suggested innovative development by integrating more of the complexity of conceptual representation and social interaction into research on the visceral, experiential facets of emotions in order to better specify conditions leading to adaptive or

not adaptive functions. The second discussant, Ulf Boekenholt, presented a model in which experiential and conceptual representations of both affects and cognitions are seen as driving decision making. He addressed the challenges bearing on design, measurement, and identifiability issues in modeling the influence of emotions on consumer choice, considering that experiential and conceptual information in many ways, feed each other in an interactive manner as they modulate the adaptive and less adaptive roles emotions may play.

Exporting Media Products: Understanding the Success and Failure of Hollywood Movies in Germany

Thorsten Hennig-Thurau, Bauhaus-University of Weimar
Gianfranco Walsh, University of Strathclyde
Matthias Bode, University of Hanover

ABSTRACT

Rising production costs in the US motion picture industry make overseas markets essential for movie studios' economic survival. However, movie marketers can rarely build on systematic research when attempting to customize movies or movie-related communications to different cultural settings. In this paper, we draw from cultural theory to develop a conceptual framework of US movies' success in foreign markets. Propositions are then developed that offer insight into the differing impact of a number of factors on movie success in the US and Germany. Marketing implications will be discussed.

INTRODUCTION

The US motion picture industry today suffers from an enormous rise of production and marketing costs. Average costs for making a movie rose from \$9.4 million in 1980 to \$54.8 million in 2000. To market a movie in 1980 it needed an additional \$4.3 million, while average marketing costs have reached \$31 million in 2001 (Lyman and Holson 2002). Due to rising costs, a global perspective has become essential to profitably market an American movie. While from the 1950s up to the 1980s exports constituted around one-third of American movie revenues, in 1997 overseas box office equaled for the first time the domestic figures. In 2002, the ten most successful Hollywood-produced movies gathered a domestic box office of \$2.4 billion, or 44.6 percent of these films' global receipts of \$5.5 billion (The Movie Times 2003).

As a reaction to this development American studios have begun to incorporate the overseas marketing in their domestic management systems (Dunkley and Harris 2001). However, to fully exploit the enormous success potential of overseas markets, it is necessary to understand the reasons why films perform differently in the US and abroad. For example, the first part of the AUSTIN POWERS series earned only \$250,000 in Germany, in contrast to a US box office of \$54 million. There is also evidence that movies that failed in their domestic release can be largely successful abroad.¹

In this paper it is argued that to optimize the success of Hollywood movies in foreign markets a global perspective is needed. To consider the global perspective the research focus is the success of American movies in the German market as the most important export market (Brown 2001; see also Neelamegham and Chintagunta 1999), with US productions accounting for almost 82 percent of admissions and hence dominating German movie theaters. A cultural framework is used to explore possible factors determining the success of US movies released abroad. Propositions are developed and discussed with references to managerial and research implications.

PROPOSITIONS ON A DIFFERENTIAL IMPACT OF MOVIE SUCCESS FACTORS ON BOX OFFICE

Culture impacts a movie's box office in three ways. First, a movie's box office within a specific country is determined by

different factors, including the movie itself. Key movie characteristics that influence the reception of motion pictures by its potential audience include the movie's genre (e.g., Litman 1983), its style (e.g., Wyatt 1991), its level of symbolicity (e.g., Hennig-Thurau, Walsh, and Wruck 2001), and the starpower of the movie (e.g., De Vany and Walls 1999). A country's culture influences the consumer's perception of these movie characteristics which results in an indirect impact of culture on movie box office. Second, the awards a movie receives (e.g., Nelson et al. 2001) and its certification (i.e., ratings by MPAA; Prag and Casavant 1994) as movie-related concretizations of a specific culture also influence box-office success. Third, a movie's perception by foreign-country consumers is not only influenced by the movie itself and the respective foreign country's market and culture, but also by the movie's success in its home country (De Vany and Walls 2003).

In Figure 1, we present a conceptual framework of the factors influencing movie success in the US and Germany and discuss the model relationships. The framework will allow us to derive propositions about the reasons for an American film's success or failure in the German market. It is based on a differentiation between a vertical and a horizontal direction of thought.

Regarding the *vertical* direction of the model, a movie's box office within a specific country (here: USA) is determined by different factors, including the movie itself. The movie is embedded within a specific cultural context and a market structure which both also influence its box office. First, culture and market influence the consumer's perception of movie characteristics which results in an indirect impact on movie box office. Second, they have also a direct impact on box office.

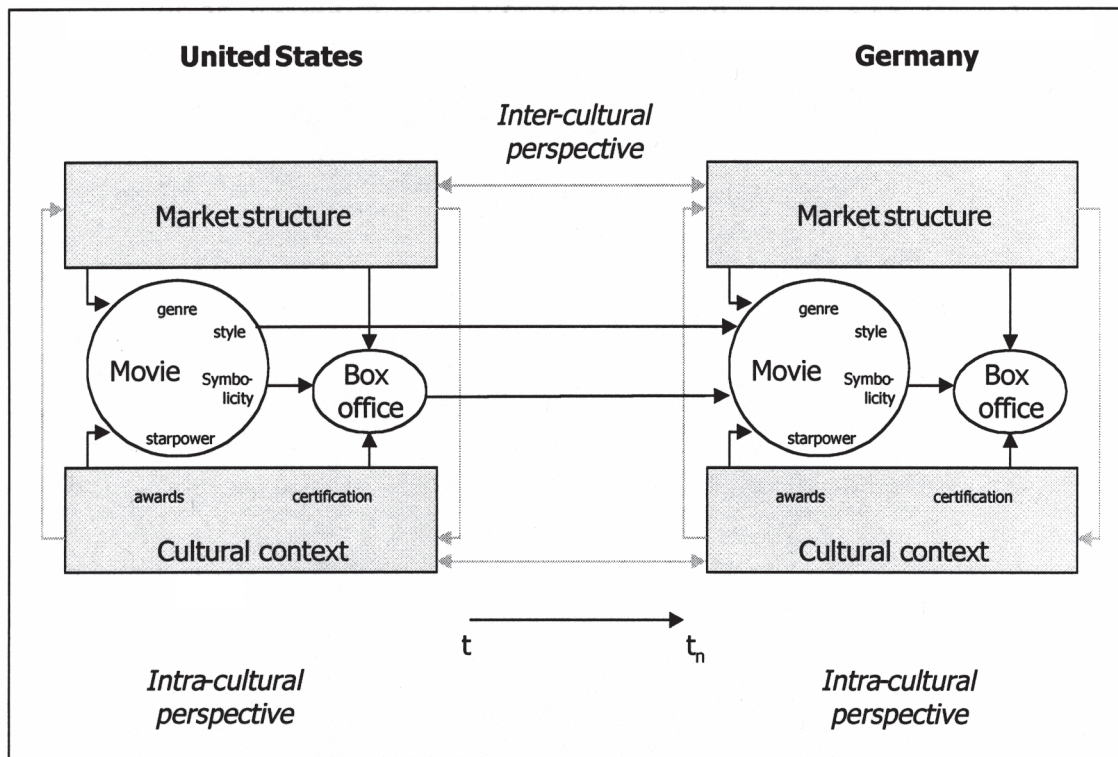

The *horizontal relations* within the model are centered on the bilateral media flow (Jensen 2002) and incorporate primarily the export of domestic movies into a foreign market (here: Germany). While interactions exist between the domestic and foreign market context (e.g., through international distributors) as well as between the domestic and foreign cultural context (e.g., through media), a movie's perception by foreign-country consumers is not only influenced by the movie itself and the respective foreign country's market and culture, but also by the movie's success in its home country (De Vany and Walls 2003).

Propositions for Cross-National Differences of Movie Characteristics on Box Office

Movie Genre. Genre has been empirically demonstrated to impact the North American box office (e.g., De Silva 1998; Prag and Casavant 1994). In these authors' view, the term "genre" requires no definition because it summarizes in a common-sensical way "movie attributes" (Neelamegham and Chintagunta 1991, p. 115) or "specific movie characteristics" (Jedidi, Krider and Weinberg 1998, p. 393). However, such a perspective overlooks that genres are not objective, timeless dimensions of a movie but dynamic, modifiable "envelopes" for a movie. Miller et al. (2001, p. 95) define a genre as a "cultural referencing system that provides pleasures for filmgoers as well as pre-sold forms for risk-averse industries". In this view the cultural and marketing perspective reconcile in the similar idea of genre as a concept connecting the production and consumption of movies, constituting "a kind of

¹For example, Roman Polanski's movie PIRATES collected \$5.8 million at the German box office, while the US box office was below \$1 million.

FIGURE 1
A Conceptual Framework on Exporting American Movies to Germany

'contract' between the media industry and its audiences" (Larsen 2002, p. 132). Based on our conceptual framework, we assume that a difference in a movie's box office success between the domestic and foreign-country market indicates a differing resonance between the marketed movie and the domestic/foreign cultural reference system. Differences are argued to exist for family-oriented movies, thrillers, and comedies.

Family-oriented movies. Considering the vertical direction of the framework, family-oriented movies have the potential to utilize the rich cultural referencing system of family related issues and values in the US. Despite the fact that the traditional family is undergoing dramatic changes in the US (Skolnick and Skolnick 2003), with new forms of family such as cohabiting couples, same-sex couples, single-parent families, and binuclear families emerging, the cultural norm of a traditional family figures large in the American public discourse. Consequently, movies with a "positive" family representation are especially recommended for family viewing.² This discussion is an indicator of a strong American cultural referencing system in regard of family-oriented movies. On the other hand, while the changing status of families is also discussed in Germany, the traditional family plays a less important role in the public discourse here (Schneider 1999; Leggewie 2001). Schneider (1999) found that "[c]ompared to North Americans, German males and females showed less appreciation for identities with family denotation and identities with religious or authoritative denotation". This leads to the expectation that family-oriented movies are more successful in the US than in Germany.

Thrillers. Movies referred to as thrillers share the narrative logic of surprise, suspense, and the name-giving thrills. Thrillers are organized around the central personae of victim, culprit/criminal and official or unofficial agents of law, order and justice (Derry 1988). On a very abstract level they incorporate a universal formula of a confrontation between good and evil. However, film research shows that the specific treatment has been closely related to the social, economic and political circumstances of the US (e.g., Leitch 2002). This is exemplified in the Depression and Prohibition era Gangster movie, as well as the conspiracy, political thrillers of the late 70s, early 80s. It has also been argued that the normative positioning of the criminal and/or avenger resonates specifically with the American public discourse or sentiments (Mandel 1984; Raeburn 1988). In the German culture, with a different law system and far less gun-related crimes, other referencing systems will be relevant. As thrillers require moviegoers to utilize a certain intertextual knowledge, including the American context as well as the specific genre conventions, thrillers are more likely to be successful in the US than in Germany.

Comedies. There are studies to suggest that the concept of humor varies between cultures, for example, the degree of humor used in advertisements and forms of humor such as sarcasm, irony, slapstick, ridicule, and situational humor (e.g., Zandpour, Chang, and Catalano 1992; Biswas, Olsen, and Carlet 1992). Palmer (1995) points out that laughter and humor require a certain situation of incongruity that is always historically and culturally local. It might imply a disregard of customs, social rules and norms and a situational knowledge of the appropriate and socially expected behavior. This refers to the nonverbal as well as verbal humor. Especially verbal humor is an important barrier for the successful export of comedies. Since in Germany the vast majority of movies screened in theaters are dubbed, it is likely that such dubbing reduces a movie's level of humor and, consequently, its attractive-

²See for instance the American religious organization Dove Foundation that awards a label for "family-friendly" movies and even sells Hollywood movies in "family-edited" video versions.

ness to movie audiences. Accordingly, American movie comedies which refer to the specific American cultural referencing system of humor and are shown in a dubbed format can be expected to perform less successful in Germany than in the US. This leads us to our first proposition:

P1: The success of US movies differs between the US and Germany due to certain genres, with family-oriented movies, thrillers, and comedies being less successful in Germany.

Movie Style. A second concept that can be expected to account for differences between US and German movie success is *movie style*. In the last several decades, the American movie industry has developed a distinct way of dramatizing and visualizing stories, which is sometimes referred to as “Hollywood style.” This specific aesthetic and narrative style differs from European kinds of story telling as well as from Asian stylistic movie patterns: “Hollywood movies move; European ones linger; Asian ones sit and contemplate” (see Miller et al. 2001, p. 98). For example, European films tend to be wordier and contain less visual dynamics as well as no or only few special effects. Although German consumers have learned to interpret the codes of the “Hollywood style” (Putnam 1998), a movie still has to have the ability to connect with the localized German cultural referencing system. Motion pictures that draw extensively on the stylistic concept of “Hollywood style” (e.g., strong use of special effects, stars, linear narration and happy end) have to be highly standardized so that they are less open to specific elements of the German cultural system. Consequently, movies with a high level of “Hollywood style” will be more successful in the US than in Germany. Therefore,

P2: The success of US movies differs between the US and Germany depending on the movie's style, with movies having a high degree of “Hollywood style” being less successful in Germany.

Movie Symbolicity. Differences between movies' US and German box office success can also be explained by the concept of *symbolicity*. Symbolicity refers to a media product's potential to be categorized by consumers into existing positive cognitive categories (Hennig-Thurau et al. 2001). Symbolicity has been proposed or empirically shown to impact US box office significantly in the case of sequels, remakes, adaptations of TV series, among others, with movie sequels exerting an especially high impact (Simonet 1987; Ravid 1999).

Symbolicity can be interpreted as a specific form of intertextuality. In an ontological sense, the concept of intertextuality refers to the idea that the reception of one text cannot be conceptualized as an isolated process as there has to be a pre-existing knowledge of a cultural text pool that can be applied to understand a new text. Symbolicity takes the perspective of the producing company in the movie context (i.e., the “author”), which, in order to “pre-sell” a movie, tries to promote a movie with references that are known to the target audience. Here it is assumed that an American movie with a high level of symbolism, as it is especially present in the case of movie sequels, will try to primarily capitalize on an existing American symbolic value. This means that the probability for a resonance with the American culture is higher than for the German culture. Therefore, we expect that US-produced movies with a high degree of symbolism (i.e., sequels) to perform more successful in the US than in Germany. This reasoning leads to the following proposition:

P3: The success of US movies differs between the US and Germany depending on a movie's level of symbolism, with sequels performing superior at the box-office in the US than in Germany.

Starpower. Finally, movie stars are also expected to account for differences in US and German box office. From the cultural point of view, stars create a certain set of audience expectations based on prior textual experiences. In this sense Albert (1998, p. 225) remarks, that “stars can mark a particular film type”. Evidence for a positive impact of “starpower” on the North American box office has been demonstrated by several authors (e.g., Sawhney and Eliashberg 1996), although others have questioned the strength of this impact (e.g., Ravid 1999). While Hollywood stars are international stars, being well known and appreciated in most parts of the world, their media coverage differs between their home country and foreign countries such as Germany. Specifically, there are disproportionately more TV shows and special magazines featuring Hollywood stars in the US than in Germany, which is at least partially stimulated by the stars' local presence. This media coverage enriches the star-related cultural system in the US, providing a wider range of intertextual references for stars that can be utilized by both movie promoters and movie audiences to make sense of a certain new movie starring these actors. In addition, the fact that American movie stars themselves have been socialized within the US culture increases the cultural similarity between these stars and their audiences. This similarity fosters the star-audience relationship and adds to the expected stronger impact of American stars on US than German moviegoers' behavior. Therefore:

P4: The success of US movies differs between the US and Germany depending on a movie's level of starpower, with starpower having a stronger impact on box-office performance in the US than in Germany.

Propositions for Cross-National Differences of External Factors' Impact on Box Office

Domestic Success. When a US motion picture is released in Germany, information on the movie's prior success in the US market is regularly widely available through advertising and neutral media, such as newspapers and television. For example, the German magazine “Der Spiegel” comments the latest US box-office figures on its website weekly. Such information, which cannot be available to moviegoers in the US before a film has been released, can be expected to serve as an important choice criterion for foreign moviegoers when deciding which movie to attend (Elberse and Eliashberg 2002). Specifically, a film's US success (and the underlying “buying decision” of the US audience) is interpreted as a quality signal by German moviegoers. Hence, a film being successful in US theaters is expected to deliver superior quality compared to an unsuccessful movie. Moreover, according to the “success-breeds-success” principle, moviegoers climb on the bandwagon for its own sake, i.e., preferring successful movies over unsuccessful ones, with their decisions being largely independent of quality matters (Elberse and Eliashberg 2002), or as Danan (1995, p. 132) notes, “[c]ontemporary international audiences are plugged into what's hot on American marquee”. The latter effect is amplified by the disproportionate budget allocation of German distributors, who put an emphasis on films that have been successful in the US. Thus, we propose that:

P5: The success of US movies in Germany depends on the movie's US box office success, with movies performing

successfully at the US box office being also successful in Germany.

Awards. Awards, such as the prominent AMPAS Academy Awards, are given to movies in the year following their domestic theatrical release (Nelson et al. 2001). Thus, their impact on US moviegoers tends to be, although significant, limited to theatrical re-releases of award-winning movies and the latter's video exploitation (Dodds and Holbrook 1988). However, as US motion pictures regularly open in Germany with a time lag, information on award nominations and winners are often available during a movie's initial German theatrical release. We offer the following proposition:

P6: The success of US movies in Germany depends on the movie's award nominations and winners, with movies being nominated and/or winners performing better in Germany than in the US.

Certifications. Finally, the varying certification procedures in both countries can also be expected to account for differences in box-office success. In the US, the certifications given by the Motion Picture Association of America (MPAA) are reported to have a significant impact on the box office of movies in the US, with restrictive ratings such as "R" serving as barriers for parts of the audience to attend a movie and therefore limit their success potential (Prag and Casavant 1994). As ratings express a culture's attitude toward movie elements such as violence and sexuality, movies can be rated differently in countries such as Germany and the US. In the case a movie is rated differently, the target audience might be restricted from attending the movies to a differing extent. Consequently, a movie rated more restrictive in the US than in Germany is expected to perform more successful in Germany, where fewer people are restricted from attending the movie. Vice versa, a movie rated less restrictive in the US than in Germany will probably be more successful in the US. Therefore, we propose that:

P7: The success of US movies in Germany depends on the movie's certification in both countries, with films having a more restrictive rating in Germany performing less successful in Germany and films with less restrictive German ratings being more successful in Germany.

CONCLUSION

The purpose of this paper was to explore differences in the factors that determine the success of a movie that is sequentially released in the US and Germany. Our research contributes to a more sophisticated understanding of movie success factors in an inter-cultural context and builds on previous work, which has focused on the US movie market. Propositions were developed on how those factors affect the box office in both countries. We argue that there is an interaction effect between movies and cultures that has an impact on movies success. Insofar this research may help film studios to target their international audiences more effectively, especially by giving heed to different movie characteristics and cultural factors.

From a research perspective, our study could help developing methodologies and approaches to better understand the impact of culture on the overseas success of US movies. Because the proposed framework distinguishes between an inter- and intra-cultural perspective, the hypothesized framework offers a fine-grained understanding of interrelated mechanisms. Our primary contribution to theory lies in developing a model of movie success in an

inter-cultural context. It is hoped that our proposed model will trigger some interesting future research. Naturally, the most powerful research addition would be an empirical test of our propositions. For some factors of the model, it is possible to draw on existing measures used in earlier studies. Other measures could be constructed with data from different sources. Table 1 lists those measures which are found to be most relevant for empirically testing the conceptual model presented in this paper.

Our study also has implications for future research in terms of examining movie success in a cross-cultural context. The advent of global markets and marketing movies across national boundaries require companies to become familiar with relevant moviegoers' behavior in different culture. Once empirically corroborated, the framework could be used to forecast the acceptance of a new motion picture in Germany even before the production stage of motion picture management. Gathering similar information for other important foreign markets can contribute to a global early warning system which may help Hollywood studios to reduce the dangers of economic failures of future movies outside the US market. To understand the effects of culture on movie consumption, it may be important to examine other factors than those considered in our framework.

TABLE 1
Existing Relevant Measures

<i>Variable</i>		<i>Description of measure</i>	<i>Data source</i>
Movie Success	US box office	The overall theatrical box-office generated by a movie during its US release	Internet Movie Database (imbd.com)
	German box office	The overall theatrical box-office generated by a movie during its German release	Filmförderungsanstalt (FFA)
Movie-Inherent Factors	Movie genres and themes	(a) Genre assignments by imdb.com can be taken as nominal genre variables. (b) The degree of family appeal, sexual-erotic themes, romance, suspense, and humor as movie themes can each measured on 10-point rating scales. Assessments on each element can be made by movie experts of the motion-picture information service Reel.com	imbd.com, Reel.co
	Movie style	The movies' degree of "Hollywood style", can be included as assessments from Reel.com experts.	Reel.com
	Movie symbolism	For sequel, remake, and films being based on a TV series, nominal variables can be constructed (e.g., sequel/no sequel). In the case of sequels and remakes, the absolute US and German box office of the respective predecessor was used as an indicator	imbd.com
	Starpower	The Hollywood Reporter's Star Power® measure can be used. The measure contains a starpower assessment by branch insiders which indicates the respective star's impact on the US box office.	The Hollywood Reporter
External Factors	Previous success	See description of US box office gathering above	imdb.com
	Awards	A scoring model can be developed to address the different categories of Academy Awards adequately when transferring the number of awards and nominations into a single scale value. For example, 50 points could be attributed to a Best Picture Academy Award, 25 points for each Best Actor, Best Actress and Best Director award, and 10 points could be given for each remaining award category.	AMPAS
	Timing	For each film, its' theatrical release dates in the US and Germany can be recorded and a difference score measuring the weeks between the two time points calculated	imbd.com
	Certifications	US: MPAA ratings could be used to measure movies', with G, PG, PG-13, and R ratings each being treated as nominal variables. Germany: FSK movie ratings can be used in a similar way, adding nominal variables for each of the rating categories ("general access", "6", "12", "16", "18") to the database	MPA, FSK

Advertiser Portrayal of Consumer Time in the Late 20th Century U.S.: An Update

Barbara L. Gross, California State University Northridge

ABSTRACT

The study extends previous work by Gross and Sheth (1989), providing evidence of continued U.S. advertiser emphasis on time-oriented advertising appeals. Additionally, the specific character of time-oriented appeals has changed consistent with recent societal developments. In addition to themes such as “fast to use,” “saves time,” “portrays the consumer as busy,” and “specifies amount of time required,” recent advertising sometimes attempts to reflect consumer desire to achieve “balanced use of time” and “reprieve from a time-oriented lifestyle.”

Gross and Sheth (1989) examined advertising appearing in the *Ladies' Home Journal (LHJ)* magazine over a roughly 100-year period from 1890 and 1988. Consistent with the notion that industrialization is associated with time pressures, perceived time scarcity, and concern about precise measurement and efficient use of time (Lewis and Weigert, 1981; Zerubavel, 1982), they found increasing advertiser emphasis on time-related concerns and product benefits. They also found the characteristics of time-oriented advertising to vary over the decades, reflecting corollary societal values and trends.

Advertising both reflects and influences societal values (Fox, 1990; Pollay, 1984, 1986). As observed by Pollay (1985, p. 24), one role of advertising is to articulate the “rationale for consumption.” The present study updates Gross and Sheth’s (1989) analysis, warranted because consumer and societal developments since the mid-1980s have led to probable further evolution of consumers’ time-oriented concerns. As advertisers perceive changes in both general and specific concerns with time, it is expected they will reflect them in advertising appeals.

Four developments that might lead to changing consumer concerns are discussed in the following section. The list is not represented as exhaustive and the section is not represented as presenting formal hypotheses to be tested. Rather, the discussion merely presents *a priori* observations and propositions giving rise to the current study.

RECENT DEVELOPMENTS AND RELATED PROPOSITIONS

Slowed Growth of Women’s Workforce Participation

Gross and Sheth (1989) observed that, as compared with earlier decades, ads appearing in the *LHJ* during the 1960s and 1970s showed pronounced emphasis on the ability of products to enhance time productivity. Women, and particularly married women with young children, entered the U.S. workforce in unprecedented numbers (Hayghe, 1990, 1997; Hayghe and Bianchi, 1994). Society felt the shock of women taking on new roles and aspiring to new statuses while also attempting to maintain traditional homemaker roles. Advertisers emphasized that products could relieve working wives’ busy schedules. This was consistent with economic views of time emphasizing the substitution of goods for time spent in housework (Becker 1965). Numerous researchers investigated the effects of changing women’s roles on the consumption of convenience products (e.g., Nickols and Fox, 1983; Reilly, 1982).

During subsequent decades it became the norm for wives and mothers to be employed (Fullerton, 1999; U.S. Department of Labor, 1999, 2000). Family structures and roles evolved in support of this expectation (Robinson and Godbey, 1997). By the 1980s,

segments of the female population most likely to join the workforce had largely done so, and so growth in women’s labor force participation slowed (Hayghe, 1997). Though working women still felt time-pressured, society became more accustomed to the demands of juggling work and family. What were previously experienced as new time pressures became expected. Convenience products were used routinely, and less perceived as representing fresh solutions to family time pressures.

Gross and Sheth observed in their analysis of early-1980s advertising what may have been the beginning of advertisers placing less emphasis on products as time-saving solutions for the new female workforce. Whereas earlier advertising had explicitly “sold” consumers on the necessity of using time-saving products, often providing a fully articulated rationale, the tone of 1980s time-oriented ads implied that consumers had already integrated time-saving products into their lives. The expectation that this trend should continue gives rise to Proposition 1.

Proposition 1: Advertisers will de-emphasize explicit rationalization of time-saving product benefits, particularly as they pertain to pressures faced by working wives.

Widespread Acceptance of Convenience-Oriented Products

One purpose of advertising is to articulate the rationale for consumption (Pollay 1985). Thus, as new time- and labor-saving products were introduced over the past century, advertisers explicitly urged readers that the use of these products could improve their lives. Gross and Sheth (1989) observed that ads accompanying the introduction of vacuums, washing machines, prepared foods, and the like typically emphasized time savings as the most salient product benefit. Sometimes the desire to save time was seen as controversial, and advertisers promoting what amounted to a lifestyle change no doubt felt challenged to convince consumers of the acceptability of using products to save time. For example, convenience foods initially met with resistance as consumers associated their use with laziness (Haire, 1950).

In contrast, consumers today readily accept and use a wide array of convenience-oriented products (Berry, 1990). Consumers buy them *specifically* because they are fast to use. Thus, other appeals (e.g., health and taste in the case of convenience foods, efficacy in the case of appliances) may now be more salient than time in differentiating these products. These observations give rise to Proposition 2.

Proposition 2: With saving time now an accepted and well-understood benefit, advertisers will emphasize other benefits even when promoting products perceived and traditionally advertised as time-saving.

Post-Industrial Society

The time period covered by Gross and Sheth’s analysis was one in which the U.S. experienced a rather gradual transformation from an agrarian and largely rural economy to an advanced industrial and urbanized society. By contrast, the 1980s and 1990s saw a comparatively sudden transformation from a U.S. economy dependent on manufacturing to one variously called an information-, service-, or post-industrial economy. It is said the U.S. experienced a technological and information revolution akin to, but more accelerated than, the earlier industrial revolution. Foreseeing

the coming of a post-industrial economy, social commentators such as Bell (1973) and Toffler (1980) predicted less dependence on the precise accounting of time so necessary in a manufacturing economy. As such, they predicted consumers would enjoy a return to more personal discretion over time.

To some degree and for some consumers this prediction has come to pass. However, consumers generally report feeling no less time pressured. Recent polls (e.g., Roper Center, 1998) consistently report a sizable percentage responding that time pressure is getting worse. Consumers have also acquired a new time-oriented vocabulary indicating a new type of, and perhaps even heightened, time sensitivity. Terms such as “multitasking” and “24-7” suggest not a lessening of perceived time pressure, but rather possibly time pressure of a different type. Consumers increasingly blur the distinctions between personal and work time (Oechsle and Geissler, 2003). It might be argued consumers are adjusting to a new and perhaps uncomfortable time reckoning based on polychronicity (combining activities simultaneously, and possibly blurring the distinctions between work and discretionary time) as compared with monochronic time reckoning (doing one thing at a time and dividing time into discrete units) that has traditionally characterized industrialized societies (Graham, 1981; Kaufman et al., 1991). Various authors have suggested that today’s consumers feel *more* pressured due to a sense of time fragmentation and inability to immerse oneself in just one activity (e.g., Robinson and Godbey, 1997). These trends give rise to expectations associated with Proposition 3.

Proposition 3: Advertisers expressing empathy with consumers’ time concerns will increasingly reflect concerns associated with the post-industrial society (e.g., desires for leisure time distinct from work time, and pressures associated with multitasking or polychronicity).

Living in the Present and Desire for Balanced Use of Time

Popular media suggest that, as compared with the past, consumers today express a greater longing for balanced and present-oriented lives. This may be in reaction to earlier forces that rendered the U.S. time-oriented. For example, as compared with older cohorts, Generation X has been observed to be less willing to sacrifice current family and personal pursuits for the sake of longer-term career aspirations (Ritchie, 1995). Working mothers have largely abandoned the so-called “superwoman myth,” and expect to re-balance priorities as they pass through various life stages. Fathers express the desire to nurture as well as provide economically for their families. Regular columns on “Work and Family” in the *Wall Street Journal* (Schellenbarger, 1999) focus on the desire of even hard-driving professionals to establish balance between career, family, and personal pursuits; and report that many say they would choose more free time over money.

The orientation toward living a balanced and present-oriented life was not discussed in Gross and Sheth’s (1989) analysis of time-oriented ads. However, it is readily seen in ads today. For example, a recent real estate ad stated, “The rest of your life isn’t somewhere in the future. Or what remains after you’ve worked your heart out. It’s a part of every day if you strike the right balance.” This apparent emphasis on balance gives rise to Proposition 4.

Proposition 4: Advertisers will increasingly appeal to consumers’ desires for balanced time use, focusing on making time available for personal pursuits; and products will increasingly be promoted as enhancing scarce leisure time.

RESEARCH METHOD

Prior to embarking on the current study, a pilot study was conducted in which ads from recent issues of general interest and women’s magazines were analyzed. Of 589 ads analyzed, 122 (21%) were judged to be time-oriented. The pilot study confirmed that time-oriented advertising is still prevalent. Further, all coding categories used by Gross and Sheth were observed. The results of the pilot study, coupled with observations discussed in the previous section, led to the development of additional coding categories.

Because the purpose was to extend Gross and Sheth’s (1989) analysis, the present study used similar methodology. As in their investigation, the current study analyzed advertising appearing in the *LHJ*. Gross and Sheth explained their rationale for choosing magazine advertising in general (based on content characteristics and accessibility) and *LHJ* advertising in particular (based on the magazine’s prominence, audience characteristics, editorial and audience stability, and history of use in documenting social and marketing trends). They noted in 1989 that *LHJ* had ranked among the top ten circulated magazines since its inception. According to Magazine Publishers of America, it was ranked ninth in 1998. The magazine’s target audience and editorial emphasis have remained stable, with focus on the practical work- and family-oriented pursuits of American women.

Gross and Sheth analyzed advertising appearing over ten decades from 1883 to 1988, and examined three issues per decade. As shown in Table 1, the current investigation began with 1986 issues and continued through 2000, thus overlapping slightly with the previous analysis. Three to six randomly selected issues were sampled during each even-numbered year, allowing analysis of at minimum 300 ads per sampled year. In total, 31 issues and 3,012 ads were analyzed. All ads one-fourth page or larger were studied. Each was examined first to determine if it reflected an orientation toward time. Ads containing no time-oriented elements were simply tallied and received no further analysis. Roughly 19 percent (561 ads) were judged to contain time-oriented elements and were subjected to further analysis.

Each ad was examined to determine if it used time as a primary appeal. Time-oriented elements were judged to be primary if headlined, listed first and with prominence, presented in larger/bolder type, illustrated through photograph or drawing, afforded a substantial proportion of copy, and/or otherwise emphasized as prominent. Two or more appeals could be judged to be primary when they received relatively equal emphasis (e.g., quick and delicious). Thus, to be coded as primary, an ad did not have to use time as *the* primary appeal, but only as *a* primary appeal. Time-oriented appeals were considered secondary in the absence of such observations (e.g., when merely included as one of several appeals in the fine print). A few ads were judged to use time-oriented appeals in only a tertiary manner.

Following the coding of each time-oriented ad as primary, secondary, or tertiary, ads were further coded based on categories of appeal. The following categories developed by Gross and Sheth (1989, p. 78) were used as *a priori* categories:

- Presents the advertised product as *fast to use*.
- Presents the advertised product as a means of *saving time*.
- Presents the *consumer as busy* and as regarding *time as scarce/valuable*.
- Specifies the *amount of time* required to use the product.
- Presents the product as a means of making *double use of time*.
- Presents the product as a means of *escaping a typically time-oriented lifestyle*.

TABLE 1
Proportion of Ads Containing Time-Oriented Appeals
(Sampled Issues 1986-2000)

Year	Number of Issues Sampled	Number of Ads Analyzed	% Containing Time-Oriented Appeal(s)	% of Time-Oriented Ads Using a Time-Oriented Appeal as Primary
1986	3	348	18.4%	45.3%
1988	3	345	17.4	51.7
1990	5	469	16.2	57.9
1992	3	362	13.8	44.0
1994	4	362	16.9	52.5
1996	4	341	21.1	45.8
1998	3	315	21.6	52.9
1999-2000	6	470	23.4	54.5
Total		3,012		

TABLE 2
Proportion of Time-Oriented Ads Using Each Coded Category of Appeal

Category	1986	1988	1990	1992	1994	1996	1998	1999-2000
Fast to use	58%	58%	78%	70%	75%	44%	54%	48%
Saves time	20	23	28	24	49	24	27	17
Presents consumer as busy	19	27	13	26	31	19	31	26
Specifies amount of time required	23	17	38	30	53	33	24	22
Double use of time	2	2	1	2	3	6	3	2
Escape time-oriented lifestyle	5	0	5	2	5	11	9	16
Desire for balance	0	3	4	8	7	6	16	22
Value scarce leisure time	5	7	5	2	10	10	15	17
Control over time	6	7	11	2	10	3	7	10
Immediate/timely results	28	30	20	12	8	15	19	18

Additionally, four new categories were identified. The first three were informed by the observations discussed at the beginning of this paper and were observed during the pilot study. The fourth was observed in the pilot study and believed to reflect a time benefit/concern not specifically addressed by the other categories.

- Represents a desire to achieve *balance between work and non-work pursuits* (i.e., leisure, time for self and personal interests, time for family and relationships).
- Represents a high *value* placed on scarce *leisure* time.
- Presents benefits related to consumers' desires for *control over time*.
- Presents the product as providing *immediate or timely results*.

Coding was conducted by the author and by a trained but independent judge (the same methodology used by Gross and Sheth). Few disagreements occurred between coders, and all were resolved through discussion. The author also replicated the coding a few weeks following the initial analysis to ensure test-retest reliability. Reliability rates were slightly lower than those reported by Gross and Sheth, but all were greater than the 85 percent and most exceeded 90 percent.

RESULTS

Table 1 shows the proportion of ads from each sampled year judged to contain time-oriented appeals. The proportions from 1986 and 1988 (18% and 17%, respectively) are comparable with those reported by Gross and Sheth for the late-1980s. During the early- to mid-1990s, the proportions declined somewhat, ranging from roughly 14 to 17 percent. This is consistent with the observations leading to Propositions 1 and 2. The proportions were greatest during the late-1990s, ranging from roughly 21 to 23 percent. Table 1 also shows the proportion of time-oriented ads using time as a primary appeal (roughly 45 to 55 percent) to be consistent with the high proportions found during the final years of the Gross and Sheth analysis.

Gross and Sheth (1989) observed that a wider range of time-oriented appeals was employed during the latter decades of their sample. The current analysis similarly found a wide range of appeals. The proportions of time-oriented ads using each category of appeal are presented in Table 2. Most notable, and consistent with Propositions 3 and 4, is the increased use of appeals coded as "desire for balance," "escape time-oriented lifestyle," and "value scarce leisure time." The appeals "fast to use," "saves time," and "amount of time," were used with most frequency during the early- to mid-1990s. Though no numerical trend is evident for the cat-

egory “presents the consumer as busy,” qualitative differences regarding this appeal are substantial and consistent with observations leading to Propositions 1 and 2. This is discussed in the following section. The nature of ads reflecting the categories “double use of time,” “immediate/timely results,” and “control over time” are also discussed.

DISCUSSION AND QUALITATIVE OBSERVATIONS

The 1980s

Gross and Sheth (1989, p. 81) observed that, in comparison with advertising from earlier decades, advertising during the 1980s:

... largely implies that consumers *expect* products to facilitate time savings and need not justify this expectation. Time-oriented concerns and benefits are communicated with unprecedented simplicity, suggesting time-orientation is a well-understood value.

Comparing ads from the 1980s sample with later ads, the trend toward simpler communication of time-oriented appeals appears to have continued. By later standards, even late-1980s advertising appeared copy-heavy. As compared with the more minimalist style evidenced in recent advertising, ads from this period contained more explicitly rationalized time-related claims.

As in the Gross and Sheth sample, a large proportion of ads from the 1980s presented the sponsors’ products as “fast to use.” For example, the Dirt Devil vacuum was promoted as allowing “quick clean-ups,” and Hershey’s chocolate advertised “quick and easy recipes.” Ads frequently made reference to “saving time.” Hunt’s canned sauces advertised, “all pre-simmered to save you cooking time.” Some ads implied that products saved time because they were “the fastest” or “faster” than other alternatives. For example, Hormel canned chili claimed “quicker to fix than a peanut butter and jelly sandwich.”

A large number of ads specified the short amount of time required to use the product. Stove Top stuffing, for example, advertised “ready in just 15 minutes.” Often the amount of time was headlined or featured as part of a time-saving recipe. Advertising for personal care products frequently specified an amount of time (e.g., Epilady promised smooth hair-free legs in “only a minute or two”). Many advertisers capitalized on time benefits associated with the microwave oven. Whirlpool offered the TimeMaster “because we know the value of your time;” and Pillsbury advertised “just 7 minutes in your microwave.”

Particularly prominent in the late-1980s were appeals to working women as being busy and as regarding time as scarce and valuable. For example, Legg’s hosiery was advertised as for “non-stop legs”... “throughout your hectic day.” This type of appeal was also sometimes communicated through testimonial. Advertising for Lightdays pantliners and ExLax laxatives featured working women discussing their busy lives.

Ads often appealed to the competing demands on women’s time. An ad for the Correctol laxative stated, “A woman’s day never seems to stop. Between family and work, time’s just not her own.” Nivea face cream stated, “You work hard at work, you work hard at home. You’re under a lot of pressure.” Ads also referred to busy families. Rubbermaid advertised its cookware as “perfect for families on the go,” and Black & Decker advertised the company’s small kitchen appliances by featuring a family “too busy for breakfast.”

Though more prevalent in more recent years, a few 1980s ads promoted products as providing control over time by allowing flexibility in scheduling. The Roto Rooter plumbing service adver-

tised “any time ... 24-hour service;” and Black & Decker promised “coffee’s ready when you are. Just set the 24-hour timer.” A few products promised consumers “double use of time.” The Black & Decker cordless can-opener was promoted as “leaving hands free to do other things around the kitchen.”

Perhaps appealing to demands for immediate gratification, many cosmetics and personal care products promised immediate or at least timely results. Revlon introduced a skin-care product as “the 10-day turnaround,” with results “ten days from today.” Coty introduced Overnight Success, pledging improved skin “in just three nights.” Weight loss products made similar claims; and over-the-counter medications emphasized that busy women need “fast relief.”

Finally, a few advertisers offered products as means to temporarily “escape a time-oriented lifestyle.” Royal Caribbean cruise lines enticed, “You can leave the pressure behind, and renew the energies sapped by all those years of full-speed-ahead.” As precursor to advertising themes more prevalent in the late-1990s, Parliament cigarettes were advertised as “the perfect recess ... a break from activity for rest and relaxation.”

The Early-1990s (1990-1994)

As compared with the majority of decades examined by Gross and Sheth, the early 1990s saw time-oriented appeals used with relatively high frequency. However, as shown in Table 1, the overall rate was lower than during the late-1980s. This is consistent with Proposition 1, which anticipated that explicit rationalization of time benefits might be de-emphasized as women’s workforce participation became routine and commonplace. It is also consistent with Proposition 2. The study found that convenience-food ads appearing during the early 1990s frequently omitted time-oriented claims or made them secondary in emphasis to such benefits as health, taste, and ease of preparation.

As shown in Table 2, all categories of appeal observed in 1980s ads were also observed in early-1990s ads. However, they occurred in different proportions and with different qualitative emphasis. Simple claims promoting products as “fast to use” were most prevalent. From 1990 through 1994, a substantial 70 to 78 percent of sampled time-oriented ads included this claim. For example, Del Monte canned fruits advertised “think quick, think delicious;” and Fantastik household cleaner promised a “quick fix,” making “short work [of] hardcore messes.”

Many ads promising time saved also specified the “amount of time required.” Food advertisers very frequently included this appeal. For example, Hormel advertised “heats in two minutes so you can put your favorite dish on the table in record time,” and Betty Crocker advertised “non-stop from simmer to sensational ... [ready] in 15 minutes.” Non-food product advertisers used it too. Johnson & Johnson introduced a home cholesterol test requiring “only 15 minutes;” and Quick Lube offered car service in “29 minutes guaranteed.”

Sometimes the benefit of saving time was communicated by drawing relatively subtle comparisons with alternative brands. Bounty adopted the now long-running slogan “the quicker picker upper.” Others made more direct claims. Swift headlined “If you have to wait around for the great taste of sausage, you bought the wrong sausage.” Some food ads emphasized that consumers can save time while appearing to have prepared a time-consuming dish. Ore-Ida claimed, “even though they look like you spent all day in the kitchen, you can prepare them fast, fast, fast.”

Most time-oriented food ads used simple claims as compared with those from the 1980s, often communicating “fast to use” and “time-saving” benefits by merely stating the required preparation time or by offering quick recipes. Quaker oatmeal straightfor-

wardly claimed “cooks in 1 minute;” and Tyson chicken featured recipes with such headlines as “From 0 to fajitas in 8 minutes flat.” Others merely presented recipes with “prep time” and “cook time” prominently featured in bolded and blocked print.

Advertisers during the early 1990s continued to emphasize that consumers were busy. However, the overall look and tone of such ads differed from those appearing in the 1980s. Substantially less copy was devoted to explaining *why* the consumer was busy, and ads contained fewer specific references to women in the workforce. Advertisers may have perceived that women had become accustomed to juggling work and family and so those pressures no longer needed to be described. For example, whereas 1980s ads for the Correctol laxative specifically delineated the various components of a busy woman’s life, in 1992 the company simply stated “with all the demands in a woman’s life.” Food advertisers often depicted consumers as too busy to cook but did so with little explanation. Campbell’s soups offered “recipes that fit your busy lifestyle,” and Quaker oatmeal headlined “for moms who have a lot of love but not a lot of time.”

A few ads depicted consumers as not only busy but as also desiring more balanced use of time. S&W advertised its canned vegetables and sauces with “quick” recipes for “when you have more to do than dinner.” The ad promised “will get you out of the kitchen and back to your family in less than 15 minutes.” A few offered temporary reprieve from a typically time-pressured lifestyle. An ad for the Jeep sport utility vehicle read “designed to leave the hassles and commitments of everyday life behind.”

Some advertisers emphasized control over time and its scheduling. First Response and Johnson & Johnson promoted the convenience of in-home medical tests by stressing that they require no pre-scheduled and time-consuming doctors’ office visits. Similarly, the discount store Kmart highlighted the convenience of consulting an in-store pharmacist “any time.” As compared with the 1980s sample, fewer early-1990s ads emphasized immediate or timely results. Particularly noticeable was the decreased emphasis among cosmetics and skin-care advertisers.

Late-1990s (1996-2000)

A marked change was observed in the most recent sample. Though “fast to use,” “saves time” and “amount of time” appeals continued to be popular, increased proportions also reflected a desire for balanced use of time, appreciation of scarce leisure time, and desire to escape a typically time-oriented life-style. Advertising more frequently articulated consumers’ desires for balance between time for work and personal pursuits. Some presented products as allowing the savoring of small increments of leisure time. These focuses are consistent with Propositions 3 and 4. Further, consistent with Propositions 1 and 2, time-concerns were presented with less explanation and rationalization, and some advertisers who earlier consistently addressed the time-concerns of busy working mothers (e.g., Hunts Manwich sauces) used time in only a portion of their ads.

In general, food advertisers in the late 1990s tended toward minimalist execution of time-oriented appeals. Consistent with Proposition 2, time appeals were frequently secondary to nutrition or taste appeals. Some ads simply featured large product photographs with short headlines such as “quick and hearty” and “immediate gratification.” Numerous food brands (e.g., Campbell’s, French’s, Eagle, Jell-O, Comstock, Baker’s) merely presented recipes with close-up photographs, headlines such as “quick dinner recipes,” and “prep/cook time” prominently featured.

As compared with the early-1990s sample, there was a noticeable increase in the number of personal care products using “fast to use,” “saves time,” and “amount of time” appeals. New formula-

tions were promoted as faster to apply or as saving time by allowing substitution of one product for two. A wide range of other product categories also emphasized speed and saving time. For example, Dryel home dry cleaning claimed to require “only 30 minutes.” Whirlpool advertised its clothes dryer by stating that “drying clothes is a job that’s never finished but now it can be an *easier, simpler, quicker* job that’s never finished.”

As in earlier periods, advertisers in the late-1990s offered time-saving tips for working mothers. However, there was a new emphasis on family members being self-reliant. An ad sponsored by America’s Dairy Farmers featured the headline “Uh-oh, mom’s working late. Cheese to the rescue,” implying dad and kids would prepare dinner. A few portrayed the busy woman juggling work and family demands. Schilling seasonings presented the scenario “Your client cut your deadline. At least dinner can go as planned . . . ready in just 25 minutes.” However, more often the ads did not specify *why* the consumer was busy. For example, Campbell’s soups asked, “only have a pinch of time?” without explaining why the consumer would be time pressured.

Ads from the late-1990s sometimes specifically articulated control over time as a benefit. The online health site, Selfcare.com, advertised, “because you can’t squeeze 30 minutes of questions into a 10-minute doctors visit.” The office supply store Office Depot highlighted products that “today’s busy woman needs,” emphasizing “24-hour ordering” and “everything you need, when you need it.” Several sampled ads offered consumers “double use of time” by freeing them from monitoring household tasks. Reynold’s cooking bags claimed “just put [dinner] in an oven bag and forget about it.” Whirlpool advertised “laundry is a fact of life, but it doesn’t have to *be* your life.” Sometimes the promotion of double use of time was accompanied by suggesting the product could provide the reprieve of a few moments leisure or some “balance” between work and personal time. An ad for the Whirlpool dishwasher pictured a woman relaxing in a bath, and read “virtually eliminates soaking . . . as for all that soaking, you might want to save it for yourself.”

As in earlier periods, ads from the late-1990s expressed empathy regarding time pressure and acknowledged that consumers regard time as scarce and valuable. Most used minimal copy to articulate the nature of consumers’ time pressures. Liz Claiborne clothing simply asked “A full day ahead? Are you dressed for it?” In contrast, several ads portraying consumers as busy were quite copy-heavy, suggesting a return to the practice of detailing the specific sources of time pressure. However, unlike the earlier ads, the more recent ads treated the topic with humor. While sensitive to time demands, the ads expressed a sense of amused resignation. As an example, the department store retailer J. C. Penney humorously asked:

“Can you type 60 words a minute, pay bills, fix a hangnail, call your best friend, finish an expense report, call your child’s teacher, organize your calendar, balance your checkbook, call your mother, fight with your mother, meditate, solve the dinner dilemma, pick up your husband’s dry cleaning, make hotel reservations, survive a step class, eat your tuna sandwich and repair a run in your hose during the 15 minutes you have for lunch?”

An ad for Wisk liquid detergent began “the 10 million thousand things we have to do everyday,” and listed roughly 150 humorously stated tasks, goals, and interruptions, including “make a list of a million other things to do.”

Many recent ads portraying the consumer as busy offered the advertised product as a brief reprieve from a typically time-pressed lifestyle, with leisure portrayed as an occasional “stolen” moment.

As shown in Table 2, an increased proportion of time-oriented advertising has used “escape” and “value scarce leisure time” appeals. Nips candies depicted a harried office worker juggling phones and a spewing fax with the headline, “Had enough? Have a Nips.” Nivea skin care products promised, “it makes a five-minute shower feel like a spa.” An ad for Coca Cola’s caffeine-free cola showed forsaken reading material next to a hammock and headlined “there are times you don’t want caffeine.”

Such appeals have also been combined with appeals to the “desire for balance” (see Table 2). While stressing that consumers are busy, ads encouraged readers to occasionally slow down. For example, an ad for Mattel Barbie Doll Collectibles read “You graduated at the top of your class, married . . . , had 2.3 children, and just made partner at the firm. . . . It’s time to play. Take a breath. Treat yourself.” An ad for General Foods International Coffees read, “It’s that moment when the world becomes still and the most pressing thing you have to do is nothing.” Ads for Maxwell House coffee read “Study a cloud. Finish a novel in one sitting;” and “Stay in the bath until your toes wrinkle. Finish the crossword puzzle.” Some advertisers simply expressed empathy. Lee jeans headlined “what women dream about,” indicating 82 percent dream about “more free time.” An L.L. Bean ad read, “To do: Throw out to do list.”

Similar to several ads sampled from the 1980s but nearly absent in the early-1990s sample, the late-1990s sample contained ads emphasizing the busy woman’s need to “keep going.” These ads usually also suggested the benefits “immediate results” and “control over time.” For example, Vicks cold medicine depicted women who had “worked nonstop all day,” and concluded “keeps on going so you can too.” Emphasis on “immediate/timely results” was also seen in ads for exercise and weight-loss products. Finally, though the proportions were lower than in the 1980s, the late-1990s sample included cosmetics and skin-care ads promising results in a specific amount of time.

CONCLUSION

This study extended prior work by Gross and Sheth (1989). The study analyzed advertising appearing from the mid-1980s through the year 2000. As such, it examined advertising produced during in a period during which women’s workforce participation became established as the norm, during which convenience-oriented products were broadly accepted and routinely used, and during which the U.S. was largely transformed from an industrial to a post-industrial economy. These factors, as well as observations regarding consumer desire for balanced time use, led to interest in an updated analysis of time-oriented advertising.

The present study found, first, that advertisers have continued to use time-oriented appeals, including, “fast to use,” “saves time,” and “amount of time” appeals. However, consistent with observations leading to Propositions 1 and 2, these appeals were often communicated more simply during later years, and they represented lesser proportions of time-oriented advertising. Advertisers also continued to portray busy and time-scarce lifestyles, often expressing empathy regarding consumer time pressure. However, consistent with Proposition 1, ads from the early-1990s made less explicit reference to the juggling of work and family than did those from the 1980s. Further, though the late-1990s sample showed a return to the practice of detailing the causes for consumer time pressure, the later ads treated the topic with humor.

Perhaps the most significant change was an enlarged emphasis on consumer desire to achieve balance in use of time. Recent ads reflected a sensibility toward living a balanced life involving time for self and personal relationships. Along with the focus on balance is an increased emphasis on the value placed on scarce leisure time.

Leisure was sometimes presented as only a brief and “stolen” respite, and products were advertised as allowing temporary reprieve from a typically time-pressured lifestyle. These changes are consistent with observations that led to Propositions 3 and 4.

This study represents an initial inquiry chronicling *observed* advertising appeals. In presenting these findings, the author does not intend to suggest that consumers necessarily perceived the meanings of the ads in the ways suggested by the study. The analysis is based on interpretations of meaning. Though coders interpreted the ads quite consistently, this does not mean that target audiences would necessarily do so. A promising area for future inquiry is to collect consumer interpretations of time-oriented ads.

Does Crime Pay For Violent Program-Embedded Ads?

Olivier Droulers, C.R.E.M. (UMR CNRS C 6211), University of Rennes
Bernard Roulet, C.R.E.M. (UMR CNRS C 6211), University of Rennes

ABSTRACT

This paper aims at studying the impact of emotional context in television programs on ad memorization. Many experimental works show that affect is an important factor to be considered, so as to better understand both consumer behavior in general and memorization phenomena in particular. Here, we partially replicate Bushman and Bonacci's (2002) recent work and invalidate their main findings, namely that emotionally neutral TV programs entail better ad memorization and retention, whereas we confirm the major role of arousal on memory consolidation processes, by showing significantly higher memory scores for violent programs.

INTRODUCTION

A television commercial never appears alone. It is embedded in a specific program. The impact of television program context on commercial effectiveness in terms of brand recall, attitude toward the ad (Aad), attitude toward the brand (Ab) or purchase intention (PI), is a relatively old research topic, as about 20 years ago, Soldow and Principe (1981) wrote: "Research provides inconclusive findings regarding the relationship between liking a program and commercial effectiveness". Since then, several studies have been conducted, bringing sometimes, as we shall see, divergent results. A recent publication (Bushman and Bonacci, 2002) addresses the impact of violent programs on ad memory. In the advertising research field regarding the effects of program context on advertising effectiveness, the specific theme of violence is important because it has not been largely studied and it is frequently displayed on TV screens. Media responsibility is often evoked and a divide is perceptible between on the one hand, those who consider that media must be exonerated of any responsibility charge because they just relay or echo the actual surrounding violence which pervades society and those, on the other hand, who regard violence on TV as an aggravating factor. While media responsibility is debatable, the very presence of violence on television does not appear to be contested by anyone, as the violence index created by Gerbner proves it. This index, aimed at major networks, is calculated on a weekly basis of programming and published by the University of Pennsylvania's Annenberg School for Communication, since 1967. This quantitative index that allows international comparisons (the score was 130 for Canadian networks in 1994, vs. 169.5 for US networks) does take into account the number of violent acts but less easily assesses the magnitude or intensity of violence depicted in television shows. It nevertheless permits to state that violence pervades most TV shows (60% of aired programs contain scenes of violence; National Television Violence Study, 1997). Brand managers and advertising professionals must then question the influence of this type of program on advertising effectiveness, an issue that has been insufficiently addressed.

THEORETICAL FRAMEWORK AND HYPOTHESES

Emotion

Emotional states have been the subject of a growing and constant attention for more than two decades in consumer behavior research. However, as some authors have pointed out (Luomala and Laaksonen, 2000), a clear consensus has not been found yet, as far as the terminology and the taxonomy of the emotional states are

concerned. We will use here primarily two terms pertaining to emotional states: mood and emotion. The former refers to "constantly evolving general affective states felt by the individuals", while the latter represents "specific affective responses prompted by particular [consumption] experiences". Thus, moods "describe milder, more diffuse feeling states that both color and reflect the overall pattern of ongoing activity", whereas "by contrast, emotions indicate more intense, object-specific feeling states that respond to particular [consumption] activities" (Holbrook and Gardner, 2000). As for taxonomy, two great postures coexist: the discrete or categorical approach (Izard, 1977; Ekman, 1994) which considers that there are basic emotions (the number of which varies according to the authors) and the multidimensional or composite approach (Mehrabian and Russell, 1974, 1977; Russell, 1979) which posits that an emotional state is the result of underlying dimensions. According to these latter authors, affect is composed of two (or maybe three) distinct and orthogonal dimensions: arousal or activation (A) and the hedonic valence or pleasure (P), to which the concept of dominance (D) is sometimes added, this latter being related to the level of free-will, free movement or control of close environment.

Emotion and memory

Many research studies have confirmed the role of emotion or mood on memory, both at encoding and retrieval stages. Most authors agree to acknowledge that emotional stimuli are better memorized than neutral ones (Revelle and Loftus, 1992; Hamann *et al.*, 1999; McGaugh, 2000), whereas some contend that a reversal is possible for very strong emotional stimuli, which are not met in the advertising realm anyway (Kroeber-Riel, 1979). Besides, Friestad and Thorson (1986) showed the positive effect of emotion on memory and judgement, particularly for individuals denoting a strong emotional intensity, as described elsewhere (i.e. affect intensity for Moore, Harris and Chen, 1994). Other studies consider emotion not as a discrete variable but as composed of distinct dimensions: pleasure, arousal and dominance. Some authors privileged valence (Berg and Lippman, 2001), while others focused on activation levels (Srull, 1987).

Valence and memory. Goldberg and Gorn (1987) stressed that "while the literature suggests that mood has an assimilative effect on a variety of attitudes and behaviors, the literature on the effects of mood on recall is more mixed." But Isen (1984) suggested that "a positive mood may increase the efficiency of information processing", while in marketing research, Lee and Sternthal (1999) demonstrated that a positive emotion (i.e. of positive valence) was likely to enhance encoding, leading consequently to a better retrieval (recall or recognition). Beauregard *et al.* (2000) state that valence would have an impact on retrieval (recognition, particularly). Congruence, i.e. the same affective tone between current mood and valence-laden stimulus, would also play a significant part in evaluations or judgments (Blaney, 1986).

Arousal and memory. For other investigators, the real crucial emotional dimension could actually be not the valence (pleasure-displeasure), but rather arousal or activation (Bradley *et al.*, 1992), either purely physiological or emotional (Phaf and Wolters, 1986; Katzen Perez *et al.*, 2001). Thus, Blake, Varnhagen and Parent (2001), showed that memory enhancement at encoding is related to emotional arousal and this, *independently* of the polarity of valence.

In a same manner, Singh and Churchill (1987) emphasized that several reviewed works induced the conclusion that stimuli producing high arousal levels were likely to be better remembered (Archer and Margolin 1970; Kaplan and Kaplan 1968).

Most of these studies, even those implemented in marketing research, are conceived of by introducing / manipulating in a first stage a specific emotion, then by presenting target stimuli (stage 2) and finally by measuring the memorization of these stimuli (stage 3). However, this kind of studies, no matter how indicative of interesting paths they can be, are not sufficient to predict what the influence of a program on embedded ads will be, the latter having a specific status, likely to get—for instance—a very different attention according to individuals' knowledge and expectancies.

Effects of program-induced emotion on ad recall and recognition

The influence of a program's emotional tone on advertising effectiveness must be distinguished from another theme, not addressed here, i.e. the recourse and effectiveness of affect-laden commercials for brand persuasion, which has been largely scrutinized in marketing research (for a review, see Weinberger and Gulas, 1992). However, some authors have tied these two research domains, by studying the effects of emotional congruity between context and advertising, on ad memorization (Horn and McEwen, 1977; Perry *et al.*, 1997).

To address the subject of a program's emotional tone on advertising effectiveness, several approaches were chosen: (a) some researchers used TV programs containing specific emotional tonality: thriller or sit com (Kennedy 1971), sit com, documentary or action / adventure (Murphy Cunningham and Wilcox 1979), (b) other investigators varied the general emotional tone of the program: sad vs. happy shows (Golberg and Gorn 1987), humorous programs (Perry *et al.*, 1997), violent vs. neutral broadcasts (Bushman and Bonacci, 2002), (c) while others finally managed to manipulate the viewer's involvement level in function of:

- *program type*: high involving program vs. low involving program (Soldow et Principe 1981), or involving and non-involving programs (Norris and Colman, 1993)
- *advertising break location*: low vs. high elaboration locations (Lord and Burnkrant, 1988)
- *level of intrusiveness*: intrusive vs. non intrusive breaks (Tavassoli, Schultz and Fitzsimons, 1995)
- *program specificity*: involvement or not toward soccer games (Pham, 1992), or toward Super Bowl game (Pavelchak, Antil and Munch, 1988).

Dependant variables mainly observed in studies, may include memory scores in terms of free / cued recall or recognition (Kennedy, 1971; Soldow and Principe, 1981; Goldberg and Gorn 1987; Lord and Burnkrant, 1988; Pavelchak, Antil and Munch, 1988; Norris and Colman, 1992; Pham, 1992; Tavassoli, Shultz and Fitzsimons, 1995), attitude toward advertising (Kennedy, 1971; Soldow and Principe, 1981; Goldberg and Gorn, 1987; Tavassoli, Shultz and Fitzsimons, 1995), attitude toward the brand (Kennedy, 1971; Norris and Colman, 1992) or purchase intentions (Kennedy, 1971; Soldow and Principe, 1981; Goldberg and Gorn, 1987).

If one focuses on memory score, usual instrument for measuring ad effectiveness, results often differ for various independent variables. For some researchers, an increase in arousal entails a better ad effectiveness (Singh and Churchill, 1987). Others, conversely, record opposite results: for Pavelchak, Antil and Munch (1988), "*day-after recall is better when arousal is low*"; Lord and Burnkrant (1988) indicate a better memorization when commer-

cial are inserted in a program setting characterized by low levels of elaboration, while Pham (1992) shows that "*high arousal entails lower recognition scores*". Others, finally, underscore the absence of arousal level effect on ad memory scores (Mattes and Cantor, 1982). As far as involvement is concerned, while Krugman (1983) writes: "*involvement with advertising tends to be consistent with interest in the editorial environment*", Norris and Coleman (1993) note that the more subjects are involved, the less they remember commercials. Meanwhile, Tavassoli, Shultz and Fitzsimons (1995) announce a more complex relationship: "*memory scores are better under moderate as compared to low and high levels of program involvement*", as well as Pham (1992), who declares that "*effect of felt involvement on the recognition is curvilinear*". One of the main reasons which is given to explain these disparities is the fact that "*in many experiments, no attempt has been made to control for prior exposure to the advertising materials*" (Norris and Coleman, 1993). Notice that this control is sometimes undertaken but seems insufficient. Indeed, when a subject is simply requested to say if he already saw a commercial (yes or no), the "yes" answer does not give any indication on the number of ad exposures prior to the experiment. But this point is particularly important insofar as memory scores are concerned and collected.

Advertisers' main focus on the optimization of budgets, the discrepancies in results between various studies and the heavy presence of violence on television (Bushman and Bonacci, 2002; p 558), all these reasons argue for a thorough study of the influence of violent programs on advertising effectiveness.

It is legitimate to presume that exposure to a violent program entails an increase in arousal, both on physiological and affective sides. This statement will be evaluated here by comparing the subject's mood before and after exposure to the program with Mehrabian and Russell's PAD scale (1977). Henceforth, if one agrees with the statement that there is a positive relationship between an arousal level increase and memory—i.e. a high activation enhances or facilitates memorization process—then the following hypothesis may be set forth:

H1: Ads embedded in a violent program will be better recalled than ads in a neutral, low-involving program.

Should one agree with the belief that there is a negative relationship between an arousal level increase and memory—a strong activation is detrimental to memory consolidation (e.g. Pavelchak, Antil and Munch, 1988)—then the alternative hypothesis should be proposed:

H2: Ads inserted in a neutral, low-involving program are likely to be better recalled than those inserted in a violent or arousing context.

METHOD

The experiment consisted in exposing subjects to commercials embedded in neutral or violent programs, edited on video cassettes, and in asking them after the exposure to carry out tasks of explicit memorization (recall and recognition).

Stimuli selection

In this experiment, two types of stimuli have been elaborated and tested. The first type regards TV program contexts, for which we pre-selected movie or documentary clips to subsequently mimic television programs. The second type of stimuli pertains to advertising material, i.e. commercials designed to be embedded together in the program as a commercial break.

Selection of programs: Before the experiment, a questionnaire was submitted to a jury of about 50 students, requesting them to remember and write down the name of movies they saw, containing violent scenes. Based on these statements, a pre-edited video was made, i.e. a cassette containing 12 clips of movies previously judged as “very violent”. Then another group of 47 students was asked to give an evaluation mark for each sequence, ranging from 1 (“really not violent at all”) to 10 (“really very violent”), so as to get an average mark for each violent clip or sequence. The first 8 sequences, having obtained the highest marks (“Saving private Ryan”, “Another day in paradise”, “Taxi driver”, “Apocalypse now”, “Lethal weapon 4”, “Blade runner” and “The devil’s advocate”), were selected for final editing. The “neutral” program, not jury-evaluated, was composed of 2 sequences extracted from 2 documentaries: one on the ancient tribes of Easter Island, the other on the future NASA Mars Explorer mission. Both sequences were devoid of violence. All selected sequences were digitally edited then copied on video VHS tapes. The two resulting programs on video cassettes both had a total duration of 31 minutes.

Selection of commercials: The selection of commercials responded to several criteria: (a) the tested subjects being students, advertised products had to be possibly consumed by this target, (b) they were to be pertinent for both men and women, and (c) in order to minimize as much as possible the effects of previous exposures to brands or advertisements, commercials aired in 1996 were chosen. Four brands and products portrayed in these commercials have since disappeared from the market: Mukti cereal bar, Aquavital shampoo, Vie Active deodorant and Le Roule cheese. The remaining four commercials were either (1) presumably unknown by students, due to marginal market shares, or (2) absent from main distributing networks, or (3) absent from mass media communication since 1996. These latter brands are: Metaspirine aspirin tablets, ADO house curtains, Quinotone tonic and Dr Scholl’s foot products. This methodological choice was voluntary made to get as close as possible to optimal experimental conditions, where subjects are exposed for the first time to professionally-shot commercials, promoting products of “a new brand”, so as to get both acceptable internal validity and external validity.

Main experiment

Subjects: Groups of subjects (N=357; mean age 19.6 years; 64.7% were female) were randomly assigned to one of the two experimental conditions—neutral (N) or violent (V)—totaling 151 and 206 subjects, respectively. Disparity of groups (15 to 45 students) explains the discrepancy in sample size. All subjects were regularly-registered college students (mostly freshmen and sophomores) following courses in marketing or management. They voluntarily participated in the experiment, after having been plainly informed of the programs’ emotional tones, especially that of the “violence” (V) experimental condition.

Design of experiment: The type of program, neutral or violent, was manipulated in the experiment (between-subject factor). The subjects’ optimal stimulation level (OSL) and moods (pre- and post-exposure) represented the moderating variables. Right after the projection, subjects were asked to assess the program’s violence intensity and to remember the name of the advertised brands.

Procedure: The experiment was presented as part of a University research program on the evaluation of cable TV programs, regarding variety and tonality. Subjects in each group were informed that program duration was about 30 minutes; they were asked to stay relaxed, to watch the program as if at home, and to refrain nevertheless from talking with their neighbors. No mention was made of the advertisements. Before effective video projection,

participants were requested to fill in both the *Change Seeker Index* (CSI) scale from Steenkamp and Baumgartner (1995), consisting in seven 5-point items measuring the subject’s optimal stimulation level and the iconic *Self-Assessment Manikin* (SAM) scale (Bradley and Lang, 1994), comprising here two 9-point scales for tested mood dimensions (i.e. pleasure and arousal). This latter scale has the advantage to be quick to submit and non-verbal (Morris and McMullen, 1994; Morris *et al.*, 2002).

Groups of subjects (between 15 and 45), randomly assigned either to condition V or N, were invited to watch a 31-minute program. In both edited videos, the same advertisements were embedded in the middle of the program (13th minute) to form a single commercial break, totaling 2’43”. Considering that CRT monitors would not be efficient enough for the simultaneous testing of many subjects under satisfactory conditions of exposure, programs were projected using a “Barco” video projector on a wide screen, equipped with stereo loudspeakers. Immediately afterward viewing, subjects were asked to: (1) to fill in the SAM scale, to express their post-exposure mood, (2) to indicate on a 10-point scale if the program shown was: “not boring at all—extremely boring” and “not violent at all—extremely violent”, (3) to write down as much as possible the brand names promoted in the commercials (immediate free recall task), during a maximum allotted time of 1’15”, (4) to indicate if they had previously seen one or more of the projected commercials, and to specify which ones, (5) to say on average, how many hours spent daily in front of the television set, (6) to estimate approximately the share of violent programs watched, (7) to recognize the 8 promoted brands within a list of 40 brands (immediate recognition task; maximum time: 1’15”). The 40 listed brands were presented in two different orders for each half of each sample.

RESULTS

Violence ratings: The evaluations of tested subjects are coherent with those obtained at the time of the pretest sessions and thus substantiate the previous choices of sequences, since the subjects exposed to the “V” condition evaluated the program as being significantly more violent than the other subjects from the “N” condition ($p < .0001$) (see Table 1).

Mood ratings: Mood self-evaluations of subjects, who were assigned either to V or N conditions, reveal that before presentation of stimulus, respective levels of pleasure (hedonic valence) or arousal (activation) did not significantly differ (respectively $p > .1$ and $p > .5$). Whereas after exposure, mood measures show a significant variation of subjects’ mood on both controlled dimensions (see Table 2), at the $p < .0001$ level.

Also, in each condition group, within-subject comparisons of dimension mean scores, before and after exposure to video stimulus, indicate that the nature of this exposure did entail a change in subjects’ mood (significant at the $p < .0001$ level). Subjects in neutral condition had both their pleasure and arousal levels decreased (they got bored), whereas subjects exposed to a violence-laden program saw their pleasure level plummet while their arousal level soared (they got mildly shocked).

Memory ratings: Results indicate that memory scores, both for immediate free recall and recognition, are significantly different between the two program conditions (see Table 3). As for the free (i.e. unaided) recall test, subjects who were exposed to a violent TV program remembered more advertised brands than those exposed to a neutral program ($p < .0001$). Again, regarding the recognition test, subjects exposed to the violent condition displayed a better recognition memory than the other group ($p < .05$): about 5.4 brands were recognized against 5.0, respectively.

TABLE 1
Experimental conditions evaluation scores

Scores	TV program type (experimental condition)	
	Violence	Neutral
Violent	8.41*	1.51
Boring	4.81 ^{ns}	4.73

*Significant at the .0001 level. Scores scaled from 1 (not at all) to 10 (extremely).

TABLE 2
Subjects' emotional states before and after stimulus presentation

Condition	Pleasure before	Arousal before	Pleasure after	Arousal after
Neutral	6.21	3.85	5.48	3.10
Violent	6.47	3.97	4.33	4.55
<i>F</i> -test (1, 357)	2.57	.39	45.49	59.04
<i>probability</i>	>.1	>.5	<.0001	<.0001

Scores scaled from 1 to 9 for both mood dimensions.

TABLE 3
Recall and recognition of brands by condition

Condition	Immediate free recall	Immediate recognition
Neutral	0.974	5.020
Violent	1.927	5.398
<i>F</i> -test (1, 357)	37.74	3.97
<i>Probability</i>	<.0001	<.05

Scores are average number of remembered brands (from 1 to 8) for both memory measures.

Consequently, H1 is validated and H2 is rejected. Besides, no significant difference was found for other antecedent or moderating variables, such as gender and optimal stimulation level. Other computations such as structural equation modeling will shortly be undertaken to determine the existence of any explanatory personal factors.

DISCUSSION

Results obtained in the present experiment—ad memory is enhanced in a context of violent vs. neutral programming—do not replicate Bushman and Bonacci's (2002), as for the "Violence" and "Neutral" conditions, since no "Sex" condition had been tested by the present authors. These results are nevertheless consistent with prevailing views of neuropsychology, who consider that emotional arousal, more than valence of the stimulus, is a key factor of memory enhancement at encoding or retrieval (Hamann *et al.*, 1999). This discrepancy may be explained by some differences in experimental procedures. *Firstly*, Bushman and Bonacci (2002) exposed their subjects to *one* continuous clip of a violent movie (for instance "La Femme Nikita" or "Millenium"), while we purposely

exposed our subjects to an editing composed of several successive violent movie clips, less regularly aired on TV. As a matter of fact, Bushman and Bonacci's (2002) violence score in V condition reaches 6.34 (from 1 "not violent at all" to 10 "extremely violent"), which may be considered as a moderate level. Using the same violence scale, our editing in V condition attains a score of 8.41. Therefore, this would mean that a mildly violent program would impair memory of embedded commercials, while a very violent program would enhance recall and recognition of inserted ads. This point has to be carefully and thoroughly addressed, to the extent that it would mean a curvilinear, "U"-shaped (and not inverted) relationship between arousal levels and strength of memory retention. *Secondly*, Bushman and Bonacci (2002) carried out memory strength evaluations (recall and recognition) right after exposure to stimulus but also a week after (Day 7). We had opted in a first stage for the same methodology but it soon appeared that the measurement of immediate recognition memory could inherently bias subsequent delayed recall and recognition memories (Haist, Shimamura and Squire 1992). To verify this point we compared, in an initial procedure, two 30-individual groups. Results unmistakably indi-

cate that delayed recall and recognition scores significantly differ according as these measures are preceded or not by an immediate recognition memory test. If a delayed measurement is needed, the adequate sequence should be: immediate recall, delayed recall and delayed recognition. Therefore, some memory results might be biased.

Besides, it is surprising that these authors did not detect any interaction between the mnemonic performance scores and the age of the subjects: “*there were no main effects or interactions for any of the demographic variables (i.e. sex, age, race) on any of the memory measures (p > .05)*” (Bushman and Bonacci, 2002; p 560). According to these authors, the older subjects, aged 50 to 54, show performances identical to those of the 18-24 year-olds, which is certainly soothing but little in agreement with present research on cognitive aging (Reuter-Lorenz, 2002; Daselaar *et al.*, 2003). Indeed, if it seems demonstrated that implicit memory effects resist fairly well to the effects of aging, it is conversely well established in psychology (Parkin and Streete, 1988) as well as in marketing (Hawkins and Yoon, 1998) that performances obtained during explicit memory tasks—such as free recall and recognition which are manipulated here by the two authors -, requiring voluntary and conscious retrieval of specific episodes, decline with age. Moreover, the quantity of to-be-remembered items (9 commercials in three separate breaks) leaves out any possible non-significant performance differences because of a too easy task for all subjects.

Finally, it appears precarious to use recent or current advertising material, as did Bushman and Bonacci (2002) even if, as a control check, they asked the subjects to say after exposure, if they had already seen before, one or more of these commercials (yes / no). The manipulation check appears weak since the “yes” answer does not indeed give any indication on the number of ad exposures preceding the experiment; some subjects will have been exposed one or twice, while others will have maybe dozens of time. It is also important that the consumer’s familiarity and loyalty with the advertised (current) brands be controlled. No question relates to the use, by the subjects, of the advertised brands. Beside any problem of commercial exposure evoked *supra*, it is obvious that the mere regular use of a brand will have a significant impact on its further memorization and accessibility (Kent and Allen, 1994).

LIMITATIONS

In this study, we show that embedding of commercials in a violent television program facilitates ad memory. This results were obtained with 18- to 25-year-olds, generally considered as large consumers and fans of violent programs or movies. The choice of this population segment seems substantiated or justified but it now appears necessary to attempt a replication of this study with other categories of age. Besides, as other researchers previously suggested (Horn and McEwen 1977; Blaney 1986), it would be useful to investigate the subject of emotional tone congruence between the television program and the embedded commercial: does a humorous commercial inserted in a violent program, for instance, yield a lower effectiveness than in a humorous program ?

IMPLICATIONS AND FUTURE RESEARCH

Beyond current marketing research agendas, violence is a societal issue of our times. Bushman previously stated that violence-laden programming on television was detrimental to an effective ad memorization: “*if the television program bleeds, memory for the advertisement recedes*” (Bushman and Philips, 2001). Our results are opposite: violence on television does not impair memorization in any way, but on the contrary, does enhance ad memory, via reinforced encoding and retention. In an unfortu-

nate sense, crime or violence does pay in the realm of television advertising. Two final comments emerge from this statement of divergence. Firstly, as previously underscored by increasing numbers of researchers, marketing particularly needs replication works (Hunter, 2001). The present study enters this category. Secondly, should violence in television programs entail—as we think—a better memorization of inserted commercials, through a heightened level of arousal and vigilance in the individual, we should then not expect in the near future any call for reduction or curtailment from national brands and media networks.

Using Market-Specific Symbols in Advertising to Attract Gays and Lesbians Without Alienating the Mainstream

Gillian K. Oakenfull, Miami University
Timothy B. Greenlee, Miami University

EXTENDED ABSTRACT

Why should marketers risk alienating heterosexual consumers by placing ads with gay content in mainstream media? First, an enormous proportion of gays and lesbians cannot be reached through gay media. While the number of advertisers who target the "Dream Market" in gay media continues to grow (Wall Street Journal 1999), a placement of an ad in *OUT* and *The Advocate*, the two most widely circulated gay magazines, will reach only 3% of the gay and lesbian population, at most (Poux 1998). Conversely, more than 90% of gay men and 82% of lesbians reportedly read mainstream magazines. Second, by bringing gay issues into the mainstream, marketers may stand to gain from the goodwill of gay and lesbian consumers who strive for the acceptance of gays and lesbians into mainstream society. Peñaloza (1996) contends that many gay and lesbian consumers consider their inclusion in marketplace activities as recognition of the progress of the gay social movement.

Thus, to provide advertisers with a better understanding of how to effectively cross-over into mainstream media with gay- and lesbian-targeted advertisements without alienating larger mainstream audiences, this study examines the responses of both heterosexual and homosexual consumers to advertising content that includes mainstream imagery, implicit gay and lesbian imagery, and explicit gay or lesbian imagery.

To date, firms that have used gay imagery in mainstream media have predominantly used depictions of gay males in their advertising, mirroring the enormous bias toward male-oriented advertising in gay and lesbian media (Oakenfull and Greenlee, 2000). While the use of gay male imagery may represent effective targeting in gay and lesbian media with a predominantly male readership, it may result in the highest risk of backlash from heterosexual audiences in mainstream media. Bhat, Leigh, and Wardlow (1999) found that mainstream consumers reacted less favorably to advertising depicting gay male imagery than advertising depicting heterosexual imagery. Drawing on research from the social sciences that suggests that heterosexuals have more positive attitudes toward lesbians than gay males, Oakenfull and Greenlee (Forthcoming) showed that these attitudes tend to be transferred to responses to gay and lesbian imagery in advertising. Hence, advertisers may reduce the potential for negative backlash from mainstream audiences by including depictions of lesbians rather than gay males in their advertising in mainstream media (Oakenfull and Greenlee (Forthcoming)).

However, while mainstream consumers may prefer lesbian imagery to gay imagery in advertising, marketers must consider whether the use of any type of explicit same-sex imagery would be received more negatively than a mainstream advertisement by mainstream consumers, thus alienating the majority for the sake of targeting the few. Despite the fact that heterosexual consumers may be more favorably disposed to advertising depicting lesbians than those with gay males (Oakenfull and Greenlee (Forthcoming)), drawing from Identity theory, we know that consumers respond less favorably to advertisements that do not reflect their self-identity (Jaffe 1991). Thus, we can expect mainstream consumers to fail to identify with advertising that contains explicitly gay or lesbian imagery, which will result in a relatively less favorable attitude toward the advertisement.

H1: Heterosexual consumers will have a more positive attitude toward advertisements with mainstream imagery than those with explicit gay male or explicit lesbian imagery.

The key to advertising to gays and lesbians within mainstream media without alienating heterosexual consumers may lie in the tenet that "gayness is in the eye of the beholder." As with many subcultures (Hebdige 1979), the gay subculture has developed "markers of gay identity" (Tharp 2001) such as clothes, symbols, language and appearance (Altman 1987, Kates 1998, Meyer 1994) that hold meaning to members of the subculture, while creating no meaning to those who have no knowledge of the subculture. Hence, advertisers may effectively reach both gays and lesbians in mainstream media with minimal risk of alienating heterosexuals by "implicit" gay and lesbian imagery such as gay iconography or symbolism (Peñaloza 1996, Grier and Brumbaugh 1999). One may also assume that those heterosexual consumers with a negative attitude toward homosexuality, and thus most likely to be offended by gay and lesbian content in advertising (Bhat, Leigh, and Wardlow 1999), would be least likely to identify or understand gay iconography. Additionally, given the exclusive nature of the message, the use of implicit gay and lesbian imagery in mainstream media has the characteristics of an "inside joke," allowing gay and lesbian consumers to feel bonded with the advertiser against less-informed mainstream adversaries (Peñaloza 1996). Thus, such a strategy would allow gay and lesbian consumers to identify with the advertising and will be received equally as well as advertising with explicit depictions of gay male or lesbian imagery.

Therefore, we can hypothesize the following:

H2: Heterosexual consumers will have a more positive attitude toward advertisements with implicit gay and lesbian imagery than those with explicit gay or lesbian imagery.

H3: Gay and Lesbian consumers will have a more positive attitude toward advertisements with implicit gay and lesbian imagery than those with mainstream imagery.

Method

Participants in the study included 118 self-identified homosexual adults, including 46 females and 68 males, and 134 heterosexual adults, 74 females and 60 males from five geographic regions of the United States. Participants were presented with the four advertisements—1) a mainstream advertisement, 2) an advertisement with implicit gay and lesbian imagery, 3) an advertisement with explicit gay male imagery, and 4) an advertisement with explicit lesbian imagery, and instructed to answer a three-item attitude toward the advertisement measure accompanying each advertisement.

Findings

This study shows that, while depictions of gay males and lesbians in advertising will effectively target gay and lesbian consumers, they will also result in an unfavorable response from mainstream consumers. The results of this study indicate that heterosexual consumers are more averse to advertisements depicting

gay males and lesbians than mainstream advertising content. However, while heterosexual consumers preferred advertisements with mainstream imagery to those with explicit gay or explicit lesbian imagery, advertisements containing implicit gay and lesbian imagery were received as well as those with mainstream imagery. Thus, it can be assumed that mainstream audiences were either unaware that the advertisement contained gay and lesbian imagery or responded more favorably to the more subtle content.

Gay and lesbian consumers have an equally favorable response to all types of gay- and lesbian-targeted advertising including those with implicit gay and lesbian imagery. Thus, by using implicit gay and lesbian imagery in advertising placed in mainstream media, marketers can appeal to gay and lesbian consumers in mainstream media with little risk of creating negative sentiments among heterosexual consumers.

If We Know the Difference What's the Harm? The Effects of Brand Equity Misappropriation and Dilution

Richard G. Netemeyer, University of Virginia

EXTENDED ABSTRACT

Recently, the United States Supreme Court ruled in favor of a small store against a world-famous lingerie manufacturer and retailer. The owners of the little shop, which sells lingerie and other "adult novelty" items, named their store "Victor's Secret." Shortly after opening, they were sued by Victoria's Secret, claiming protection of its brand name under the Federal Trademark Dilution Act of 1995. Trademark dilution refers to a decrease in brand equity (in the *senior brand*) that is created by the unauthorized use of the brand by a third party (the *junior brand*). Trademark dilution differs from the more familiar concept of trademark infringement in that it occurs in the absence of consumer confusion about the relationship between the senior and junior brands.

A key issue before the Court was the legal standard for proof in trademark dilution cases. The Court provided only broad boundaries within which the acceptable level of proof of dilution will ultimately be defined, ruling that evidence of mere association between the brands is insufficient, while evidence of lost sales or profits is not required.

In three experiments, we examine the use of brand knowledge accessibility measures and brand choice probabilities to demonstrate dilution and to examine moderators of its effects (cf. Morrin and Jacoby 2000). Dilution occurs when a senior brand name or its distinctive associations become less accessible in memory. These are changes in brand knowledge accessibility; specifically, reductions in *brand name accessibility* or *aspect accessibility*. In practical terms, consumers are then less likely to consider the brand (because the brand name is less likely to come to mind or to be quickly recognized on the shelf) and less likely to choose the brand (because it is less likely to be seen as possessing its distinctive aspects). Hence, changes in brand knowledge accessibility are followed by changes in brand choice probabilities.

We also use brand knowledge accessibility measures to examine reinforcement effects than can accrue to the senior brand and "leveraging" and "backfire" effects that can accrue to the junior brand. Reinforcement occurs when consumers' knowledge of the senior brand is reinforced rather than diluted by the presence of a junior brand. Leveraging occurs when the junior brand benefits by gaining some of the senior brand's associations (Swann and Davis 1994), while backfiring occurs when the junior brand is hindered in its attempt to create unique associations. Reinforcement effects are of special importance because they signal that the senior brand has become implicitly associated in consumers' minds with the junior brand. Even though reinforcement does not itself constitute dilution, it is a signal that the junior brand has gained the power to dilute the senior brand via any undesirable future actions (Swann and Davis 1994).

Following the pioneering efforts of Peterson, Smith, and Zerrillo (1999) and Morrin and Jacoby (2000), we derive our predictions from associative network theory (Anderson 1983). Dilution occurs when a junior brand and its associations compete with existing associations in the senior brand network and thereby reduce the accessibility of the senior brand name and its distinctive aspects. Therefore, we expect that dilution is most likely when the junior brand belongs to a dissimilar product category or has dissimi-

lar attribute associations. On the other hand, we expect that senior brand name accessibility and aspect accessibility increase when the junior brand belongs to a similar product category or has similar attribute associations, thereby reinforcing the senior brand's associations rather than diluting them.

Following the same logic, we expect that leveraging of a senior brand's equity by a junior brand (i.e., enhanced brand name and aspect accessibility) is likely when the junior brand's distinctive associations are similar to those of the senior brand, and that backfire effects (i.e., reduced brand name accessibility and aspect accessibility for the junior brand) is likely when the junior brand's distinctive associations are dissimilar to those of the senior brand.

Results of our three computer-administrated experiments generally support our conceptualization. In Experiment 1, we examine the effects of category similarity. The senior and junior brands are moderately similar in terms of attributes (one similar and one dissimilar attribute), but vary in terms of category similarity. As expected, senior brand associations are reinforced when category similarity is high; that is, brand name accessibility and attribute accessibility both increase. Also as expected, some senior brand associations are diluted when category similarity is low. Specifically, brand name accessibility decreases, although aspect accessibility is unaffected. Leveraging and backfire effects are also consistent with expectation. Specifically, junior brand name accessibility and aspect accessibility (for aspects that are similar to the senior brand) are increased with high category similarity and reduced with low category similarity.

In Experiment 2, we examine the moderating effects of attribute similarity, and find that junior brands with attributes that are dissimilar to those of the senior brand (i.e., two dissimilar attributes rather than one similar attribute and one dissimilar attribute as in Experiment 1) dilute the senior brand regardless of category similarity. Further, both brand name accessibility and aspect accessibility are affected. Hence, the extent of dilution effects depends upon the degree and type of dissimilarity between the junior and senior brands. The relative importance of category vs. attribute similarity deserves further systematic investigation.

Finally, in Experiment 3, we examine whether the dilution of brand knowledge observed in Experiments 1 and 2 is strong enough to carry over to choice. We examine how three highly familiar senior brands are affected by highly dissimilar (i.e., dissimilar category and attributes) junior brands. For example, we examine dilution effects for Big Red chewing gum (which is cinnamon flavored) when subjects are exposed to the junior brand Big Red snack bars with strawberry flavor. As expected, exposure to the junior brand significantly decreases choice of the senior brand.

Our work demonstrates measures of dilution that go beyond mere association between the junior and senior brands, which the Supreme Court has ruled as inadequate evidence of dilution. Instead, we show that the senior brand is less likely to be recalled or quickly recognized and that it is also less likely to be chosen. How might one use these measures in the marketplace? Dilution is demonstrated by showing weakened brand name and aspect accessibility (or their close correlates) or decreased choice that is attributable to the emergence of the junior brand. While we must rely on

correlational evidence, some patterns are strongly suggestive of dilution. For example, the relevant accessibilities and choice probabilities may be depressed only in geographical areas in which the junior brand has a presence. As another example, accessibilities and choice probabilities may be lowest among those who *subsequently* report awareness of the junior brand (to avoid the possibility of self-generated validity) (Feldman and Lynch 1988).

Strategic Brand Concept and Brand Architecture Strategy—A Proposed Model

Andreas Strebinger, Vienna University of Economics and Business Administration

ABSTRACT

Some of the most pressing brand-related problems concern the management of a system of several brands, i.e. brand architecture, rather than one individual brand. By integrating three fields of theory, (a) the theory of strategic brand concepts, (b) the theory of information processing, and (c) a typology of brand architecture strategies, this paper proposes an explorative instrument, BASE, from which to derive an appropriate brand architecture strategy.

INTRODUCTION

Some of the most pressing brand-related problems concern the management of a system of several brands rather than one individual brand, be it a portfolio of several brands in isolation (“House of Brands”, see Aaker and Joachimsthaler 2000) or a complex brand architecture of several connected subbrands or endorsed brands. There are a number of reasons why the brand architectures of many companies are becoming increasingly complex. Many product categories are in the maturity stage and consumer preferences are becoming increasingly heterogeneous, forcing companies towards a higher degree of product differentiation. Furthermore, mergers and acquisitions heighten the need to merge not only different corporate cultures, but also different brand portfolios in a way that makes good business sense. The Internet provides an opportunity to develop existing brands into e-enabled offline brands or to build pure e-brands. And finally, the increasing demands of shareholders have also heightened pressure to improve the efficiency of marketing, not least with a view to creating a cost-effective brand structure. Thus, many brand manufacturers are currently streamlining their brand portfolio.

Building on an analysis of existing literature, this article contributes to the theory of brand architecture management by combining three fields of theory, (a) the theory of strategic brand concepts (Park, Jaworski, and MacInnis 1986), (b) the theory of information processing, in particular dual-process models (e.g. Chaiken, Wood, and Eagly 1996; Epstein 1983; Petty and Cacioppo 1986), and (c) a typology of brand architecture strategies.

BRAND ARCHITECTURE STRATEGY

Brand-architecture strategy pertains to the “organizing structure of the brand portfolio” (Aaker and Joachimsthaler 2000, p. 134) and defines the number and roles of brand names that a company uses for its range of products and the target groups or target markets it serves (Aaker and Joachimsthaler 2000; Kapferer 1999; Keller 1998; Laforet and Saunders 1999). As for the number of brands, brand-architecture strategy ranges from a single brand for all products and target groups of a company to a strategy in which every single product carries its own brand name. Starting from a hypothetical matrix of four products and/or service categories (P_1 to P_4) and four target groups or markets in which the company operates (T_1 to T_4), there are five brand architecture strategies representing ideal types from which to select (see figure 1). A *corporate brand strategy* (subsequently abbreviated to “C-branding”) adopts a uniform brand for all product categories and target groups. In a *product brand strategy* (“P-branding”), each product category of the company has its own brand name which yields four different brand names. These P-brands have no recognizable connection for the customer. However, one and the same brand name is used for all target groups within the product category. A P-branding strategy can be based on a fine distinction between

product categories, resulting in product brands in the narrower sense, or to a more general classification of product categories (“line” or “range brands”, e.g. Kapferer 1999, p. 188). In a *target group brand strategy* (“T-branding”), the company targets each of its four target groups with a separate brand name, which stands for a number of products. With a *product and target-group-specific brand strategy* (“PT-branding”) each field in the matrix is given its own brand name which results in 16 different brands. And finally, in a *brand family strategy* (“F-branding”), hierarchically ranked brand names have a common endorser, together with a certain number of endorsed brands or subbrands with their own personality. These brand families can also include more than two hierarchical levels and differ from the C-branding strategy in that the subbrands are not merely given purely generic product descriptions, but have registered brand names, which are generally promoted individually. These subbrands can be P-brands, T-brands or PT-brands.

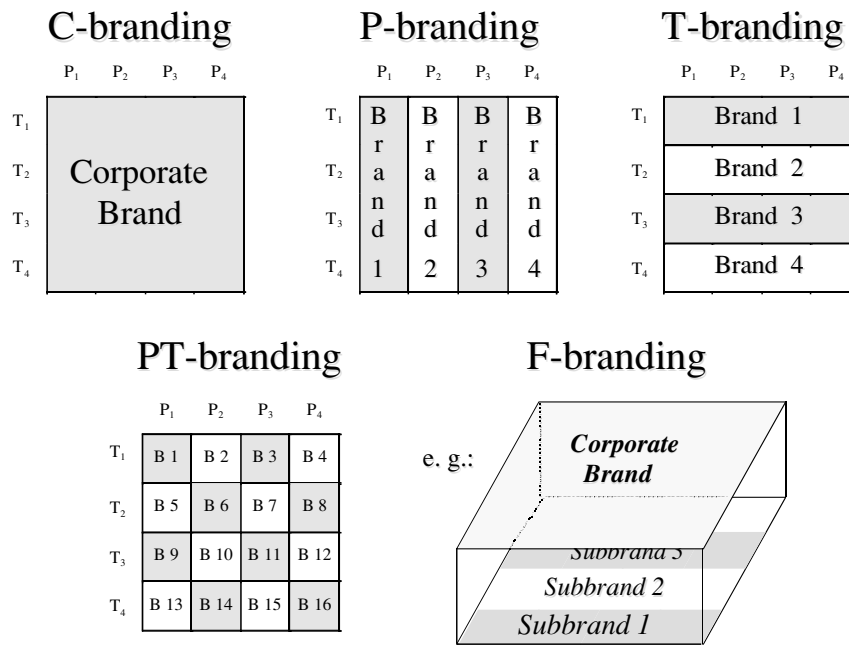

One of the core conclusions drawn from research to date is that brand architectures with a large number of brands such as P-branding, T-branding or—in extreme cases—PT-branding require compelling reasons (e.g., Aaker and Joachimsthaler 2000, p. 123; Kapferer 1999, p. 209), as more closely integrated brand architectures with fewer brands such as C-branding or F-branding generally offer a higher degree of efficiency and effectiveness (e.g., Esch 2003; Erdem and Sun 2002; Morrin 1999; Sander 1994; Smith and Park 1992; Swaminathan, Fox, and Reddy 2001). Based on the empirical findings of research on brand extension, the theory of strategic brand concepts (Park et al. 1986), and the theory of information processing, particularly dual-process models (e.g. Chaiken et al. 1996; Epstein 1983; Petty and Cacioppo 1986), this paper proposes a new model called BASE (“Brand-Architecture Strategy Explorer”), from which to derive an appropriate brand architecture strategy.

STRATEGIC BRAND CONCEPTS AND INFORMATION PROCESSING

As research on brand extensions illustrates, success not only depends on the perceived quality of the parent brand (e.g. Aaker and Keller 1990; Bottomley and Holden 2001), but also on the similarity of products (e.g. Sattler et al. 2002; Smith and Park 1992; Swaminathan et al. 2001; Taylor and Bearden 2002) and the transferability of abstract image components of the parent brand to the new product (e.g. Aaker and Keller 1990; Bottomley and Holden 2001; Bridges 1992; Broniarczyk and Alba 1994; Mayerhofer 1995; Park, Milberg, and Lawson 1991; Schweiger and Mazanec 1981). In fact, a good match between the strategic brand concept and the new product seems to contribute significantly to the success of a brand extension (Keller 1998, p. 510; Park et al. 1991). Park, Jaworski and MacInnis (1986) distinguish three strategic brand concepts—“functional”, “experiential” and “symbolic brands”, to which a fourth concept has been added here, “relational brands” (see figure 2). With a reasonable degree of plausibility, these four strategic brand concepts can be classified according to the motives and benefits as well as the predominant styles of thinking displayed by customers in their buying decisions.

Functional brand concepts promise a higher product benefit, for example, through technical superiority, higher durability, reliability or simply good value for money (e.g. Wal-Mart, see field 1 in Figure 1). As this brand concept focuses on the use of central

FIGURE 1
Brand architecture strategies

arguments (e. g. product attributes), it should be utilized by companies with leading brands especially in cases where the customer’s involvement and product knowledge suffice to enable such arguments to be processed. This style of thinking is described in the literature as “central” (e.g., Petty and Cacioppo 1986), “systematic” (e. g., Chaiken et al. 1996) or “rational” (Epstein 1983), and can be “integrative” as far as the adopted brand architecture is concerned in two respects: On the one hand, this style of thinking tends to delineate very accurately and focuses on logical connections (Epstein et al. 1992, p. 329). In cases where a brand encompasses a broad product range, for example, this prevents an excessive degree of psychological overlap between one product and another, evoking unsuitable or undesired associations. On the other hand, a wide product range encompassed by one brand, together with the fact that the brand is purchased by many consumers, are arguments in favor of brand quality and brand reliability for functionally-oriented customers (e.g., Aaker and Maheswaran 1997; Dacin and Smith 1994; DelVecchio 2000; Hellofs and Jacobson 1998; Kirmani and Rao 2000; Rao, Qu, and Ruekert 1999; Wernerfelt 1988).

Experiential brand concepts (field 3) emphasize the sensual experience of the product by building up associations with the five senses—taste, smell, hearing, sight, and touch. This includes the crispiness of potato chips as well as the freshness of toothpaste or the feel of clothes on the skin. Products are often designed to appeal to more than one of the senses. Such is the case with detergent, whose powerful cleaning properties are portrayed synesthetically through smell, color and viscosity. Experiential brand concepts aim to evoke hedonism and pleasure through a sensual product experience and are most closely comparable to the processing style termed “experiential” by Epstein (1983). In many cases, the sensual product experience is based on a largely preconscious processing which works without, or in addition to, rational processing (e.g. Epstein et al. 1992, p. 329). It is assumed that this style of thinking works

“separatively” as far as brand architecture is concerned: As a consequence of its holistic nature experiential processing tends to overgeneralize and adopts a simple covariance learning which cannot recognize logical barriers between products (cf. Adaval 2001; Lewicki, Hill, and Czyzewska 1994). A food brand, which the customer has frequently experienced in the form of savory products, will have difficulties launching sweet products under the same brand name (Strebinger et al. 2003). In addition, the consumer does not appear to be interested in “compromise products” when it comes to sensual pleasure, but in unique, clear experiences. This desire is expressed in a higher degree of variety seeking among experiential products (Inman 2001).

Symbolic brand concepts (field 2) enable the buyer to express personality, values and status and help to improve self-esteem and social self-presentation (e.g. prestige). This goal is typically linked to biased processing, creating a highly advantageous self-image or high degree of prestige—often in contrast to the facts and feedback of the social environment (e.g., Aaker 1999; Chaiken et al. 1996). This biased information processing can be both a systematic process as well as a heuristic one (Chen, Shechter, and Chaiken 1996). Considering the impact on brand architecture strategy, there are two arguments in favor of a separative effect of symbolic brand concepts: First and foremost, most consumers—at least in the western world—want to differentiate their own personality from that of others (Markus and Kitayama 1991; Markus, Kitayama, and Heiman 1996). Second, biased information processing is always a highly fragile game, which only works as long as the cue used manipulatively (e.g. a prestige brand) is absolutely clear and unmistakable. A brand personality that does not unequivocally stand for certain values or user imagery will lose its symbolic value.

Relational brand concepts try to evoke an emotional attachment to the brand and to impart a sense of familiarity with the brand. Quite often, relational brand concepts (field 4) are based on a

FIGURE 2

commitment to generally accepted social values (e.g., social responsibility, sponsoring) and advertising techniques of emotional conditioning (e.g., through pictures or music). These associations serve to build up sympathy for the brand without—in contrast to symbolic brand concepts—polarizing customers. This form of brand concept is frequently used by market leaders or in product categories where the degree of trust placed in a brand plays an important role (e.g. financial service providers). Relational brand concepts tend to be used in cases where there are either no central arguments in favor of the brand, or where the customer is not willing or unable to adequately assess such product differences (“peripheral processing”, e.g., Petty and Cacioppo 1986). As is the case with functional concepts, relational brand concepts are assumed to work integratively as far as the brand architecture strategy is concerned: In contrast to symbolic brand positioning, identification with the brand is not motivated by the desire to be different, but rather by the desire to belong socially. Relational brands therefore work with integrative advertising appeals such as generally accepted social norms or genetically determined stimulus-response mechanisms to ensure that no gap emerges between the brand’s various target groups. On the other hand, the emotional attachment to the brand is also a positive signal of trustworthiness that can be applied to a variety of products.

Two remarks need to be added. Firstly, strategic brand concepts are not linked to specific products. Functional, experiential, relational or symbolic concepts can be applied to most products. For example, a watch can be mainly functional (e.g. Timex) or can be positioned symbolically (e.g. Rolex, see Park et al. 1991). Secondly, most real brands do not correspond to the ideal “pure” forms, but are a mixture of two or more of these concepts (fields 5 to 9 in Figure 2). For example, most car brands constitute mixed forms of functional (e.g., reliability), symbolic (e.g., prestige), relational (e.g., patriotism) or experiential (e.g., comfort or the pleasure of driving) brand concepts.

BASE-LINKING STRATEGIC BRAND CONCEPT TO BRAND ARCHITECTURE STRATEGY

Building on the four strategic brand concepts and the corresponding consumer benefits and styles of thinking, the Brand Architecture Strategy Explorer (BASE) is proposed as an instrument to explore and identify an appropriate brand architecture strategy (figure 3). Companies whose positioning on the markets they serve is purely or mostly functional are assumed to benefit from a C-branding strategy, as is frequently the case in the technical goods sector (e.g., Panasonic, General Electrics, IBM). The common image denominator between products in closely linked product categories can evoke relatively specific product associations. The wider the product range, the more abstract the common values of the C-brand will be (e.g., Dawar and Anderson 1994, p. 128; Klink and Smith 2001, p. 329). Provided there are no incompatibilities of a symbolic or experiential nature, C-brands can unite a wide range of products under one roof, as consumers can get used to extensions which may seem unusual initially (e.g., Klink and Smith 2001). For example, the Yamaha name can be found on tennis rackets and Panasonic is associated with bicycles, whereas the General Electrics brand covers hundreds of different products from jet engines to power generation, from financial services to plastics as well as from television to medical imaging. As long as the common denominator of the brand schema is appropriate and important in all of the product categories covered by the brand (e.g., Bridges 1992), integration via a functional C-brand strengthens brand awareness and brand trust. In the case of large submarkets and a high degree of product and target group heterogeneity, it can, however, be worthwhile complementing an abstract C-brand with specific subbrands at product or target group level (e.g., Ford and Focus, Mustang, Taurus etc.). In this case, there is some overlap between C-branding and F-branding (see the grey shaded area between the dotted lines in figure 3).

FIGURE 3
BASE—Linking Strategic Brand Concept To Brand Architecture Strategy

The same is true for companies with a portfolio consisting of products with a relational positioning as well as for a product portfolio with a mixture of functional and relational concepts (cf. e.g., Johnson & Johnson), as both concepts do not give rise to any incompatibilities between the various products offered or target groups served. However, in this case as well, too high a degree of product heterogeneity might make it seem expedient to create subbrands for larger submarkets in addition to the C-brand, which once again overlaps with F-branding.

If the range of a company’s offerings includes a number of concepts with various symbolic traits, BASE recommends a T-branding strategy. These symbolic target group brands can include a wide range of products. For example, luxury brands like Gucci, Cartier, Louis Vuitton or Giorgio Armani have little difficulty in uniting a great variety of products under one brand, as long as the image of the typical brand users is uniform and continues in the direction desired by the target group (cf. Kapferer 1997; Park, Lawson, and Milberg 1989; Park et al. 1991). Difficulties arise whenever such brands mix up different target groups or do not protect their clients from non-clients. For example, the Chanel brand severely suffered from its Chanel T-shirts that were sold in large quantities and ended up being worn by too many women (Kapferer 1997, p. 256). Likewise, the BOSS brand, formerly targeted predominantly at male customers, recently found it very difficult to enter the market of women’s business wear. Sometimes, symbolic incompatibilities may be rather subtle in nature: When the Emminence brand, positioned as “for the tough man”, tried to extend its brand name from men’s underwear to elegant perfumes “for the fashionable gentleman”, it caused severe irritation among its customers and eventually altered its strategy. The transition to F-branding is smooth in this case, too. Provided the groups targeted are not too heterogeneous, but the costs of brand management are high in comparison to the consumers’ willingness to pay a premium for the added symbolic value of the brand, it can make sense to integrate target markets to a certain extent through hierarchical F-branding.

BASE proposes a P-branding strategy for a range of offerings with different experiential characteristics. Even if the product categories covered by such P-brands can be very broad on occasion (e.g. all sweet-tasting foodstuffs), they are limited by the physical properties of the product category due to their experiential nature, as both laboratory research and real-life examples demonstrate. In laboratory experiments, subjects appeared to be reluctant to try Crest chewing gum for fear that it would taste like toothpaste, did not like a hypothetical Heineken popcorn extension, and were suspicious of McDonald’s film processing, believing that the films would be developed quickly but would be greasy (e.g., Aaker and Keller 1990; Sullivan 1990, p. 311). In real life, the Natreen brand was successfully extended to jam as well as to fruit-juice, but failed to convince customers of the quality of its diet sausage as the latter product category was incompatible with the association of sweetness that dominates brand associations (Schiele 1999). However, as long as the brand does not make symbolic promises in addition to experiential ones (as would be the case with, e.g., gift confectionery), using the same brand name for very different target groups, as illustrated above, should not present a problem (e.g. sweets for young and old).

If a company’s product range includes combinations of symbolic and experiential brand concepts (e.g., Dom Perignon champagne, Martini vermouth), it should turn to PT-branding, the most separative (and most costly) form of brand architecture. Otherwise, the brands will either lose their symbolic credibility (as is the case with P-brands) or their experiential character (T-brands).

Mixtures of symbolic or experiential brand concepts, on the one hand, and functional or relational concepts, on the other, as well as mixtures which contain three or all four of these added value components (e.g., most car brands), require the complex brand architecture of F-branding, integrating a diverse range of combinations of C-, P-, T- and PT-brands in a hierarchical concept. If we intend, for example, to target a certain number of groups with different symbolic demands, but with the same high functional demands, a functional C-brand is recommended as a guarantee of

technological expertise and quality, beneath which T-subbrands can be distinguished symbolically for different target groups. Which of these levels is given stronger emphasis will depend on the weighting of functional and symbolic buying motives. If symbolic motives dominate, an endorsing C-brand is recommended together with strong symbolic T-subbrands (cf. Aaker and Joachimsthaler 2000, p. 104). If the functional motive has the upper hand, a strong C-brand is recommended as a “master brand”, with supplementary T-subbrands.

DISCUSSION

By linking five brand architecture strategies with the strategic brand concept model and with human information processing models, the Brand Architecture Strategy Explorer proposes standard brand architecture strategies for various combinations of strategic brand concepts. The considerations that have gone into BASE incorporate a significant number of empirical studies, which are summarized in the form of a uniform model.

Some considerable limits should be noted on the theoretical side. Firstly, the standard strategies in BASE maximize the success of the company’s brand(s) in customer terms. They do not involve further consideration of the company’s positioning with regard to other stakeholder groups such as current or future employees or shareholders. All in all, the involvement of additional stakeholders in brand architecture strategy is an even stronger argument in favor of C-branding (e.g. Meffert et al. 2002). On the other hand, the goal of avoiding channel conflicts or the intention to capitalize on consumer heterogeneity in price sensitivity through price differentiation are arguments in favor of a higher number of brands than BASE would recommend (e.g., Aaker and Joachimsthaler 2000). Secondly, BASE is based on a typical cost structure of different brand architectures, for which highly integrated brand architecture strategies are more cost-effective than highly separated strategies. The extent of this cost benefit can, however, vary from sector to sector, and the significance of this cost benefit depends, among other factors, on the size of the (sub)market and the price sensitivity of customers. Larger markets with less price-sensitive consumers in sectors where customer subgroups can be easily and selectively reached justify a higher number of brands. This results in a grey area in the standard strategy recommendations between C-branding and F-branding, and between P- or T-branding and F-branding. Thirdly, many companies have a mixture of functional, experiential, symbolic, and relational offerings and a brand architecture that has developed over time. Even in such cases, it is possible to develop strategy recommendations based on BASE. These strategies, for example, could unite the products with functional or relational emphasis through C- or F-branding, complemented by some isolated T- or P-brands. Finally, BASE is a model based on psychological assumptions, which may only be valid in western cultures. In eastern cultures, for example, the motive for symbolic consumption tends to be the desire to belong rather than to be different (e.g., Markus and Kitayama 1991; Markus et al. 1996). This could explain the emergence of very broad C-brands in Japan (e.g., Kapferer 1999, p. 128).

All in all, BASE is an explorative instrument that can provide assistance in making strategic brand architecture decisions, bearing in mind its limitations. However, it does not replace the fine-tuning required in the specific design of the brand architecture, nor the particular caution to be exercised when crossing cultural boundaries.

Consumer Responses to Discontinuance of Favorite Products: An Exploratory Study

Melissa A. Martin, George Mason University

EXTENDED ABSTRACT

How many varieties of laundry detergent do we really need? This question and others like it have become the center of recent debate among manufacturers, retailers, and marketing scholars. Trends in the marketing environment have led to product proliferation, followed by pruning of brands, creating a highly unstable "product churning" situation. Consumers are presented with a confusing, crowded, and constantly shifting landscape of products from which to make selections.

This unstable marketing environment makes it increasingly likely that consumers will encounter the discontinuance of preferred product alternatives. Although brand and line extensions have been studied extensively by researchers, the *withdrawal* of products from the market has received little attention, despite its growing frequency. Existing research on the topic has focused primarily on the impact of attributes of phantom alternatives (Farquhar & Pratkanis, 1993) and on the role of psychological reactance (Brehm & Brehm, 1981). The impact of affect, and of the customer's prior relationship with the brand, has received little attention, despite the fact that consumers' descriptions of product discontinuance events are often extremely emotion-laden.

This research increases our understanding of consumer responses to product discontinuance events, with particular attention given to emotional and behavioral responses and judgments of responsibility. As a first step in this process, consumers' stories of product discontinuance experiences were collected using the Critical Incident Technique (Flanagan, 1954). 145 subjects responded to a series of open-ended questions about a memorable discontinuance experience. Their recollections were analyzed for common trends and themes. The products mentioned by subjects encompassed a wide variety of product categories, with notable differences in the categories mentioned most frequently by males (fast food and non-alcoholic beverages) and females (toiletries, perfume, and cosmetics).

Product unavailability situations reported included *geographic unavailability* (in which the subject moved to another region or country and could no longer obtain the product), *cyclic unavailability* (in which the product is regularly withdrawn and re-introduced, as with the McDonald's McRib sandwich), *elimination of an entire brand*, *elimination of an entire category* (for example, eight track tapes), and *product line contraction*, in which the discontinued product alternative belongs to a branded product line. This last category was the most often reported, representing 68% of the incidents. In product line contraction situations, consumers' reactions to the withdrawal of the discontinued alternative may influence future evaluation of, and loyalty towards, the brand, making these incidents particularly relevant for further study.

Subjects reported a wide variety of emotional responses to the discontinuance incident, with anger and sadness being the most common affective responses mentioned. The tendency to respond with anger appeared to increase with duration of product use before its discontinuance. Different types of losses incurred were also mentioned. The most often-mentioned losses were of ease of choice (due to the need to incur additional search costs in the category) and utility (if the discontinued alternative had unique features unavailable in any other available product). Mentions were also made of loss of self-concept (typically associated with perfumes and scented products), diminished ability to perform (typically associated with sports equipment), and losses of connections to others or to the past.

Subjects were also asked why they believed the product had been withdrawn. A variety of reasons were offered, low sales

volume being the most frequently mentioned explanation. Several other explanations were proposed, including replacement of the product by a new version which did not possess the attributes valued in the original, failure on management's part to promote the product correctly, lack of retailer support, and shifting consumer tastes. The data offered some preliminary evidence to suggest that explanations attributing either willful behavior ("change for its own sake") or incompetence (failure to promote the product) to the manufacturer were more likely to be associated with angry emotional responses. This finding, if supported by future research, would be consistent with Weiner's (1995) work on judgments of responsibility, blame, and the incidence of anger.

Subjects were asked to report purchase behavior before the preferred alternative became available (if they were able to remember such a time), and also their purchase choices after the preferred alternative was discontinued. The patterns of subjects who reported product line contraction events were analyzed, and the following patterns emerged:

- (1) After discontinuance of a preferred product alternative, subjects in this study selected an alternative from a different brand more often than they selected another alternative within the same brand (43% to 34%, with the remainder exiting the category or switching between brands with no reported preference).
- (2) Subjects who had switched to the discontinued product from another product in the same brand (i.e., from one type of Pantene shampoo to another that became their favorite) were more likely to select an alternative within the brand after discontinuance than to switch. Even among these subjects, though, 42% either switched to another brand or cycled between brands frequently with no reported preference.

It is difficult from these data to identify the reason for the brand switching behavior observed. The search for preferred product attributes may offer a satisfactory explanation; however, it is also possible that discontinuance experiences may damage the consumer-brand relationship (Fournier, 1998), making a previously loyal consumer more prone to defect to another brand.

While statistical inferences should not be drawn from these data, which among other things may suffer from retrospective bias, the patterns identified in these incident reports suggest that discontinued product alternatives have affective consequences for consumers which may lead to behavioral consequences relevant to marketers. Further research should study these patterns in more detail. In particular, it would be helpful to marketers to understand the impact of marketing communications when discontinuing a product on consumers' judgments of motives and intent, and on subsequent brand loyalty. While this research by no means intends to suggest that product should never be discontinued, it may be possible to identify strategies to minimize negative consequences for manufacturers and their brands, while still pruning unprofitable offerings from their product lines.

Processing General versus Specific Brand Information: The Influence of Relationship Norms in Consumers' Choice of Processing Strategies

Pankaj Aggarwal, University of Toronto
Sharmistha Law, University of Toronto

EXTENDED ABSTRACT

Recent work has shown that sometimes consumers cross the threshold of commercial transactions and bring the brand 'alive' by giving it quasi-human qualities (Fournier 1998; Aaker 1997; McGill 1998). More recently, Aggarwal (2001) finds that consumers' evaluation of a brand is influenced by the norms of relationship that are salient at the time of brand evaluation. In the present research, we extend prior work on consumer-brand relationships to investigate differences in information processing strategies adopted by consumers depending on the type of relationship that they perceive with the brand.

We study two types of relationships, adopting a distinction developed by Clark and Mills (1993) between communal relationships, in which concern for a partner's need is paramount (for example, relationships with friends and family members) and exchange relationships, in which a matched benefit is expected back from the partner (for example, relationship between business partners). There is substantial evidence that people's information processing strategies are influenced by a variety of situational and contextual factors in which the decisions are made, for example, experimental instructions (Meyers-Levy 1991), competitive ads (Malaviya, Kisielius and Sternthal 1996), level of involvement (Petty, Cacioppo and Schumann 1983), motivation to achieve an outcome (Crowe and Higgins 1997), age-differences (Koutstaal and Schacter 1997) and cultural orientation (Nisbett, Peng, Choi and Norenzayan 2001).

Our thesis that different relationship types will be associated with alternative information processing strategies is based on the premise that an exchange orientation will be associated with greater item-specific encoding of brand information whereas a communal orientation will result in more holistic processing. Prior work (Clark 1984) has found that people working on a task jointly with their partner were more likely to keep track of their own inputs separately from their partner's when in an exchange relationship but attend more to information about others' needs when in a communal relationship. Presumably, keeping track of inputs in exchange relationships is done in order to allocate the final benefits in proportion to the inputs but such record keeping is unnecessary in communal relationships where benefits are distributed according to partners' needs. As a result, we expect exchange oriented consumers to keep close track of specific attributes of the brand since only that can enable them to track the balance between inputs and outcomes from brand consumption. Additionally, we expect communal consumers not to do such a close scrutiny of specific brand attributes but instead to attend more to information about overall brand benefits to assess if the brand satisfies their needs.

Across three studies we test the overall hypothesis that consumers with a communal orientation towards a brand are more likely to attend to general brand information relative to exchange consumers who attend to every nitty-gritty detail. All three studies are scenario-based laboratory experiments.

In Study 1, relationship norms were first manipulated using an inter-personal interaction situation. Participants then read a short passage about a fictitious clothing store, described using both specific as well as general information. Later, the participants took a four-alternative multiple-choice recognition test. There were six questions in all each with four choices consisting of a *correct*

specific, correct general, plausible inference, and incorrect response. Since we expect the exchange-oriented participants to attend more to specific brand details, we hypothesized such participants to show higher rates of acceptance for correct specific responses, and higher rejection of incorrect responses relative to communal participants. Results supported this prediction. In addition, we hypothesized that since communal participants attend to general brand information, they would show higher rates of acceptance of correct general responses relative to exchange participants. This hypothesis was not supported. There are two alternative explanations for these results. First, it was possible that contrary to our prediction, an exchange orientation does not make people differentiate between specific and general brand information. Instead, this orientation prompts individuals to attend to all brand information equally deeply. Alternatively, it is possible that exchange participants do indeed attend primarily to specific brand information at encoding, but use their specific brand knowledge to correctly construct responses about general brand information.

Study 2 explored these two alternative hypotheses with the help of an additional measure, namely, recognition response latencies. We reasoned that since recognition requires search and retrieval from memory, if respondents are actively constructing the general brand information, the time required to complete such a task would be long, and should reflect, to a large extent, memory construction. However, if the general brand information had been encoded as such, and not based on construction, then participants should respond quickly. Thus, we expected the response time measure to be particularly revealing of information processing strategies in that communally oriented individuals relative to their exchange counterparts, were expected to take less time to identify the correct general information and plausible inferences. Recognition performance replicated the results of Study 1 and the response latency measure confirmed our predictions: exchange orientation resulted in significantly slower responses to the general information and plausible inferences compared to a communal orientation. Together, these results suggest that exchange orientation prompt people to attend primarily to brand specific information whereas a communal orientation makes people attend mainly to general information about a brand.

The first two studies manipulated the relationship norms using a scenario independent of the brand context. Even though such a manipulation provides a conservative test of the theory, we wanted to ratify the results with a brand-specific manipulation. In addition to this, in Study 3 we used a conjoint like experiment to evaluate people's relative weights for general and specific brand attributes. Results were consistent with the findings of the first two studies, that is, communal participants put greater weight (part-worth) on general but not on specific brand attributes.

In summary, results of the three studies offer insights about how the type of relationship, that consumers have with a brand, influences the way in which they process information about that brand.

SPECIAL SESSION SUMMARY

Investigating Links between Consumption Emotions and Behavior

Adam Duhachek, Northwestern University

SESSION OVERVIEW

This session presented research examining the relationship between emotional states and behavior. Consonant with recent consumer research suggesting that emotions impact behavior and attitude, this session explored the nexus between consumer affect and behavior across an array of behavioral phenomena. The three papers in the session investigated links between emotions and conscious behavioral processes, as well as more subtle relationships existing between emotions and non-conscious processes. This session contributed to extant understanding of emotion's influence on consumers by focusing on emotions as both an antecedent and consequence of, consumer phenomena (papers 2 & 3).

The first paper by Duhachek and Iacobucci considered how consumer emotions and stress appraisals influence choice of coping strategies across two studies. The first study considered how consumer emotions resulting from a service encounter interact with stress appraisals to affect consumer's choice of particular coping strategies. Drawing from cognitive theories of emotions, hypotheses are formulated identifying unique influences of two negative consumption emotions (anger and threat) on coping. A second study replicates these relationships in the context of sports fans coping with a defeat in a highly publicized college football game. This study provides additional support for the hypotheses as well as a dynamic view of coping, where specific emotional reactions influence coping strategy selection over time.

In the second paper, Ramanathan and Williams examined mixed emotional responses to impulsive consumption, specifically focusing on the interaction between immediate (hedonic) and delayed (self-conscious) emotions (Giner-Sorolla 2001) and their influence on future behavior. In the first experiment, both impulsive and prudent consumers are induced into impulsive behavior via a priming manipulation. Emotional responses are measured immediately after engagement in the impulsive act, as well as one day later. Results show that hedonic emotions prevail in the short-run among all consumers. However, these are mixed with self-conscious emotions among prudent consumers. After one day, however, those short-term hedonic emotions decay for both groups, leaving only prudent consumers with a negative trace. This in turn, reduces intentions for prudent consumers to re-engage in the same impulsive behavior, relative to impulsive consumers. A second experiment finds that giving prudent consumers the opportunity to engage in a utilitarian (versus impulsive) behavior, after an initial act of impulsive consumption, reduces their experience of self-conscious emotions immediately after the impulsive act. Finally, a third experiment examines the degree to which mixed emotional responses to impulsive acts impact future actions in the same versus different behavioral domains.

In the third paper, Chartrand examined the consequences of non-consciously pursued goal states. Once a nonconscious goal is activated and pursued, individuals either succeed or fail at this goal, and this can have downstream consequences. Studies presented suggested that succeeding at nonconscious goals leads to positive "mystery moods", whereas failing leads to negative "mystery moods". The consequences of these mystery moods for self-enhancement, aggression, and performance were discussed, along with the implications of this research for consumer choice and emotion.

SHORT ABSTRACTS

"An Examination of the Relationship between Emotions, Appraisals and Coping,"

Adam Duhachek, Northwestern University

Dawn Iacobucci, Northwestern University

The growing consumer literature on consumption emotions and coping has documented a diverse array of strategies consumers employ to cope with emotion-arousing consumption episodes. This research examines the premise that the experience of certain emotions implicates the choice of certain coping strategies. We demonstrate that specific negative consumption emotions systematically predict consumers' choice of particular coping strategies. Data from two studies are presented to show that consumers' choice of coping strategies differ as a function of their predominant emotional reaction. The research also finds that consumers' perceived level of coping efficacy moderates the influence of emotions on coping. These findings are discussed in the context of recent research demonstrating emotional influences on consumer behavior.

"Oops, Will I Do It Again? Mixed Emotions After Impulsive Behaviors,"

Suresh Ramanathan, University of Chicago

Patti Williams, University of Pennsylvania

Impulsive behaviors are often accompanied by mixed emotions where pleasure mingles with guilt. We investigate how these emotions evolve differentially across time among impulsive and prudent people and how such differences manifest in the likelihood of engaging in similar behaviors. We show that prudent people are most likely to experience intense ambivalence immediately after an impulsive act. Presenting such people with an opportunity to "launder" their emotional ambivalence by engaging in a subsequent utilitarian behavior reduces feelings of conflict.

"Mystery Moods: The Consequences of Success and Failure at Nonconscious Goal Pursuit"

Tanya Chartrand, Ohio State University

Although individuals are often cognizant of deliberately choosing goals and engaging in goal-driven behavior, goals can also be automatically activated by features of the immediate environment and nonconsciously pursued (e.g., Chartrand & Bargh, 1996). This includes consumer-related goals, which can be primed to guide consumer behavior outside of one's conscious awareness and intent (Shiv, Huber, & Chartrand, in progress). Once a nonconscious goal is activated and pursued, individuals either succeed or fail at this goal, and this can have downstream consequences. Studies presented will suggest that succeeding at nonconscious goals leads to positive "mystery moods", whereas failing leads to negative "mystery moods". The consequences of these mystery moods for self-enhancement, aggression, and performance will be discussed, as will the implications of this research for consumer choice and emotion.

Effects of Consumer Ethnocentrism and Product Knowledge on Consumers' Utilization of Country-of-Origin Information

Byeong-Joon Moon, KyungHee University¹

ABSTRACT

This article is concerned with the effects of consumer ethnocentrism and product knowledge on consumers' utilization of country-of-origin information for their product evaluation. The data suggest that, regardless of consumers' ethnocentrism, low-knowledge consumers' product attitude is more strongly influenced by country-of-origin perception than high-knowledge consumers' product attitude.

The data also show that, when domestic and foreign products are given as alternatives, regardless of consumers' knowledge, low-ethnocentric consumers' product attitude is influenced by country-of-origin perception; however, high-ethnocentric consumers' product attitude is not influenced by country-of-origin perception.

Previous studies on the role played by the country-of-origin in consumers' evaluation of products have revealed that consumers tend to utilize extrinsic cues, such as information about the country-of-origin, as alternatives to intrinsic product attribute information when the latter is unavailable or when little useful information is yielded (Heimbach et al. 1989; Hong and Wyer 1989; Johansson 1988; Maheswaran 1994; Olson and Jacoby 1972; Szybillo and Jacoby 1974). As such, these studies have pointed out that country-of-origin information plays the role of a proxy variable for intrinsic product attribute information.

When this approach is applied to product knowledge, the argument goes that low-knowledge consumers with little ability to process intrinsic product information will be more likely to utilize stereotypical information regarding the country of origin when evaluating products. In other words, these studies have identified a negative relationship between consumers' product knowledge and their utilization of country-of-origin information (Hong and Toner 1989; Maheswaran 1994; Petty and Cacioppo 1981).

On the other hand, others have suggested that high-knowledge consumers are more likely to utilize country-of-origin information when conducting their product evaluation. Thus, these scholars have identified a positive relationship between consumers' product knowledge and their utilization of country-of-origin information (Heimbach et al. 1989; Johansson 1988; Johansson et al. 1985; Johansson and Nebenzahl 1986). In sum, previous research regarding the relationship between consumers' product knowledge and their utilization of country-of-origin information has yielded contradictory results.

Conversely, previous research on the effect of consumer ethnocentrism on consumer behavior indicates that high-ethnocentric consumers arrive at unreasonably favorable evaluations of domestic products vis-à-vis imported products (Bilkey and Nes 1982; Han and Terpstra 1988; Johansson et al. 1985; Sharma et al. 1995; Wall and Heslop 1986; White 1979). Consumer ethnocentrism derives from the more general construct of ethnocentrism, which is defined as people viewing their in-group as central, as possessing proper standards of behavior, and as offering protection against apparent threats from out-groups (Brislin 1993).

However, there has not yet been any research on the effects of consumer ethnocentrism on their utilization of country-of-origin information. If we examine the role of consumer ethnocentrism

from the perspective of country-of-origin information, when both domestic and foreign products are provided as alternatives, high-ethnocentric consumers' evaluation of products will not necessarily be influenced by their perception of country-of-origin information. In other words, consumer ethnocentrism is likely to hinder country-of-origin information from working as a proxy variable for intrinsic product attribute information.

This paper delves into the effects of consumer ethnocentrism and product knowledge on consumers' utilization of country-of-origin information when conducting their product evaluation. First, previous studies on the effects of consumers' product knowledge on their utilization of country-of-origin information will be analyzed in order to synthesize the conflicting results achieved by previous research. Second, this paper will look into the question of the impact of consumer ethnocentrism on their utilization of country-of-origin information. In sum, this study will attempt to analyze, both theoretically and empirically, facets that have been overlooked in previous research on country-of-origin.

EFFECT OF PRODUCT KNOWLEDGE ON THE UTILIZATION OF COUNTRY-OF-ORIGIN INFORMATION

Petty and Cacioppo (1981), who developed the Elaboration Likelihood Model, argue that low-knowledge consumers are more dependent on country-of-origin information when they evaluate products; accordingly, in their ELM, they argue that country-of-origin information works as peripheral routes, or clues. Hong and Toner (1989) found that women consumers are more dependent on country-of-origin information than men consumers when evaluating masculine products (for example, automobiles); on the contrary, men consumers are more dependent on country-of-origin information than women when evaluating feminine products (for example, hygiene products). Based on this, they argue that low-knowledge consumers are more dependent on country-of-origin information when conducting their product evaluation. For his part, Maheswaran (1994) analyzed the moderating role of consumers' objective product knowledge in order to verify the effects of message strength and country-of-origin image on product evaluation. His study revealed that when consumers' knowledge is high only message strength affects their product evaluation. Contrarily, when consumers' knowledge is low, only country-of-origin information affects their product evaluation. In essence, these studies indicate the existence of a negative relationship between consumers' product knowledge and their utilization of country-of-origin information.

In contrast, research undertaken by Johansson and his colleagues (Johansson 1988; Johansson et al. 1985; Johansson and Nebenzahl 1986) has identified a positive relationship between consumers' product knowledge, or familiarity with the product, and their utilization of country-of-origin information. To explain this positive relationship, Johansson (1988) argues that, the more familiar a person is with a product, the higher the possibility that he/she will use country-of-origin information.

Park (2001) argues that these contradictory research results are caused by the use of different methodologies. As such, previous research showing a negative relationship between product knowledge and the utilization of country-of-origin information is primarily based on the use of objective methods to measure product knowledge. Contrarily, previous research exhibiting a positive relationship

¹This work was supported by Korea Research Foundation Grant (KRF-2003-041-B00223)

between product knowledge and the utilization of country-of-origin information is based on the use of subjective familiarity to measure product knowledge. If the suitability of research methods is compared, the likeliness grows that the argument posited by those advocating a negative relationship will emerge as the more valid one.

In the same vein, we can expect a negative relationship to emerge between product knowledge and fluctuations in favorable and unfavorable attitudes toward a product. Thus, low-knowledge consumers who have little ability to process intrinsic product information will more heavily depend on their perception of stereotypical information regarding the country of origin when conducting their product evaluation. As a result, low-knowledge consumers may evaluate a product made in a country with a high image more favorably than high-knowledge consumers. In addition, they may evaluate a product made in a country with a low image more unfavorably than high-knowledge consumers. Based on this reasoning, the following hypothesis is formulated:

Hypothesis 1: Low-knowledge consumers' product evaluation is more strongly influenced by their country-of-origin perception than high-knowledge consumers' evaluation of products

EFFECT OF CONSUMER ETHNOCENTRISM ON THE UTILIZATION OF COUNTRY-OF-ORIGIN INFORMATION

Shimp and Sharma (1987) have noted that "consumer ethnocentrism gives the individual a sense of identity, feelings of belonging, and, most importantly, an understanding of what purchase behavior is acceptable or unacceptable to the in-group" (p. 280). Moreover, they argue that consumer ethnocentrism is closely correlated to patriotism, politico-economic conservatism, and dogmatism. For their part, Sharma, Shimp, and Shin (1995) maintain that consumer ethnocentrism is positively correlated to patriotic and conservative attitudes, but has a negative correlation with cultural openness. Accordingly, a consumer who has a high ethnocentric tendency will be dogmatic and not open to foreign cultures, and as such he/she will have generally unfavorable attitudes toward foreign culture and products.

As mentioned above, consumer ethnocentrism derives from the more general construct of ethnocentrism, which can be defined as people viewing their in-group as central, as possessing proper standards of behavior, and as offering protection against apparent threats from out-groups (Brislin 1993). As Klein, Ettenson, and Morris (1998, p.90) have noted, "Shimp and Sharma (1987) apply ethnocentrism to the study of marketing and consumer behavior and have coined the term "consumer ethnocentric tendencies" to represent beliefs held by consumers regarding the appropriateness and morality of purchasing foreign made products." Previous research on the effects of consumer ethnocentrism on consumer behavior has revealed that high-ethnocentric consumers make unreasonably favorable evaluations of domestic products vis-à-vis imported products (Bilkey and Nes 1982; Han and Terpstra 1988; Johansson et al. 1985; Sharma et al. 1995; Wall and Heslop 1986; White 1979). Accordingly, it can be predicted that consumer ethnocentrism will most likely have a negative influence on consumers' attitudes toward foreign products.

Moreover, when the impact of consumers' ethnocentrism and perception of the country of origin on their attitude toward a certain product are considered simultaneously, consumer ethnocentrism is likely to offset the impact of the perception of the country-of-origin. Put differently, high ethnocentric consumers' are likely to have a

less favorable attitude toward foreign products than domestic ones; and this despite the fact that their perception of the country of origin of the product in question may be higher than their perception of their own country. Based on the above, the following hypotheses are presented:

Hypothesis 2a: When domestic and foreign products are provided as alternatives, low-ethnocentric consumers' attitude toward products is influenced by their country-of-origin perception.

Hypothesis 2b: When domestic and foreign products are provided as alternatives, high-ethnocentric consumers' attitude toward products is not influenced by their country-of-origin perception.

METHOD

Subjects

Two hundred and seven undergraduate students from the management department participated in a study on the evaluation of new products. As compensation for their participation, each individual was given \$3 worth of food tickets to be used in the university cafeteria. The subjects of this study were placed into groups of ten or less.

Stimulus Materials

The following three criteria were considered when selecting the stimulus material. First, in order to assure that the subjects of the study could easily be classified as high-knowledge consumers or low-knowledge consumers, there had to be substantial variations in the level of knowledge about the product. Second, the product had to be sufficiently familiar to subjects, so that even low-knowledge consumers could comprehend and process the product information and message content. Third, the product had to be made and marketed by diverse foreign countries so that the country-of-origin variable could be manipulated. A pretest indicated that the camcorder category was likely to conform to all of the above criteria.

Only one variable—the country-of-origin—was manipulated when collecting the data for this study. Moreover, a pretest was administered in order to choose two foreign countries, one with a substantially higher product quality image than Korea and one with a lower product quality image, to whom the Korean camcorder makers could be compared. The pretest was administered to fifty undergraduate students. Five countries—Korea, U.S., Japan, Hong Kong and Taiwan—were selected and the subjects were asked to, on a scale of one to five, reveal their perceptions of the quality of the camcorders made in each of these countries. The results revealed, as shown in Table 1, that Japan was regarded as being tops, Korea and the U.S. as being in the middle, while Hong Kong and Taiwan were seen as having relatively low quality levels when it came to the manufacturing of camcorders. Based on the pretest results, Japan was selected as the high quality image foreign country and Taiwan as the low quality image foreign country.

The country-of-origin variable was manipulated using stimulus advertisements. As such, three ad copies from each origin country—Korea, Japan, and Taiwan—were made and put in a booklet that was handed out to each subject.

Procedure

The subjects of the study were given booklets that contained a description of the study's purpose, the advertisement message, and the dependent variables. Subjects were then made to read the

TABLE 1
Results of Pretest for Country-of-Origin Perceptions

	Japan	U.S.	Korea	H.K.	Taiwan
Camcorder	4.75	3.97	3.88	2.85	2.76

first page of the booklet, which was explained to them as being a statement of the study's purpose. The subjects were then informed that they were among a group of people whose opinions were being solicited by the manufacturer of a new camcorder to be launched shortly. Once the subjects had read the statement, they were then made to read three advertisement copies at their own pace. After reading each ad, the subjects were asked to turn to the next page of the booklet and indicate their attitude toward the camcorder described in the ad based on a five-point Likert scale. These scales included two items regarding product quality, two items regarding general sympathy as well as one item regarding purchase intention. The Cronbach's α for these five items was 0.84, which is bigger than the critical level of 0.7 recommended by Nunnally (1978). Based on this, the average of the five items valence was used as the subjects' attitude toward the advertised product.

Next a manipulation check was administered. As part of this process the subjects were asked about their perception of the camcorder in the ad's country of origin. This manipulation check was followed by a three-item questionnaire designed to assess the subjects' subjective product knowledge, in this case of the camcorder. The subjects were asked to respond by choosing from three, five-point scales. The Cronbach's α for these three items was 0.78, thus also bigger than the critical level of 0.7 recommended by Nunnally (1978). In accordance with this, the average score for the three items was used as the subjects' product knowledge. Finally, the degree of consumer ethnocentrism displayed by the subjects was measured using the CETSCALE developed by Shimp and Sharma (1987). The subjects were asked to use 7-point Likert scales to note their reactions to the 17-item CETSCALE. The average for the 17-item CETSCALE was used to represent the subjects' degree of consumer ethnocentrism.

RESULTS

Product Knowledge

The classification of subjects as high-knowledge consumers or low-knowledge consumers was carried out first. As discussed above, the average score for the three items was used to represent the subjects' product knowledge. Moreover, the subjects were classified as high-knowledge consumers or low-knowledge consumers based on a median split of 2.9. As a result 104 people were classified as being high-knowledge consumers while 103 were listed as low-knowledge consumers.

Consumer Ethnocentrism

The classification of subjects as high-ethnocentric consumers and low-ethnocentric consumers was performed next. As mentioned above, the average for the 17-item CETSCALE was used to represent the subjects' degree of consumer ethnocentrism. In this case as well, the subjects were classified as being high-ethnocentric consumers or low-ethnocentric consumers based on a median split of 3.1. As a result 103 people were classified as being high-ethnocentric consumers while 104 were listed as low-ethnocentric consumers.

Manipulation Check

To check the effectiveness of the manipulation executed with the stimulus ad, an ANOVA was performed. The subjects' perception of the quality of the camcorder made by each country was analyzed to confirm whether there were any differences between the three origin countries. The average score for each country, with regards to the subjects' perception of product quality, was 4.8 for Japan, 3.8 for Korea, and 2.9 for Taiwan ($N=207$). The ANOVA performed on the average score for subjects' perception of product quality indicated the main role played by country-of-origin ($F(2, 204)=28.5, p<0.01$). This outcome offers evidence that the country-of-origin variable was manipulated successfully.

Demand bias problem may exist where a subject of an experiment responds to what s/he believes is desired of her/him by the experimenter. Sawyer (1975) denoted that artifacts such as suspiciousness of the experimenter's intent, willingness to participate, past experience, etc. can produce demand bias. There are several methods which can be employed to determine if demand bias exists. They include post-experimental inquiry, the non-experiment, manipulation of suspected demand cues. Post-experimental inquiry was employed in this research. A question, "what do you think is the purpose of this research?" was given on the last page of the questionnaire. No subjects grasped the genuine purposes of the research.

Product Attitude

Means for product attitudes categorized by product knowledge and consumer ethnocentrism are summarized in Table 2. To verify Hypothesis 1, the difference between the high-knowledge consumer group and the low-knowledge consumer group's attitudes toward products made in high-image country and low-image country was compared. As shown in Table 3, the high-knowledge consumers' attitude toward the camcorder made in Japan (PA_J) was 4.33, while the high-knowledge consumers' attitude toward the camcorder made in Taiwan (PA_T) was 2.52, for a difference of ($PA_J - PA_T$) 1.81. Meanwhile, low-knowledge consumers' attitude toward the camcorder made in Japan (PA_J) was 4.57, and low-knowledge consumers' attitude toward the camcorder made in Taiwan (PA_T) was 2.22, for a difference between the two ($PA_J - PA_T$) of 2.35. The pairwise t-test conducted on all pairs of origin countries, and found in Table 5, reveals that the subjects' attitudes toward products made in Japan, Korea, and Taiwan are significantly different. Moreover, the result of a pairwise t-test conducted on high-knowledge consumers and low knowledge consumers with regards to the differences in their attitudes toward products made in Japan and Taiwan ($T=3.26, p<0.01$) demonstrates that low-knowledge consumers' evaluation of products is more strongly influenced by their country-of-origin perceptions than is the case with high-knowledge consumers. Accordingly, Hypothesis 1 is validated.

To verify Hypothesis 2a, low-ethnocentric subjects' attitude toward products made domestically, the high-image foreign country, and the low-image foreign country were compared. As shown in Table 4, the low-ethnocentric consumers' attitude toward the camcorder made in Japan (PA_J) scored 4.63, while their attitude

TABLE 2

TABLE 3
Means for Product Evaluation Categorized by Product Knowledge

	High-Knowledge Consumer (N=104)			Low-Knowledge Consumer (N=103)		
	Made in Japan (PA _J)	Made in Korea (PA _K)	Made in Taiwan (PA _T)	Made in Japan (PA _J)	Made in Korea (PA _K)	Made in Taiwan (PA _T)
Attitude Toward Product	4.33	3.86	2.52	4.57	3.87	2.22
	PA _J - PA _T =1.81			PA _J - PA _T =2.35		

toward the camcorder made in Korea (PA_K) scored 3.28, and Taiwan's (PA_T) 2.37. As discussed in a prior section, the pairwise t-test conducted on all pairs of origin countries, as seen in Table 5, demonstrates that the subjects' attitudes toward products made in Japan, Korea, and Taiwan are significantly different. That is, the result shows that, when domestic and foreign products are provided as alternatives, low-ethnocentric consumers' product attitude follows the sequence of their country-of-origin perceptions (PA_J > PA_K > PA_T). Consequently, Hypothesis 2a is also validated.

In order to verify Hypothesis 2b, a comparison of the high-ethnocentric subjects' attitude toward products made domestically, in the high-image foreign country, and in the low-image foreign country was carried out. As shown in Table 4, the high-ethnocentric consumers' attitude toward the camcorder made in Japan (PA_J) was 4.27, while their attitude toward the camcorder made in Korea (PA_K) scored 4.46, and Taiwan's (PA_T) 2.37. Thus, the result indicates that, when domestic and foreign products are provided as alternatives, high-ethnocentric consumers' attitude toward products does not necessarily follow the sequence of their country-of-origin perceptions (PA_J < PA_K > PA_T). As high-ethnocentric consumers are usually dogmatic and not open to foreign cultures, it is highly likely that they will have generally unfavorable attitudes toward foreign culture and foreign made products. As a result, even though they perceived the quality of the camcorder made in Korea as being inferior to the one made in Japan, they nevertheless displayed a more favorable attitude toward the camcorder made in Korea. Therefore, Hypothesis 2b is also validated.

DISCUSSION

The results of this study indirectly supports previous research showing a negative relationship between consumers' product knowledge and their utilization of country-of-origin information.

To be exact, by proving that low-knowledge consumers' evaluation of products is more strongly influenced by their country-of-origin perceptions than is the case with high-knowledge consumers, the negative relationship between consumers' product knowledge and their utilization of country-of-origin information is partially confirmed. As Figure 1 indicates, the product attitude curve of low-knowledge consumers is steeper than that of high-knowledge consumers.

The results of this study also indicate that consumer ethnocentrism does interact with country-of-origin perceptions. As Figure 2A makes clear, when the quality of a domestic product is perceived as being superior to that of a foreign product, as is the case with the camcorder made in Korea and the one made in Taiwan, the product attitude curve of high-ethnocentric consumers is steeper than that of low-ethnocentric consumers. Namely, when the quality of domestic products is perceived as being superior to that of foreign products, consumer ethnocentrism strengthens the impact of country-of-origin perceptions on consumers' product evaluation.

The results of this study also reveals that consumer ethnocentrism does interact with country-of-origin perception in an asymmetrical fashion. As Figure 2B demonstrates, when the quality of a domestic product is perceived as being inferior to that of a foreign product, as is the case with the camcorder made in Korea and the one made in Japan, the product attitude curve of high-ethnocentric consumers is the reverse of that of low-ethnocentric consumers. That is, when the quality of a domestic product is perceived as being inferior to that of a foreign product, consumer ethnocentrism does offset the impact of country-of-origin perceptions on consumers' product evaluation.

Two consumer behavior implications emerged from this research. One is that high-knowledge consumers and low-knowledge consumers differ in the extent to which they utilize country-of-

FIGURE 2B
when domestic product is perceived as being inferior

origin information when conducting their evaluation of a product. For experts, country-of-origin perceptions are not so critical because they possess enough information processing ability to process intrinsic cues. On the other hand, country-of-origin perceptions do swing novices' attitudes towards products because they do not have the level of ability required to process complex intrinsic cues.

The other implication is that there is a need to consider the effects of consumer ethnocentrism on their utilization of country-of-origin information. When domestic and foreign products are provided as alternatives, if we take into account the impact of consumer ethnocentrism on product evaluation, high-ethnocentric consumers' product evaluation may not necessarily be influenced by their country-of-origin perceptions.

Future research might further the present analysis by addressing issues that have emerged, but have not been resolved by this study. One such issue pertains to the question of whether consumers' product knowledge and consumer ethnocentrism have an interactive effect on their utilization of country-of-origin information. Another area of research of potential interest would be the examination of the effects of consumer motivation or of the various types of message on consumers' utilization of country-of-origin information.

“Is It a Foreign Product?” A Scale to Classify Products in an Era of Globalization

Jufei Kao, The City University of New York¹

ABSTRACT

This paper defines *foreign product competence* as a base to classify products in an era of globalization. *Foreign product competence* is the knowledge required to adopt foreign products. It includes three dimensions: (1) product cultural uniqueness, (2) language, and (3) change behavior. *Foreign product competence* is the antecedent of expertise and the affective involvement. It indirectly influences attitude. However, *foreign product competence* is not related to the cognitive involvement. The scale distinguishes those products perceived as foreign from those perceived as non-foreign. The scale's managerial implications are discussed.

PRODUCT CLASSIFICATION DEVELOPMENT

The product classification approach is the hallmark of commodity school of marketing thought (Sheth, Gardner, and Garrett, 1988). The benefit of classifying products into homogeneous groups is that the same marketing tactics can be utilized for all products in that particular category. This approach usually provides pragmatic recommendations to marketing practitioners as well as insights to consumer behavior theory.

The bases to classify products have evolved since Copeland (1923). Based on *search behavior*, Copeland classified products into convenience, shopping and specialty goods. As consumer behavior theory developed, it was posited that *involvement* determines search behavior. Therefore, classifying products based on involvement became a better approach (Lastovicka, 1979). In high involvement cases, attitude preceded behavior; in low involvement cases, behavior preceded attitude (Rothschild, 1979). In addition to involvement, the FCB model (Vaughn, 1980, 1986; Ratchford, 1987) introduced *decision mode* to classify products into four groups: the high involvement/think, the high involvement/feel, the low involvement/think, and the low involvement/feel products. Hence, the bases to classify products have evolved from a tangible construct, behavior, to more abstract yet fundamental constructs, i.e. involvement and decision mode.

Recent research on involvement posits that cognitive structure is the underlying construct that determines involvement (Laaksonen, 1994). However, it has not attracted much attention to use cognitive constructs to classify products. Also, the relationship between cognitive structure and involvement is less defined. Some previous research posited that involvement influenced consumers' motivation to attend to and comprehend information; domain knowledge affected consumers' ability to process information (Celsi & Olson, 1988). Involvement and domain knowledge were expected to exert independent effects on consumers' information processing. Still, other research found that involvement was positively related to domain knowledge (Sujan, 1985).

This study has two objectives. The first is to develop a scale to classify products based on cognitive constructs in an era of globalization. The second is to investigate the relationships among knowledge, involvement and cross-cultural adoption intention.

CULTURE AS SYSTEMS OF KNOWLEDGE

Cognitive anthropology holds the notion of cultures as systems of knowledge (D'Andrade, 1984). Culture refers to the cogni-

tive knowledge aggregated by people and accumulated over time within a culture (Resnick, 1991). A society's culture reflects what one ought to/ought not to do to be considered as a member of the community by other members. Members learn cultural knowledge through participation in cultural group activities. The structure of cultural knowledge systems is the result of the dynamic learning process (Roth and Moorman, 1988). Hence, "culture at once is constituted and constituting (Sherry, 1986)."

Consumer good are one of the locations of cultural meaning (McCracken, 1986). Products carry a repertoire of cultural information. Cultural practices, values and beliefs are accumulated in products within a cultural group. Through consumption, consumers acquire culture (McCracken, 1986; Oswald, 1999). Brand is also a cultural symbol (Aaker & Benet-Maartinez, 2001). "The meaning embedded in brands can serve to represent and institutionalize the values and beliefs of a culture." The dimensions of *brand personality* carry both specific and universal cultural meaning.

In cross-cultural consumption, consumers encounter unfamiliar products. There is little foreign product knowledge in their memory. In addition to rudimentary foreign product knowledge structure, product attributes are also not well-linked to relevant personal consequences nor values. In a cross-cultural consumption decision, learning new product knowledge and updating prior knowledge are more important than retrieving existing product knowledge, consequences, or values. Therefore, this paper posits that the knowledge associated with learning the foreign products can be a base to classify products.

CONSTRUCT DEFINITION

This study defines *foreign product competence* as the knowledge required to adopt foreign products. Here the term "product" is used in a broad sense. It refers to any object in an exchange transaction. The object includes product categories, services, ideas, religions, customs, and brands etc. Knowledge is a complex construct. This paper is not to exhaust the list of knowledge required to adopt foreign products. However, from reviewing relevant literatures, it is hypothesized that there are three types of knowledge most relevant in foreign product adoption:

The first dimension refers to the knowledge accumulated in the foreign products that the consumers have to learn to adopt them. Knowledge is classified into declarative knowledge, procedural knowledge (Anderson, 1976), and conditional knowledge (Alexander, Schallert & Hare, 1991). Declarative knowledge refers to knowledge of facts about the products, e.g. product attributes, benefits, and attitudes. Procedural knowledge is knowledge about how to do things, e.g. how to use Windows Office 2000 software. Conditional knowledge is knowledge to make judgment about when, where or under what conditions to take proper actions, e.g. business suits are proper for corporate meetings. This dimension includes the cognitive structure associated with the foreign products. It is the product knowledge structure shared by the foreign cultural members that defines the first dimension of *foreign product competence*. For example, the western consumers perceive that there is specific knowledge associated with tea ceremony practiced by Japanese consumers. Because of the multidimensional property of knowledge structure, this dimension may be a multi-facet construct itself.

¹The author is grateful to Patrick Bishop and Nobuhide Zushi, of Baruch College, for their support in completing this study.

The second dimension is language. Language carries a repertoire of cultural knowledge (Goodenough, 1981). For example, the classification elements in language, the *classifiers*, provide specific schemes for classifying objects in the world. The culture classification schemes are inherent in the *classifiers* to organize external objects. Speakers of a language classify products differently from speakers of another language (Schmitt and Zhang, 1998). Language is also the communication media to transfer cultural knowledge, and the mediator of cultural identities (Northover, 1988). Language competence is the major dimension of bicultural competence (LaFromboise et. al., 1993). Language competence influences consumers' cross-cultural learning and communication processes. Therefore, products that demand the proficiency of a foreign language are considered more foreign than products that do not.

The third dimension refers to the dimension of change. The ability of acquiring more than one area of expertise within adjacent or radically different fields is one dimension of *professional expertise* (Van der Heijden, 2000; Van der Heijden and Verhelst, 2002). Professional experts are capable of developing a strategy to master a new area of expertise, i.e. to learn faster. Van der Heijden (2000) termed these experts as "flexperts." For example, expert computer programmers are able to respond quickly to changes in computer technology. However, novice programmers cannot bridge the gap easily. The ability to change may involve the ability to analyze information, and the ability to elaborate on given information (Alba and Hutchinson, 1987). Qualitative research found that a learning pattern could be developed as bicultural competent consumers exposed to different cultures over a period of time (Kao, 2002). Although the dimension of change is not directly related to foreign product knowledge itself, it influences learning processes. The more effort necessary to bridge the foreign product knowledge with consumers' existing knowledge, the more foreign the objects are to the consumers.

SCALE DEVELOPMENT

The scale development follows the procedures defined by Churchill (1979) and psychometric theory (Nunnally & Bernstein, 1994).

1. Item Generation:

Two preliminary studies were conducted for item generation. The first study was two focus groups. One consisted of 4 subjects from western countries. The other consisted of 5 subjects from eastern countries. They ranged in age from 24 to 33. In these two focus group sessions, the subjects were asked to talk about their cross-cultural product/brand consumption experience over time. This data provided longitudinal aspects of cross-cultural consumption. In the second preliminary study, 50 objects² were randomly assigned to 55 undergraduate students in a business school in New York City. Each subject was shown 10 objects. These objects

²The 50 objects were sushi, martial art, cola, kimchi, goat cheese, French food, cocktail, balsamic vinegar, bubble bath, dental floss, chopsticks, sashimi, Chinese food, Tamagotchi, brush calligraphy, Korean traditional clothes, fast food stores, milk, cheese fondue, frappuccino/coffee, soymilk, sake, boba milk tea, soy sauce, instant noodle, Chinese herb medicine, Daewoo, Samsung, Morning Glory, Home Depot, BMW, GOYA, Iron Chef, Hello Kitty, SONY, the Great Wall, Shanghai, Buddhism, Italy opera, Chinese opera, Broadway show, Brazil carnival, Crouching Tiger Hidden Dragon, American Idle, Jackie Chan, Bob Marley, Martha Stewart, Thanksgiving, Lunar New Year, and Halloween.

originated from various cultural backgrounds. For each object, the subjects answered the open-ended questions: "What do you think about the object?" "Are you willing to adopt the object? Why or why not?" The data provided cross-sectional aspects of cross-cultural consumption.

Content analysis of the two preliminary studies resulted in 10 categories: (1) *product cultural knowledge*: refers to intangible cultural value, knowledge or historical tradition associated with the objects. (2) *Aesthetic standard*: refers to cultural unique concepts of beauty. (3) *Sensory flavor*: refers to specific taste of food. (4) *Practice/technique*: refers to unique cultural practice or technique associated with the objects. (5) *Language*: refers to how learning the foreign language can facilitate product adoption. (6) *Change of existing behavior*: refers to how adopting the objects will lead to change of current habit. (7) *Country image*: refers to the associated country images to the objects. (8) *Self-image*: refers to how the objects reflect the individuals' personality or ideal self-image. (9) *Utility*: refers to how the objects provide functionality. (10) *Quality*: refers to the perceived quality of the objects. 48 items were generated from these two preliminary studies with multiple items in each dimension.

2. Content Validity:

The 48 items were further investigated. Among them, *self-image* and *utility* were two dimensions of *consumer involvement profile (CIP)* (Laurent & Kapferer, 1985). They were eliminated since they were involvement constructs. *Quality* and *country image* were also eliminated since they were evaluation constructs. This process resulted in eliminating 19 items. The remaining 29 items were subjected to further analysis. The scale was a 5-point Likert scale.

3. Reliability and Dimensionality:

The 29-item scale was administered to 90 undergraduate students in a business school in New York City. 17 objects³ were randomly assigned to the subjects. Each student was given 2 to 3 objects. Subjects were asked to indicate their home culture.⁴ Those from western countries were given objects from Asia. Those from eastern countries were given objects from the United States or Europe. If a subject had never heard of the object, s/he was not qualified to answer the questionnaire, and was given another object. After eliminating some records with non-response items, there were 118 records.

The initial 29-item scale had a Cronbach coefficient alpha of 0.80. However, several items were only marginally correlated with other items. Also, factor analysis with Varimax rotation was performed on the 29 items. Initially it resulted in a 4-factor structure based on eigenvalue > 1. However, the factor structure was not clear-cut. Some items were loaded on multiple factors, and their factor loading scores were low, which made the interpretation difficult. Therefore, those items that had low item-to-total correlation were removed.

With each item removed, new Cronbach alphas were calculated, and factor analyses with rotation were performed. This process continued until the model had a satisfactory Cronbach

³The 17 objects were green tea, soymilk, chopsticks, cheese, coffee, Hello Kitty, SONY, Buddhism, the Great Wall, Jackie Chan, martial art, Daewoo, Peking opera, sushi, Chinese herb medicine, brush calligraphy, and GAP.

⁴American 25%, Asian 23%, Caribbean 21%, European 19%, Southern American 5%, Other 7%. Female 71%, Male 29%. 80% of them spoke a second language other than English.

TABLE 1
The Foreign Product Competence Dimensions

	Item to Total Correlation	Factor Loading		
		Product Cultural Uniqueness	Language	Change Behavior
1. The object involves some unique technique that is not common in my home culture.	.55	.701		
2. The object gives me an opportunity to experience the foreign culture.	.50	.629		
3. The object involves some unusual practice that is not common in my home culture.	.60	.596		
4. The object involves some value that is not common in my culture.	.46	.557		
5. Consuming the object lets me understand the foreign cultural life-style.	.47	.506		
6. Foreign language plays an important role in learning about the object.	.51		.847	
7. Proficiency in the foreign language will help me understand the object.	.47		.818	
8. Adopting the object requires me to learn the foreign language.	.53		.685	
9. If I adopt the object, I will need to change my current routine.	.55			.800
10. Adopting the object requires me to change my current habit.	.48			.647
11. Adopting the object will change my life-style.	.45			.642
Variance explained by each dimension (proportion)		.69	.26	.15
Cronbach alpha of each dimension (Cronbach alpha of the 11-item scale is .83)		.78	.87	.79

alpha and non-ambiguous factor loading structure. Also, attention was paid to check if the factor structure reflected the construct definition. *Aesthetic standard* and *sensory flavor* items were loaded ambiguously among several factors, and their item-to-total correlations were low. Some of them were single-item factors. This indicated that they were trivial given other items in the model, or they were not the same constructs. These items were eventually eliminated. Also, *practice/technique* fused with *cultural knowledge*. It implied that consumers perceived them as one single dimension. This factor was renamed *product cultural uniqueness*.

The result of the scale purification was an 11-item scale. Further elimination of any items reduced the reliability and blurred the factor structure. The final scale had a Cronbach alpha of 0.88. Item to total correlations ranged from .48 to .77. The three factors accounted for 100% of the variation. The three factors are (1) *product cultural uniqueness*: which includes the perceived culture-specific value, culture-specific technique, and unique cultural life style. The *product cultural uniqueness* dimension includes both declarative knowledge and procedural knowledge associated with the foreign objects. (2) *Language*: which refers to the ability to speak a foreign language required to adopt the foreign products. (3)

Change behavior: which refers to the perceived necessity to change behavior. The three-dimension result supports the hypothesis that the *foreign product competence* has three facets.

4. A Second Sample:

To further test the reliability and validity of the scale, a second sample of 135 subjects from the same business school in New York City were recruited. In this study, the 11-item scale along with the 10-item *personal involvement inventory (PII)* scale (Zaichkowsky, 1994), and the 5-item *consumer ethnocentrism scale (CETSCALE)*⁵ (Shimp & Sharma, 1987) were administered to the second sample. At the same time, *attitude, familiarity, and adoption intention*, were measured on a 5-point scale. Each individual was randomly assigned two foreign objects. There were 9 objects⁶ in total. Each object cell had 27-31 subjects. After eliminating non-qualified or

⁵The original scale had 17 items. To ensure parsimony, only 5 items were selected based on the researcher's judgment.

⁶The 9 objects were green tea, martial art, Chinese herb medicine, chopsticks, brush calligraphy, the Great Wall, coffee, jazz music, and IKEA.

TABLE 2
Correlation Matrix of Foreign Product Competence, Familiarity, PII and ECTSCALE

	Foreign Product Competence			Involvement (PII)		Familiarity	Consumer Ethnocentrism (ECTSCALE)

* significant at .05

missing value records, there were 266 observations. The 11-item scale had a Cronbach alpha of .83. It was lower than the first sample. Nonetheless, the factor structure remained the same as before. Table 1 summarizes the results from the second sample.

5. Convergent and Divergent Validity:

Since foreign product competence is assumed to be the antecedent of expertise, it should show convergent validity with expertise. Expertise was measured via one item, “are you familiar with the object?” Although familiarity is not the same as expertise (Alba and Hutchinson, 1987), it is an acceptable proxy of expertise in this scale development study. Also, since the foreign product competence is related to consumers’ cognitive structure, it is expected that it will have convergent validity with involvement. The 10-item PII scale was used to measure involvement. However, the PII scale measures “a person’s perceived relevance of the object based on inherent needs, values, and interests. (Zaichkowsky, 1985)” Therefore, the correlation between PII and foreign product competence should not be too high.

Further, a third construct, consumer ethnocentrism, was correlated with the existing scale as a comparison. It was measured via the 5-item CETSCALE scale. Consumer ethnocentrism refers to “the beliefs held by consumers about the appropriateness, indeed morality, of purchasing foreign-made products. (Shimp & Sharma, 1987)” Foreign product competence is much more different from ethnocentrism than from expertise and involvement. Therefore, the correlation with CETSCALE should be lower than that with familiarity or PII.

The 10-item PII scale had a Cronbach alpha of 0.92 and 2-factor structure, affective and cognitive components. The 5-item CETSCALE has a Cronbach alpha of 0.77 and one-factor structure. Table 2 summarizes the correlations. All three dimensions of

foreign product competence are correlated with familiarity. *Product cultural uniqueness* is correlated with the affective component of involvement. Most importantly, the coefficients with CETSCALE are smaller than those with familiarity or the affective involvement. The results support the scale’s construct validity.

6. Nomological Validity:

As defined, foreign product competence includes foreign product specific knowledge, and knowledge related to communication and learning. The more foreign product competence associated with the products, the more effort required to adopting them. Therefore, the three dimensions of foreign product competence should be negatively correlated with familiarity.

H_1 : *Familiarity is negatively correlated with product cultural uniqueness, language, and change behavior.*

Also, since the current scale measures the knowledge required to adopt foreign products, it is related to the cognitive structure. Therefore, the three dimensions should be correlated with involvement.

H_2 : *Involvement is correlated with product cultural uniqueness, language, and change behavior.*

Furthermore, attitude theory posits that consumers form their attitudes based on various product related attributes and the associated values. High familiarity and high involvement lead to accessible attitudes. Therefore, familiarity and involvement should be correlated with attitude. Since *foreign product competence* is the antecedent of involvement, it should not be directly correlated with attitude. Therefore,

TABLE 3
Regression Analyses

Dependent Variable	Independent Variables (Regression Coefficients)									
	Intercept	Foreign Product Competence			Involvement		Familiarity	Attitude	F	R ²
		Product Cultural Uniqueness	Language	Change Behavior	Affective	Cognitive				
Familiarity	3.409 ***	-.177 *	-.358 ***	-.190 **					***	.15
Affective Involvement	-	.253 ***	-	-					***	.06
Cognitive Involvement	-	-	-	-					-	-
Attitude	2.777 ***	-	-	-	.245 ***	.277 ***	.243 ***		***	.42

*** significant at .001 ** significant at .01 * significant at .05

H_{3,1}: Attitude is positively correlated with involvement and familiarity.

H_{3,2}: Attitude is correlated with neither product cultural uniqueness, nor language, nor change behavior.

Finally, familiarity, involvement, and attitude lead to adoption intention. Since *foreign product competence* is the antecedent of familiarity and involvement, it is hypothesized that the three dimensions will not directly correlate with adoption intention. Therefore,

H_{4,1}: Adoption intention is positively correlated with attitude, familiarity and involvement.

H_{4,2}: Adoption intention is correlated with neither product cultural uniqueness, nor language, nor change behavior.

Backward/forward regression analyses were performed to test the nomological framework. Table 3 summarizes the results of the regression analyses. In the *familiarity* model, as predicted, the three dimensions have significant regression coefficients with familiarity. The model is significant and the coefficients are all negative.

In the *involvement* model, only product cultural uniqueness is related to the affective involvement, and none of the three dimensions are correlated with the cognitive involvement. The results suggest that the foreign product knowledge associated with the objects does not evoke cognitive involvement. This finding is consistent with the qualitative data from the two focus groups. The participants frequently talked about how they felt about the foreign objects, but none of them mentioned any cognitive evaluation processes.

Although the above two models are significant, the variances of these two models explained by the three dimensions are low. This is an expected result, since the antecedents of involvement are numerous, and familiarity is the consumers' accumulated experi-

ence and exposure to the object. The current scale does not intend to include all related antecedents of involvement and familiarity. Hence, the low R² values are not crucial in judging nomological validity.

In the *attitude* model, as predicted, involvement and familiarity significantly influence attitude formation. Also, as expected, the three dimensions of foreign product competence do not influence attitude directly.

In the *adoption intention* model, attitude and familiarity, as predicted, correlate with adoption intention. However, only cognitive involvement correlates with adoption intention. Affective involvement does not have direct effect on adoption intention. Also, language and change behavior both directly contribute to adoption intention though of weaker impact. Moreover, the coefficient of change behavior is negative. Change behavior seems to be a blocking factor in cross-cultural adoption.

In sum, the result from the nomological validity analysis suggests that the three dimensions play differential roles in cross-cultural adoption decision. The data provide evidence that the three dimensions of foreign product competence are the antecedents of familiarity and involvement. Familiarity and involvement in turn influence attitude formation. Most interestingly, only product cultural uniqueness influences the affective involvement. None of the three dimensions are related to the cognitive involvement. However, cognitive involvement directly influences adoption intention, but affective involvement does not. These findings are worthy of further investigation.

7. Criterion-Related Validity:

To fulfill criterion-related validity, the scale scores should be sensitive to the differences among objects. Mean factor scores of the 9 objects in the second sample were calculated. The ANOVA tests showed object effect was significant for all three dimensions. Table 4 summarizes the sample sizes, the average factor scores and standard deviations of the 9 objects.

TABLE 4
Mean (Standard Deviation) of Factor Scores by Object

Object	Sample Size	Product Cultural Uniqueness	Language	Change Behavior
Green Tea	30	-0.70 (0.68)	-0.36 (0.73)	-0.40 (0.61)
Martial Art	30	0.37 (0.66)	0.17 (0.93)	0.50 (0.91)
Chinese Herb Medicine	30	-0.08 (0.75)	-0.10 (0.74)	0.29 (0.73)
Chop Sticks	29	0.54 (0.79)	-0.87 (0.43)	0.48 (1.02)
Brush Calligraphy	27	0.22 (0.73)	0.39 (1.04)	0.22 (0.81)
The Great Wall	29	-0.09 (0.72)	0.15 (0.71)	-0.47 (0.77)
Coffee	30	-0.45 (0.84)	-0.09 (0.74)	-0.29 (0.71)
Jazz Music	30	0.50 (0.69)	0.77 (0.83)	-0.10 (0.83)
IKEA	31	-0.25 (0.81)	-0.04 (0.94)	-0.21 (0.63)
F Value		10.04***	9.62***	6.66***

*** significant at .001

Jazz music (0.50), martial art (0.37), and chopsticks (0.54) score high on product cultural uniqueness. These product categories are highly associated with unique cultural meaning and technique. On the other hand, the most globally marketed product categories, e.g. coffee (-0.45) and green tea (-0.70), score low on product cultural uniqueness.

Learning foreign language is important in Jazz music (0.77) and brush calligraphy (0.39). However, some product, e.g. chopsticks (-0.87), does not require proficiency in foreign language. Even a product as complicate as Chinese herb medicine (-0.10) does not require foreign language competence. This finding is consistent with the qualitative data from the focus group discussions. Some subjects mentioned that because translations of product usage instructions were readily available, they did not need to learn the foreign language to adopt the products. Although language has been reported as the most important factor in acculturation (LaFromboise, Coleman, and Gerton, 1993), in cross-cultural consumption, language may have weaker impact on product adoption.

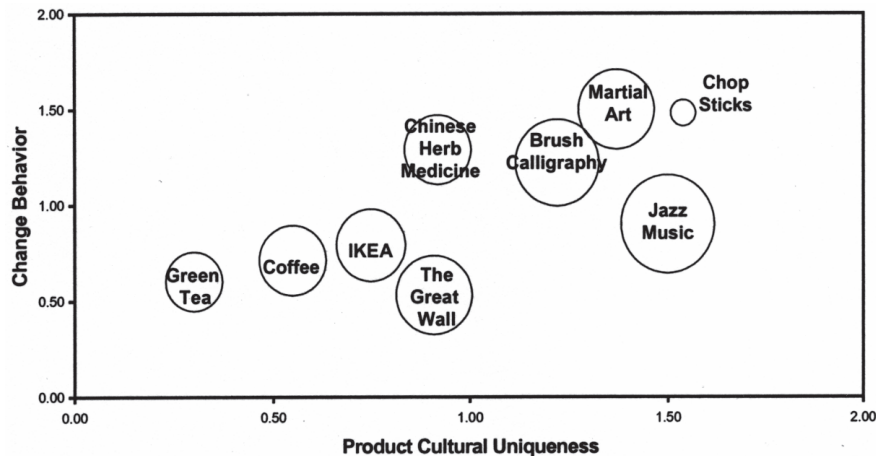

Martial art (0.50) and chopsticks (0.48) score high on change behavior dimension since they require consumers to change their current regime of exercise or the way to handle food. On the other hand, visiting the Great Wall (-0.47) is just a temporary exposure to Chinese culture. It requires no change of behavior. Also, green tea (-0.40), and coffee (-0.29) score low on change behavior. Since consumers have probably already adopted these products, they do not have to change any existing behavior.

CONCLUSION AND MANAGERIAL IMPLICATION

This study defines *foreign product competence* to classify products in an era of globalization. *Foreign product competence* has three dimensions: (1) *product cultural uniqueness*, (2) *language*, and (3) *change behavior*. Firstly, the three dimensions have important implications in cross-cultural marketing communications. Only *product cultural uniqueness* is linked to affective involvement. Surprisingly, none of the dimensions of *foreign product competence* directly influence cognitive involvement. It suggests that affective advertising may be more effective than informative advertising in cross-cultural consumption communication. Also, *language* and *change behavior* directly influence adoption intention. These two dimensions are not directly related to product knowledge, but they facilitate learning. It suggests that simply conveying foreign product-related information to consumers may not be sufficient. Marketers need to help consumers to learn the foreign products. Moreover, *change behavior* has negative effect on adoption intention. Hence, in global marketing, steps should be taken to reduce the adoption barriers. Strategic focus should be on minimizing the perceived difficulty to change behavior, or on identifying creative usage that can integrate the foreign objects into consumers' current consumption.

Secondly, the current scale provides a measure of the objects' degree of globalization. Figure 1 plots 9 objects against *product cultural uniqueness* and *change behavior*. The size of the bubble

FIGURE 1
Object Degree of Globalization

* Original factor scores are rescaled to [0, 2].

FIGURE 2
Foreign Product Competence Triangles

* Original factor scores are rescaled to [0, 2].

represents the *language* dimension. The objects on the lower-left corner indicate a higher degree of globalization. Consumers perceive the objects as low in product cultural uniqueness and they do not perceive any need to change their behavior to adopt the objects. They perceive the objects as “non-foreign.” On the other hand, the objects on the upper-right corner are perceived as “foreign.” These objects are perceived to have unique cultural knowledge and require change of existing behavior.

Thirdly, figure 2 depicts the objects’ *foreign product competence* dimensions in triangles. These *foreign product competence triangles* provide a visualization of the intrinsic product characters that may influence each object’s diffusion pattern. The objects demonstrating larger triangular areas are those perceived to require higher *foreign product competence* to adopt. These objects demand

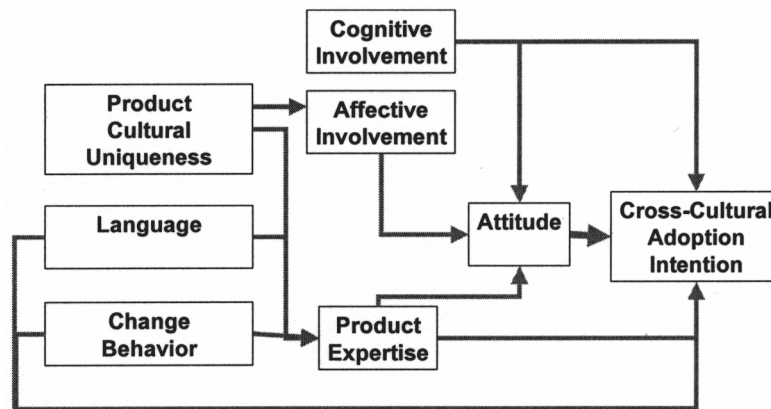

more cultural unique knowledge, changing existing behavior and learning a foreign language. Therefore, these objects may have limited global acceptance. Martial art, brush calligraphy, and jazz music belong to this type of product. Most likely, the diffusion pattern of this type of products remains a cultural mosaic.

On the other hand, products demonstrating smaller triangular areas demand less *foreign product competence* to adopt, for example, coffee and green tea; these enjoy greater acceptance in the global market place. Most likely, these objects have become part of the converged global consumption culture.

FUTURE RESEARCH

The relationship between knowledge and involvement is less studied. This study finds that product specific knowledge, lan-

FIGURE 3
Causal Relationship among Foreign Product Competence, Product Expertise, Involvement, Attitude and Cross-Cultural Adoption Intention

guage, and ability to change are three types of knowledge that are perceived as relevant in cross-cultural product adoption. This study also provides a plausible relationship among *foreign product competence*, involvement, product expertise, attitude, and adoption intention (Figure 3). Attention should be addressed to the differential roles the three dimensions of *foreign product competence* play in cross-cultural adoption. All three dimensions of *foreign product competence* are the antecedents of expertise. In turn, expertise influences attitude and adoption intention. However, only product cultural uniqueness contributes to the affective involvement. None of the three dimensions of foreign product competence are related to the cognitive involvement. In turn, cognitive involvement directly influences adoption intention, but affective involvement influence adoption intention indirectly through attitude.

On the other hand, the knowledge that is required to bridge the foreign product knowledge with the consumers' prior knowledge, i.e. both language and change behavior, directly influence adoption intention. Future research may investigate in more detail this causal relationship via structural equation modeling.

Consuming in Hell: The Burning of Papier Mache Replicas of Consumer Products in the Chinese Culture

Francis Piron, University of Guam

EXTENDED ABSTRACT

Within the Chinese culture, paper has been burnt for millennia to accompany the departed on their journey to the netherworld and as a medium to carry relief for those already there. Eventually, and more so now, paper has been used to construct replicas of contemporary consumer products that are burnt for enjoyment and comfort in hell! This research traces the history of the ritual, offers, as an example, an inventory of in-store, available reproduced products, and reports on a series of in-depth interviews of consumers. Interviewees identify the products they wish to consume in the after-life and elaborate on their selection and reasons.

Introduction

In most cultures, families send along significant items and memorabilia with their departed, such as pictures, food items, favorite toys or objects, or religious ornaments. Thus, it is not surprising that money has been found in burial sites over the world. While the ritual may have subsided as cultures modernized, the practice of burning paper replicas of money and consumer goods has remained strong wherever the Chinese have settled. In the People's Republic of China, such traditional beliefs and customs were strongly discouraged and often punished, and children were instructed to view such rituals as feudal superstitions to be done away with. However, the practice of burning paper and paper products survived, but almost exclusively in Guangdong and Guanxi provinces. For instance, as a part of this research, the author investigated the phenomenon in Beijing and Shanghai, and could only find a handful of stores carrying a very limited range of products in the specialized street of each city. In comparison, overseas Chinese did not experience such political and cultural pressures and, as a result, the offering of money and paper products to the deceased has flourished, uninterrupted, into an extremely rich experience. For that reason, this research was conducted in Singapore and Malaysia where Chinese traditions have remained solid.

To better investigate the depth of the behavior, four investigative approaches were used: in-store observation, structured interviews with store managers and with religious experts, and in-depth interviews with consumers. During in-store observations, permission was requested to take photographs. Stores and their managers were interviewed in Singapore and in two Malaysian cities (Kuala Lumpur and Ipoh). One locally renowned Taoist priest and one respected Buddhist monk were interviewed and 14 consumers participated in in-depth interviews in their home.

Adeology: Advertising as A Battlefield of Ideologies in Transitional China

Xin Zhao, University of Utah

EXTENDED ABSTRACT

China has witnessed dramatic social and ideological changes since the turn of last century. As early as the 1880s when China was forced to open its market to the world, advertising began to play important roles in preparing consumers for an emerging consumer society. Till the 1920s, people in some urban areas such as Shanghai had enjoyed a prosperous consumer culture with an established advertising infrastructure and many global brands competing with each other. Happiness was represented in advertising as not from studying Confucian works as it used to be taught before but from possessing consumer goods. Merchants were removed from the lowest social strata and touted by many. China was moving from a Confucian society to a Consumer society. However, when CCP (Chinese Communist Party) took over China, advertising and consumerism were again severely criticized under communist ideology and replaced by political propaganda from public space until the economic reformation in the late 1970s. With more than twenty years of market socialization, advertising in China has entered its second "Golden Age", and ad expenditures have reached \$11 billion in 2001. Consumerism again is promoted as an important incentive to economy. China has become one of the most promising consumer societies in today's world. Though advertising has long been acknowledged as an important factor in shaping social and ideological changes, such inquiries have seldom been conducted in a Chinese context. What was the role of advertising in this dramatic ideological transition and how the ideology of consumption was established through advertising in China still remain unclear in our literature. This paper attempts to address these questions by drawing upon theories of semiotic, discursive analysis and representation.

Current literature on Chinese advertising mostly concentrates on cultural values reflected in advertisements and compares them with those of other countries such as US. The results showed that while there was an apparent shift towards Western values, some traditional values still remained strong. Unsatisfied with the simple count of content analysis, some researchers conducted in-depth interviews with some viewers of ads, and found that Chinese consumers had different interpretations of the global images in advertising. However, advertising's influences on social and ideological changes in transitional China have been generally ignored. Literary theory has been introduced in advertising research on Western societies and proved especially rewarding in deciphering the historically and ideological constructed meanings in advertising. Advertising has been found to be a rich source of the ideology of consumption and works by means of signification, discourse production, and representation.

Theories of semiotics, discursive analysis and representation provide the theoretical and methodological basis of this paper. Images are proposed by some as not only denoted but also connoted. When used in advertising, the denoted images are usually deprived of their original meanings and put to naturalize the cultural values associated with them. Such naturalization also has ideological effects, which serves to fix the values imposed and to maintain the status quo. As part of the commercial discourses, advertising also produces knowledge about consumption, constructs the subjectivity of consumer, and provides an easy way for consumers to become updated—purchasing the promoted products. The differences between "being modern" as a consumer and "being obsolete" as a non-

consumer are also constructed in Chinese advertising through stereotyping and other representation practices.

In transitional China where the new ideology strives to replace the old, advertising provided a public arena for the transition to happen. In the case of 1920s Shanghai, it was the substitution of consumerism for Confucius; in the case of contemporary China, it is the ideology of consumption replacing communism. In both cases, the authority of the old ideology is transferred to the new, and the sacredness of the old is secularized through the commercial use in advertising. The new ideology replaces the sacred public space that used to be occupied by the old. As a visual discourse and materialized ideology, advertising in transitional China also produces the subjectivity of consumers. However, the discussion on the ideological aspects of advertising never claims that advertising alone can lead to the dramatic social changes. There are also other forces at the same time that form the discourses. Nevertheless, the ubiquity and immediacy of advertising make it among the most influential and powerful ones. The dialectic characteristics of social discourses and advertising also invoke complex reactions to advertisements in audience. Advertising needs to be re-considered as a public arena for ideological transitions and advertisers should also take into account the complexities of existing and competing ideologies besides cultural values when planning ad campaign in transitional China. This paper also contributes to the field by applying literary theories to Chinese advertising research. Limitations and future research are discussed as well.

SPECIAL SESSION SUMMARY

Effects of Preference Elicitation Task on Consumer Reactions to Product Customization

Ana Valenzuela, San Francisco State University
Ravi Dhar, Yale University

SESSION OVERVIEW

Customization of products and services is key to enhancing customer value and a source of competitive advantage. In a classical sense, this requires capturing consumer preferences and offering product assortments that include the consumers most preferred alternatives. From a constructionist perspective, consumer preferences are not well defined and, therefore, inferred from their constructed responses when consumers are required to make a choice or judgment (e.g. Bettman, Luce and Payne, 1998). These constructed preferences are volatile and preference reversals may occur since preference elicitation is sensitive to contextual factors (e.g. Park, Jun and Macinnis, 2000; Simonson and Tversky, 1992; Nowlis and Simonson, 1997; Hsee and Leclerc, 1998).

Different preference elicitation tasks might highlight different attributes and tradeoffs leading to inconsistent evaluations. In that case, different methods of preference evaluation may result in a different object being viewed as most preferred, or may lead to different levels of satisfaction with the chosen option. Additionally, different preference elicitation tasks may facilitate learning and influence expectations about the quality and control over the choice decision. For example, Huffman and Kahn (1998) showed that the presentation of product information attribute-by-attribute facilitated preference learning, reduced perceived process complexity and increased consumers' readiness to make a choice. That relative ease of learning preferences also increased satisfaction with the sale interaction.

Although the recent literature has begun to explore how product customization may lead to different choice outcomes, it is still unclear how different customization processes may affect final product choice and the evaluation of both the customized product and the customization process. The three papers in this session are a step forward in that direction. All three papers not only explore how product customization may lead to inconsistent consumer evaluations and choices but also identify important moderating factors. They deal with research questions ranging from the effects of preference elicitation task transparency and amount of control afforded by customization, to distortions of customization outcomes depending on customization procedures. The three papers are complementary and share a common focus in examining the impact of product customization on consumer preference matching and on the overall purchase experience.

In the first paper, Kramer examines a condition that moderates consumers' ability to deduce their preferences from their measurement responses and recognize that the customized offer fits their preferences more closely than alternative product options. He proposes that such moderator is the transparency of the preference elicitation task, defined as the ease with which consumers can "see through" the measurement to infer their preferences from their measured responses.

In the second paper, Godek, Brown and Yates show that there are other aspects of product customization that plausibly lead to advantages above and beyond mere preference matching. For example, perceptions of control afforded by customization should lead to higher evaluations of both the process and the product selected. Customization also allows decomposition of the decision problem into a series of smaller sub-problems affecting consumers' evaluations of a product selection process.

In the third paper, Dhar, Valenzuela and Zettelmeyer examine how different preference measurement tasks distort customization outcomes as well as the satisfaction with the customization process. They find that customization procedures based on attribute-by-attribute choice instead of choice between fully specified alternatives affects product choice, satisfaction with the choice, confusion with the process and readiness to buy.

As a whole, these three papers highlight the notion that product customization influences consumer choices and evaluations in systematic ways but not equally for everyone. With a well-developed framework and extensive data, all three papers account for how customization processes affect decision-making. Professor Pat West provided the impetus for the discussion by not only summarizing the work but also highlighting areas of future research. She noted that all three papers seemed to conclude that decomposing the choice process for the consumer augmented satisfaction with the outcome and probability of purchase. She called for more research on the impact of choice decomposition on consumer behavior.

INDIVIDUAL PAPER ABSTRACTS

"The Effect of Preference Measurement Transparency on Consumer Responses to Customized Offers"

Thomas Kramer, Baruch College/CUNY

In the age of customization, marketing activities frequently involve measuring the preferences of consumers and tailoring product offerings or recommendations to such individual specifications (Simonson 2003). Common underlying assumptions of these individual marketing approaches are that consumers can express their preferences in a preference elicitation task and recognize the superior value of an offer that is customized to their responses to the measurement task.

However, research on the constructive nature of preferences suggests that consumers may not always have stable, well-defined preferences that marketers can elicit (e.g., Bettman, Luce, and Payne 1998). One implication of such preference instability and uncertainty is that consumers may need to construct the values they express in the measurement task. A second implication is that consumers may need to infer their preferences from their constructed responses to the measurement task to evaluate whether the customized offer matches their tastes better than alternative product options. Thus, consumers who do not identify their measured responses correctly are less likely to recognize the superior value of a customized offer tailored to their individual specifications.

Therefore, it is important to examine the conditions that moderate consumers' ability to deduce their preferences from their measurement responses and recognize that the customized offer fits their preferences more closely than alternative product options. In this research, I propose that one such moderator is the transparency of the preference elicitation task, defined as the ease with which consumers can "see through" the measurement to infer their preferences from their measurement responses.

Results of two experiments show that consumers' responses to customized offers correspond more closely to their expressed preferences when they are obtained using a more transparent measurement technique, such as the self-explicated approach, as

opposed to full-profile conjoint analysis. Subjects who expressed their preferences for digital cameras (study 1) or personal digital assistants (study 2) using the self-explicated approach were more likely to accept a personalized product recommendation that matched their measured preferences most closely and was ranked highest on a list of recommended options. However, consumers' understanding of their measured preferences may become less accessible over time (e.g., Fazio, Powell, and Williams 1989), and task transparency may therefore moderate responses only when the evaluation of the customized offer follows preference measurement without delay. In support of this hypothesis, both experiments find that the difference in response due to task transparency is no longer obtained when offer evaluation follows preference measurement after a longer delay of one week.

A third study suggests that, with less transparent preference measurements (e.g., full-profile conjoint analysis), reminding people of their expressed preferences can lead to less favorable responses to a customized offer derived from these preferences. Following less transparent measurement, subjects who were provided with a personalized product recommendation after a delay responded to it less favorably when reminded of their measured responses to the earlier elicitation task. Such a reminder had no effect on subjects in the transparent measurement task condition.

“Customization Decisions: The Effects of Perceived Control and Decomposition on Evaluations”

John Godek, University of Oregon

Christina L. Brown, University of Michigan

J. Frank Yates, University of Michigan

Technological advances have led to increased collaboration between consumers and firms in the product selection process to the point where consumers are often able to specify some or all of the attributes to be included in the products being purchased. Such customization is seen as a desirable, and perhaps even a necessary, strategy by firms in order to be competitive in the marketplace. This belief is based primarily on the notion that allowing consumers to specify product features should lead to closer matches between consumers' preferences and selected products. However, in addition to this benefit, there are other aspects of customization that may plausibly lead to advantages above and beyond preference matching. Two features in particular, attribute specification and product selection task decomposition, provide additional mechanisms through which customization can influence consumers' decision process. The present research identifies several conditions under which customization yields benefits above and beyond preference matching, and tests when and for whom these conditions apply.

The first aspect of customization examined in this research concerns the consumer's ability to specify some or all of the attributes to be included in the product purchased. This attribute specification increases the consumer's perceptions of control over the process and the product selected by affording the consumer greater input into what is eventually chosen (Averill 1973). Prior research concerning control (Langer 1975; Thompson 1981; White 1959) suggests that people value control, and that increases in perceived control positively influence both how they feel about the current situation as well as their thoughts about the outcome. There are conditions, however, where consumers may wish to relinquish control to someone else in order to facilitate a better decision (Hollander and Rassuli 1999). This past research suggests that the perceptions of control afforded by customization should lead to higher evaluations of both the process and the product selected. These effects should interact with the degree to which consumers desire to retain or relinquish control in order to facilitate a better decision outcome. In order to test these predictions, an experimen-

tal study was conducted where perceived control and desired control were manipulated. The results of this study indicated that, in a purchase situation where there is a match between perceived and desired levels of control, such that they are both high or low, process and product evaluations are higher. Mediation analyses per Baron and Kenny (1986) showed that process evaluations fully mediated the effect of this interaction on product evaluations. These results provide strong evidence concerning how changes in perceived control afforded by customization can increase or even decrease consumers' evaluations of the process and product selected.

The second aspect of customization examined in this research concerns how customization breaks down or decomposes the decision problem into a series of smaller sub-problems. Such decomposition has been shown to improve decision making relative to holistic evaluations of entire alternatives by allowing decision makers to more easily consider a larger number of alternatives and factors (Fischer 1977; Morera and Budescu 1998), while simultaneously reducing judgment errors by relaxing the information processing demands on the decision maker (Kleinmuntz 1990). Easing the cognitive burden on decision makers should reduce feelings of frustration while also positively influence expectations about the quality of the resulting decision. Decomposing the decision task too much, though, can make it too simple and lead to distraction or counter-arguing against the wisdom of the consumer's choice, and thus lower evaluations (Anand and Sternthal 1989; Wright 1973). Accordingly, this suggests an inverted U-shaped relationship between decomposition and evaluation. Since more difficult problems require additional cognitive resources to complete, this curve should shift in the direction of more decomposition as problem difficulty increases. The results of a second study support the prediction of an inverted U-shaped relationship between level of decomposition and process evaluation, and that this curve will shift in the direction of higher decomposition when problem difficulty increases. The relationship between level of decomposition and product evaluation shows a similar pattern, but is less definitive. These results suggest that too little or too much customization can lower consumers' evaluations of a product selection process, and that such effect depends upon the level of difficulty associated with the decision problem.

In a third study, we examine the moderating effects of outcome ambiguity in order to determine when and for whom customization will influence both process and product evaluations. We hypothesized that since people tend to be ambiguity averse (Ellsberg 1961), they will tend to search the decision context more for information when outcome ambiguity is high. Under such circumstances, information about the process should be accessible and seem diagnostic (Feldman and Lynch 1988), making it more likely to be used for generating product evaluations. Such a mechanism received support from the third study where high-experience SUV-users and low-experience SUV-users were queried about a new automobile hybrid designed to address many of common complaints by SUV-users. As expected, there was a large main effect such that all participants evaluated the choice process higher when there was customization instead of choosing from an assortment. Of note though was that for low-experience SUV-users, product selection mode (assortment or customization) had the same effect on product and process evaluations, while for high-experience SUV-users there was no such difference on product evaluations between the product selection conditions. Together, these results suggest that higher ambiguity concerning the outcome does indeed make it more likely for process evaluations to influence product evaluations.

“The Effects of Customization Procedures on Consumer Preferences and Satisfaction”

Ravi Dhar, Yale University

Ana Valenzuela, San Francisco State University

Florian Zettelmeyer, UC Berkeley

The rapid proliferation of options in many product-markets and the potential for information overload has created an important role for customization. A basic precursor to any customization requires preference elicitation. A major finding in the behavioral decision theory literature is that consumer preferences are not well defined and different preference elicitation tasks might highlight different attributes and tradeoffs leading to differing product evaluations and choices. We propose that different preference elicitation methods (i.e. customization interfaces) affect not only a consumer's final product choice, but also his/her reaction to that choice. We propose that different tasks for arriving at customer preferences will systematically distort final outcomes as well as the satisfaction with the customization process. Specifically, different methods of preference elicitation may result in (i) a different final product being perceived as most preferred, (ii) different degree of choice difficulty and satisfaction and (iii) different percentage of no choice.

We examine these propositions in a series of studies using two common means of measuring consumer preferences in the conjoint literature (e.g., Srinivasan and Park 1997) that are widely used in the business world. Specifically, preference measurement is based on information presented about fully specified products (“full-profile” approach) or by rating in isolation the desirability of the different levels for each attribute for all attributes (similar to “self-explicated” approach). In contrast to the focus on modeling partworths, our emphasis is the effect of these approaches on impacting the most preferred alternative. We propose that the customization procedure based on eliciting customer desirability level for each attribute should increase the preference for intermediate options as opposed to more extreme options. Specifically, when each attribute is presented in isolation, the consumer uncertainty about absolute attribute levels should increase choice of compromise options to reduce the probability of making a sub-optimal choice by selecting intermediate levels for most attributes (Simonson 1989). In contrast, when respondents are confronted with multiple alternatives in a fully specified customization format, they are likely to experience greater conflict (Dhar 1997; Iyengar and Lepper 2000). Respondents that want to avoid making choice conflict often resort to lexicographic decision rules (Dhar 1996, 1997) where alternatives are preferred that have the highest value on the most important attributes.

Different customization procedures should also affect experienced states during and after customization. As noted by Huffman and Kahn, learning within-attribute preferences from alternatives is difficult. The reason is that such learning requires consumers to decompose the alternative into its attributes and infer how each contributes to the overall evaluative reaction. On the other hand, presentation of information by attribute is easier to process because information is presented in smaller pieces (e.g. Chase and Simon 1973). Since consumer learning is easier when product information is presented by attribute, we expect consumers to feel less confusion in this type of customization process. The relative ease of learning preferences may also increase satisfaction with the sale outcome.

Finally, we propose that customization procedure will have an effect on the consumer readiness to make a choice. A psychological variable that has received much attention is the degree of difficulty in deciding among the options provided (Dhar 1997; Tversky and Shafir 1992; Luce 1998). These studies show that when consumers confront several attractive options such that none easily stands out as the best, they often tend to put off choice. If product alternatives

are presented simultaneously, the decision process typically involves making tradeoffs between relatively equally attractive alternatives. This process is likely to increase the difficulty of choosing any one alternative. As a consequence, we expect to find larger choice deferral when consumers customize products choosing from fully-specified alternatives.

Studies 1 and 2 show that consumers tend to choose an intermediate (compromise option) significantly more often when they customize a product attribute-by-attribute. The increase in compromised choices in attribute-by-attribute customization tasks seems to be robust across product categories and is not affected by the consumer's familiarity level with the product category. On the other hand, familiarity level with the product category does moderate choice tradeoffs when consumers customize choosing between fully specified alternatives. Subjects choose lower price-lower quality options on average when their familiarity with the category is low, but choose higher price-higher quality choices when their familiarity is high. Additionally, Study 2's findings support that consumers experience less confusion with the choice process in an attribute-by-attribute customization task. Lower confusion with the choice process (in other words less uncertainty about having made the right choice) results in more satisfaction with the final choice. At the same time, when consumers confront several attractive product alternatives, such that none easily stands out as the best, they often tend to put off choice. Consistent with this argument, by-fully-specified-alternative customization results in a larger percentage of product no-choice.

Finally, Studies 3 finds a boundary condition to Study 1 and 2's findings. We argue in study 1 and 2 that, when product alternatives are presented simultaneously, the decision process typically involves explicit inter-attribute comparisons. The process of making tradeoffs between relatively equally attractive alternatives is likely to increase the difficulty of choosing any one alternative (e.g., Luce, Bettman and Payne 2001). Making tradeoffs makes counterfactuals become more salient. Counterfactual thinking drives consumers to the realization that they are giving up on certain attribute levels when they are making a choice. As a consequence, consumers confronted with explicit trade-offs in a customization task are likely to experience greater choice conflict (Dhar 1997; Iyengar and Lepper 2000). Study 3 reverses Study 1 and 2's results by constructing an attribute-by-attribute condition in which trade-offs in the choice between attributes are explicit (choosing between features within a fixed-priced product). In that condition, attribute-by-attribute customization leads to lower satisfaction and a lower probability to purchase.

SPECIAL SESSION SUMMARY

The Economics and Psychology of Consumer Search: Process-Level Perspectives

Benedict G. C. Dellaert, Maastricht University

Gerald Häubl, University of Alberta

SESSION OVERVIEW

Most research on consumer search to date has taken as a starting point a normative model of optimal search. Typically, the work has then gone on to show that consumers do not fully adhere to the decision rules prescribed by such models. Relatively little work to date has used alternative approaches to examining consumer search that are closer to the actual search behavior of consumers in real-world settings, e.g., by starting from a more descriptive analysis.

The objective of this session was to bring together recent work on consumer search that takes initial steps in this direction. The session combined three papers that, from different perspectives, examine specific facets of consumer search processes. All three use detailed, process-level data to investigate consumer search using data-rich experiments and survey research. The papers in this session operate at the nexus of economic and psychological analysis, to capture both the normative and behavioral dimensions of consumer search. Thus, by bringing together and discussing three detailed process-level studies that address different facets of consumer search, this session was aimed at stimulating discussion on the theory of consumer search processes and how they can best be investigated.

The first paper (by Ratchford, Lee, and Talukdar) focuses on consumer search for product information. It uses detailed data on types of Internet sources used by automobile buyers from a survey of consumers who recently bought automobiles. The authors study the determinants of the choice of using different types of Internet sources, and substitution patterns between those types and other, non-Internet sources. To do so, they develop and test a general model of the choice of information sources in consumer searches for product information.

The second paper (by Hutchinson and Meyer) experimentally examines the consumer search process for information or products in the context of a finite-sample search problem. The authors address the effect of learning on two psychological phenomena that have been shown to lead to under-searching: risk aversion and underestimation of the future benefits of search. The results suggest that risk aversion is a stable part of search decisions, but that underestimation of maxima is transient and tends to vanish as consumers learn through task experience.

The third paper (by Häubl and Dellaert) conceptualizes the process of consumer search for multi-attribute products as a series of micro decisions and introduces a behavioral theory of consumer product search that augments normative search theory with three extensions: (1) the effects of the complexity of consumers' micro decisions at each search stage, (2) consumers' reliance on perceptual cues to simplify their micro decisions, and (3) searchers' tendency to optimize locally. The authors report the results of an internet-based shopping experiment, which provide support for the predictions implied by this behavioral theory of search.

This discussion was led by Eric Johnson, and explored patterns of effects with respect to behavioral aspects of consumer search. Some promising avenues for further research in this area were also discussed. Thus, the session generated promising starting points for furthering a process-level theory of consumer search.

"Consumer Use of the Internet in Search for Automobiles"

Brian T. Ratchford, University of Maryland

Myung-Soo Lee, Baruch College

Debabrata Talukdar, SUNY Buffalo

One can think of the expenditure of time with different information sources as inputs to a process of producing better buys. Using a model based on this approach, we studied consumer use of the Internet as a source of information for purchasing automobiles (2003). One of our findings was that time with the Internet appears to draw time from other sources in equal proportion to their use. However our measure of Internet use was an aggregate across all types of Internet use.

We have since collected more detailed data on types of Internet sources used from a survey of consumers who bought automobiles in Summer 2001. Using these data we extend our earlier study to make more detailed inferences about the determinants of choice of types of Internet sources, and about substitution between those types and other non-Internet sources.

For this purpose we develop and test a more general model of the choice of information than the one used in our earlier study, which had the restrictive IIA property. Our model assumes that consumers add new information to a stock of prior information to produce better choices, defined as moving closer to an optimal choice as compared to a random choice. The new information is produced by allocating time to specific Internet and traditional information sources. The function used to translate time into new information is a modified version of the Cobb-Douglas function, which allows for flexible substitution patterns between information sources. Using this model, we are able to derive expressions for the share of time devoted to each source as a function of the use of other sources and consumer characteristics. We are also able to derive an expression for total search effort.

Employing this framework, we estimate the determinants of shares of use of alternative Internet and non-Internet sources, and we also estimate the determinants of total search effort across all sources. We employ our survey data for this purpose. The data set, which was collected to be compatible with earlier surveys done by us in 1990 and 2000, was obtained by a mail survey done in early 2002 on a sample of new car buyers in the Buffalo, N.Y., MSA who bought in July and August 2001. Our data contain 767 usable responses from a sample of 3000. Though the response rate is slightly lower than in our earlier surveys, it is still above 25 percent, which is reasonable for a mail survey. Our survey asked questions about time spent on 11 categories of search, which can be classified into the categories: friend/relative, 3rd party magazine/book sources such as *Consumer Reports*, manufacturer/dealer sources, and Internet. In addition we collected data on proportion of Internet time spent with the following Internet sources: manufacturer web sites, dealer web sites, auto buying services (e.g., autobytel), 3rd party information services on line, bulletin board/chat online (e.g., Yahoo!Auto).

Our results indicate that approximately 54 percent of the 2001 car buyers in our sample used the Internet, compared to approximately 39 percent in our 1999 sample. Higher uncertainty about dealers, lower satisfaction with previous dealer, lower experience in terms of past car purchases and living in the area, being in the market for higher end cars, lower age, higher education and higher

income are associated with an increased share of search time with the Internet. Compared to 1999, however, we find that people with higher age, lower income and females were more likely to use the Internet in 2001 than in 1999. This is evidence that Internet usage is diffusing across socio-economic groups.

We have examined substitution patterns between the Internet and other sources, and between specific types of Internet sources and other sources. Consistent with our 1999 data, our results indicate that an increased share of time with the Internet is associated with a decreased share of time with dealer/manufacturer non-Internet sources. These sources appear to be substitutes. However, contrary to our 1999 study, our preliminary results indicate that an increased share of time with the Internet is associated with an increased share of time with Friends/relatives, suggesting that these sources are complements.

We have examined relationships between the use of specific types of web sites, and the use of non-Internet sources, something that we could not do in our earlier study. One of our results is that share of use of off-line 3rd party sources is positively related to the share on-line 3rd party sources. This suggests that these sources are complementary, with heavy users of these sources accessing them from both media. Another result is that time spent on-line with manufacturer web sites is negatively related to the share of use of manufacturer/dealer sources. This is consistent with buyers using the web to gather information on what car to buy rather than using the dealer as a source of this information. This allows them to come to the dealer better informed about what they will buy, and to cut down on time with the dealer.

An issue to be investigated with our data by the time of the conference is the relationship between use of different Internet sources and total search effort. While the Internet should lead to increased efficiency at search (presumably consumers would not use it otherwise), it could lead to increased total search if it increases the potential gains to search as well. We would like to know under what circumstances the Internet increases or decreases search, and will investigate this with our data.

“Are Consumers Really Suboptimal Searchers? The Effect of Learning and Task Format on the Optimality of Stopping Decisions in Sequential Search Tasks”

J. Wesley Hutchinson, University of Pennsylvania

Robert J. Meyer, University of Pennsylvania

Dating back to the work of Stigler (1961), optimal search models have been used as a starting point in attempts to study the process that consumers use to decide how much information to gather prior to making a market choice. A common finding in this work is that consumers often systematically depart from the predictions of such models, such as by being sensitive to normatively-irrelevant localized features of a sequential data series (e.g., large contrast in data values between adjacent time periods), and a global tendency to search less than would be prescribed by a risk-neutral normative model. Exactly why we observe these departures from optimality and how robust they are, however, is far from resolved. Unknown, for example, is whether observed tendencies to under search primarily accrue to risk aversion versus underestimating the future benefits of search—two different psychological accounts that predict the same bias. Likewise, also unclear is whether departures from optimality are momentary consequences of task unfamiliarity, and would vanish among consumers who have had extensive experience in conducting searches.

In this paper we examine these issues by reporting the results of two experiments that examine the ability of individuals to learn to solve a finite-sample search problem designed as a casino game.

The game involves a player and a house dealer, where the dealer first takes a single draw from an urn that contains 100 balls numbered from 1 to 100, and reveals the outcome to the player. The player is then given the opportunity to purchase a fixed number of additional draws from the urn at a cost of c per draw, with the goal of drawing at least one ball whose value is greater than that of the dealer. The game is equivalent to the class of a priori search problems first considered by Stigler (1961) and more recently explored in Marketing by Feinberg and Huber (1996). To test whether departures from optimality in this task accrue to risk aversion versus mis-estimation of the benefits of search (the expected value of the maximum draw from a certain sample size), we study behavior in a second game that directly requires players to guess the maximum value from N -draws from a uniform distribution.

Analyses of the data reveal two important findings. First, replicating previous work in experimental tests of optimal search models, subjects systematically purchased fewer observations than would be predicted under optimal search theory, however this bias diminished in size—but without completely vanishing—after several rounds of play. Second, respondents displayed a strong systematic tendency to underestimate the maximum value from N draws of a uniform given limited task experience, seemingly supporting a calculation-error explanation for under-searching. In contrast, this bias completely vanished with task experience. The data thus suggest that under-searching is a consequence of a coupling of both forces, with risk aversion being a stable part of search decisions and underestimation of maxima a transient one that vanishes with task experience.

“A Behavioral Theory of Consumer Product Search”

Gerald Häubl, University of Alberta

Benedict G.C. Dellaert, Maastricht University

A well-articulated normative theory of consumer product search, based primarily on the notions of search cost and (expected) returns to search, has been developed in the literature (see, e.g., Ratchford and Srinivasan 1993; Weitzman 1979). However, while this theory makes very specific predictions about the manner in which consumers ought to search for new products, relatively little is known about how consumers actually go about this type of search.

We conceptualize the process of sequential search for multi-attribute products with recall as a series of “micro” decisions. At each stage of the search process (i.e., for each inspected alternative), the consumer, either explicitly or implicitly, makes two related micro decisions: (1) whether the current product is the most attractive one encountered thus far and (2) whether to terminate the search and buy the best of the inspected alternatives or continue searching.

This paper introduces a behavioral theory of consumer product search, which is based on the normative theory, but augments the latter with three broad non-normative extensions. The three extensions are (1) the effects of the complexity of consumers’ micro decisions at each search stage, (2) consumers’ reliance on perceptual cues to simplify their micro decisions, and (3) searchers’ tendency to optimize locally, i.e., to overrely on recently encountered product information. We propose that the first of these extensions will contribute to our understanding of when consumers stop searching, and the latter two will help explain the perceived attractiveness of an inspected product relative to the most attractive one up to that point.

Effects of the complexity of consumers’ micro decisions. One of the limitations of normative search theory is that it fails to

recognize that markets vary in how easy or difficult it is for consumers to make a purchase decision. By contrast, we suggest that the complexity of this decision is an important determinant of search behavior. The complexity of searchers' micro decisions is inversely related to differences between products in terms of total utility (Shugan 1980). We distinguish between two facets of complexity. The first is tied to the degree of variability in both quality attributes and price across the entire set of available products ("market complexity"). The second facet of decision complexity is due to the difference in subjective utility between the current alternative and the most attractive one encountered prior to it ("situational complexity"). Prior research has shown that greater uncertainty as to which alternative is the subjectively most attractive one leads to more extensive consumer search (Moorthy et al. 1998). Furthermore, work on choice deferral suggests that decision makers are more likely to delay their choices and seek new alternatives when choice among the available options is difficult (Dhar 1997). Therefore, we propose that each of the two facets of decision complexity is inversely related to the probability of stopping at a given search stage.

Decision simplification through use of perceptual cues. According to normative search theory, consumers make the micro decisions at each search stage based only the marginal cost and the expected marginal benefit of further search. One important implication of this is that products' concrete attribute levels should affect search behavior only to the extent that they are reflected in consumers' judgments of subjective product utility. This implies that a searcher processes all available pieces of attribute information about a given alternative and forms an overall evaluation of that product. This represents an instance of alternative-based, as opposed to attribute-based, information processing (Payne, Bettman, and Johnson 1988). However, decision makers rarely choose from a set of multi-attribute alternatives by first determining the subjective utility of each alternative and then comparing alternatives in terms of their utilities (Russo and Doshier 1983). Instead, individuals tend to use simplified decision strategies that are attribute based and involve perceptual heuristics (Tversky 1972). This suggests that, rather than integrating the multiple pieces of attribute information about a product into an overall evaluation, searchers may use the perceptual cues associated with alternatives as direct input for their micro decisions. Consequently, we propose that, in addition to utility-based considerations, consumers' search behavior is also influenced by perceptual cues in the form of products' concrete attribute levels.

Local optimizing. The normative theory of search with recall suggests that consumers' micro decisions at each search stage should be based on a comparison of the current alternative and the most attractive alternative inspected up to that point. However, this assumes that consumers have perfect memory for information about the most preferred product. By contrast, we propose that this assumption often does not hold and hypothesize that consumers will also rely upon alternatives that they have encountered since the currently most preferred one. That is, searchers will, in their micro decisions, consider normatively irrelevant information merely on the basis that it has been obtained closer in time than the relevant information. This is consistent with work on order effects suggesting that more recently encountered information tends to have greater relative salience when decision makers—as in sequential product search—obtain and evaluate information in a step-by-step fashion (Hogarth and Einhorn 1992). We, therefore, hypothesize that searchers tend to engage in local optimizing in that they overrely on recently viewed alternatives as reference points when making their micro decisions.

To test our proposed behavioral extensions of the normative theory of sequential product search, we conducted an internet-based experiment with a consumer panel in the Netherlands. Using a simulated electronic shopping interface, participants shopped for a vacation home or a stereo system, completing this task by choosing their preferred alternative. The results provide strong support for the predictions implied by our behavioral theory of search. Situational decision complexity has a negative effect on the probability of terminating search at a given stage. In addition, our results clearly suggest that consumers simplify their micro decisions by relying on perceptual cues in the form of products' concrete attribute levels. Finally, we show that searchers tend to engage in local optimizing in that they overrely on recently viewed alternatives as reference points when making their micro decisions.

The Effect of Family Communication Patterns on Mothers' and Fathers' Perceived Influence in Family Decision Making

Aviv Shoham, University of Haifa

Gregory M. Rose, University of Washington, Tacoma

Aysen Bakir, Illinois State University

EXTENDED ABSTRACT

Background

The influence of children on family decision making has continued to increase in recent years. Recent research estimates that children between the ages of 2 and 12 years of age indirectly influence \$320 billion worth of household purchases, in addition to the \$290 billion worth of goods and services that they purchase independently with their own money (McDonald and Lavelle 2001).

Previous research has concentrated primarily on adolescents and established that adolescent influence varies across product categories and families. Surprisingly, only one study (Foxman, Tansuhaj, and Ekstrom 1989), has examined the relationship between child's influence and family communication. That study assessed the influence of socio- and concept-oriented communication on American adolescents' purchase influence. This study, in contrast, assesses the relationship between four specific types of family communication and children's purchase influence among the Israeli parents of children between the ages of 8 and 12.

Method

A questionnaire was distributed to mothers and fathers of children between the ages of eight and twelve years old in Israel. The sample was obtained from cities in both the Northern and Southern part of Israel. A total of 260 questionnaires were distributed and 117 were returned for a response rate of 45% from different mothers and fathers. The sample consisted of primarily employed, educated, upper income families.

All measures were translated and back translated from English to Hebrew by separate bi-lingual individuals with any discrepancies settled by a meeting of the translator, the back translator, and a separate bi-lingual individual.

Two dimensions of family communication were assessed and four types of family communication were created based on a median split of these dimensions. Both were assessed with Moschis, Moore, and Smith's (1984) scale which included a total of ten items. Typical items for these dimensions were: "I tell my child that buying things that he/she likes is important, even if others don't like them," for concept orientation, and "I tell my child what things he/she should buy" for socio-orientation. All items were measured on a 5-point scale with 1 being very seldom and 5 being very often.

Child's influence (Mangleburg, Grewal, Bristol 1999) was measured for three product categories: durables, non-durables, and children's products. Durable products included a family TV, living-room furniture, and a microwave. Non-durable products included family toothpaste, family cereal, family sweets, and family soft drinks, while children's products included children's clothing, a discman, children's bed sheets, deodorant, movie, shampoo, and aftershave / perfume. All three scales were measured on a seven point scale where 1=the child makes the decision alone to 7=the parent makes the decision alone.

A MANOVA was conducted with mothers' or fathers' perceived influence of their children for durables, non-durables, and children's products as the dependent variables and family communication pattern as the independent variable.

Findings

The influence of product type can also be assessed and our findings are consistent with the literature regarding this issue. The higher mean value for family durables than for non-durables or children's use products indicate that children have a lower level of influence on these products. This finding is consistent with findings among adolescents and their families, where the perceived influence of the adolescent varies inversely with the expense and importance of the product with some consideration given to the extent of product use by the adolescent (Foxman and Tansuhaj 1988; Foxman, Tansuhaj, and Ekstrom 1989; Moschis and Moore 1979; Beatty and Talpade 1994).

Differences across family communication patterns were generally consistent with previous theory and findings. Child's influence was generally highest for pluralistic and consensual parents, which is consistent with Foxman, Tansuhaj, and Ekstrom's (1989) study where the authors found that adolescents had more influence in concept-oriented family communication environments. More specifically, pluralistic parents allowed their children a significantly higher level of influence than protective or laissez-faire parents for durables, a significantly higher level of influence than protective parents for non-durables, and a significantly higher level of influence than all groups, including consensual parents, for children's products.

Gender differences were also found among family communication patterns. The observed differences among family communication patterns, moreover, fit traditional gender roles quite well, where females are considered more communal and males are considered more agentic. Mothers were categorized primarily as pluralistic or consensual. Fathers, on the other hand, were more likely to be categorized as protective (high on vertical socio-oriented communication but low on horizontal, concept orientated communication).

The Role of Culture and Gender in Consumer Information Processing Styles: Exploring the Effects on Ad Memory and Attitude

Lufang Meng, University of Minnesota

EXTENDED ABSTRACT

Two information processing styles, relational and item-specific processing, have recently been proposed as an alternative to the magnitude of elaboration to influence consumers' memory and attitude toward brands and ads (e.g. Bellezza et al. 1977; Bower 1970; Einstein and Hunt 1980; Meyers-Levy 1991). Relational processing is defined as the encoding of similarities or commonalities among discrete items. It is also referred to as organizational processing and can be induced by, for example, showing context-focused pictures, pictures of situations where the product can be used. Item-specific processing, however, focuses on the distinctiveness or uniqueness of each specific item. It is usually regarded as a kind of in-depth processing of single items and can be activated by, for instance, showing pictures of specific product attributes (e.g. Malaviya et al. 1996). This theory also posits that people with increased relational processing often demonstrate better performance in categorization tasks, whereas increased item-specific processing will lead to better performance in recognition tasks. Further, the activation of both processing types is required for optimal recall given the complementary properties of the two.

Though theoretically informative, this theory has only been empirically tested by a few studies, so it is important to further examine its viability by applying the theory to different experimental conditions. Moreover, while most previous studies focused on the effects of the two processing styles, little has been done about the antecedents. My current study therefore tries to extend extant theorizing by investigating culture and gender as two determinants of the two processing styles. Specifically, my research questions include: 1) how easterners and westerners/females and males differ in their preferences for these two processing styles: relational vs. item-specific; and 2) how those inclinations interact with the characteristics of the stimuli (such as ads) and what memory & attitude effects will occur.

Two streams of literature provide important insights for the above questions. First, numerous cross-cultural studies have suggested that westerners hold an independent self-view, whereas easterners have an interdependent self-view (e.g. Fiske et al. 1998). Such different self-views can lead to distinctive cognitive consequences such as different self-regulatory goals (Aaker and Sengupta 2000), different accessibility of certain self-knowledge (Markus and Kitayama 1991; Trafimow et al. 1991), and distinctive cognitive styles. For instance, it has been shown that easterners are more likely to process information in a holistic fashion, while westerners have a preference for focusing on single items, for breaking items into components, and for conducting linear and deterministic analysis (e.g. Nisbett et al. 2001). It seems to suggest that westerners, with a dominant independent self-view, are more likely to view things as separate and independent items and to emphasize the distinctiveness and uniqueness of single items. It follows that when processing message, they will devote more cognitive efforts to the specificity or distinctiveness of each item rather than the relationships among each item. However, easterners may be more likely to view the world as interconnected and they may pay more attention to the relationships among things or people. Therefore, it is plausible to argue that easterners are more likely to adopt a dominant relational processing style.

Second, evidence from the literature of gender differences has suggested that men are generally assumed to be more agentic or achievement-oriented. They tend to hold a preference for viewing things as separate, unique, and independent from the collective. By contrast, females are more communal or affiliation-oriented. They focus more on interpersonal affiliations and relationships between the self and others, thus naturally having the tendency to view things in a more connected and interdependent way and to devote more attention to the relationships between disparate items (e.g. Cross and Madison, 1997; Meyers-Levy, 1988). Such gender difference may be a result of the interplay of various biological/neurological characteristics and the different social roles men and women have been playing along human history (e.g. Eagly 1987; Meyers-Levy, 1988; Buss, 1995; Kashima et al, 1995). Therefore, it seems reasonable to argue that females and males may also differ in their preferences for these two processing styles. Specifically, I hypothesize that females are more likely to adopt a dominant relational processing style, whereas males are more likely to focus on item-specific processing.

Two experiments were conducted to test the above hypotheses. In study 1, both American and Chinese subjects were presented with a list of pseudo-brand names paired with respective product category information. Their different processing styles were assessed by two memory tests: recognition and categorization. Results showed that Americans had a higher mean score than did Chinese subjects in the recognition test ($p < .05$), whereas in the categorization test, Chinese demonstrated better performance than did Americans, although the difference was not statistically significant ($p > .05$). Results also revealed a strong main effect of gender as predicted ($p < .01$). That is, females had a higher mean score than did males in the categorization test, whereas males performed better in the recognition test. Altogether, the results provided strong support for my hypothesis of gender difference in processing styles, although my prediction of cultural differences was only partially supported.

In study 2, subjects were shown an ad for a mobile phone. It was a 2 (culture) X 2 (gender) X 2 (picture conditions) factorial design. Attribute- or context-focused pictures were presented in the ad to activate either a relational or item-specific processing style. The dependent variables included free recall, attitude toward the product, and purchase intention. Results indicated a significant culture-by-picture interaction effect ($p < .05$). Specifically, Americans demonstrated better recall performance in the context-focused picture condition, whereas Chinese's recall scores were higher in the attribute-focused condition. The 2-way interaction effect on attitude was also marginally significant ($p = .09$). Further analysis showed that Chinese evaluated the product higher in the attribute-focused than in the context-focused picture condition, but Americans' attitude toward the product did not differ in the two picture conditions. As for gender, the results revealed a strong gender-by-picture interaction effect on recall; that is, females recalled more ad information in the attribute-focused picture condition, whereas males showed better recall performance in the context-focused condition.

Finally, practical implications for international advertising strategies, particularly for the design of ad visual information, were

discussed based upon the findings. Future research is needed to further clarify the effects of the two processing styles on memory and particularly on attitude. It is also important to explore other ad execution methods by which the two processing styles can be activated.

Happiness in a Box. The Magic of Packaging at McDonald's

Helene Brembeck, Göteborg university

EXTENDED ABSTRACT

The paper discusses the magic of Happy Meal boxes in a Swedish context. That packaging dissociates commodities from production process and standardisation is often claimed. The paper suggests that the understanding of the Happy Meal box and its relation to the child might be enlarged by the help of Latour-inspired French sociologist Madeleine Akrich (1994). According to her, a package (or any object) can be understood as a "script" or a "scenario" of the company's vision of the child and of the world. Not, however, a script in terms of an idea to be interpreted by the receiver, but in terms of a design or blueprint inscribed on the object. The package is designed to be handled by a child with certain preferences and competencies that is part of a cultural and social context of a certain kind. Which child subjectivities that are actually produced, is not at all presupposed, but produced in the meeting between the package and the child. It depends on the potentials and qualities of both parts that are realised and linked together at the meeting. Using this theoretical framework, Swedish Happy Meal boxes from 1979 till today and the toys included are analysed. The focus is on inscribed child subjectivities. The results show that the child inscribed in the late 70s boxes is a radiant but obedient child. The overall representation referred to was a Rousseauian, playing, natural child, even though with hedonistic overtones: that play demands playthings. In the 1990's there is a new inscription on the boxes and toys of a media wise child, familiar with the commercial world. This is a rather choosy child, not easily satisfied, a demanding child, that adults must make an effort to please. The level of what accounts for as an experience is all the time raised; bigger toys, in several parts, that can be handled in ever more refined ways. This inscribed child is more equal to adults, no longer living in the protective cocoon of the home, but in the same, commercialised, medialised society as their parents. A child with the right to consume experiences, the right to consume his or her subjectivity. Part of the explanation can be the ambivalence among adults to the combination of children and consumption, argued by historian Gary Cross (2002). Western parents consider children as creatures to be protected from commercialism and, at the same time, as recipients of consumer spending. Children serve as guarantors of innocence, naivety, simplicity, and the sanctities of private life and as valves of adult desire to consume. Merchandisers quickly learn to exploit the youthful desire, provoking anger among adults/parents, wanting to maintain children's "wondrous innocence", Cross maintains. Maybe it is this anger, or at least hesitation among many Swedish parents, that is the reason for the recent development. Maybe the child script produced by McDonald's during the late 90s has given birth to a child that is regarded as too fastidious, too spoilt and too competent to agree with a Swedish audience, a child regarded as having too many traits of the "cool child", that Cross argues have followed the child characterised by "wondrous innocence", a child script that needs to be supplemented by a design of a child defined as learning, growing, put in place in relations to adults by the help of pedagogical games and activities. A first example is "Learn for life", in cooperation with the non-profit association "Movement for reading", resulting in a Happy Meal with children's books, small booklets with covers, that were distributed in 1 _ million copies at all the McDonald's restaurants in Sweden during the spring of 2001. In 2002 the campaign was followed by "Play & Learn CD-ROM". During three weeks time six

pedagogic CD-ROM discs were included in the Happy Meal, with titles like "Maths", "Pre-school", "First Grade" and "English". Also CD-ROM Happy Meal was an immediate success and was later during the fall of 2002 followed by "Clever and fun Happy Meal", consisting of six different activity books, learning children "useful facts", like how to make a kite and how to equip your bike in a fun way. McDonald's chooses to prolong new, supplementing values already via the packages. At the bags with the pedagogical CD-ROM games, the words "Play & Learn" are repeated in large letters and the paper is filled with drawings seemingly made by children, all in order to elucidate and prolong the value of the disc. Another kind of child subjectivity is inscribed; another type of action is presupposed. The urge to learn is emphasizes, as well as values like curiosity, fantasy, and creativity. The fanciful, creative child in the new knowledge society. But it is equally important that aspects of learning do not become too prominent. Most important is experience value and it is the "experience part" that is the most important to go in for in the years ahead, the marketing manager argues. Pedagogical values and Swedish morality of moderation is absent. "A birthday party at McDonald's is a way for you as a parent to make your child the centre of attraction, without reservation.... The fact is that the restaurants arranging the parties are built just to make children have fun and feel at home!" the homepage is blazoning. Obviously the child in the experience economy should develop his or her creativity and fantasy with the help of the artefacts of consumer culture. It is all about consuming qualities and subjectivities.

Intergenerational Influence in Mothers and Young Adult Daughters

Carter A. Mandrik, Koç University

Edward F. Fern, Virginia Tech

Yeqing Bao, University of Alabama in Huntsville

EXTENDED ABSTRACT

Introduction

It is commonly believed that parents are instrumental in shaping, through the socialization process, their children's values, attitudes and behaviors. Consumer research, for example, suggests that this intergenerational influence is found in the similarity between children's marketplace beliefs and behaviors and those of their parents (Arndt 1971; Heckler, Childers and Arunachalam 1989; Moore and Berchmans 1996; Moore and Lutz 1988; Woodson, Childers and Winn 1976). However, the degree to which this intergenerational influence occurs, its scope and the conditions that affect it are not well known.

This study responds to a pressing need for empirical research in this area (e.g., John 1999; Moore, Wilkie, and Lutz 2002; Viswanathan, Childers, and Moore 2000) by exploring two main issues. The first issue is to identify the actual extent of intergenerational similarity between parent and young adult offspring, specifically mothers and college-age daughters. We address concerns raised elsewhere (e.g., Acock 1984; Viswanathan, Childers, and Moore 2000) about the use of inadequate measures in intergenerational research by employing measures that have been well validated in prior work. Moreover, evidence supplied by earlier studies regarding the extent of intergenerational similarity may be more speculative than originally thought, owing to an inappropriate standard of comparison by which intergenerational influence was judged. We attempt to overcome this limitation by using a more valid standard of comparison.

The second issue is enhancing our understanding of factors that may affect the intergenerational influence of preferences and consumption orientations. One factor suggested to be important in consumer socialization is family communication (e.g., Carlson, Walsh, Laczniak, and Grossbart 1994; Moschis 1985). Here we investigate the degree to which daughters' prediction accuracy, an outcome measure of the effectiveness of parent-child communication (Chaffee and McLeod 1968; Moore and Lutz 1988; Moschis 1985, 1988), affects the similarity of preferences and consumption orientations among mothers and daughters. Additionally, addressing the "surprisingly small amount of research that exists on this topic" (John 1999, p. 206), in this study we examine differences in intergenerational similarity that may occur because of differential influence from peers arising from daughter's tendency to conform.

Research Hypotheses

H1: The similarity between mothers and daughters is greater than the nominal effect for (a) brand preferences; (b) price-quality schema; (c) convenience orientation; (d) value consciousness; (e) prestige sensitivity; and (f) brand name-quality schema.

H2: Daughter's prediction accuracy is positively related to mother/daughter similarity of (a) brand preferences; (b) price-quality schema; (c) convenience orientation; (d) value consciousness; (e) prestige sensitivity; and (f) brand name-quality schema.

H3: Compared to low-ATSCI daughters, high-ATSCI daughters will exhibit less similarity with mothers regarding (a) brand preferences; (b) price-quality schema; (c) convenience orientation; (d) value consciousness; (e) prestige sensitivity; and (f) brand name-quality schema.

Method

Data were obtained through 65 mother and young adult daughter dyads. Daughter's prediction accuracy and ATSCI are independent variables in this study. The extent of intergenerational influence is the main dependent variable in this study. As in past research, it is operationalized as the mother/daughter agreement regarding brand preference and consumption values. However, stimulated by the real group vs. nominal group testing paradigm used in certain quantitative applications in focus group research (e.g., Fern 1982), in this study we use the nominal dyad as the basis of comparison. Specifically, we constructed nominal mother-daughter dyads by taking real dyads, randomizing the daughters, and then regrouping mothers with the randomized daughters; we repeated this process 250 times in order to obtain stable estimates of means for nominal dyads. In the nominal dyads, the level of agreement is regarded as the nominal effect from factors other than intergenerational transfer; we use this effect as a benchmark to test the extent of intergenerational influence.

Results

Paired *t*-tests and multiple regressions were conducted to test the research hypotheses. Results show that in all consumption domains tested, mother-daughter agreement in nominal dyads is significantly greater than zero, supporting our criticism of past research that has used simple agreement to indicate intergenerational transfer. Simple agreement appears to overstate the degree of congruence between mothers and daughters due to intergenerational transfer. Regarding the hypotheses, H1 (a), (b), (c), (d), and (f) are supported, while H1 (e) is not.

Further, it is found that more agreement exists between mothers and daughters for those daughters who know more about their mothers' preferences and marketplace orientations. Results support H2 (a) through (f).

For H3, only (e) is supported and (a) receives marginal support ($t=-1.89$, $p=.06$). It appears that children's ATSCI may impact intergenerational transfer of brand preferences, but not consumption orientations. The one exception was prestige sensitivity, H3 (e). A possible reason is that brand choice behavior is more socially visible than beliefs and values and, therefore, may be more prone to influence from peers. Similarly, prestige sensitivity reflects a person's usage of higher-priced brands to gain social status, thus it has more socially visible behavioral referent than the other consumption orientations.

Conclusions

This study adds to the growing body of research in consumer socialization and intergenerational influences. Like earlier work (e.g., Moore and Lutz 1988), we study transmission of consumer values and beliefs from parent to child; however, unlike this prior

work, we examine consumption-relevant constructs that have been well validated in past research, adding to the ability to generalize and make theoretical advancement. Our method of analysis offers several advancements over prior work. One of these advances is using the nominal dyad, created by the random pairing of mothers and daughters, as a baseline for comparison. Thus, we attempt to control for external influences (e.g., market share, local norms) on dependent measures typically examined in intergenerational research, such as brand preference or value agreement.

Intergenerational research is necessary to more fully understand the processes involved in consumer socialization. Future research should explore the domain differences of influence (e.g., product category differences) as well as influence strategies. Cross-cultural research in this area is also greatly needed.

Relative Judgments in a Competitive Ad Context

Chingching Chang, National Chengchi University

ABSTRACT

This study suggests that the competing ad in an ad-viewing context can alter participants' evaluations of the target ad and the target brand. Results of two experiments have indicated that, for a new brand, the diagnosticity and effectiveness of ad messages is determined by the uniqueness of product attributes featured in the ads. Further, findings have demonstrated that perceived ad diagnosticity affects participants' ratings of ad liking and ad persuasiveness, thereby influencing their brand evaluations. However, for a familiar brand, participants' existing brand attitudes are more diagnostic than ad messages. Therefore, when viewing an ad for a familiar brand, participants' post-exposure brand evaluations are determined by their existing brand attitudes, not by the uniqueness of the featured product attributes, ad liking or ad persuasiveness.

Consumer researchers have argued that judgments of a product are affected not just by the product's features, but also by the features of products that are judged simultaneously (e.g., Farley, Katz, & Lehman, 1978; Lynch, Chakravarti & Mitra, 1991). Implicit in this argument is the assumption that, in a competitive ad-viewing context, ads, as well as advertised brands, may be evaluated in a relative sense. Surprisingly, this assumption has received little attention in advertising research. Rather, recent research exploring the influence of context on the effectiveness of advertising has focused on program context. Even when the interference from competing ads has been explored, the exploration has been limited to reduced message recall for the target ad, rather than the changes in brand judgments resulting from the interplay of ad strategies by the competing brands. Therefore, how competitors' ads in the ad-viewing context affect judgments of a target brand needs more research attention and will be the focus of this paper.

Given that segmentation strategies are nearly universally adopted by the media, each program, magazine or newspaper is specifically designed to attract certain segments. As a result, it is common to see different brands that appeal to similar segments in the same product category selecting the same media vehicles for ad placement. Serious clutter problems may result from this practice. Since cognitive psychologists have argued that individuals rarely retrieve all the information that is potentially relevant for judgments, but rather rely on what is available in their working memory to form judgments (Wyer, Bodenhausen & Srull, 1984), it is therefore reasonable to assume that an ad or a product will be judged differently when embedded in different contexts.

Drawing upon Feldman and Lynch's (1988) Accessibility-Diagnosticity Model, this paper will explore how relative judgments may occur in different ad contexts, where the diagnosticity of a piece of accessible information varies. The Accessibility-Diagnosticity Model proposes that the likelihood that a particular piece of information will be used as an input for judgments and inferences depends on the accessibility of the information, as well as the diagnosticity of the information to the judgment or inference. Specifically, this study proposes that, in a competitive ad-viewing context, ad diagnosticity is a function of the relative uniqueness of featured product attributes. Most importantly, when competitors' ad messages are present, ads featuring unique product attributes, in comparison to ads featuring shared product features, will be perceived to be more diagnostic, thereby increasing participants' favorable responses toward the ads, as well as the advertised products. Experiment One will specifically test the effectiveness of presenting unique product attributes in a competitive ad context.

Experiment Two will provide a comparison to show that the effects of presenting different product attributes will only emerge in a competitive ad context, not in an ad-viewing context in which competing ads are not present. Further, Experiment Two will specifically test the process via which perceived ad diagnosticity affects brand evaluations through its influences on ad liking and ad persuasiveness ratings. Moreover, Experiment Two argues a step further that the different judgments incurred by ad viewing contexts will only be observed for familiar brands. Additionally, this study will provide more evidence for the proposed process by testing the relative influence of participants' existing brand attitudes, ad persuasiveness and ad liking in evaluating a familiar brand.

AD COMPETITION ON BRAND EVALUATIONS

A fair amount of research has indicated that competing ads in the viewing environment cause memory interference. As the number of ads present in the ad processing environment increases, recall of brand information declines (Keller, 1991; Pillai, 1990). However, the interference caused by ad competition is not limited to message retrieval failure. Another important concern is the possible influence from competing ads on brand evaluations. However, past explorations were mainly concerned with the number of competing ads present in the viewing context of the target ad (e.g., Keller, 1991; Baumgardner, et al., 1983). In general, these findings have suggested that, as the degree of ad clutter increases, evaluations of the target brand deteriorate, especially when the competing ads are for brands in the same category. Given that a typical ad-viewing situation can be characterized by serious clutter from competing ads in the same product category and evaluation deterioration is likely to be critical, it is thus important to further explore this issue.

THE ACCESSIBILITY-DIAGNOSTICITY MODEL

It is well accepted among cognitive psychologists that individuals are cognitive misers and are not likely to engage in effortful information processing when it is unnecessary. Wyer and Srull (1986) have proposed that, in making judgments, individuals first search their working memory and rely mainly on the information that is accessible there. Due to the limited effort individuals are likely to engage in, what is more accessible is more likely to be used as input for making judgments. Within this paradigm, Feldman and Lynch's (1988) Accessibility-Diagnosticity Model has extended Wyer and Srull's argument further by suggesting that the likelihood that a particular piece of information will be used as an input for judgments and inferences depends not only on the accessibility of the information but also on the diagnosticity or relevance of the information to the judgments or inferences.

In Feldman and Lynch's (1988) theorization, even though a piece of accessible information is more likely to be diagnostic, being accessible is not sufficient for that information to be used as an input for judgments. The likelihood that any information will be used as an input for later judgments is: (1) a positive function of the accessibility of the earlier information in memory, (2) a positive function of the diagnosticity of the earlier information for the judgments, (3) a negative function of the accessibility of alternative inputs, and (4) a negative function of the diagnosticity of these alternative inputs. Similar to Kisielius and Sternthal's (1986) Availability-Valence Model of consumer judgments, the Accessibility-Diagnosticity Model has proposed that the evaluation of the target is also determined by the valence of the information that is used as input for the judgment. To the extent the diagnostic

information is positive, the target object will be evaluated in a more positive light.

The diagnosticity of a piece of information is not objective, but depends on the relative informativeness of the accessible information. For example, Herr, et al. (1991) have argued that prior product beliefs, being persistent and resistant pieces of information, are more likely to be perceived as more diagnostic than other product information. Moreover, Purohit and Srivastava (2001) have suggested that brand reputation and retailer reputation are high-scope cues, cues that evolve over time, whereas product warranty is a low-scope cue, one that is more transient in nature. Most importantly, in Purohit and Srivastava's empirical explorations, high-scope cues have been shown to be more diagnostic than low-scope cues in consumers' brand judgments.

Drawing upon the Accessibility-Diagnosticity Model, this study proposes that information contained in competitors' ads in the same context will affect the relative diagnosticity of the product information featured in the target ad and thus affect participants' evaluations of the target ad and the target brand. Specifically, presenting unique attributes will increase the diagnosticity of the ad and generate more favorable ad attitudes and brand evaluations.

DIAGNOSTICITY OF UNIQUE PRODUCT FEATURES

Comparative advertising literature suggests that how typical a featured product attribute is can affect the effectiveness of comparative advertising (Pechmann & Ratneshwar, 1991). These findings suggest that the effectiveness of product attributes presented in comparative ads is not determined by their absolute values but by their relative uniqueness. Based on similar reasoning, this paper argues that, in a competitive viewing context, the effectiveness of featured product attributes is a function of its uniqueness. A product attribute that is featured in all the ads is less diagnostic than the unique product attribute that is only featured in an ad for one brand. In line with the Accessibility-Diagnosticity Model, this study proposes that, in a competitive ad context, to the degree the featured product attributes are unique and positive, the more likely it is that they will generate more positive ad and brand evaluations.

H1: Participants rate the target ad more positively when a unique attribute is presented than when a shared attribute is presented in terms of ad liking (H1a), ad persuasiveness (H2a) and brand evaluations (H1c).

EXPERIMENT ONE

Methodology

Design

An experimental study was employed to investigate the hypotheses stated earlier. This was a one-factor experimental design: product attributes featured in the target ad (two levels: shared versus unique, see Table 1). Participants were exposed to one ad for the target brand and one ad for the competing brand. The order of the two ads to which participants were exposed was rotated and no order effects were detected on any of the dependent measures; therefore, participants' responses for ads presented in different orders were collapsed in subsequent analyses.

Selection of Products and Brands and Stimuli Development

A pretest facilitated selecting sneakers as the product category. Another pretest (N=40) determined the brand name for the target product. A real brand, Sperry, not known to any participants in the pretest, was selected to be the target brand. The competing brand was New Balance, which is ranked second in market share in the area where the experiment was conducted. Stimuli ads were

created by professionals working at Ogilvy & Mather Ad Agency were inserted among three genuine filler ads.

Participants and Procedures

This study recruited two hundred and two participants from undergraduate classes at a university in a metropolitan area. The sample was comprised of an equal number of males and females. Participants were seated and read brief instructions about the procedures and the purpose of the study. Participants were told that the study involved research about how different layouts of printed ads impact viewers' information processing. Then they were asked to read a packet of five ads (two stimuli ads and three filler ads) that were bound together as they would appear in magazines. Each stimuli ad was preceded and followed by a filler ad. After reading the ads, the moderators collected the stimuli packets and distributed questionnaires for participants to complete.

Independent Variable-Uniqueness of Featured Attributes

Based on the results of a pretest, a comfortable fit, the most important attribute, was selected to be the shared attribute that was featured in the target ad as well as in the competing ad, whereas waterproof was chosen to be the unique attribute for the target brand and was only emphasized in the target ad.

Dependent Measures

Participants rated their liking of each ad on a five-item seven-point Likert scale. The five items were adopted from Madden, Allen, & Twible (1988). Cronbach's reliability alphas of ad liking were deemed satisfactory at .93 for Sperry and .92 for New Balance. Participants also rated the persuasiveness of each ad on a four-item seven-point Likert scale to measure participants' perceptions of the ads' persuasiveness. The four items were adopted from Beltramini's (1982) advertising believability scale. Cronbach's reliability alphas of ad persuasiveness were deemed satisfactory at .85 for both Sperry and New Balance. Brand attitudes were measured with a five-item seven-point Likert scale. The items were adopted from Mitchell and Olson (1981) and Holbrook and Batra (1987). Cronbach's reliability alphas for this scale were deemed satisfactory at .92 for Sperry and .93 for New Balance.

Results and Analyses

Hypotheses 1a-1c examined the main effect of attribute types featured in the target ad on participants' ratings of ad liking, ad persuasiveness, and brand attitudes. ANOVA indicated that the main effect on each variable was significant (for ad liking, $M_{\text{shared}}=3.53$, $M_{\text{unique}}=4.01$, $F(1, 201)=8.92$, $p<.01$; for ad persuasiveness, $M_{\text{shared}}=3.53$, $M_{\text{unique}}=4.04$, $F(1, 201)=11.97$, $p<.01$; for brand attitudes, $M_{\text{shared}}=3.65$, $M_{\text{unique}}=4.11$, $F(1, 201)=6.73$, $p<.01$). Therefore, hypothesis 1a through hypothesis 1c were supported.

Discussions

Findings of this experiment suggest that the uniqueness of the target brand's attribute relative to that of the competing brand's boosts participants' responses to the target brand. It seems that, for products that are not known to the audience, product attributes underscored in ads have a determining influence on ad persuasiveness and brand evaluations. Even though the featured product characteristic is not as important as the shared characteristic, it provides more diagnostic information than the shared one. However, this experiment used only one unique and one shared attribute. It is possible that the results found in Experiment One might be attributed to the novelty of the product attribute selected for Sperry. Moreover, this experiment did not explicitly test the process via which perceived ad diagnosticity affected brand evaluations. Finally, to provide a stronger test, it is important to compare how participants evaluate the target brand when the competing ad is

TABLE 1
Research Design for Experiment One

Cell	Uniqueness of Product Attributes	Presence of the Competitor's Ad (New Balance)	Presence of the Target Ad (Sperry)
1	Shared	Attributes-Comfort	Attributes-Comfort
2	Unique	Attributes-Comfort	Attributes-Waterproof

present, as opposed to when the competing ad is not. Therefore, more replications rotating the same product attributes for the two brands were necessary to help us reach stronger conclusions regarding the influence of attribute uniqueness.

COMPETITIVE AD CONTEXTS VERSUS NON-COMPETITIVE AD CONTEXTS

The Accessibility-Diagnosticity Model proposes that available information may not always be diagnostic. Different contexts will alter the relevance and diagnosticity of a piece of available information and determine the likelihood that it will be used as input for judgments. Therefore, it is important to compare the different patterns of results generated from contexts wherein the target brand is evaluated alone, as opposed to when the target brand is evaluated in a competitive ad context. Specifically, it theorizes that, in a competitive ad context, promoting unique attributes is more effective than promoting shared attributes in terms of improving participants' ad liking, perceptions of ad persuasiveness, brand attitudes and purchase intentions. In contrast, in a non-competitive ad context, all the featured product attributes should be similar in terms of diagnosticity if they are equivalent in importance to start with. Therefore, when competitors' ads are not present, what attributes the target brand promotes in the ad will not influence how participants evaluate the ad and the advertised brand.

Additionally, in order to argue that ads featuring unique product attributes lead to more effective responses mainly due to their diagnosticity, it is necessary to put this assumption to the test. Thus, other than ad liking, ad persuasiveness and brand evaluations, this paper will specifically examine whether or not, in a competitive ad-viewing context, ads promoting a target brand on unique attributes are perceived to be more diagnostic than ads promoting the target brand on shared attributes. Whether difference will emerge for purchase intentions will also be tested.

H2: When there are ads for competitors in the same ad-viewing context, emphasizing unique attributes generates higher ratings in terms of ad diagnosticity (H2a), ad liking (H2b), ad persuasiveness (H2c), brand evaluations (H2d) and purchase intentions (H2e), whereas when there are no ads for competitors, featuring various attributes does not generate different ratings.

Most importantly, the central idea behind the Accessibility-Diagnosticity model is that the more diagnostic the information is, the more likely it is that the piece of information will be considered when individuals make judgments. Also, if the diagnostic information provides positive information, the target object will be evaluated more favorably. It is important to test this underlying process. Specifically, how participants perceive the ad in terms of its diagnosticity will affect their ad liking and their ratings of ad

persuasiveness, which in turn will affect their brand evaluations.

H3: Ad diagnosticity will affect brand evaluations through its influence on ad liking and ad persuasiveness.

BRAND FAMILIARITY AND THE UNIQUENESS OF PRODUCT FEATURES

Will the cognitive interference effects be different when the brand in the competitive ad context is familiar to participants? In a typical ad-viewing context, different types of information cues are available to aid ad processing, some of which are ad-based, and some of which may be retrieved from a participant's memory. Preexisting product preference is one of the potential information cues that can be activated from an individual's memory when processing ad messages. Most importantly, it has been shown that preexisting product preference is perceived to be more diagnostic than other attribute cues (e.g., Herr, et al., 1991; Purohit & Srivastava, 2001). Purohit and Srivastava (2001) have also demonstrated that when multiple information cues suggesting different directions of valence are available in the same context, a participant's existing preference, being a diagnostic cue, dominates the judgment process. In their study, a positive warranty, being a less diagnostic cue, will not override the influence of a negative brand preference, which is relatively more diagnostic than the valence of the warranty.

Drawing upon the Accessibility-Diagnosticity Model and Purohit and Srivastava's (2001) arguments, this paper proposes that, for familiar brands, existing brand evaluations will be more diagnostic than attribute information. Therefore, participants' evaluations of a familiar brand will not be affected by the attributes that are presented by competing brands. In contrast, when evaluating an unfamiliar brand, an existing product evaluation is neither available nor accessible. Ad messages thus provide diagnostic information. Under these circumstances, judgments of the unfamiliar brand are more subject to the influence of attributes promoted by competing brands. This paper theorizes that evaluations of brands with established preferences are less likely to be affected by attributes featured in competing ads or the relative uniqueness of promoted attributes. On the other hand, for unfamiliar products, the uniqueness of product attributes featured in their own ads, compared to those featured in competitors' ads, is more diagnostic and will alter the way participants evaluate the ads and the products.

H4: When an unfamiliar brand is considered, emphasizing unique attributes generates higher ratings than shared attributes in terms of ad diagnosticity (H4a), ad liking (H4b), ad persuasiveness (H4c), brand evaluations (H4d) and purchase intentions (H4e), whereas when a familiar brand is considered, ads emphasizing either unique or shared attributes do not generate different ratings.

TABLE 2
Research Design for Experiment Two

Cell		Presence of the Competitor's Ad (Nike)		Presence of the Target Ad (Sperry)
1	Yes	Attributes-Set A (shared)	Yes	Attributes-Set A (shared)
2		Attributes-Set B (unique)		Attributes-Set A (unique)
3		Attributes-Set A (unique)		Attributes-Set B (unique)
4		Attributes-Set B (shared)		Attributes-Set B (unique)
5	No		Yes	Attributes-Set A
6				Attributes-Set B

To argue that the reason why evaluations of a familiar brand are not affected by ad content is due to the influence of existing brand liking, a piece of more diagnostic information, it is important to explicitly test whether or not, when evaluating a familiar product, participants' existing product evaluations will significantly account for the variance in their brand evaluations. At the same time, participants' responses toward the ad in terms of liking or perceived persuasiveness should not affect their brand evaluations.

H5: When the product is familiar, participants' existing product evaluations will significantly predict their brand evaluations, whereas their perceived ad liking and ad persuasiveness will not.

EXPERIMENT TWO

Methodology

Design

This was a two-factor experimental design. The two factors were: presence of competitor's ad (two levels: presence versus absence), product attributes featured in the target ad (two levels: set A versus set B, see Table 2). Participants in the condition in which the competitor's ad was present were exposed to one ad for the competing brand and one ad for the target brand, whereas participants in the condition in which the competitor's ad was absent were exposed to only one ad for the target brand.

Selection of Products and Brands and Stimuli

Sneakers were also selected as the product category in Experiment Two. The same brand, Sperry, was selected to be the target brand. The competing brand was Nike, which was ranked top in market share in the area where the experiment was conducted. Stimuli ads were created by professionals. To reduce confounding effects from using visuals that may generate different favorable ratings in different conditions, visuals were pretested to be similar in terms of liking, interesting, attention drawing, attractive and suitable for advertising shoes.

Participants and Procedures

This study recruited eighty-three participants from undergraduate classes at a university in a metropolitan area. Forty-eight percent of the participants were male. Participants were told that the study was composed of two sessions. The first session was supposedly conducted by the Consumer Protection Committee. The purpose was to understand how college students make purchase decisions regarding ten high involving product categories in order to establish a web site that would provide important product information to college students when they were contemplating a purchase in these categories. Participants were told that to prevent fatigue in answering all the questions regarding each of the ten

product categories, each participant would be randomly assigned two product categories on which to provide his/her views. The product categories assigned to the participants were sneakers and watches. Participants rated the important features they would consider when they purchased sneakers and watches, as well as their evaluations of the leading sneaker and watch brands in the market. The procedures were designed to prevent participants from guessing the true purpose of the study. Participants were told that the second session involved a study being conducted by a professor in the advertising department. The research was designed to understand how different layouts of printed ads impact viewers' information processing. Then, depending on which condition they were assigned to, they were either asked to read a packet of four ads (one stimuli ad for Nike, one stimuli ad for Sperry and two filler ads) or a packet of three ads (one stimuli ad for Sperry and two filler ads). Then participants rated their responses to the ads.

Independent Variables

Presence of the Competitor's Ad. Participants were either exposed to the Sperry ad alone or to both the Sperry ad and the Nike ad. In the former condition, the Sperry ad was inserted between one real ad for a watch and another ad for a soft drink. In the latter condition, the Nike ad was either presented before the Sperry ad and after the watch ad, or after the Sperry ad and before the soft drink ad.

Uniqueness of Featured Attributes. A pretest ($N=20$) asked participants in an open-ended question, the attributes they would take into consideration when they purchased a pair of sneakers. Their responses were coded and ranked. The four attributes ranked at the top were selected. They were: comfortable fit, durability, lightweight and breathability. The four attributes were grouped into two sets, with comfortable fit and lightweight being grouped together in set A and durability and breathability together in set B. The reason for rotating the two sets of attributes for the two products was to reduce confounding effects caused by the idiosyncrasy of the product attributes featured in the ads. In the analyses, the only focus will be on whether the attributes were shared attributes or unique to each brand, regardless of which set of attributes was featured in the ads.

Existing Brand Attitudes toward Nike. Brand attitudes were measured in the first stage with a five-item seven-point Likert scale. The items were adopted from Mitchell and Olson (1981). Cronbach's reliability alpha for this scale was deemed satisfactory at .91.

Dependent Measures

Participants were asked to rate ad diagnosticity on a 3-item seven-point Likert scale. Cronbach's reliability alphas for the scale were assessed at .90 for Sperry and .89 for Nike, which were both satisfactory. Participants rated their liking and the persuasiveness of each ad using the same scales as in Experiment One. Cronbach's

reliability alphas of ad liking were deemed satisfactory at .92 for Sperry and .91 for Nike and Cronbach's reliability alphas of ad persuasiveness were deemed satisfactory at .88 for Sperry and .87 for Nike. Brand attitudes were also measured using the same scale as in Experiment One. Cronbach's reliability alphas for this scale were deemed satisfactory at .90 for Sperry and .92 for Nike. Participants were asked to rate how likely they were to purchase the product in the future on a three-item seven-point Likert scale. The three items were adopted from Zhang (1996). Cronbach's reliability alpha for this scale was deemed satisfactory at .95 for Sperry and .89 for Nike.

Results and Analyses

Hypothesis 2a concerns ad diagnosticity. Analyses showed that when competing ad was present, whether or not the featured attribute was unique had a significant impact on how participants rated the ad on its diagnosticity, $F(1, 39)=5.93, p=.02, M_{\text{shared}}=3.23, M_{\text{unique}}=4.32$. However, when there was no competing ad, featuring various attributes did not have an impact on how participants rated the ad on its diagnosticity, $F(1, 42)=.03, p=.87, M_{\text{set A}}=4.00, M_{\text{set B}}=3.70$. Therefore, supportive results were found for hypothesis 2a.

Hypothesis 2b concerns ad liking. Analyses showed that when competing ad was present, whether or not the featured attribute was unique had a significant impact on how participants evaluated the ad, $F(1, 39)=13.79, p=.01, M_{\text{shared}}=3.20, M_{\text{unique}}=4.55$. However, when there was no competing ad, featuring various attributes did not have an impact on participants' ratings of ad liking, $F(1, 42)=2.22, p=.14, M_{\text{set A}}=4.53, M_{\text{set B}}=3.97$. Thus, hypothesis 2b was supported.

Hypothesis 2c concerns ad persuasiveness. Analyses showed that when competing ad was present, whether or not the featured attribute was unique affected the way participants evaluated the ad in terms of persuasiveness, $F(1, 39)=8.20, p=.01, M_{\text{shared}}=3.40, M_{\text{unique}}=4.46$. However, when there was no competing ad, featuring various attributes did not have an impact on participants' ratings of ad persuasiveness, $F(1, 42)=.19, p=.67, M_{\text{set A}}=4.13, M_{\text{set B}}=3.97$. Therefore, hypothesis 2c was supported.

Hypothesis 2d concerns brand evaluations. Analyses showed that when competing ad was present, whether or not the featured attribute was unique had a significant impact on how participants evaluated the brand, $F(1, 39)=14.59, p=.01, M_{\text{shared}}=3.26, M_{\text{unique}}=4.65$. However, when there was no competing ad, featuring various attributes did not have an impact on participants' brand evaluations, $F(1, 42)=.30, p=.59, M_{\text{set A}}=3.88, M_{\text{set B}}=4.10$. The clear contrast provided support for hypothesis 2d.

Hypothesis 2e concerns purchase intention. Analyses showed that when competing ad was present, whether or not the featured attribute was unique had a significant impact on participants' levels of purchase intention toward the advertised brand, $F(1, 39)=7.91, p=.01, M_{\text{shared}}=1.94, M_{\text{unique}}=3.35$. However, when there was no competing ad, featuring various attributes did not have an impact on participants' levels of purchase intention, $F(1, 42)=.01, p=.99, M_{\text{set A}}=3.01, M_{\text{set B}}=3.02$. Therefore, hypothesis 2e was supported.

Hypothesis 3 suggests that ad diagnosticity will affect brand evaluations through its influence on ad liking and ad persuasiveness. Regression showed that: (1) ad diagnosticity exerted a significant impact on ad liking, $t=9.23, p<.01, b=.72$, and ad persuasiveness ratings, $t=9.76, p<.01, b=.74$; (2) ad liking and ad persuasiveness contributed significantly to brand evaluations (for ad liking, $t=10.39, p<.01, b=.76$; for ad persuasiveness, $t=10.31, p<.01, b=.75$); (3) ad diagnosticity had a significant impact on brand evaluations, $t=6.31, p=.01, b=.57$; (4) when ad diagnosticity, ad

liking and ad persuasiveness were in the equation, the impact of ad diagnosticity on brand evaluations disappeared, $t=-.28, p=.78, b=-.03$, but the impacts of ad liking and ad persuasiveness were still significant (for ad liking, $t=2.93, p=.01, b=.42$; for ad persuasiveness, $t=2.74, p<.01, b=.41$). These results supported hypothesis 3.

To test H4a-4e, repeated measure MANOVA was first conducted. The results indicated that the significance of the interaction between brand difference (Nike vs. Sperry) by uniqueness of featured attributes (unique vs. shared) on ad diagnosticity, ad liking, ad persuasiveness, brand evaluations and purchase intention was at .055, $F(1, 39)=2.47$. Hypothesis 4a concerns ad persuasiveness. ANOVA indicated that the interaction was not significant, $F(1, 39)=.53, p=.47$. Yet, whether or not the featured attribute was unique had a significant impact on how participants rated the Sperry ad on its diagnosticity, $F(1, 39)=5.93, p=.02, M_{\text{shared}}=3.23, M_{\text{unique}}=4.32$. In clear contrast, the uniqueness of the featured attributes did not have an impact on how participants rated the Nike ad on its diagnosticity, $F(1, 39)=1.89, p=.18, M_{\text{shared}}=4.38, M_{\text{unique}}=3.70$.

Hypothesis 4b concerns ad liking. ANOVA indicated that the interaction was significant, $F(1, 39)=8.81, p=.01$. Whether or not the featured attribute was unique had a significant impact on how participants evaluated the Sperry ad, $F(1, 39)=13.79, p=.01, M_{\text{shared}}=3.20, M_{\text{unique}}=4.55$. On the other hand, the uniqueness of the featured attributes did not have an impact on participants' liking of the Nike ad, $F(1, 39)=.61, p=.44, M_{\text{shared}}=4.65, M_{\text{unique}}=4.40$. Therefore, supportive results were found for hypothesis 4b.

Hypothesis 4c concerns ad persuasiveness. ANOVA indicated that the interaction was significant, $F(1, 39)=4.10, p=.05$. Whether or not the featured attribute was unique affected the way participants evaluated the Sperry ad in terms of persuasiveness, $F(1, 39)=8.20, p=.01, M_{\text{shared}}=3.40, M_{\text{unique}}=4.46$. In contrast, whether or not the featured attributes were unique did not affect how participants rated the Nike ad on persuasiveness, $F(1, 39)=.45, p=.51, M_{\text{shared}}=4.76, M_{\text{unique}}=4.50$. Therefore, hypothesis 4c was supported.

Hypothesis 4d concerns brand evaluations. ANOVA indicated that the interaction was significant, $F(1, 39)=7.75, p=.01$. Whether or not the featured attribute was unique had a significant impact on how participants evaluated Sperry, $F(1, 39)=14.59, p=.01, M_{\text{shared}}=3.26, M_{\text{unique}}=4.65$. Conversely, the uniqueness of the featured attributes did not influence participants' evaluations of Nike, $F(1, 39)=1.32, p=.26, M_{\text{shared}}=5.33, M_{\text{unique}}=5.11$. Hypothesis 4d was thus supported.

Hypothesis 4e concerns purchase intention. ANOVA indicated that the interaction was significant, $F(1, 39)=7.79, p=.01$. Whether or not the featured attribute was unique had a significant impact on participants' purchase intentions toward Sperry, $F(1, 39)=7.91, p=.01, M_{\text{shared}}=1.94, M_{\text{unique}}=3.35$. However, whether the featured attributes were unique or not did not have an impact on participants' purchase intentions toward Nike, $F(1, 39)=1.32, p=.26, M_{\text{shared}}=4.75, M_{\text{unique}}=5.34$. Therefore, hypothesis 4e was supported.

Hypothesis 5 proposes that when the product is familiar, participants' existing product evaluations will predict their brand evaluations, whereas their perceived ad liking and ad persuasiveness will not. As expected, when brand evaluations were regressed upon participants' existing attitudes toward Nike, their ad liking and their ad persuasiveness, the impact of existing ad attitudes was significant, $t=4.51, p=.01, b=.54$, yet ad liking and ad persuasiveness did not exert significant influence on brand evaluations (for ad liking, $t=.77, p=.45, b=.19$; for ad persuasiveness, $t=.78, p=.44, b=.20$). These results indicated that, when evaluating a familiar

product, existing brand attitude was a more diagnostic cue than the responses generated by one-shot ad exposure. Therefore, hypothesis 5 was supported.

Discussion

Findings of Experiment Two provided strong evidence regarding the influence of attribute uniqueness in two ways. First, the clear contrasts in terms of ratings of ad diagnosticity, ad liking, ad persuasiveness and brand liking in the two different contexts were directly presented. This indicated that it was indeed the competitive ad context that caused the differences. Second, two sets of product attributes were rotated for Nike and Sperry. This ensured that it was attribute uniqueness, not the idiosyncratic characteristics of the selected product attributes that led to different ad and brand evaluations. Additionally, Experiment Two proffered more evidence for the Accessibility-Diagnosticity Model by showing that the ads featuring unique product attributes were perceived to be more diagnostic, as well as by establishing the mediational process via which ad diagnosticity affects brand evaluations through its influence on ad liking and ad persuasiveness ratings. Experiment Two also extended the exploration of attribute uniqueness effects by demonstrating that brand familiarity moderated the influence of uniqueness of featured attributes.

GENERAL DISCUSSION

Findings of the two experiments suggest that the effectiveness of advertising should not be considered without taking the competitive ad context into account. Brand judgments in a competitive advertising context are partly determined by information presented in the target ad, and partly affected by information presented in competitors' ads. The findings can be well explained by Accessibility-Diagnosticity Model, which theorizes that information that is accessible at the time judgments are made does not necessarily affect brand evaluations unless the piece of information is relatively diagnostic. Experiment Two further establishes the process via which ad diagnosticity affects ad liking and ad persuasiveness, thereby influencing participants' brand evaluations.

Ad exposure does not exert significant influence on brand evaluations for familiar products. This is consistent with Kent and Allen's (1994) findings which indicate that, in a cluttered viewing environment, consumers' ad recall for a familiar brand is less affected by exposure to competitors' ads, as well as Machleit, Allen and Madden's (1993) findings which demonstrate that consumers' brand attitudes for a familiar brand are less affected by ad exposure. Within the Accessibility-Diagnosticity Model, this study reasons that existing brand attitudes provide more diagnostic information than product information presented in ads, therefore, whether or not the featured product attributes are unique does not affect the way participants respond to ads or products, as it does when ads feature an unfamiliar product.

One of the important implications that can be derived from this study's findings is that, for advertisers of newly introduced products, it is important to use caution in selecting which product attributes to emphasize in ad messages. When a new brand introduces or highlights an attribute that is not readily associated with competing brands, more positive evaluations will be developed. In other words, me-too strategies will definitely not help a new brand. A more effective way to avoid the failure of a new product would be to focus on an important, yet less featured attribute, which will help break up ad clutter and lead to more favorable responses toward the ad and the brand, and even generate higher purchase intentions.

The final, yet most important implication for marketers, is that it is crucial to test ad effectiveness in real viewing contexts. Given that the effectiveness of ad messages may vary depending on other ads in the viewing context, the interference from these surrounding advertisements may be too important for advertisers to ignore. Overlooking the interplay between the target ad and competing ads may limit our understanding of consumers' ad-viewing processes, inflate estimates of ad effectiveness and even bias marketers' decision-making regarding which strategy is going to be effective.

Discerning Store Brand Users from Value Consciousness Consumers: The Role of Prestige Sensitivity and Need for Cognition

Yeqing Bao, University of Alabama in Huntsville
Carter A. Mandrik, Koç University

ABSTRACT

Research shows that consumers who seek value are the main purchasers of store brands or private labels. In this paper we corroborate that value consciousness is positively related to store brand purchase. We further demonstrate that two other personality traits, prestige sensitivity and need for cognition influence store brand usage. Prestige sensitivity has a direct effect, but contrary to our hypothesis, need for cognition did not. Moreover, both prestige sensitivity and need for cognition were shown to moderate the effects of value consciousness on private label usage.

DISCERNING STORE BRAND USERS FROM VALUE CONSCIOUSNESS CONSUMERS

Research interest in store brand or private label consumption has seen a revival concomitant with the rapid growth of the private label in recent years. Store brands provide fairly good quality but lower price compared to national brands, which constitutes a good value perception to some consumers and compels them to buy (e.g., Richardson, Jain and Dick 1996; Burton, et al. 1998). But national brands use sales promotions to enhance their value proposition, a tactic recommended as a way to keep the value conscious segment (e.g., Quelch and Harding 1996). Thus, it seems that for this segment in particular, competition between manufacturers and retailer has intensified, increasing the need to understand the relationship between value consciousness and store brand usage.

In line with recent research (e.g., Ailawadi, Neslin, and Gedenk 2001), the current study seeks insight into store brand usage and value seeking. We examine the relationship between value consciousness (Lichtenstein, Netemeyer, and Burton 1990) and store brand usage, proposing factors that may moderate this relationship. Specifically, we test the influence of prestige sensitivity (Lichtenstein, Ridgway, and Netemeyer 1993) and need for cognition (Cacioppo and Petty 1982) in moderating the effect of value consciousness on consumers' purchase of store brands.

CONCEPTUAL DEVELOPMENT

Perceived value has long been considered an important driver of a consumer's purchase decision (e.g., Dodds, Monroe, and Grewal 1991; Szybillo and Jacoby 1974; Zeithaml 1988). Generally, if a product provides better value than others, then consumers' purchase intention of this product will be high (Dodds, Monroe, and Grewal 1991). A simple expression of perceived value is the ratio of quality received relative to price paid (Lichtenstein, Netemeyer, and Burton 1990; Lichtenstein, Ridgway, and Netemeyer 1993; Monroe and Petroshius 1981). Store brands, although not providing quality as high as national brands are able to deliver high perceived value because of their lower prices, making them attractive to value-conscious consumers (Richardson, Jain and Dick 1996; Burton, et al. 1998). However, if value-conscious consumers prefer some unique benefits that cannot be met by store brands then their desire to purchase store brands might be weakened.

In particular, store brands are generally thought to suffer a deficit compared to national brands in regard to the social symbolic or image benefits they offer. Factors that increase consumer's desire for these benefits should affect store brand purchase, and additionally, may moderate value-seeking tendencies. For example, some consumers may be motivated in brand purchase by

factors related to impression management, for example social conformity and reference group influence (e.g., Bearden and Etzel 1982; Bearden and Rose 1990). One such factor is prestige sensitivity, a personality trait that reflects consumers' "favorable perceptions of the price cue based on feelings of prominence and status that higher prices signal to other people about the purchaser" (Lichtenstein, Ridgway, and Netemeyer 1993, p. 236). To the extent consumers associate store brands with lower prices and are concerned about what using a lower-priced product may signal to significant others, store brand usage should diminish.

In addition, there is reason to believe that store brand choice may be affected by how consumers process brand-related information. The brand cue is often used as a signal of quality when other more probative information is lacking or the consumer lacks the motivation to invest cognitive resources necessary to use this information (e.g., Dodds, Monroe, and Grewal 1991; Zeithaml 1988). Motivation is also affected by a person's need for cognition, a trait reflecting the person's inherent enjoyment of engaging in effortful thought (Cacioppo and Petty 1982). There is ample research evidence demonstrating that high need for cognition individuals engage in more information-processing activity than low need for cognition individuals (Cacioppo, et al. 1996). One study proposed that need for cognition was somehow related to store brand usage but did not find a significant effect (Ailawadi, Neslin, and Gedenk 2001). However, we believe need for cognition may yet be related to store brand usage both directly and as a moderator of the effect of value consciousness.

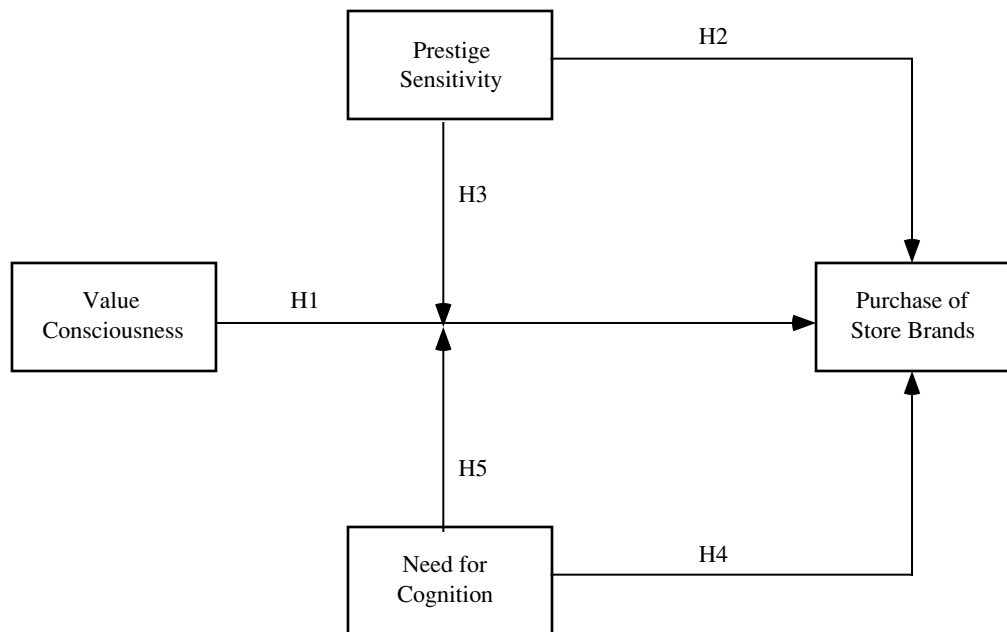

The model depicted in Figure 1 shows the proposed relationships examined in this study. In the model, prestige sensitivity and need for cognition moderate the effect of value consciousness on consumer's purchase of store brands. We now develop each hypothesis in turn.

Value Consciousness and Purchase of Store Brands

Value consciousness reflects consumers' concern for price paid relative to quality received in a purchase transaction (Lichtenstein, Ridgway, and Netemeyer 1993). However, this does not necessarily mean any product will provide good value: low priced products provide good value to consumers only if these products also meet certain quality specifications (Corstjens and Lal 2000; Lichtenstein, Netemeyer, and Burton 1990). Although store brands used to be considered inferior to national brands, they have achieved great quality improvement in recent years (DeNitto 1993; c.f., Corstjens and Lal 2000). More and more consumers accept that store brands carry fairly good quality yet much lower price, hence good value. This is attested to by the faster growth of store brand sales than national brand sales (*Supermarket Business* 1998). Thus, to many value-conscious consumers, store brands represent a better bargain than national brands and provide good incentive to purchase. Although we contend that not all value-conscious consumers will purchase store brands, past research has demonstrated a relationship between value consciousness and store brand proneness (Burton et al. 1998). Therefore, it is proposed that,

H1: Value consciousness is positively related to purchase of store brands.

FIGURE 1
Consumers' Purchase of Store Brands

Prestige Sensitivity and Purchase of Store Brands

Prestige sensitivity is related to favorable perceptions of the price cue based on the status or prominence higher-priced products signal to others (Lichtenstein, Ridgway, and Netemeyer 1993). Consumers with high prestige sensitivity may buy expensive goods not because of quality perceptions *per se*, but because of the perception that others may perceive them as socially positive because of the high price. Store brands are normally priced at approximately 30% lower than national brands (Information Resources Inc. 1999), thus could seldom serve the purpose of signaling prominence and status to other people. Hence, it is proposed that consumers with high prestige sensitivity will buy fewer store brands than those with low prestige sensitivity.

H2: Prestige sensitivity is negatively related to purchase of store brand.

Interaction between Value Consciousness and Prestige Sensitivity

As indicated above, in general value-conscious consumers tend to buy store brands. However, a value-conscious consumer may be high or low in prestige sensitivity. For those who are highly value-conscious as well as highly prestige sensitive, the good value provided by the store brands may not be attractive because these brands normally do not signal prominence and status to others. Value consciousness for these consumers may appear as actively pursuing name brands on promotion. Thus, for these consumers, the association between value consciousness and purchase of store brands will be weak, if any.

On the contrary, for highly value-conscious consumers with low prestige sensitivity, the prominence and status attached to the high price is less important. Therefore, for these consumers, the association between value consciousness and purchase of store

brands should be strong. The above contention leads to the following hypothesis,

H3: The relationship between value consciousness and purchase of store brands is stronger for low prestige sensitivity consumers than for high prestige sensitivity consumers.

Need for Cognition and Purchase of Store Brands

Need for cognition refers to an individual's intrinsic enjoyment of and motivation to engage in effortful cognitive information processing (Cacioppo and Petty 1982). Consumer researchers have long recognized the need for cognition as an important factor in influencing consumers' purchasing behaviors (e.g., Inman, Peter, and Raghurir 1997; Inman, McAlister, and Hoyer 1990). How consumers arrive at a brand-related judgment, such as judgments of quality or value, is affected by need for cognition because of the implications of processing intrinsic (attribute-related) information.

Low need for cognition individuals are more likely to rely on easily processed peripheral cues or other marketplace signals and provide little elaboration on such information to form an attitude. High need for cognition individuals rely more on message content and engage in more elaboration of such information in forming their attitude (e.g., Inman, Peter, and Raghurir 1997; Zhang and Buda 1999). Store brands have limited distribution, engage in less advertising, and typically charge lower prices than national brands. Taken as extrinsic cues or market signals, these characteristics place them at a disadvantage compared to national brands. Extrinsic cue effects were shown to play a more important role in brand evaluations than product ingredients in comparisons between the two brand types (Richardson, Dick, and Jain 1994). These easily processed information cues may signal inferior quality to consumers with low need for cognition. However, consumers with high

need for cognition may pay more attention to information from product labels and engage in more extensive comparisons with national brands. This effort may lead them to more greatly appreciate the quality offered by store brands, and thus deem them good purchase values. Therefore, consumers with high need for cognition should be more likely to consider store brands than those with low need for cognition.

H4: Need for cognition is positively related to purchase of store brands.

Interaction between Value Consciousness and Need for Cognition

H1 proposed that value consciousness is positively related to store brand usage. However, value is a perceived construct and, as argued above, judgments of quality and value—which affect purchase intentions—are influenced by the manner in which these judgments are formed. If consumers form judgments based on extrinsic cues and they are high in value consciousness, they may opt not to buy store brands but instead buy national brands or national brands on deal. On the other hand, if the consumer forms judgments based on elaborated processing of intrinsic attributes and they are highly value conscious, they should be more likely to perceive a better value in store brands. Therefore, it is proposed,

H5: The relationship between value consciousness and purchase of store brands is stronger for high need for cognition consumers than that for low need for cognition consumers.

METHODOLOGY

Sample

A survey was designed and undergraduate college students participated in the study for extra credit. In total, 213 useable cases were obtained of which freshmen, sophomores, juniors, and seniors are roughly evenly distributed (19.4%, 20.9%, 34.6%, and 25.1%, respectively). A bit more than half (70.4%) are females and the majority is White (76.7%), followed by Asian (10.0%) and Black (9.5%).

Measures

Value consciousness, prestige sensitivity and need for cognition are independent variables and purchase of store brands is the dependent variable in the study. The measure for value consciousness was taken from Lichtenstein, Netemeyer, and Burton (1990). Subjects were asked to rate their agreement on a 7-point scale (1=strongly agree to 7=strongly disagree) with seven items such as “I am very concerned about low prices, but I am equally concerned about product quality” and “When I shop, I usually compare the ‘price per ounce’ information for brands I normally buy.” After reverse coding, the score for the scale should range from 7 to 49, with the higher score indicating greater value consciousness. For our sample, the mean score was 38.06 (s.d.=7.05). The Cronbach reliability coefficient alpha was .78, comparable to that in the original study.

The measure for prestige sensitivity was taken from Lichtenstein, Ridgway, and Netemeyer (1993). The scale includes nine items, asking subjects to indicate their agreement on a 7-point scale (1=strongly agree to 7=strongly disagree) with statements such as “Buying a high priced brand makes me feel good about myself” and “Even for a relatively inexpensive product, I think that buying a costly brand is impressive.” After reverse coding, the

score for the scale should range from 7 to 63, with higher scores indicating greater prestige sensitivity. For our sample, the mean score was 29.68 (s.d.=10.39). For this scale Cronbach’s alpha was .86, indicating good reliability.

Need for cognition was measured by Cacioppo, Petty, and Kao’s (1984) abbreviated 18-item scale. Subjects were asked to indicate their agreement on a 7-point scale (1=strongly agree to 7=strongly disagree) with statements such as “I would prefer complex to simple problems” and “I find satisfaction in deliberating hard and for long hours.” After appropriate coding, the scale should range between 18 and 126, with higher scores on the scale reflecting greater need for cognition. Subjects in this study exhibited a mean score of 80.79 (s.d.=14.81). Cronbach’s alpha was .87, which is consistent with previous studies (e.g., Cacioppo, Petty, and Kao 1984; Inman, Peter, and Raghuram 1997).

For consumers’ purchase of store brands, an index of private label usage was developed. Subjects were asked to report the brand they most often buy or would be most likely to buy next time they purchase the product for 20 grocery goods (see Appendix), pre-tested for relevance to the sample and similar to the ones used in past research (e.g., Richardson, Jain, and Dick 1996). Subjects were instructed to write down “do not use” or “any brand” if applicable. Then, the ratio (expressed in percentage) of the number of store brands over the number of products they use is computed as the index of consumers’ purchase of store brands. Although some past research has used frequency scales (i.e., purchasing the brands “very often” to “not very often”) to indicate store brand usage (e.g., Myers 1967; Richardson, Jain, and Dick 1996), an index was deemed less prone to subjective interpretation. Theoretically, this index could range between 0 and 100; for our sample it ranged between 0 and 75, with a mean of 16.73 (s.d.=15.83).

Analysis

Hypotheses 1, 2 and 4 predict main effects and are tested by multiple regression. Hypotheses 3 and 5 predict moderation effects and are tested according to the method proposed by Baron and Kenny (1986).

RESULTS

Table 1 reports the bivariate correlations between the independent variables and dependent variables.

Hypothesis 1, 2 and 4 predict that the main effects of consumers’ value consciousness, prestige sensitivity, and need for cognition on their purchase of store brands. Although the Pearson correlations between value consciousness and prestige sensitivity and that between value consciousness and need for cognition are significant, the coefficients are fairly small (see Table 1). Hence, it is deemed that multicollinearity will not be a severe problem if the three variables are entered simultaneously to a regression. As expected, the collinearity tolerance for all three variables is very high ($\geq .94$, see Table 2).

The multiple regression show significant results, with $R^2=.09$, $F(3, 202)=6.90$ ($p<.001$). Coefficients are significant for value consciousness and prestige sensitivity ($p=.05$, and $.00$, respectively), but not for need for cognition ($p=.09$). Thus, H1 and H2 are supported but H4 is not.

Hypothesis 3 and 5 predict the moderating effect of prestige sensitivity and need for cognition on the relationship between value consciousness and purchase of store brands. Following Baron and Kenny’s (1986) suggestion, the moderators are first dichotomized at the median point. Then, the effect of value consciousness on purchase of store brands is measured at each level of the moderators. Results are presented in Table 3.

TABLE 1

TABLE 2
Effects of Value Consciousness, Prestige Sensitivity, and Need for Cognition on
Consumers' Purchase of Store Brands

Independent Variables	Dependent Variable Purchase of Store Brand Index				Collinearity Tolerance
	Unstandardized Beta	Std. Error	t	p-value	
(Constant)	4.28	8.83	.49	.63	
Value Consciousness	.31	.16	1.98	.05	.94
Prestige Sensitivity	-.32	.11	-2.99	.00	.96
Need for Cognition	.13	.07	1.72	.09	.98

Note. -R²=.09, F (3, 202)=6.90 (p<.001).

TABLE 3
Moderating Effects of Prestige Sensitivity and Need for Cognition

Moderator	Level of Moderator	Independent Variables	Dependent Variable Purchase of Store Brand Index				Comparison of Betas
			Unstandardized Beta	Std. Error	t	p-value	
Prestige Sensitivity	Low (n=110)	(Constant)	-1.14	9.47	-.12	.91	<i>t</i> =10.71***
		Value Consciousness	.53	.24	2.25	.03	
Need for Cognition	High (n=102)	(Constant)	5.90	7.19	.82	.41	<i>t</i> =-7.53***
		Value Consciousness	.21	.19	1.07	.29	
	Low (n=105)	(Constant)	4.09	8.59	.48	.64	<i>t</i> =-7.53***
		Value Consciousness	.29	.23	1.28	.20	
	High (n=103)	(Constant)	-1.99	8.45	-.24	.82	
		Value Consciousness	.52	.21	2.45	.02	

Note: ***-p<.001

For prestige sensitivity, the upper group exhibits a mean of 38.72 (s.d.=4.92, n=102) and the lower group has a mean of 21.31 (s.d.=6.30, n=110). The impact of value consciousness is significant for consumers with low prestige sensitivity ($t=2.25$, $p=.03$) but not for those with high prestige sensitivity ($t=1.07$, $p=.29$). The difference between the unstandardized coefficients is significant ($t=10.71$, $p<.001$). Therefore, H3 is supported.

For need for cognition, the upper group exhibits a mean of 92.21 (s.d.=9.31, n=103) and the lower group has a mean of 69.58 (s.d.=9.77, n=105). The impact of value consciousness is significant for consumers with high need for cognition ($t=2.45$, $p=.02$) but not for those with low need for cognition ($t=1.28$, $p=.20$). The difference between the unstandardized coefficients is significant ($t=-7.53$, $p<.001$), supporting H5.

DISCUSSION

This study attempts to shed light on the relationship between value consciousness and store brand usage. Consistent with past research (Burton et al. 1998; Deveny 1993), this study shows value consciousness to be positively related to using private labels (H1). The value consciousness measure developed by Lichtenstein et al. and used here captures the degree to which consumers are concerned for value and the level of effort they devote toward value-seeking behavior, such as side-by-side price and quality comparisons. Naturally, then, with this added effort, consumers can make quality and value judgments less biased by extrinsic cue effects, as they might otherwise (e.g., Hoyer and Brown 1990; Richardson, Dick, and Jain 1994).

However, we further demonstrate that all value-conscious consumers are not equally attracted to store brands. As a matter of fact, those with high prestige sensitivity and those with low need for cognition are not attracted to store brands at all (see Table 3). For the former, it is probably because store brands do not provide a feeling of prestige, although it may exhibit good value. For the latter, it is probably because they do not evaluate store brands in great detail thus do not appreciate or recognize the value such brands provide. Examining the value consciousness scale reveals that it is comprised of both behavioral items (e.g., related to use of unit price information) and attitudinal items (e.g., related to how consumers appreciate getting low priced but adequate quality goods). Future research might explore the value consciousness concept in more detail, perhaps by separating components related to effort-involving behavior from components related to preferences for perceived value. In sum it seems that consumers who are value conscious but also pay little attention to product prestige or enjoy effortful cognitive information processing play the leading roles in purchasing store brands (H3 and H5).

This finding provides good implications for retailers who carry store brands and manufacturers who produce name brands. Manufacturers have been concerned that retailers are competing with them for value-conscious consumers via store brands. However, a combination of store brand and national brand users can be beneficial to retailers (Corstjens and Lal 2000), necessitating those who develop store brands to find ways to attract more consumers to their own brands but not disenfranchise national brands or their consumers. A recent study suggests that this is possible if manufacturers and retailers carefully segment the market and target appropriate segments (Ailawadi, Neslin, and Gedenk 2001). The results of our study reinforce this suggestion.

The hypothesis regarding the main effect of need for cognition on purchase of store brands (H4) is not supported. One reason we suspect behind this failed finding may be the use of college students as subjects. On average, college students are higher in need for

cognition than general consumers. In the current study, subjects' need for cognition score ranges from 42 to 126 with the mean of 80.79 (s.d.=14.81). And most (71.15%) are located within the range of one s.d. to the mean. Apparently, they are skewed toward the high end and are restricted around the mean. This range restriction may have reduced the testing power of H4. Therefore, future research is called to retest the relationship with a more general set of consumers.

Past research seems to reveal a general pattern regarding store brand consumption, related to two main factors. First, store brands seem to benefit from a higher level of consumer information processing. Thus, factors related to consumers' ability and motivation to process brand-relevant information should be considered topics for research. Second, store brands seem to suffer a disadvantage compared to national brands on the basis of value expressive benefits offered. Thus, factors related to a consumer's social and self-image should be investigated in the context of the store brand versus national brand choice.

Kids, Causes, and Culture: Expansion of Commodities and Consumers In the 1990s

Daniel Thomas Cook, University of Illinois, Urbana-Champaign

SUMMARY

The papers in this panel explored three distinct arenas of social life that have encountered new and intensive forms of marketization in the 1990s. Daniel Thomas Cook investigated the new and contradictory notions of the “child consumer” that have come to occupy an increasingly central place in marketing discourse and practice. Cook detailed the schizoid character of the new child consumer through an analysis of market research reports and trade literature of several children’s industries. He discussed how the discursive transformation of children’s consumer identity made the boom in the kids’ market morally palatable and thus economically viable.

Inger Stole examined the proliferation of cause-related marketing, questioning whether the altruism behind such efforts is helped or hindered when subordinated to the ultimate goal of branding. Teasing out the differing public relations functions behind cause-related efforts, in particular that of American Express, Stole argued that this new marketing initiative serves to displace other, more effective and direct forms of philanthropy. Blurring the boundaries between consumption and charity may reinforce the corporate sponsor’s image at the expense of the groups in need of help.

Douglas Holt and David Crockett focused in the commodification of poor black urban neighborhoods, euphemistically termed “urban culture.” They delineated the idea of “strategic racialization” as the use of race to reference potent cultural sites used to add brand value. Pinpointing the rise of this phenomenon to late 1980s, Holt and Crockett gave a close reading of the racialized branding in Mountain Dew television commercials. The authors noted the particular challenges facing marketers in articulating racialized value to such brands in a credible manner.

Panel discussion leader, Linda Scott, noted how all the papers took what seemed to be unconnected associations, images and practices and turned them on their head exposing unseen dimensions of ideology and meaning. She also remarked on the highly contextual nature of these investigations, calling for more research and thinking which makes use of social and political context in the investigation of consumption and consumer behavior.

“The Gift that Keeps on Giving: Cause-Related Marketing in the 1990s”

Inger L. Stole, University of Illinois, Urbana-Champaign

By most accounts, the coveted prize as “innovator” of cause-related marketing (CRM) goes to American Express. In 1983, the credit card company launched its frequently cited campaign to help restore the Statue of Liberty and Ellis Island. The company promised to contribute 1 cent for every card transaction and \$1 for every new card issued during the last quarter of 1983 to the cause. While the restoration effort, which collected \$1.7 million, was the immediate beneficiary, the 28 percent increase in use of American Express cards showed the financial institution to benefit as well (Andreasen, 1996; Weeden, 1996). The newly minted strategy was not lost on others, and by the early 1990s U.S. businesses were plunging into cause-related marketing on a grand scale. Between 1990 and 1998 the amount spent on such efforts rose from \$125 million to over half a billion dollars annually (Bishoff, 2000/2001). By 1999, American businesses were spending \$630 million on cause-related marketing (“Good deeds,” 1999).

What, exactly, is cause-related marketing? How did it develop and how does it differ from previous forms of corporate philanthropy? Who benefits from cause-related marketing? What are some of its advantages and what are some of its problems or shortcomings? Drawing on secondary literature, the study utilizes historical, economic and sociological frameworks to answer these questions. It traces the roots of cause-related marketing to the rise of corporate public relations in the early 20th century (Marchand, 1987; Marchand, 1998; Ewen 1996) and teases out similarities between early forms of public relations, which rose in response to a corporate need to connect with publics beyond the mere point of purchases and service, and cause-related marketing of today. Having established a historical context for cause-related marketing, the study positions the phenomenon within the larger framework of what is commonly referred to as “strategic philanthropy” and explore how cause related marketing distinguish itself from its other forms. It also provide an overview of the techniques and strategies most commonly used in cause-related marketing campaigns.

Departing from recent studies concerning the effect of cause-related marketing on company sales and image (Barone, Miyazaki and Taylor, 2000; Till and Nowak, 2000; Bronn and Vroni, 2001; Welsh, 1999, Webb and Mohr, 1998; Mizerski, Mizerski and Sadler, 2001), the study explores the broader, and more political ramifications, behind this marketing strategy. While cause-related marketing, at least at first glance, appear to be a perfect solution for financially strapped non-profit groups and large corporations alike, it also raises some important questions. What, for example, are the criteria used by business to determine issues that warrant cause-related attention? Do some social causes lend themselves more easily to cause-related marketing ventures than others? And what are some of the larger ramifications of trying to solve social problems through acts of consumption (Andreasen, 1996; Andreasen, 2001; Hutton, 2001; King, 2001; Polonsky and Wood, 2001; Pringle and Thompson, 2001; Peeples, 2002)?

"Contradictions and Conundrums of the Child Consumer: The Emergent Centrality of an Enigma in the 1990s"

Daniel Thomas Cook University of Illinois, Urbana-Champaign

The child consumer today appears as a contested figure on the public landscape of consumption. It stands both for corporate exploitation and individual autonomy. It's appetite for apparently all things commercial has been seen, on one hand, as evidence of over-indulgence on the part of parents and relatives and, on the other, as the child's active partaking in the deserved pleasures of childhood (and, to a less explicit degree, of consumer capitalism).

Since the late 1980s, the children's market has exploded. James McNeal (1999) estimated that children's direct and indirect (i.e., influence) purchases tripled during the 1990s accounting for perhaps \$30 billion in annual sales toward the end of the decade in the US alone. During this time, market forces have made inroads into children's lives new ways. With the advent of school-based television network, Channel One, now in use in about 12,000 classrooms, many children experience commercials as a routine and unremarkable part of their daily lessons. In the 1990s, new licensing agreements, tie-in promotions and cross-branding of

merchandise made logos and media characters ubiquitous and have worked to interweave previously disparate products—from fast food to film, from clothing to television shows, from action figures to greeting cards—into a single promotional mix. In addition, new child-targeted media like cable stations and the internet together with special sections of newspapers, new magazines, radio programs and stations have combined to increasingly delineate, and thereby deliver, "children" as a market.

Monetary measures and commercial innovation offer only a surface glimpse at deeper developments in the kids' market generally, and in social understanding of "the child" more specifically. Underlying and supporting the growth in the children's market has been an ongoing transformation of a quite fundamental kind—a transformation in the conceptualization of the kind of being a "child" is, particularly as an economic actor, i.e., as a consumer.

Beginning in the 1970s, consumer socialization emerged as the dominant paradigm to understanding the changing contours of children's involvement in the market sphere over the early life course (John 1999). Consistent with an "ages and stages" template of growth, most consumer socialization research assumes an essentially linear trajectory of child development from less to more knowledgeable, from simple to complex information processors, from unskilled to skilled consumers (see Gunther and Furnham 1998). Since the 1980s, the working model of the "child consumer" informing marketing and advertising *practice* (but not necessarily the academic research) has gradually discarded a developmental or socialization approach—but not completely—in favor of treating and portraying children as "independent" consumers.

Most generally, the view of "the child" has been moving in the direction of seeing children as increasingly complete beings unto themselves, with pre-existent desires for goods and, importantly, with the socially adjudicated right and wherewithal to request, demand and/or purchase these goods. In short, "the child" has been emergent as more or less a full person, in the social sense, particularly in the realm of consumption (see Cook 2000).

The view of "the child" as autonomous consumer-person is not limited to market perspectives and discourse as evidenced, for instance, by the increasing role children play in family purchasing decisions. Children's personhood status also cannot be divorced from their ever-intensifying role and posture as consumers. Yet, children's identity as consumers is fraught with controversies and conundrums.

There has arisen a schizoid image of the child consumer. One the one hand, there is the view of the child as a purposeful economic actor who exhibits competence in information processing and consumer choice. This "child" is favored by those invested in selling to children and parents. Prior to the mid-'80s, this view took the form of the "sophisticated" or "savvy" child who was portrayed in advertisements and discussed in the trades as a knowing consumer who makes informed choices about goods. By the 1990s, this view began to mutate into a discourse of child "empowerment" whereby "the child"—knowing or not, sophisticated or not—would gain social power through gaining access to specially-designed goods and entertainment. The implication behind this construction was that to deny the child goods was tantamount to disempowering her or him.

This new "child" has clashed with another set of dominant images—those of innocent, vulnerable children—who are subject to all sorts of dangers from the marketplace and beyond. Social critics and watchdog groups like Action for Children's Television have made their presence felt in the political arena surrounding children and consumption. From this perspective, the tactics used by marketers—such as the media tie-ins, cross-branding and the

active cultivation of “pester power” by some—amounts to the exploitation of *unknowing* or less than competent consumers.

Drawing upon more than a decade of market research, trade literature and advertising campaigns from a variety of industries focusing on children’s direct and indirect purchasing influence—clothing, toys and food, in particular—this paper offers an interpretive analysis of the recent (1990s+) transformations in the depiction and definition of children as competent, knowledgeable consumers/audience members. In what ways has the transformation of children’s consumer identity made the boom in the kids’ market morally palatable and thus and economically viable?

The discussion offers a perspective which avoids an either/or understanding of the issues and instead focuses on delineating the conceptual conundrums involved in the ongoing battle over which model of the child will govern the place of children in an increasingly marketized world.

A Preliminary Study on Common Variable Selection Strategy in Data Fusion

Jonathan S. Kim, Hanyang University
Seung Baek, Hanyang University
Sungbin Cho, Konkuk University¹

ABSTRACT

Data fusion has been known as a major approach for estimating missing values in large databases. Although selecting common variables is one of the important factors in data fusion, few studies have systematically investigated the various methods available. In this study three strategies are considered for selecting a set of common variables and their results are compared using a Monte Carlo simulation. Selection strategies by variance and by weighted importance perform better than random selection. The results also show that, in locating a donor, the Euclidean distance-based selection outperforms the inter-respondent correlation-based selection. Directions for future research are also discussed.

INTRODUCTION

Data Fusion

Data fusion (Baker et al. 1989; Kim and Hamano 1995) is one of the major approaches used to estimate the missing values that occur frequently in surveys conducted in social science research. In data fusion, both respondents and questionnaire (question items) are split into two subsets. One subset has missing information, and the other has complete information. The subset of respondents who have missing information is called recipients and their missing information is estimated (replaced) by the complete information available from another set of respondents called donors, who have answered the missing part of the survey questionnaire. This process is called fusion. In addition, the data fusion approach requires all respondents (both donors and recipients) to answer a common set of question items in a survey called common variables.

In data fusion, a donor is typically found for a recipient who has the highest proximity to the recipient. Proximity among respondents is computed on the basis of a set of common variables. Proximity can be defined according to the Euclidean distance among respondents, inter-respondent similarity, inter-respondent correlations, or some other measures. In cases where the common variables are categorical variables in which distances, similarities or correlation coefficients cannot be directly computed, one can use the chi-square metric method from multiple correspondence analyses (Carroll et al. 1986; Hoffman and Franke 1986), which is a special type of multidimensional scaling technique (Kruskal and Wish 1986).

Data fusion is becoming more and more important these days. With the development of information technology and the explosion of customer data, a methodology is needed to reduce the amount of data to be collected. Successful fusion results in the savings of time and cost in data collection, and consequently less time is needed to analyze the data. Data fusion can be applied to many areas including database marketing (DBM; Hughes 1994; Jackson and Wang 1997) and customer relationship management (CRM; Brown 2000).

As is well known, conditional independence is a theoretical assumption of data fusion. In other words, the donor variables and the recipient variables are conditionally independent given the common variables. Jophcott and Bock (1998) claimed that this assumption becomes more realistic in planned media fusion with conditional independence in mind, than it is in unplanned fusion studies.

Research Objectives

The main objective of this study is to explore the possibility of selecting an optimal set of common variables in the data fusion approach. While data fusion is popular in social science research, to the best of our knowledge, few research have yet been carried out to determine the optimal method to find common variables in data fusion research. In this research, we create missing values by deleting the original values and try to recover them for each individual via data fusion. We adopt three different approaches to select the set of common variables: (1) to select common variables at random, (2) to select those variables with high variances, and (3) to select those variables with high importance weights.

We also adopt two approaches to locate the donors for the purpose of imputing the missing values of the recipients. One approach is to use the inter-respondent correlation coefficients, and the other is to use the inter-respondent Euclidean distances. We manipulate the number of variables with missing information at three levels in our study: (1) one missing variable, (2) two missing variables, and (3) three missing variables.

We try to achieve our research objective by comparing the performance measures, which is the extent to which data fusion recovers the original values of the missing (deleted) variables. The correlation coefficients of the original and the recovered values are taken at an individual level as performance measures of the fusion approach.

The specific research questions include the following:

- (1) How do these three common variable selection strategies perform? What is the impact on the accuracy of the recovered values for each selection strategy?
- (2) How do the two approaches for locating donors perform?
- (3) How much loss occurs in the accuracy of the recovered values by increasing the number of missing variables?

The research objectives are pursued via Monte Carlo simulations of two real world data sets.

METHOD

Data

Two different sets of data from conjoint experiments (Green and Srinivasan 1978; 1990) were used in this study. The first data set deals with the preference (part-worths) for the automobile dealership collected from 700 respondents. The second data set deals with the preference for the credit card service collected from a sample of 480 respondents. The automobile data and credit card service data involve 13 and 12 variables (attributes), respectively. The number of attribute levels for an attribute ranges from two to eight. The attributes of the automobile dealership data include types of vehicles sold (6 attribute levels), outlet location (3 levels), showroom (4 levels), shopping center (3 levels), vehicle financing (3 levels), purchase transaction (3 levels), trade-ins (4 levels), specialized employees (3 levels), new vehicle service (4 levels), availability of loaners and rentals (2 levels), service plans (3 levels), parts (3 levels), and discounts (8 levels). The attributes of the credit card service data include annual fee (6 attribute levels), cash refund

¹Corresponding author

(3 levels), message delivery (3 levels), purchase item insurance (2 levels), air travel insurance (3 levels), rental car insurance (2 levels), luggage insurance (3 levels), airport lounge/club (3 levels), credit card coverage (4 levels), emergency vehicle (2 levels), limousine service (2 levels), and 24 hour customer assistance (2 levels).

Experimental Design

In this research, we first select a set of common variables and create missing values by deleting one, two, or three non-common variables (attributes) at random. We then recover the missing values by applying the fusion approach and compare the recovered values to the original values at an individual level.

Common Variable Selection Strategies

We selected the set of common variables using three different selection strategies as described below.

- (1) Selection at random: We select a set of common variables at random.
- (2) Selection by variance: We select a set of common variables that have the highest variances.
- (3) Selection by weighted importance: We select a set of common variables that have the highest variable importance weights.

The variance and importance weight of the variables have been adopted because we expect that they produce a higher level of variability among respondents, which might help in the donor locating processes. The variances and the importance weights are important bases in cluster analysis (Howard and Harris 1966; Green and Krieger 1991) and other distance models such as multidimensional scaling. The data fusion approach is also one kind of distance model. In this research, we have fixed the number of common variables at six in all simulation runs.

Donor Location Strategies

We adopt two different strategies for locating donors to estimate (recover) the missing values that have been generated. The first strategy is to use the inter-respondent correlation coefficients. In this strategy, the missing value of an attribute (variable) of recipient i is substituted with the value of that variable of donor j , the donor who has the highest correlation coefficient with recipient i . If the value of the donor with the highest correlation with the recipient is also missing, the respondent with the next highest correlation with the recipient becomes the donor.

The second strategy utilizes the Euclidean distance among respondents. In this strategy, the missing value of an attribute (variable) of recipient i is substituted with the value of that variable of donor j , the donor who has the minimum Euclidean distance to recipient i . If the value of the donor with the minimum distance to the recipient is also missing, we locate the respondent with the second minimum distance to the recipient as the donor.

In both approaches, proximity measures (inter-respondent correlations and inter-respondent distances) were calculated with six common variables for both the automobile dealership data and the credit card service data.

Number of Variables Deleted

After selecting the set of common variables according to the three different strategies described above, we delete one, two, or three variables at random for each respondent.

Therefore, the experimental design for the research can be summarized as follows.

- (1) Common Variable Selection Strategies (3 levels): At Random; By Variance; and By Weight.

- (2) Donor Location Strategies (2 levels): By Correlation and By Euclidean Distance.
- (3) Number of Variables with Missing Values (3 levels): Deleting One Variable; Deleting Two Variables; and Deleting Three Variables.

A 3 X 2 X 3 full factorial design of the three experimental factors produced 18 combinations. For each combination of the factor levels, 20 simulations were carried out. For each simulation, the correlation coefficient was computed between the original and the recovered values for each respondent and the average correlation coefficient was subsequently computed (based on 700 and 480 respondents for the automobile dealership and the credit card service data sets, respectively) and analyzed.

RESULTS

We measured the accuracy of the recovered values of the missing variables compared to the original ones using correlation coefficients. Since we deal with two different data sets, we analyze them separately.

Table 1 shows the results of the analysis of variance for the automobile dealership data. All experimental factors are significant at $p=0.0001$ level, except the donor location strategy ($p=0.1167$). Two out of three interactions are statistically significant. Table 2 shows the means of the experimental factors. As expected, as the number of missing values increases, the performance of the fusion approach decreases. In terms of the common variable selection strategy, selecting by variance performs best while selecting at random produces the poorest result. The two donor location strategies are not statistically significant but finding donors by the inter-respondent Euclidean distance seems to produce slightly better results than finding donors by inter-respondent correlation.

Table 5 shows the results of the analysis of variance for the credit card service data. Results are generally similar to those of the automobile dealership data, but we noticed some differences. First, all experimental factors are significant at $p=0.0001$ level. Second, only one interaction (selection strategy by the number of variables deleted) is statistically significant. One major finding to note is that selecting a set of common variables by importance weight leads to the best performance while selecting at random produces the poorest results again. Finding donors by Euclidean distance leads to better recovery of the missing values with a statistical significance.

DISCUSSION AND DIRECTIONS FOR FUTURE RESEARCH

This study tries to evaluate the performance (the accuracy of the recovered values) of the strategies for selecting a set of common variables that might be used in the data fusion approach. Considering the exploratory nature of the study, these results seem promising. However, it would be hasty to make a conclusion on the value of the selection strategies we have considered in the current study. Albeit tentatively, however, we can summarize these findings as follows.

- As the number of missing values increases, the performance of the fusion approach decreases for both the automobile dealership data and the credit card service data.
- In terms of the donor location strategy, it seems that using inter-respondent Euclidean distance leads to better results.
- In terms of selecting a set of common variables, selecting at random consistently produces the poorest results in both data sets.
- In terms of the common variable selection strategy, this study produced mixed results. In the automobile dealership data set, selecting a set of common variables by variance

leads to the best performance, whereas selecting a set of variables by importance weight leads to the best performance for the credit card data set. We do not have explanations for the difference at this point, but we can only attribute this difference to the characteristics of the data sets at hand.

Considering its exploratory nature, the current study has made a valuable contribution to the field of data fusion research. The data fusion approach can be applied to many research areas. For example, as implied by our study with conjoint part-worths data, data fusion can find its value in solving one of the major problems in conjoint analysis. When conjoint experiments involve a large number of attributes and attribute levels, the number of hypothetical product profiles increases multiplicatively. By using the fusion approach one can greatly reduce the number of product profiles each respondent needs to evaluate.

It might be worthwhile to address the limitations of this study. As a way to enhance generalization of our findings, although never be enough, two different kinds of data sets were employed. The consistency of two experimental results reveals a moderate level of external validity. Another limitation of our method to be pointed out is that systematic bias can hardly be controlled in an experiment such as in this study. One might argue that correlation existing between variables was not properly taken care of in our study. It is usual to suspect a correlation existing between some variables selected, e.g., the shopping center variable and the outlet location variable. One possible remedy for this would be for us to adopt the Mahalanobis distance-based locating strategy instead of the Euclidean distance-based in future research.

Before a conclusion on the value of the strategies for the common variable selection can be made, more research is obviously needed in this area. Future research should examine the impact of the number of common variables on the performance of the fusion approach, while we have fixed the number of common variables at six in all simulations. Future research should consider the value of the different types of common variables in the fusion approach. For example, while this study utilized metric variables (conjoint part-worths) as a common variable set, future research should consider the value of categorical variables such as demographic or lifestyle characteristics of the respondents as common variables.

Finally, future research should consider the performance of the pre-planned fusion approach. In the current study, we created and tried to recover the missing values from a complete (non-missing) data set. But future research should utilize the pre-planned fusion where two kinds of data are collected: one with full (no missing) information and the other with partial information (with missing data), then evaluate the worth of data fusion approach.

Research in this area is currently under way in the context of a conjoint experiment, but future research should not be limited to the context of conjoint analysis and instead use general survey data.

How Mood and Ad-self-congruency Affect the Relative Influence of Hedonic Ad Appeals and Utilitarian Ad Appeals on Product Evaluations

Chingching Chang, National Chengchi University

ABSTRACT

This study argues that participants' affective states determine the relative influence of hedonic ad appeals and utilitarian ad appeals on participants' evaluations of dual function products. Specifically, this study shows that a positive affective state, in comparison to a neutral affective state, increases participants' reliance on their attitudes toward hedonic ad appeals in developing their product evaluations. As a result, ads featuring congruent self-concepts generate more favorable ad and product evaluations when participants are in positive affective states as opposed to in neutral affective states. Moreover, this study demonstrates that the relative influence of hedonic ad appeals and utilitarian ad appeals on brand evaluations is a function of participants' affective states, as well as the congruency of image portrayals in the hedonic ad with participants' self concepts.

The two most dominant types of advertising appeals are believed to be the hedonic (value-expressive or image) appeal and the utilitarian (functional) appeal (Johar & Sirgy, 1991; Snyder & DeBono, 1985). However, past literature does not provide sufficient information regarding how different contextual factors may affect the influences of different ad appeals on brand evaluations. What is better known is that, for a product that provides mainly hedonic satisfaction, a hedonic ad appeal is more persuasive, whereas for a product that is primarily evaluated on the basis of its functional attributes, a utilitarian ad appeal is more effective (Rossiter & Percy, 1987). Unfortunately, there has been a notable lack of attention paid to the question of which type of ad appeal is more effective for a dual-function product, one that offers hedonic satisfaction in addition to fulfilling utilitarian functions. This study, therefore, will specifically explore the influence of hedonic ad appeals and utilitarian ad appeals in different contexts for a dual-function product.

Adaval (2001) has proposed that participants' affective states may either confirm or disconfirm their responses to product-related information, thereby altering the weight of the piece of information that is being taken into account, a phenomenon known as the affect-confirmation effect. According to Adaval's theorization, happy individuals may allocate more weight to favorable information than to unfavorable information when they make judgments, because the valence of the former is congruent with the individuals' affective states and the valence of the latter is incongruent with their affective states. As Adaval's affect-confirmation effect theory suggests, the argument that affective states encourage heavier weighting of hedonic product attributes will only hold true if the hedonic ad information generates favorable evaluations which are similar in valence to the participants' affective states. It is important to note that literature examining the effectiveness of hedonic ad appeals from the self-congruency perspective has clearly suggested that the effectiveness of an ad appealing to user image is a function of the way participants perceive themselves on the same image dimension. To the extent that participants' self-concepts are congruent with image portrayals in a hedonic ad, consumers will generate more positive affective responses. Thus, it is reasonable to argue that, under the condition in which positive affective states are induced, positive affective responses evoked by self-congruent ad messages will encourage affect-confirmation and bias participants' evaluation of ads and brands positively.

Adaval (2001) has further demonstrated that affect-confirmation effects occur only when consumers base their product evaluations on hedonic criteria, (criteria that pertain to affective responses), not when they develop their product evaluations based on utilitarian criteria, (criteria that mainly concern product performance and are not directly linked to affective consequences). This study carries Adaval's theory one step further by arguing that when both utilitarian and hedonic product information is available for a dual-function product, a product that can be judged either on the basis of its hedonic qualities or its utilitarian functions, participants' positive affective states can increase the relevancy of hedonic product information and thus alter the weight participants assign to hedonic messages when they evaluate the product. In addition, this study proposes, that the relative importance of hedonic ad appeals and utilitarian ad appeals in rendering judgmental influence on product evaluations also hinges on the congruency of the portrayed images with participants' self-concepts. Yet, when the portrayed image is incongruent with participants' self-concepts, participants are motivated to elaborate on messages. Therefore, their product beliefs and their evaluations of the utilitarian ad become important judgmental inputs for brand evaluations.

HEDONIC VS. UTILITARIAN AD APPEALS

Advertising appeals can generally be categorized as either hedonic (image or value-expressive) appeals or utilitarian (functional) appeals (Johar & Sirgy, 1991; Snyder & DeBono, 1985). The hedonic ad appeal involves building a personality for the product, from which consumers may project images, such as the values and lifestyles of product users (Johar & Sirgy 1991; Snyder & DeBono 1985). In clear contrast, the utilitarian ad appeal explicitly addresses product attributes or focuses on product quality claims (Johar & Sirgy, 1991; Snyder & DeBono, 1985).

Past literature has indicated that the effectiveness of hedonic and utilitarian ad appeals is moderated by other factors. For example, a product's inherent characteristics determine if it is effective to employ either a hedonic or utilitarian appeal. A match between product characteristics and ad appeal has been shown to generate more favorable responses (Davis & Lennon, 1989; Rossiter & Percy, 1987). Additionally, it has been demonstrated that the effectiveness of hedonic appeals and utilitarian appeals is a function of individual differences, such as participants' genders (Covell, Dion, & Dion, 1994), their levels of self-monitoring (DeBono & Packer, 1991; Snyder & DeBono, 1985) and their levels of control orientations (Zuckerman, Gioioso & Tellini, 1988). In a similar vein, this study argues that the effectiveness of hedonic appeals and utilitarian appeals is determined by participants' affective states.

AFFECT CONFIRMATION EFFECTS

Past research has shown that mood has a direct influence on product judgments in that a positive affective state will generate more favorable product evaluations than a negative or neutral affective state (Gorn, Goldberg & Basu, 1993; Pham, 1998). It has also been suggested that mood can render an indirect impact on product judgments through its influence on the relative weight allocated to specific information (Adaval, 2001). Adaval proposes an affect-confirmation process to argue that, individuals' affective states may either confirm or disconfirm their responses to a piece of product-related information, thereby altering the weight that the

piece of information is allocated. In Adaval's theorization, individuals are sometimes confused as to the sources of their affective states and, therefore, when the valence of their affective states and their perceptions of product information is similar, they will be more confident that their perceptions of the product information are correct and will then increase the weight of this information in their product judgments.

MOOD AND THE RELATIVE EFFECTIVENESS OF HEDONIC AND UTILITARIAN APPEALS

Adaval (2001) has reasoned that affect-confirmation effects are mainly limited to judgments that are based on affect. Drawing upon the distinctions between the two general types of product criteria, hedonic and utilitarian, Adaval has argued that evaluating products on the basis of hedonic criteria involves more affective responses, whereas evaluating products on the basis of utilitarian criteria concerns the products' ability to perform and does not pertain to affective responses. Therefore, affect-confirmation effects are more likely to emerge in the former context than in the latter. Indeed, Adaval's study has demonstrated that affect-confirmation effects occur only when consumers develop their product evaluations based on hedonic criteria, not when consumers base their product evaluations on utilitarian criteria.

Similarly, a hedonic ad appeal is characterized by its focus on promoting attractive user portrayals, thus it mainly appeals to affective responses. Utilitarian ad appeals, on the other hand, emphasize specific product attributes and do not pertain to any affective reactions directly. Extending Adaval's (2001) argument, it is reasonable to propose that, in an ad-viewing context in which a consumer may be exposed to both hedonic and utilitarian ad appeals for the same dual-function product, the relative importance of the different appeals in determining brand evaluations will be a function of participants' affective states. In positive affective states, hedonic ad messages may be more relevant and, therefore, the relative importance of hedonic ad messages to utilitarian ad messages on brand evaluations may be enhanced, whereas in neutral affective states, participants' responses to hedonic ad messages and utilitarian ad messages should both equally be taken into account in determining brand evaluations.

However, it is important to note that hedonic ad appeals, aimed at evoking positive affective states, sometimes may not produce the expected positive emotional responses. The hedonic ad appeal has been closely associated with the research tradition that explores the interaction between self-concepts and ad portrayals (Johar & Sirgy, 1991). Most importantly, this line of literature suggests that the effectiveness of hedonic ad messages is a function of the congruency between individuals' self-concepts and portrayed product images. To the extent that ad-portrayed product images are congruent with their self-concepts, individuals will generate more positive responses (Chang, 2000). Therefore, the assumed valence congruency between positive affective states and hedonic ad appeals, the underlying driving force of Adaval's (2001) affect-confirmation process, may not exist when hedonic appeals depict product users that are incongruent with the images that participants project for themselves.

HEDONIC AD APPEALS AND SELF-CONGRUENCY EFFECTS

The underlying assumption of self-congruency research in consumer behavior lies in the symbolic functions of consumption. This line of research suggests that consumers maintain or enhance their self-images through product consumption (Sentis & Markus, 1986). Possessing self-congruent products serves as a way to

complete the self-enhancement functions of consumption. As a result, products that appeal to self-congruent images are favored to products with self-incongruent images (Sirgy, 1982). Moreover, advertising that portrays self-congruent images is also rated more positively than advertising that depicts self-incongruent images (Hong & Zinkhan, 1995). Specifically, it has been established that self-congruent ad messages generate more positive affective responses and higher levels of self-referencing, thereby enhancing ad and brand evaluations (Chang, 2000).

When different dimensions of self-concepts are explored, evidence converges toward the same conclusion suggesting the superiority of ads that depict self-congruent image portrayals to ads that portray self-incongruent portrayals. For example, Jaffe (1994) has indicated that feminine participants and masculine participants respond in divergent ways to ads with different positioning strategies, with a masculine positioning strategy appealing more effectively to masculine participants and a feminine positioning strategy appealing more effectively to feminine participants. Similarly, Chang (2000) has demonstrated that feminine participants generate more positive emotional responses to ads depicting feminine users than to those with masculine users. Additionally, supportive findings regarding ad-self-congruency effects have been documented regarding personality differences (Hong & Zinkhan, 1995) and values (Leach & Liu, 1998; Wang & Mowen, 1997).

The reviewed evidence suggests that hedonic appeals depicting product users with different profiles may not always lead to positive affective states unless the portrayals are consistent with individuals' self-images. Additionally, it is important to note that recent research has posited that the interaction between self-concepts and ad portrayals depicted in hedonic ads may hinge on other factors. Interestingly, individuals' affective states are factors that have been shown to moderate the influence of the interaction between self-concepts and ad messages on individuals' evaluations of the advertised brands.

MOOD AND SELF-CONGRUENCY EFFECTS

As reviewed earlier, an individual's positive affective state can enhance his/her reliance on hedonic ad messages, when the affect-confirmation effect occurs. Similarly, in self-congruency literature, Chang (2002) has demonstrated that participants' affective states moderate the influence of ad and self-concept congruency. When participants are in positive affective states, participants respond to ad messages in a selective way, with self-congruent messages generating more favorable ad evaluations and brand attitudes. Conversely, when participants are in negative affective states, the interaction effect between self-images and ad portrayals does not emerge. Chang argues that when participants are in positive affective states, they are less motivated to process information in analytical ways. Due to a lack of motivation, they engage in peripheral route processing and rely on ad-self-congruency as a cue for developing their brand evaluations. But, when participants are in negative affective states, they are motivated to process information in detail and to elaborate on ad messages to a greater degree, which reduces the influence of ad-self-congruency.

Findings in the past literature seem to reach the same conclusion: Affective states can determine the degree to which participants rely on ad-self-congruency information, information that appeals to hedonic values and involves affective responses. When participants are happy, they are more likely to rely on hedonic ad messages for brand judgments. As a result, whether or not the image portrayals are congruent with their self-images will render judgmental influence on ad and brand evaluations. In addition, it is important to note that Chang's (2002) investigation directly com-

compares participants' responses in positive affective states to those in negative affective states. Given that ad viewers, when not provoked by program context, editorial content, or preceding ads, may likely be in neutral affective states, it is important to directly include neutral affective states in the investigation. In partial replication of Chang (2002), this study will test whether or not the level of congruency between ad portrayals and self-concepts affects product evaluations when participants are in positive affective states as opposed to neutral affective states.

H1: When participants are in positive affective states, the interaction between ad appeals and self-concepts will significantly determine their attitudes toward the hedonic ad. In contrast, when participants are in neutral affective states, the interaction between ad appeals and self-concepts will not affect their attitudes toward the hedonic ad.

H2: When participants are in positive affective states, the interaction between ad appeals and self-images will significantly determine their product evaluations. In contrast, when participants are in neutral affective states, the interaction between ad appeals and self-images will not affect their brand evaluations.

MOOD, SELF-CONGRUENCY AND THE RELATIVE INFLUENCE OF HEDONIC ADS AND UTILITARIAN ADS

This study proposes that when participants are in positive affective states, they are more likely to rely on their ad attitudes toward hedonic ads than their ad attitudes toward utilitarian ads to develop their brand evaluations. Moreover, as reviewed earlier, self-congruency literature argues that hedonic ad appeals may not generate more favorable affective responses unless featured user portrayals are congruent with individuals' self-concepts. Therefore, when participants are in a positive affective state where user portrayals are congruent with self-concepts, affect confirmation may occur and participants will feel confident about their affective responses. As a result, participants' attitude toward hedonic ads may be diagnostic for brand judgments making them more likely to exert dominating influence on brand evaluations. They are thus less likely to take their product beliefs or attitudes toward the utilitarian ad into account.

H3: When participants are in positive affective states and ad portrayals are congruent with their self-concepts, participants' attitudes toward the hedonic ad will significantly determine their brand evaluations, but their attitudes toward the utilitarian ad will not significantly affect their brand evaluations.

In clear contrast, message incongruency has been shown to increase participants' motivation to process messages and thus override the lack of motivation invoked by positive affective states (Maheswaran & Chaiken, 1991). For example, within the heuristic-systematic model, Maheswaran and Chaiken have indicated that product incongruent information encourages systematic processing among participants, who are not otherwise motivated to do so. Building upon the same framework as Maheswaran and Chaiken, Jain and Maheswaran (2000) have further demonstrated that inconsistent information is processed more systematically in comparison to consistent information. Therefore, this study proposes that incongruency will motivate happy participants to process information. As a result, even when participants' positive affective states

encourage their reliance on their hedonic attitudes as judgmental inputs, they may still be motivated to take their product beliefs, as well as their attitudes toward utilitarian ads, into account when evaluating the advertised products.

H4: When participants are in positive affective states and ad portrayals are incongruent with their self-concepts, participants' brand evaluations will be determined by their attitudes toward the hedonic ad and the utilitarian ad, as well as their product beliefs generated from ad exposure.

Conversely, when participants are in neutral affective states, bias toward hedonic ad attitudes as judgmental inputs may not occur. Therefore, participants will only take their attitudes toward hedonic ad messages into account when the portrayed images are congruent with participants' self-concepts. In addition, participants in neutral affective states, whose motivation to elaborate on messages is not reduced by their affective states as are happy participants' (Schwarz, 1990; Schwarz & Bless, 1991), will be able to elaborate on messages in both hedonic and utilitarian ads. Therefore, participants' product beliefs, as well as their attitudes toward hedonic ads and utilitarian ads, will together affect their evaluations of advertised brands.

H5: When participants are in neutral affective states and ad portrayals are congruent with their self-images, participants' brand evaluations will be determined by their attitudes toward both the hedonic ad and the utilitarian ad, as well as their product beliefs.

On the contrary, when hedonic ads portray images that are incongruent with participants' self-concepts, they may not provide additional diagnostic information for participants' brand evaluations and, therefore, participants' attitudes toward hedonic ads will not generate significant influence on their brand evaluations. Rather, participants' brand evaluations will be formed mainly on the basis of their product beliefs and their attitudes toward utilitarian ads, which provide relatively more diagnostic information for their brand evaluations.

H6: When participants are in neutral affective states and ad portrayals are incongruent with their self-concepts, participants' brand evaluations will be determined by their product beliefs and their attitudes toward the utilitarian ad.

METHODOLOGY

Design

This study was a two-factor experimental design. The two manipulated factors were: ad difference (two ad user profiles: feminine vs. non-feminine) and affective states (two levels: positive vs. neutral). In addition, participants were further categorized into high feminine groups and low feminine groups. Given that self-concepts are multi-dimensional (Markus & Wurf, 1987), this study will explicitly focus on one dimension of self-concept, namely, femininity.

Product Selection

As noted earlier, a product can serve hedonic functions or utilitarian functions (Batra & Ahtola, 1990; Mano & Oliver, 1993). This study will only focus on products that can provide both hedonic and utilitarian satisfaction for consumers. A pretest ($N=20$)

was conducted to select a product that college students were likely to purchase, and also could be evaluated both on hedonic and utilitarian criteria. As a result of the pretest, sneakers were chosen to be the product.

In addition, participants in the study were asked the degree to which they agreed with two pairs of two statements describing their sneaker purchase behaviors. The first two items were designed to measure the hedonic element of the product: "When purchasing sneakers, I will select those that fit my image" and "when purchasing sneakers, I will select those that my friends will feel jealous of." The two items were significantly correlated, Pearson's $R=.40$, $p=.01$, and, therefore, were summed and averaged to represent the hedonic element. The other two items were designed to capture the utilitarian element of the product: "When purchasing sneakers, I will consider product quality" and "when purchasing sneakers, I will take product functions into account." These two items were also significantly correlated, Pearson's $R=.55$, $p=.01$, and, consequently summed and averaged to represent the utilitarian element. A t test indicated that, as expected, the hedonic functions and utilitarian functions of sneakers did not differ in importance, $t(165)=1.03$, $p=.31$, $M_{\text{hedonic}}=5.27$, $M_{\text{utilitarian}}=5.39$.

Stimuli

Professionals working at Ogilvy & Mather Ad Agency in Taipei created stimuli ads. Utilitarian ads contained specific product attribute information, such as weight, breathability and fit. Visuals and layouts were similar for ads with different user portrayals. All ads used in this study were pre-tested to ensure that message manipulations would be successful. To improve external validity, the ads were inserted between real filler ads. Moreover, a fictitious brand was used to reduce any possible confounding influence of brand familiarity.

Participants

One hundred and sixty-seven participants were recruited from the campus of a college in a metropolitan area of Taiwan. Forty-nine percent of the participants were male. All of the scales used in the study were translated into Chinese following Brislin's (1987) translation and translation-back procedure.

Procedures

At the beginning of the experiment, participants assigned to the positive affective state condition were told that the study session was composed of three parts. Participants were informed that the first part was a pretest for the researcher's next project, which would explore the effectiveness of television commercials. In order to create the scripts for these commercials for use in the future study, the participants were asked to provide the researcher with stories of happy life events they had experienced.

The second part of the study started with participants' ratings of their affective states. Then the second coordinator told them that this part of the study was designed to examine the effects of various ad formats or techniques on viewers' information processing, a false story designed to camouflage the purposes of the study from the participants. Next, participants read a filler ad followed by two stimuli ads for the same product, one using hedonic ad appeal and the other employing utilitarian ad appeal. Finally, participants read another filler ad. The order of the two ads was rotated. Given that the order of ad presentation did not have any significant effect on how participants evaluated the hedonic ad, $F(1, 166)=.29$, $p=.59$, the utilitarian ad, $F(1, 166)=.33$, $p=.57$, or the brand, $F(1, 166)=1.19$, $p=.28$, responses from the two sequences were collapsed. After reading the ads, participants provided their cognitive responses and

rated their perceptions of the user images in the ads, after which they rated their ad and product attitudes.

At the beginning of the final part, participants were told that this part of the study was a nation-wide survey designed to explore college students' values and lifestyles in Taiwan. They rated their agreement with select items from Bem's (1974) Sex Role Inventory measuring their femininity, as well as other self-related scales. Participants in the neutral affective state condition were told that the study was composed of two short sessions, instead of three. They started from the second session described for participants in the positive affective state condition. After each group finished the study, the coordinator provided a short debriefing.

Independent Variables

Affective States

Nineteen items were selected from the UWIST mood adjective checklist (Matthews, Jones, & Chamberlain, 1990) to measure participants' affective states. Participants rated their agreement with each item on a 19-item 7-point Likert scale. Factor analyses with varimax rotation generated four factors with eigen-values larger than one. The first factor, with an eigen-value of 6.28, accounted for 19.86% of the variance and was labeled "negative emotions." The second factor, with an eigen-value of 2.46 accounted for 12.95% of the variance and was labeled "positive emotions." The third factor, with an eigen-value of 2.01, accounted for 10.59% of the variance and was labeled "passiveness." The final factor, with an eigen-value of 1.01, accounted for 5.29% of the variance and was labeled "calmness." Cronbach's reliability alphas for negative emotions, positive emotions, and passiveness were satisfactory at .84, .81, and .79 respectively. Additionally, the two items in the calmness scale were significantly correlated, Pearson $R=.67$, $p=.01$. ANOVA indicated that participants in the positive affective state condition had significantly higher ratings on the subscale of positive emotions, $F(1, 165)=6.38$, $p<.01$; $M_{\text{positive}}=4.77$, $M_{\text{neutral}}=4.32$, than did those in the neutral affective state. Moreover, participants in the positive affective state condition generated significantly lower ratings on the subscale of passiveness, $F(1, 165)=4.18$, $p<.04$; $M_{\text{positive}}=3.42$, $M_{\text{neutral}}=3.84$, than did those in the neutral affective state. However, participants in the positive affective state condition and the neutral affective state condition did not differ in their ratings of negative emotions, $F(1, 165)=.17$, $p=.68$, and calmness, $F(1, 165)=.71$, $p=.40$. Therefore, the results of the manipulation checks were satisfactory.

Self-Difference: Self-ratings on Femininity

Participants rated their agreement regarding whether or not the items listed accurately described themselves. The 20 items were selected from Bem's (1974) Sex Role Inventory. Cronbach's reliability alpha for the subscale of femininity was satisfactory at .85.

Ad Difference: Feminine Ads vs. Non-feminine Ads

This study created hedonic ad appeals through the description of users in the ads. Participants were exposed to ads containing messages delineating ad characters with either feminine or non-feminine values. Feminine items in Bem's (1974) Sex Role Inventory were employed as a manipulation check measure. Cronbach's reliability alpha for this subscale was satisfactory at .91. ANOVA indicated that users portrayed in the feminine ad received significantly higher ratings on femininity than did the characters depicted in the non-feminine ad, $F(1, 167)=35.44$, $p<.01$; $M_{\text{feminine}}=4.77$, $M_{\text{non-feminine}}=3.94$. Therefore, the result of the manipulation check was satisfactory.

Ad-self-congruency

Based on the two groups of individual differences and the two groups of ad differences, participants were further categorized into

either the ad-self-congruent group or the ad-self-incongruent group. Specifically, high feminine participants assigned to read feminine ads and low feminine participants assigned to read non-feminine ads were categorized to be ad-self-congruent participants. On the other hand, feminine participants assigned to read non-feminine ads and low feminine participants assigned to read feminine ads were categorized to be ad-self-incongruent participants. In all, 79 participants were categorized in the ad-self-congruent group, with 50% of the participants being male. Eighty-eight participants were categorized in the ad-self-incongruent group, with 47% of the participants being male.

Dependent Measures

Multi-attribute Product Beliefs

A pretest of 20 participants was employed to determine the most important product attributes participants consider when purchasing sneakers. The six top attributes were: "color selection," "durability," "comfort," "style," "weight," and "ease of putting on." Participants in this study were asked to rate how important each of the six attributes was to them when selecting a pair of sneakers. Additionally, they were also asked to rate how likely it was that the advertised product had each of the six attributes. Multi-attribute product beliefs were estimated first by multiplying the importance rating by the likelihood rating for each attribute and then summing the scores of all six attributes.

Ad Attitude toward the Hedonic and the Utilitarian Ad

A 5-item 7-point Likert scale was used to measure participants' attitudes toward the ads. The five items were adopted from Madden, Allen, & Twible (1988). Cronbach's reliability alpha was deemed satisfactory at .91. The same scale was used to measure the utilitarian ad. Cronbach's reliability alpha for ad attitude toward the utilitarian ad was deemed satisfactory at .88.

Brand Attitude

Brand attitudes were measured with a 5-item 7-point Likert scale. The items were adopted from Holbrook and Batra (1987) and Mitchell and Olson (1981). Cronbach's reliability alpha for this scale was deemed satisfactory at .91.

Results and Analyses

To test H1, regression analyses first considered responses of participants in the positive affective state condition. When ad attitudes were regressed upon self-ratings on femininity, ad difference (dummy coded with the feminine ad being -1 and the non-feminine ad being 1), and the interaction between self difference and ad difference, R^2 was estimated at .30, $F(3, 84)=11.36$, $p=.01$. Results showed that only the self-difference by ad difference interaction was significant, $t=3.51$, $p=.01$, $Beta=.52$. In contrast, the impacts of self-difference, $t=.29$, $p=.77$, $Beta=.04$, and ad difference, $t=.15$, $p=.88$, $Beta=.02$, were not significant. When the three variables were regressed on participants' ad attitudes in the neutral affective state condition, R^2 was estimated at .21, $F(3, 80)=6.89$, $p=.01$. As expected, the influence of the self by ad interaction was not significant, $t=.33$, $p=.75$, $Beta=.26$. In addition, the impacts of self-difference, $t=.90$, $p=.37$, $Beta=.42$ and ad difference, $t=.85$, $p=.40$, $Beta=.44$, were not significant, either. Therefore, H1 was supported.

To test H2, regression analyses first considered responses of participants in the positive affective state condition. When brand evaluations were regressed upon self-ratings on femininity, ad difference, and the interaction between self and ad, R^2 was estimated at .31, $F(3, 84)=12.06$, $p=.01$. Results showed that only the influence of the self by ad interaction was significant, $t=2.52$, $p=.01$, $Beta=.37$. In contrast, the influences of self-difference, $t=1.87$, $p=.07$, $Beta=.25$, and ad difference, $t=1.40$, $p=.17$, $Beta=.16$, were

not significant. When the three variables were regressed on participants' brand evaluations in the neutral affective state condition, R^2 was estimated at .20, $F(3, 80)=6.31$, $p=.01$. As expected, the influence of the self by ad interaction was not significant, $t=1.58$, $p=.12$, $Beta=.29$. In addition, the impacts of self-difference, $t=.96$, $p=.34$, $Beta=.17$, and ad difference, $t=.04$, $p=.97$, $Beta=.01$, were not significant, either. H2 was thus supported.

Regression analyses were conducted to test H3. When brand evaluations were regressed upon attitudes toward the hedonic ad, the utilitarian ad, and product beliefs, R^2 was estimated at .45, $F(3, 40)=10.25$, $p=.01$. As expected, only attitude toward the hedonic ad was significant, $t=3.23$, $p=.01$, $Beta=.45$. Participants' attitudes toward the utilitarian ad, $t=1.73$, $p=.09$, $Beta=.22$, and their product beliefs did not exert significant influence on brand evaluations, $t=1.50$, $p=.14$, $Beta=.20$. Therefore, H3 was supported.

Regression analyses were conducted to test H4. When brand evaluations were regressed upon attitudes toward the hedonic ad, the utilitarian ad, and product beliefs, R^2 was estimated at .62, $F(3, 41)=20.85$, $p=.01$. As expected, all three variables had significant influence on brand evaluations (for attitude toward the hedonic ad, $t=3.11$, $p=.01$, $Beta=.32$; for attitude toward the utilitarian ad, $t=4.57$, $p=.01$, $Beta=.51$; for product beliefs, $t=2.51$, $p=.02$, $Beta=.27$). Therefore, hypothesis 4 was supported.

For H5, results indicated that when brand evaluations were regressed upon attitudes toward the hedonic ad, the utilitarian ad, and product beliefs, R^2 was estimated at .82, $F(3, 33)=46.56$, $p=.01$. As expected, all three variables had significant influence on brand evaluations (for attitude toward the hedonic ad, $t=6.70$, $p=.01$, $Beta=.61$; for attitude toward the utilitarian ad, $t=3.15$, $p=.01$, $Beta=.28$; for product beliefs, $t=2.35$, $p=.03$, $Beta=.21$). Therefore, H5 was supported.

For H6, results showed that when brand evaluations were regressed upon attitudes toward the hedonic ad, the utilitarian ad, and product beliefs, R^2 was estimated at .36, $F(3, 43)=7.58$, $p=.01$. As expected, the influence of attitude toward the utilitarian ad was significant, $t=3.15$, $p=.01$, $Beta=.43$, whereas attitude toward the hedonic ad was not significant, $t=1.89$, $p=.07$, $Beta=.27$. However, inconsistent with expectation, the influence of product beliefs was not significant, $t=.59$, $p=.56$, $Beta=.09$. Therefore, in terms of the reduced influence of the hedonic ad, findings were supportive.

DISCUSSION

Findings in this study indicate that positive affective states encouraged participants to evaluate the advertised product on the basis of their attitudes toward the hedonic ad. As a result, whether or not the hedonic ad portrayed images congruent with participants' self-concepts significantly contributed to their evaluations of the ad and the advertised brand. In contrast, when participants were in neutral affective states, ad-self-congruency did not affect their ad and brand evaluations.

Moreover, participants' affective states can bias their brand evaluation process. When participants are in a positive affective state, their attitudes toward the hedonic ad messages are deemed important. Yet, the likelihood that affective states may increase the importance of hedonic product information is implicated by the congruency of portrayed product images in hedonic ads with participants' self-concepts. As a result, when they were in a positive affective state and the portrayed ad images were congruent with their self-concepts, attitudes toward hedonic ads helped determine brand judgments and, therefore, exerted significant influence on brand evaluations. The findings were in line with Adaval's (2001) affect-confirmation effect theory, in that positive affective states confirmed the positive affective responses generated by self-congruent hedonic ad messages and increased the influence of the

hedonic ad on brand evaluations. On the contrary, when happy participants processed self-incongruent ad messages, they were motivated to elaborate on messages and to take their product beliefs, as well as their attitudes toward the utilitarian ads, into account.

When neutral participants processed self-congruent ad messages, as expected, participants' product beliefs, developed from messages in the utilitarian ad, together with their attitudes toward the hedonic ad and the utilitarian ad, influenced their brand evaluations given all the information was relevant for brand judgments. However, inconsistent with expectations, under the self-incongruent condition, neutral participants did not take their product beliefs into account. It is likely that ad messages describing a brand with self-incongruent images might be treated as being less credible, and thus participants were less likely to develop product beliefs based on its ad information.

Findings of this study should be discussed within its limitations. For example, the fact that participants in the neutral mood did not engage in the first phase of the study might introduce unnecessary confounding influences to the findings. Nevertheless, findings of this study still have important implications for marketers. It is common for advertisers to use mixed ad strategies, employing hedonic ad appeals for television commercials and introducing product attributes in print advertisements. Therefore, findings of this study can help marketers develop more effective media planning. For example, when running a hedonic television spot, marketers should consider selecting a humorous or warm-hearted program that can evoke positive affective states, in order to enhance the effectiveness of hedonic ad appeals. Conversely, to help readers focus on product attributes, media planners should select a neutral editorial context for an attribute-focused print ad.

Content Analysis Research Themes 1977-2000: Evolution and Change

Michael S. Mulvey, University of Ottawa

Barbara B. Stern, Rutgers University

ABSTRACT

More than two decades ago, Hal Kassirjian introduced the content analysis methodology to consumer researchers in his 1977 *Journal of Consumer Research* article "Content Analysis in Consumer Research." Our research has two goals. First, from a historical perspective, we trace the evolution in the use and application of content analysis in-field from 1977-2000. Second, we analyze the substantive issues and thematic domains that dominate this body of research. By integrating the set of studies in terms of themes, we are in a better position to describe current knowledge and practice, evaluate theoretical progress, identify gaps and weak points that remain, and plot a course for future research.

From its earliest days, content analysis has been a vital and popular technique in the consumer researcher's tool kit. In 1977, Kassirjian's article "Content Analysis in Consumer Research," appeared in the *Journal of Consumer Research*. The article is considered "a catalyst" for later research (Kolbe and Burnett p. 243) and served as a "methodological benchmark" for more than two decades. Just as earlier researchers investigated the *how* of content analysis (methodology), we focus on the *what* (theoretical focus) of such research from 1977-2000.

The purpose is to trace the evolutionary development of research themes so that future content analysts can make sense out of what has been studied and make more informed decisions about what to study in the future. Here, the unit of analysis is the "subject thematic unit," (Riffe, Lacy, and Fico 1998, p. 68), defined by Berelson as "an assertion about a subject matter" (1952, p. 18) and by Holsti as "a single assertion about some subject" (1969, p. 116)—in a word, its "aboutness." The study first examines the "original themes" ("research questions") in Kassirjian's first-generation article, and organizes them into baseline categories. Next, it identifies themes in content analysis studies from 1977-2000, and organizes them into an updated categorical scheme that reveals post-1977 changes. Last, it offers suggestions for new research directions. In this way, thematic development over time is organized into a system that reveals the relationship between changes in content analysis research and changes in society, the advertising and consumer behavior disciplines, the media, and data sources.

Original Themes: Baseline

Historically, content analysis predates the foundation of the field of consumer research. The method was borrowed from other social sciences, and was introduced to the field in 1969 at an AMA Task Force on Marketing Methodology and held at Ohio State University. In a session on "Communication: The Mass Media and Informal Channels," Harold Kassirjian's paper, "The Negro and Mass Media: A Preliminary Analysis of 1969 Magazine Advertisements," demonstrated its use in a study whose theme was the role of blacks in advertisements. His 1977 article formalized the introduction of the method as a valuable new tool for systematic analysis of the content of mass communications, "most useful whenever documentary evidence is available," (Kassirjian 1977, p. 16) and provided a list of themes from past research and directives for the future.

A total of 21 original themes was presented, divided into 12 used in pre-1977 research and 9 suggested for future research. In the pre-1977 summary, the largest number of themes (10) were adver-

tising-related, and of that group, 5 were about images of women and minorities. Five others were about other advertising themes such as social values, product and company images, recruitment for technical/managerial positions, information content, and decision-choice models. The remaining two themes were about other media, including the content of best-selling novels and the readability of marketing and consumer behavior journals. The 9 directives for future themes extended media vehicles to non-advertising communications such as multinational companies' press releases, comic strips, graffiti, bumper stickers, and historical documents recording early consumer behavior. The categorization scheme that we derived to classify the original themes into groups follows:

I. Advertising

- A: Images: women, minorities, product, company
- B: Societal values: social, recruitment
- C: Appeal type: informational content, decision models

II. Other Media

- A: Popular Culture: comic strips, graffiti, bumper stickers
- B: Historical: novels, press releases, documents related to consumer behavior
- C: Disciplinary journals: readability

All of the themes are united by two commonalities: (1) the data source is mass communication messages (marketer-generated), and (2) the collection of themes centers on social issues in the media. That is, content analysis was used to examine public communication about public issues. Under this umbrella, the main categories were differentiated by the media in which the communication appeared—advertising or other media. The original themes of images, values, and appeal types reflected societal changes in the 1960s and early 1970s related to the emergence of the civil rights, women's rights, and consumer rights movements, and the expectation that such changes would continue to be studied. Non-advertising themes in other media were proposed for future study, specifically popular culture media, literature and news, and the disciplinary literature itself, reflecting directives for the development of the new field of consumer research. In the last quarter of the century, a multitude of changes in society and the discipline as well as in the media and data sources calls for reassessment of the original themes to determine where content analysis is now, and where it might go in the future. The current study uses the following method to identify and categorize post-1977 themes.

METHOD

Sample

Articles using content analysis were located in a search of 57 journals indexed in the *Social Sciences Citation Index* (SSCI) "Business" category. Journals included generalist publications such as *Journal of Marketing*, *Journal of Consumer Research*, and *Journal of Marketing Research*, and specialist ones such as *Journal of Public Policy and Marketing*, *Journal of Retailing*, and *Journal of Advertising*. The criterion for inclusion was citation of Kassirjian's (1977) article, and, after excluding 3 misclassified articles that lacked the criterion citation, we constructed a sample set of 158 articles.

180	<i>Total</i>

Note: The sample consists of articles in business journals that cite *at least one* of the following: Kassirjian (1977), Hughes and Garrett (1990), or Kolbe and Burnett (1991). Articles citing multiple sources are counted only once.

A subset of articles for a holdout sample was also collected (Miles and Huberman 1994) from “second generation” articles, defined as articles in business journals that did not cite Kassirjian directly, but that did cite two influential methodological articles based on his work: Hughes and Garrett (1990) and/or Kolbe and Burnett (1991). The reason for selecting these two articles is that they are the springboard for the most recent discussions (2001) of reliability assessment by Kent Grayson, Dawn Iacobucci and Roland Rust. After excluding duplicates, the holdout sample contained 22 articles, bringing the total sample to 180 articles.

The final sample contained articles from 21 business journals (see Exhibit), with the highest number in *Journal of Advertising* (42), *Journal of Consumer Research* (19), and *Journal of Advertising Research* (18). The time series graph (Figure 1) shows that the number of articles per year citing Kassirjian (1977) rose steadily from 1977 to 1990, reaching a maximum of 12 articles in 1990. Since then, the number of articles per year has leveled off at about 9 studies per year, underscoring the method’s enduring popularity. The second time series (the holdout sample) in Figure 1 shows that although a few researchers look exclusively to second-generation articles for methodological guidance, the majority continues to recognize Kassirjian’s paper.

Data Analysis and Coding

Analysis began with each author’s identification of article themes in the sample and holdout data sets, and disagreements were resolved by discussion. A provisional coding scheme was derived for the sample article themes via inductive and iterative analysis of the sample data (Noblit and Hare 1988; Miles and Huberman 1994;

Spiggle 1994), and then applied to the holdout article themes to assess their fit in the provisional scheme (Miles and Huberman 1994). No thematic differences between the two sets were found, and after re-analysis of both data sets, the final coding scheme was agreed upon and used to derive categories for all of the articles.

FINDINGS: CATEGORIZATION SCHEME

Findings reveal that from the 1970s to the 1990s, Kassirjian’s original themes were dominant, augmented by newer ones related to socio-cultural changes. The original data sources—marketer-generated mass communications in advertisements and other media—continued to be used, and the object of analysis was the messages’ manifest meanings. However, in the 1990s, three new research interests emerged: (1) refinement of quantitative methodology; (2) introduction of qualitative methodology; (3) and use of personal communications as data sources. The Table shows the categorization scheme that we derived from the post-1977 sample, and it reveals the extension and enrichment of the original themes. Kassirjian’s original two categories have evolved/expanded to five, of which three relate to data sources, including mass communications, personal communications, and disciplinary/academic documents; one relates to quantitative issues (problems and improvements); and one relates to qualitative methods. The following sections examine thematic expansion in detail.

1: Mass Communications: Advertisements and Other Media

Themes in mass communications including but not limited to advertisements form the largest category, comprising 114 articles (63%). And the articles can be grouped into three sub-categories.

FIGURE 1
Number of Articles in Sample, 1977-2000

A: Executional Devices.

Content analysis of executional devices is a new category, one that includes both macro and micro-level stimulus elements. On the macro level, themes include comparison of appeals by media (Bush and Leigh 1984), target market (Alexander, Benjamin, Hoerrner and Roe 1998), product (Cutler and Javalgi 1993; Turley and Kelley 1997), and so forth; on the micro level, they include small textual elements such as headline figures of speech (Beltramini and Blasko 1986; Leigh 1994; Soley and Reid 1983), cartoon characters and animation (Bush, Hair and Bush 1983; Kelly, Slater, Karan and Hunn 2000), color (Clarke and Honeycutt 2000; Huang 1993), and pictorial or musical elements (Haley, Staffaroni and Fox 1994). The trend toward close analysis of small textual units can be attributed to the incorporation of fine arts theory, semiotics, and literary criticism in consumer and advertising research, a development that began in the mid to late 1980s.

B: Informational/Emotional Appeals.

At about the same time, the original theme of informational content expanded to include the new themes of comparative ad content and emotional appeals, both of which arose in response to societal and disciplinary changes after 1977. Comparative advertising provides information about one named brand versus another, often including scientific evidence or product demonstrations to convey the superiority of the advertised brand. These appeals became popular in the 1970s, after the Federal Trade Commission began advocating brand comparisons (1972) to provide consumers with information that would enable them to evaluate competing brands. Television networks, which had long banned comparative ads, now permitted them, and the investigation of their effectiveness that began in the mid-70s (Wilkie and Farris (1975) still continues. Studies of comparative appeals in print media are

common, especially in magazine advertisements (Harmon, Razzouk and Stern 1983; Jackson, Brown and Harmon 1979; Swayne and Stevenson 1984, 1987), but also in direct mail (Stevenson and Swayne 1995).

In the late 1980s, content analysis of emotional advertising appeals was spurred by a confluence between the rise of "image" advertisements and the introduction of postmodern ideas in consumer research (Holbrook and Hirschman 1982). The assumption that consumers are driven by rational motivations was re-examined, and researchers began to study the influence of emotions on consumer responses to advertising (Holbrook and Batra 1987; Olney, Holbrook and Batra 1991). Emotional advertisements appealing to positive feelings (humor, fun, nostalgia) or negative ones (guilt and fear) as well as cultural differences in attitudes to emotional appeals are the objects of interest in current research (Huhmann and Brotherton 1997; McCullough and Taylor 1993; Spotts, Weinberger and Parsons 1997; Stern 1992; Weinberger and Spotts 1989).

Nonetheless, even though post-1977 themes include emotional content, most of the articles in this category are about informational content, emphasizing a variety of information cues such as location, price, or hours presented to consumers, and the value of this information both to consumers and marketers (Abernathy and Franke 1996; Taylor 1997; Taylor and Taylor 1994; Zaichkowsky and Sadlowski 1991). Empirical studies examine differences in information content by media (Stern, Krugman and Resnik 1981; Stern and Resnik 1991), target market (Lee and Callcott 1994; Muehling and Kolbe 1998), and product (Abernathy and Butler 1993; Dube, Chattopadhyay and Letarte 1996; Grove, Pickett and Laband 1995; James and Vanden Bergh 1990). Cross-cultural comparisons gather evidence of relationships between a

country's regulatory environment and the informativeness of print and broadcast messages (Dowling 1980; Madden, Caballero and Matsukubo 1986; Mueller 1991; Rice and Lu 1988; Sepstrup 1985; Taylor, Miracle, and Wilson 1997; Weinberger and Spotts 1989). In the United States, marketing and public policy researchers monitor firms' compliance with government legislation and scrutinize the effectiveness of self-regulation programs (Kassarjian and Kassarjian 1988). This is particularly true in industries whose advertising is prone to controversy, notably cigarettes and tobacco (Ringold 1987; Ringold and Calfee 1989), drugs (Roth 1996; Shimp and Dyer 1979), food products (Pappalardo and Ringold 2000), and motor vehicles (Ford and Mazis 1996). Regulation of advertising stems from concerns about product risk disclosure and the nature of claim substantiation and aims at preventing misleading, deceptive, or "puffed" advertisements that exaggerate product attributes/benefits (Healey and Kassarjian 1983; Simonson and Holbrook 1993). Related research analyzes the information content of legal contracts to identify safeguards that effectively protect firms against opportunism in business-to-business exchanges (Achrol and Gundlach 1999; Gundlach and Achrol 1993).

C: Sociocultural Issues.

Research attention continues to focus on positive and negative stereotyping, with age-related themes now added to the original ones of women and minority images. The theme of women's media images now includes analysis of changing portrayals of women, effects of stereotyping on children, ad portrayals of the elderly. Synchronic analysis of media representations describes gender role portrayals in particular countries (Ford, Voli, Honeycutt and 1998) or media outlets (Reese, Whipple and Courtney 1987), and diachronic analysis presents evidence of women's shifting occupational roles

(Ferguson, Kreshel and Tinkham 1990; Zhou and Chen 1997). Studies of inappropriate gender stereotypes and advertising effectiveness (Jaffe and Berger 1994) emphasize negative effects on consumers, particularly vulnerable consumers such as children and teens, likely to be harmed by gender stereotyping (Browne 1998; Macklin and Kolbe 1984; Maynard and Taylor 1999). Interestingly, research by Klassen, Jasper and Schwartz (1993) was the only study in the sample that examined images of both men and women portrayed together in advertisements.

Many researchers have followed Kassarjian's proposal to examine depictions of blacks in advertising (Bristor, Lee and Hunt 1995; Motley 1995; Stevenson and Swayne 1999; Williams, Qualls and Grier 1995). In addition, new themes of minority underrepresentation or misrepresentation now include Asian-Americans (Taylor and Lee 1994) and Hispanics (Wilkes and Valenci 1989), reflecting the growth in minority immigration in the past two decades. Some articles develop more complex representational benchmarks by treating the racial composition of models along with their social and occupational roles (Stevenson 1991; Taylor and Stern 1997). Most recently, researchers have broadened the scope of inquiry by analyzing consumers' responses to ads targeted to different cultural groups (Grier and Brumbaugh 1999). Further, content analysis of portrayals of the elderly—an age group likely to be "disappeared" in advertisements—reflects the aging of the population as the baby-boomers grew older (Carrigan and Szmigin 1999; Peterson and Ross 1997; Swayne and Greco 1987; Ursic, Ursic and Ursic 1986).

Cultural values depicted in popular culture and other media follow the original suggestion that future research should branch out from analysis of more traditional media (novels, magazine

articles, advertisements) to more ephemeral ones such as comic books (Belk 1987), underground “comix” (Spiggle 1986), bumper stickers (Stern and Solomon 1992), and so forth. In spite of this progress, advertising remains the dominant source of data, for only a few studies examine the cultural values depicted in such long-established sources as magazine articles (Homburg and Pflesser 2000; Olson 1995) and novels (Friedman 1985). The themes in these studies tend to be the negative values associated with a commercialized society and the unintentionally negative ones in media targeted to the young. However, a new positive theme is the increase in ecological and environmental “green” advertisements, following the socio-cultural concern that arose in the 1980s when the public was made aware of the consequences of worldwide pollution and depletion of resources. New themes have arisen, such as types and prevalence of green appeals (Carlson, Grove and Kangun 1993; Peterson 1991), their structural characteristics (Iyer, Banerjee and Gulas 1994), strategic goals (Banerjee, Gulas and Iyer 1995), and tactics used to construct messages (Carlson, Grove, Lacznia and Kangun 1996). Related themes include evaluation of the accuracy of environmental claims (Polonsky et al. 1998) and consumers’ perceptions of green issues (Zimmer, Stafford and Stafford 1994).

From the late 1980s on, articles about value changes across space, time, and media began to appear, extending the original themes both spatially and temporally. The theme of changing representations of time and timestyles relates to that of gender images, with women’s time-impoverishment a new development (Gross and Sheth 1989). Other changes in consumer values are also content analyzed, including those depicted in advertisements for a single product such as automobiles (Tansey, Hyman and Zinkhan 1990), an entire industry, especially tobacco and cigarette ads (King, Reid, Moon and Ringold 1991), and advertising itself in a newly Westernized country (Zhou and Belk 1993). Single country studies of value appeals consider advertisers’ adoption of new values (Lill, Gross and Peterson 1986), the shifting incidence of specific social values such as achievement and motivation (Zinkhan, Hong and Lawson 1990), and the character of a nation’s value system (Hetsroni 2000).

Changes in values across countries in terms of themes such as globalization, Westernization, standardization, and similarities/differences between cultures are also associated with economic changes in the 1990s. Among such changes are the rise of Pacific Rim nations as world-class competitors, rapid growth in developing nations, and ongoing debate about economic alliances, most recently, NAFTA. American advertising is compared to that of longtime trading partners like Japan (Hong, Muderrisoglu and Zinkhan 1987; Javalgi, Cutler and Malhotra 1995; Mueller 1992) or the United Kingdom (Cutler and Javalgi 1994) and emerging partners including China (Cheng and Schweitzer 1996), Korea (Cho, Gentry and Cropp 1999) and Taiwan (Zandpour, Chang, and Catalano 1992). Multi-country comparisons offer additional insight into different nations’ advertising styles (Albers-Miller and Gelb 1996; Graham, Cutler and Javalgi 1992; Karmins and Oetomo 1993).

Changes in values in persuasive messages across different media vehicles are associated with the rise of product placements since 1982, when sales of Reese’s Pieces rose 70% after being featured in *E.T.* Themes of placement effects of covert persuasive messages—those embedded in entertainment or educational vehicles—occur in studies of brand placements in television programs (Avery and Ferraro 2000); brand associations with major television characters (Way 1984); alcohol and tobacco product placements in soap operas (Diener 1993) or magazine articles

(Ford, Ringold and Rogers 1990); and brand placements in curriculum materials for classroom use (Rudd and Buttolph 1987). New interest in the ethics of placements reflects the success of product embeds at a time when the effectiveness of advertising persuasiveness is being questioned.

2: Content Analyses of Personal Communications

The most innovative change since 1977 is the addition of personal communications—consumer-generated and employee-generated verbal protocols—as new data sources. Nonetheless, expansion of the source is rooted in early conceptualizations of “content” by Berelson, Kerlinger, Holsti, and Lasswell, which Kassarian summarizes as “the communications that people have produced” (Kerlinger, in Kassarian, p. 9). What has occurred is a broadening of the concept of “verbal and symbolic behavior” encoded in written and spoken language (p. 8) now taken to include analysis of language in real-life communication. The thematic subcategories based on the data sources are consumer-generated and employee/manager-generated responses to open-ended or survey questions.¹

A: Consumer-generated Data.

Latent and manifest meanings encoded in consumers’ thoughts, feelings, and perceptions about media representations, especially advertisements, are related to the study of media documents themselves. For example, themes such as consumer ad comprehension (Mick 1992), brand associations (Bijmolt, Wedel, Pieters and DeSarbo 1998; Curlo and Lerman 1999), and aspects of the decision-making process (Miyazaki, Langenderfer and Sprott 1999; Palan and Wilkes 1997; Reynolds and Gutman 1988) link stimuli appeals to response effects in boundary-spanning research that connects the field of consumer behavior to that of advertising. Once the consumer’s words became the object of interest, themes such as the nature of consumer responses to the real-world consumption environment as distinct from responses to media representations reveal themes about shopping experiences and retailing. For example, consumers have been asked about their impressions of retail stores (Zimmer and Golden 1988), buying impulses (Rook 1987), unmet shopping needs (Lambert 1979), salesperson role performance (Harich and LaBahn 1998), gift-giving (Goodwin, Smith and Spiggle 1990; Mick and DeMoss 1990; Mick, DeMoss and Faber 1992; Ruth, Otnes and Brunel 1999), and attachment to irreplaceable possessions (Grayson and Schulman 2000).

B: Managerial/Employee-generated Data.

In the second category, data sources include employee- and manager-generated protocols as well as consumer verbatims. Themes related to the consumption environment are commonly found in service industry research, where the critical incident technique (CIT) is used to generate consumer and employee responses about satisfaction/dissatisfaction with service processes (Bitner, Booms and Tetreault 1990; Goodwin, Grove and Fisk 1996; Grove and Fisk 1997; Williams and Burns 1994), brand switching (Keaveney 1995), negative (positive) word of mouth (Sundaram, Mitra and Webster 1998), and complaining behavior (Davidow and Dacin 1997; Garrett and Meyers 1996; Stephens and Gwinner 1998). Manager-generated data can be found in the supply chain, sales management, and marketing strategy literature, which includes themes such as relationships with channel partners (Bello and Williamson 1985; Gundlach and Cadotte 1994), effective team

¹Content analysis of verbal data is also called “protocol analysis” and “discourse analysis,” terms that are used interchangeably even though they are not identical.

building (Barczak and Wilemon 1989, 1992; McDonough 2000; Morgan and Piercy 1998), evaluations of salesperson performance (DeCarlo and Leigh 1996; Evans, Kleine, Landry and Crosby 2000; Perrien, Paradis and Banting 1995), the buying process (Kennedy 1993; Woodside and Sherrell 1980) and strategy formulation (Frankwick, Walker, and Ward 1994; Frankwick, Ward, Hutt and Reingen 1994; Varadarajan and Johnston 1987).

3: Content Analysis of Research Impact

The original focus on disciplinary text has broadened into the increasing use of content analysis to examine marketing literature. Since the mid-1980s, journal articles and SSCI author citations are used as data for the purposes of identifying current “where we are” knowledge, research trends over time, and publication quality. In this way, the original theme of research readability has been expanded to include the impact of the discipline’s scholarly output (Oliva and Reidenbach 1985; Tripp 1997; Ward, Klees and Wackman 1999), individual contributions to research (Holbrook 1992; Jacoby 1995; Passadeos, Phelps and Kim 1998), and journals (Tellis, Chandy and Ackerman 1999; Yale and Gilly 1988). The theme of authorial “impact on the field,” especially popular in the tenure and promotion process, is found in articles that present citation analysis of various authors’ works, often considered a proxy measurement for determining an author’s contribution to knowledge. Knowledge synthesis is also advanced by means of topical literature reviews (Tyebee 1979; Varadarajan and Ramanujam 1990) and meta-analysis of research findings (Farley, Lehmann and Ryan 1981; Ryan and Barclay 1983).

4: Advances in Content Analysis Methodology

The post-1990s emergence of methodological articles revisits the *how* of content analysis, especially the controversial matter of reliability. Kolbe and Burnett (1991) examined the problematics of reliability and validity in 1978-1989 research; Hughes and Garrett (1990) proposed a generalizability theory approach to apportion variance based on raters and coding conditions; and Finn and Kayande (1997) demonstrated additional benefits of improved reliability assessment. The methodological shift is reaffirmed by a 1995 content analysis of articles published in the *Journalism & Mass Communication Quarterly* that identified the most frequently studied issues as “data representativeness, reliability, and validity” (Riffe and Freitag 1997, p. 521). The common theme is the method itself, with evaluative articles that examine adherence to the original guidelines stating that content analysis methodology “must be *objective, systematic, and quantitative.*” (Kassarjian 1977, p. 9, italics in original) and/or propose improvements in the calculation of intercoder reliability. Among the topics studied are the difficulty in coding “fuzzy data” (Varki, Cooil and Rust 2000); the development of computer programs to calculate measures of intercoder reliability (Kang, Kara, Laskey, and Seaton 1993); and a warning the unreliability of communication content as a measure of effects on consumers’ knowledge, attitudes, or behavior (Cohen 1989).

5: Qualitative Methods: New Frameworks

After the Consumer Odyssey in 1987, articles began to appear in which qualitative methods adapted from other disciplines were used to derive new typologies. Most of these articles can be categorized as “pre-content analysis,” for new frameworks and themes were proposed for future content analysis, but no data sources were themselves content analyzed. Among the methods proposed were textual analysis, found in sources such as literary criticism (Stern 1989), semiotics (Holbrook and Grayson 1986), and rhetoric (Bush and Boller 1991), and ethnographic analysis,

found primarily in ethnography (Arnould and Wallendorf 1994), but also in sociology and anthropology (Belk, Sherry and Wallendorf 1988; Greco and Swayne 1992). The purpose of these articles was to build grounded theory inductively by examining the data first and then introducing new frameworks for generating categories and developing coding schemes. For example, Stern’s articles on textual analysis of advertising offer directives to identify the formal properties of persuasive communications such as the type of company persona who speaks the message (1988a) or the allegorical conventions that underlie the message (1988b). These papers also exemplify the use of techniques to study latent as well as manifest content, another noticeable change. Interpretive techniques have been used to explore experiential aspects of consumption, identify thematic dimensions, and synthesize information into new frameworks (for a review see Spiggle 1994 or Stern 1998). Qualitative research aims at building innovative coding schemes for use in future content analyses. Comparisons between content analysis and other methods such as rhetorical analysis, syntactic analysis, degrees-of-freedom analysis, or the nominal group technique focus on methodological differences between quantitative and qualitative analysis (Claxton, Ritchie and Zaichkowsky 1980; Wilson and Woodside 1999).

CONCLUSIONS

In sum, this study’s investigation of content analysis research themes indicates that Kassarjian’s original themes served as a framework for expanded topical domains over time. Findings show that the current framework has been enriched by sociocultural and disciplinary changes such as the emergence of new themes, data sources, qualitative methods, disciplinary self-reflexiveness, and renewed interest in quantitative examination. Rather than discarding the original themes, researchers have applied them to new situations, and we found no articles that challenged the original questions. Hence, the study provides empirical support for the claims that Kassarjian’s article served as a benchmark for later thematic research and that the method remains a vital addition to the researcher’s tool kit.

Many research opportunities lie ahead, for the categories can be further enriched by the new themes, data sources, and media that arise in a rapidly changing environment. In the sociocultural category, for example, emergent topics as well as neglected ones await future researchers. Among the under-studied themes are political advertising, values in newly capitalist countries, theme-media relationships, and new media advertising. New ones surface regularly, such as the shrinking economy, an increase in minority populations, and the upsurge in patriotism after the terrorist attacks. So, too, do new media, including but not limited to the Internet, which provide fertile grounds for research on themes relevant to unexplored data types such as banner ads, chat groups, and edutainment; readily available data sources such as digital archives of print and TV ads; and legal or ethical issues such as privacy laws, content regulations, or ethical codes for research.

New synergies between qualitative methods and personal data sources also pave the way for innovative multi-method research that combines content analysis of textual stimuli with more accurate measurement of consumer response effects. Qualitative studies that adapt literary and language theory to advertising messages have led to greater awareness of executional or formal elements, allowing researchers to construct advertising stimuli free from confounds and to measure their effects empirically (Riffe, Lacy and Fico 1989). The confluence between qualitative analyses and empirical testing is likely to accelerate theory development by enabling researchers to derive theoretically grounded hypotheses testable in

experiments that elicit open-ended responses. The future of content analysis as a technique adaptable to research on themes as yet unthought of is bright, for the method's limits still seem to be "only the limits of the ingenuity and creativity of the consumer researcher" (Kassarjian 1977, p. 16).

'THE QUIET MARKET'

A Critical Realist Account of C2C Exchange in the West of Ireland

Damien McLoughlin, University College Dublin, Ireland
Geoff Easton, Lancaster University, United Kingdom

ABSTRACT

This paper presents a single case example of exchange in a C2C setting. This case is drawn from a longitudinal qualitative and quantitative study of a Local Exchange Trading System (LETS) group in Westport, County Mayo on the West coast of Ireland known as Meitheal Na Mart (MnM). LETS are a system of economic exchange designed primarily to free members from the labour-wage economy. This paper uses critical realism to illustrate the causal relationship between the focal actors behaviour as well as the causal potentialities and the environment in which she operated.

INTRODUCTION

The issue of consumer-to-consumer (henceforth referred to as C2C) exchange has only rarely been considered by researchers in consumer behaviour, or other fields of socio-economic enquiry. As Grayson (1999) points out there have been some exceptions although a great deal of fundamental exploration is required to establish this area as one of value to the mainstream reader of consumer research. This paper reports the findings of a longitudinal, qualitative and quantitative study of a system of C2C exchange. The paper has two purposes. Firstly to illustrate the variety of influences that can affect the progress of an individual acting as both buyer and seller. Secondly to highlight the potential for critical realism to provide a pathway to understanding this and other economic behaviours. The paper progresses through four main stages, an explanation of critical realism, an introduction to the case study location, the presentation of the case study and a discussion of some of the issues arising from this case.

CRITICAL REALISM

As Easton (2000) suggests, realism has broadly won a long battle to take the position as the leading epistemology within marketing. This paper, its theoretical framework and approach to data analysis are built around one particular form of this known as Critical Realism. Historically Critical Realism is traced to the work of Roy Bhaskar (1975) however its origins can be more readily accessed in the work Collier (1994), and Sayer (2000). In this section, the 'bare bones' of this understanding will be reviewed and their implications discussed. The emphasis is on the potential for critical realism as an alternative ontology for studies of the kind undertaken here.

The Transitive and Intransitive Dimensions of Knowledge

The basic belief of the critical realist is that a reality exists, can be discovered and exists independently of the researcher (Easton, 1998). This is built from Bhaskar's (1975) distinction between 'transitive' and 'intransitive' aspects of knowledge. The objects of study are the intransitive dimensions. Regardless of the theories that explain them, or the changes in those theories, they remain the same. The transitive dimension refers to the explanatory theories that can and do change. As Collier (1994: 51 in Sayer, 2000) puts it, while different branches of science may have different theories (transitive objects) the objects of study (intransitive dimensions) remain the same—otherwise there would not be rival theories.

The Real, the Actual, and the Empirical

As was discussed above, critical realism distinguishes between the real world and the researcher's experience of that world. However, it also distinguishes between the real, the actual, and the empirical worlds. Sayer (2000: 11-12) outlines the distinctions particularly well. The *real* is whatever exists, be it natural or social regardless of whether it is of interest to the researcher. The real is also the location of objects, their structures, and powers. Every object has structures and powers, causal liabilities and passive abilities, or the capacities to behave and change in certain ways. The task of the critical realist is to identify relationships and possibilities given these properties. The *actual* refers to the outcomes when these structures, powers, and capacities are activated. The *empirical* is the domain of experience. Insofar as it is possible to do so successfully, this may refer to the real or the actual. However, it may not always be possible to observe a phenomenon. Such observability may lead to researcher confidence about existence. For the critical realist, existence does not depend upon observability. They also accept a causal criterion. That is, a reasonable case for the existence for unobservable entities may be made from observation of effects that could only be explained by the products of such entities. The next level of this position is that powers may exist unexercised. That is, what has been observed to happen in a particular situation may not be the sum of all possibilities. Different configurations of real objects at a particular time may lead to a different set of outcomes. Critical realism is thus particularly useful at explaining change and dynamics in social settings.

Stratification and Emergence

The 'stratified' distinction between the real, actual, and empirical differentiates critical realism from other 'flat' epistemologies offering either the actual or the empirical. In addition, critical realism characterises a world of emergence. That is, two or more features may lead to the emergence of a phenomenon. However, that object is not reducible to its constituent parts. Sayer (2000) suggests the relationship between water and its constituent parts of hydrogen and oxygen as one example of this. Socially, similar relationships apply. For example, a marketing manager's ability to act is drawn from a complex of powers related to their relationships and the institutions within which they operate. This sensitivity to context makes social phenomena far more susceptible to change than their counterparts in the natural world. The implication for theorising is the need to constantly re-examine concepts for relevance.

Causation

One of the most prominent aspects of critical realism is its approach to causation. As has already been discussed, objects are part of structures. Structures consist of a set of related elements with a set of causal powers that when combined are emergent from those of their constituents. The outcome of the activation of causal powers depends upon the conditions that exist at the time of action. For critical realists, causation is not understood as the regularity of occurrence of particular events, as positivists might suggest. Rather, identifying the causal mechanisms that underlie an event, how they

work, and how they have been activated provides an understanding of causation. The understanding of a mechanism is dependent on revealing the nature of the structure or object that possesses the mechanism or power. Exploring the nature of causal powers further it can be said that the same causal powers can produce different outcomes, depending on the conditions that prevail at the time. Equally, different causal mechanisms can produce the same result. Thus when an effect or event is observed it should be borne in mind that this may or may not have been the only possible outcome. A different configuration could have led to a different effect. The final point to make regarding causation is that it is a fallible process. It requires some judgement to identify the various elements of the causative relationship. However, such judgement is a characteristic of all scientific effort.

The Interpretative or Hermeneutic Dimensions

Critical realism recognises that social phenomena have an intrinsic meaning that is not simply externally descriptive but also constitutive of them (Sayer, 2000: 17). Such meaning requires interpretation and so there is an inevitable interpretative hermeneutic element to social science. Where critical realism differs from hermeneutics is in its requirement to explain material aspects of life. Secondly, critical realism views reasons as potentially playing a causative role in the sense that they prompt actors to behave differently. The example that Sayer (2000) provides is the link between voting behaviour and the political experience of the individual.

The Critical Dimension

The critical aspect of critical realism gives it a licence to be critical of the practices and subjects that it studies. This is linked in particular to Bhaskar's belief in the emancipatory potential of social science. This is driven by the recognition that social science is based on ideas, where these ideas are the cause of unjust behaviour it is the duty of the researcher to intervene.

LOCAL EXCHANGE TRADING SYSTEMS (LETS) AND MEITHEAL NA MART

LETS are complex socio-economic systems that have been characterised in a variety of ways. The most succinct description of LETS has been provided by Williams (1996) 'LETS are local associations whose members list their offers of, and requests for, goods and services in a directory, and then exchange them priced in a local unit of currency (e.g. acorns in Totnes, favours in Calderdale). To maintain a record of the exchanges, cheques written in the local currency are sent to a treasurer who functions in a similar manner to a normal bank, sending out regular statements of account to members. No notes or coins are issued and neither is any interest charged or paid. As such, the local currency functions as a 'scoring system', much like matchsticks in baby-sitting circles. It has no 'value' outside of the local system. The local currency accumulated by members can be used to buy other local goods and services offered on the system. LETS, moreover, are a source of interest-free credit since members can spend local currency before earning it'. (Williams, 1996: 231).

The Westport LETS system, known by the Irish name of Meitheal na mart (henceforth referred to as MnM) was officially launched in February 1993. Like all LETS it had its own currency, known as the Reek, so called after Croagh Patrick, the local mountain that dominates the region, and which is referred to as the Reek. MnM had a sophisticated accounting function with a regular circulation to each member of his or her financial position within the system. Other publications included a newsletter and a directory

that listed the contact details for every actor and the goods or services they sought to make available. Exchange took place in a number of formats, between actors, at a weekly stall in the town market square, at regular Reek only auctions and through work parties when groups of members would visit the home of another members to carry out some large project, usually over a weekend.

A CRITICAL REALIST ACCOUNT OF EXCHANGE IN MEITHEAL NA MART

In this section, the basic model of causation offered by Sayer (2000) is worked through to identify why one actor in MnM behaved as she did. The case study reported here is the result of a three-year case study of the group in question. Data was collected from three main sources, interviews with regular members of the system and with key informants. Like many LETS systems this one operated a computerised central banking function which recorded the date and value of transactions between members for the years of the case study. Finally, MnM produced a number of publications, directory's and newsletters many of which were made available in the course of the case study. A process of member check was operated through multiple interviews with members such as the one featured below, Maureen. Also, leading members were presented with summary findings and their feedback sought. We shall now proceed with the case analysis.

Event

In this case the event that we wish to consider is the behaviour of one actor, Maureen, within MnM. The event can be specific along two dimensions, firstly why she became a member of MnM and secondly why she behaved as she did in the system. Maureen had been a member of MnM since its inception. Her exchange behaviour is summarised in table one below. Maureen had significant exchange partnerships with actors 13, 40 and 124. With actor 13 Maureen had exchanges in 1995 and 1996. This exchange totalled 12 purchases and 8 sales episodes in 1995 and 5 purchases and one sale in 1996. The value of these purchases was 1033 and 200 Reeks in 1995 and 1996 respectively. The value of sales was 1800 and 73 Reeks in 1995 and 1996 respectively. The total value and volume of sales and purchases are summarised in the final column on the right. What this shows is that Maureen had 17 purchasing and 9 selling exchanges with actor 13. The total value of these being 1233 and 1873 Reeks respectively. The final three rows summarise Maureen's total exchange behaviour that is purchases and sales, both with the highlighted significant partners and with all other actors in the system. Total personal exchanges summarises the value and volume of activity with other individual actors. Total stall exchange summarises the value and volume of activity that took place through the weekly market stall operated by MnM.

In aggregate Maureen's exchange behaviour can be described in a number of ways. Firstly, she is a high volume actor who has bought and sold more than average in the system. From table one below it can be seen that the total number of exchanges Maureen undertook during the study period was 164 (81 purchases and 83 sales). As can be seen from the break down by year, there was some fluctuation in this level of activity between years.

Secondly, she has bought and sold roughly the same number of times. What is interesting about this is that, as with the total activity measure this figure fluctuates between years, its fluctuation is broadly consistent across each year. For example, in 1998 Maureen had 9 purchases and five sales, compared to 31 purchases and 23 sales in 1997. It is unclear what this pattern is indicative of, however, strict reciprocity can be ruled out. This actor had only

TABLE ONE
Time and Value Analysis of Maureen’s Exchange Behaviour

Partner/Year	1995	1996	1997	1998	Volume: Buy/Sell Value: Buy/Sell
13	12/8 1033/1800	5/1 200/73	-	-	17/9 1233/1873
40	0/2 0/260	2/0 350/0	-	-	2/2 350/260
124	-	2/0 500/0	3/0 2380/0	-	5/0 2880/0
Total Personal Exchanges	18/16 2,198/3830	9/4 1,050/473	6/8 2,710/2100	5/0 114/0	38/23 6,072/6,423
Total Stall Exchanges	11/21 1,492/1685	3/14 200/1,340	25/21 2,474/3106	4/5 94/196	43/60 4,260/6,307
Total Exchanges	29/37 3690/5515	12/18 1250/1813	31/23 5184/5206	9/5 208/196	81/83 10332/12730

three significant exchange patterns, actors 13, 40 and 124. Significant exchange partners are those with whom Maureen had four or more exchanges over the four-year period of the case study. As with activity, so with pricing, Maureen charged roughly the same prices for sales as she paid for purchases. The final noteworthy feature of Maureen’s behaviour relates to her partner network. As was noted above she had relatively few relational partners, but she did exchange with a wide range of other actors within the system.

To summarise, Maureen was an active trader with a wider network of partners, although only three of these could be described as significantly relational. In the following section a mechanism to explain this behaviour will be presented.

Mechanism

It can be suggested that the mechanism through which this was achieved was recognition by Maureen that the system could meet a significant proportion of her social, political and economic needs.

Structure

In explaining Maureen’s behaviour we know that every actor within MnM exists within a set of necessary relations, what is referred to as structure. This structure is comprised of three main elements: a social exchange with the system, an acceptance of the Reek as a measure and store of value and Maureen’s own exchange strategy. Each of these is considered in turn.

Social Exchange

Although not from the local area, Maureen was historically a rural Irish person, having spent her childhood in a small town on the East coast. She had moved to Westport in search of an alternative way of life that she felt would provide healing for the suffering she had endured although Maureen was generally unspecific about the nature of this suffering. However the principle of relief is significant in two ways. Firstly, when she arrived in Westport she was in search of a place where she felt she could belong. The achievement of this

was secured through interaction with other actors living in the Westport region. She explained her experience as follows ‘...when I landed in Westport it was like home, I started connecting with people straight away’. She felt that ‘...Westport... has a striking hold on people and what people are doing here is...looking at their lives, they are looking for more in their lives, they are looking to find happiness’. Together these forces suggest two emergent processes. The first was the creation of a cultural space around the Westport region. This was because the presence of a group of people with similar aspirations for social and personal change gave credence to plans for action within which a LETS such as MnM might reasonably be expected to prosper. Secondly, as Maureen saw her own issues being solved in a group setting it could be suggested that she was prone to identifying with and participating in, group solutions to social issues. This predisposed her not only to membership of, but also enthusiasm for, groups such as MnM.

The idea of Westport as a particular cultural space suited to LETS type exchange can be treated further by considering Maureen’s socio-political ideology. That is her belief about how society, particularly in proximate rural locations, should operate and feed into broader society. Maureen felt that the difficulties of modern life actors arose because ‘...people are getting too materialistic, their sole aim is to be independent of one another... they have to have all of these material things that enables them to be totally independent of one another’. What Maureen possesses that perhaps the majority do not is the memory of a society in which such a system of social governance did not prevail. Although only in her late thirties Maureen can recall the operation of a Meitheal system in the area she lived in as a child. She described how she ‘...grew up exchanging with others...the financial stage was very, very minimal and so...you’re always depending on others...there was a lot of exchanging going on because there wasn’t enough money to be totally independent’. From these two statements we can see that Maureen could not only anticipate a role for a co-operative exchange system such as LETS but could also anticipate both how the system as a

whole might work and also what her role within the system might be. It might be suggested that this structural element left her well disposed to enthusiastic participation in LETS exchange. A final aspect of this was the role Maureen felt that MnM could play in educating her children. Two of her children were old enough to be youth members of MnM, she felt that it could play an important role in allowing them 'to get a feel of that letting go (of material things)...to share things, pass them round, reuse them'.

To summarise the social relationship between Maureen and MnM could be seen as one in which Maureen identified Westport as a location for personal healing. Such healing could be best achieved in a group setting. Westport provided a significant number of people with a similar aspiration. MnM was one formal institutional structure through which such change, healing or development could be achieved. In addition, Maureen expressed a particularly communitarian socio-political ideology which identified economics as a particular reason for the breakdown of traditional societal structures. This suggests a particular social alignment between Maureen and an alternative system of exchange such as MnM.

The Reek as a Medium of Exchange and a Store of Wealth

The second structural aspect of Maureen's participation in MnM is her acceptance of the Reek or local currency as a store of wealth and a medium of exchange. This aspect of Maureen's membership is particularly interesting. For her it appears that the Reek was not a particularly noteworthy store of wealth. She pointed out that '...the figures don't mean that much to me... they would only mean a lot if I became aware if I was in the red hugely...'. What is interesting about this is that her strong positive balance is not too important to her. However, a negative or debit balance would not be acceptable. This issue is discussed further below. The need to maintain this balanced relationship within the system was highlighted when Maureen pointed out that in the future she expected to be charging Reeks for jobs that she had done for 'free' because she wanted to use Reeks to part pay for a new house she planned to build. There does appear to be a contradiction in this understanding on the part of Maureen. However, the explanation is consistent with the earlier discussion of her social relationship with MnM. For this actor the Reek played an unusual role, essentially it was a lubricant for exchange in the sense that it gave her the ability to ask for services from another, but to also accept their refusal or to refuse services to another, without a loss of face.

This suggests the presence of an emergent property of the system. In its fundamental form, LETS proposes a market within which actors exchange goods and services for a local rather than a national currency. As discussed earlier actors can borrow against the LETS currency, interest free, in order to improve their standard of living. Maureen has taken an alternative route in which she has actively avoided taking on debt, and views deficit as a negative within the system. It has been suggested that the location of MnM in Westport provided the system with a supportive cultural environment and was an important reason for its success. This approach to the currency may be one of the costs of that location. Many rural people have an informal system of exchange within which reciprocity is not measured but is carefully noted (Salazar, 1996). This exchange culture has overlapped with that of MnM to create a hybrid within which people were willing to exchange, felt liberated to exchange but were unwilling to rely on the system as a source of finance for that trade. The significance of this emergent property lies in the effect it had and looks likely to continue to have on Maureen's trade in the future. If she had valued the Reek or local currency more highly perhaps she would have traded more actively and recorded her exchanges more accurately. She notes that for

future exchanges she will record her credits more accurately as she wishes to use Reeks to support a building project. She could have relied on readily available Reek credit to complete this work but instead she seeks to build a surplus in advance.

To summarise, for Maureen the Reek was a useful medium of exchange in that it removed the notion of reciprocal obligation. This will have contributed to her perception of the system as one within which trade was possible. However, it could not be significantly observed as a store of wealth. Finally, the system of exchange that appears to prevail in MnM is an emergent property of its structure rather than a feature of its intended design.

Actor Exchange Strategy

The final structural element to be considered is Maureen's exchange strategy within MnM. Maureen was clear as to what the role of exchange in MnM was in her overall portfolio of economic activities. She saw LETS as 'running alongside' the main economic activities of her household, providing 'bits and pieces' in addition to the necessities provided for by national economy employment. This was a common feature of exchange in MnM as actors felt that they could easily secure luxuries through the system. These luxuries often arose through hobby services such as massage or alternative therapies of various kinds. Alternatively they arose through goods purchased at the weekly stall. The latter was the one most commonly employed by Maureen at the time of interview. Although she had offered her labour for Reeks in the early stages of the system.

To summarise, Maureen was apparently a convenience actor, who improved the margins of her material life through LETS exchanges. What this review of structure has revealed is an actor with a strong historical disposition to co-operative ventures such as LETS. In addition, she had a clear understanding of how the system might work for her and the contribution that she might make to it. In the following section, the impact of contingent relations on this structure will be used to explain the dynamic aspects of Maureen's exchange profile.

IDENTIFYING THE IMPACT OF CONTINGENT RELATIONS

To explain the outcome of Maureen's exchange behaviour it is necessary to examine the contingent relations that arose during the course of her membership of MnM. In this case the particular product/service offering, the overlap between the national and local economy and the interaction of social and economic forces appear to have been most significant. Each is discussed below.

Product/Service Offering

Maureen offered both a service and goods for sale in MnM. The service was her own labour that was offered for Reeks only to actor 13 who was setting up a cheese business and required assistance. This established a significant base of high activity for Maureen within the system. This valuable service was offered not simply because it was what Maureen was capable of, if that were the case all actors in the system would offer similar resources. This was certainly not the case. Rather the high volume of activity associated with this service was a result of Maureen's willingness to provide it for Reeks only and the valuable and high demand nature of the service to the entrepreneurial actor 13. An emergent consequence of this exchange was that Maureen accumulated large amount of Reeks for her services, through the operation of the enthusiasm mechanism she also set out to spend these Reeks. Table one demonstrates the almost balanced nature of Maureen's activity with the value of buying and selling almost equal. The goods that Maureen offered for sale can be treated together. In the early days

of the system Maureen and other actors baked bread for sale through the stall. The purpose being to convince others that they system could provide for daily needs and so was a worthwhile activity. Maureen's other offering was household goods sold through the weekly stall. In each case Maureen was offering generally desirable goods, at substantial discount to normal prices through the central distribution mechanism for the system. The products and services that Maureen offered through the system were highly valuable. She offered these as a result of her own enthusiasm for the match between the ideals MnM and her own social, economic and political outlook. In addition, we also know that her purchasing ambition within the system during the period of the case study at least were limited to marginal enhancements of her utility through buying 'bits and pieces' as they became available. Thus the product/service offering contingency offers one particularly persuasive explanation for the high activity profile of Maureen's account.

Thus far the explanation of Maureen's exchange behaviour has focussed on explaining the enthusiastic nature of her participation in MnM. However, it should be noted that in the final year of the case study her activity had subsided. The following two contingencies will consider reasons for this reduction.

Overlap between the National and Local Economy

When MnM was initiated in 1993, Ireland was an economic backwater notable only for high unemployment and emigration, particularly from the West coast where Westport is located. However, the so-called Celtic Tiger of the 1990's would see the country enjoy double digit growth. By the mid 1990's this growth had seeped from the industrialised east coast to the rural West and was particularly felt in Westport. From an exchange perspective within MnM this meant that the material need of many actors to participate in MnM was reduced or eliminated. The effect of this on Maureen was to reduce the number of opportunities she had for trading with other actors. The implications of this will be considered in conjunction with the next contingency.

Interaction of Economic and Social Exchange

The interaction of economic and social exchange is an interesting and significant explanation both for fluctuation and reduction of Maureen's economic commitment within the system. Essentially this contingency suggest that relationships that begin with an economic orientation, that is actors trading Reeks for goods or services, move beyond the MnM framework as the social relationship between actors develops. Maureen offers one particular example of this. She highlights one particular exchange partner within which this occurred. She noted that '*...we had a lot of transactions, it was just more handy than saying this amount for Reeks, you owe me this amount... because there was definite things that he was doing for us and definite things he wanted one for him*'. This outcome can be considered in two ways. The first is as an inevitable result of the type of local and social interaction that occurs in rural areas. If, as Maureen points out there was ongoing direct exchange between two actors it is perhaps not surprising that such exchange would move beyond the system. However, if the earlier consideration of Maureen's commitment to the MnM project is revisited this behaviour is actually very surprising. Why would this actor wish to undermine a system to which she had such a large commitment?

There was considerable evidence in the case as a whole that, over time, intra-system feuds reduced the willingness of actors to trade with each other. It also retarded the type of enthusiastic idealism for the system that many such as Maureen showed at the outset. One emergent consequence of this from an individual actors perspective was to lead to a reliance on reciprocation rather than the

open market for exchange opportunities. This explanation interestingly does not undermine the confidence that Maureen showed in the Reek and its ability to repay efforts as discussed earlier. Her understanding of the system was primarily a personal one '*...I just know there are enough people in that system to do something for me for Reeks if I wanted*'.

To summarise, it has been seen that Maureen, as a result of the dynamics of the system explains her reduction in trading through the emergence of reciprocal, non-system exchange with key exchange partners. It is suggested that such behaviour is a widespread pattern within the system.

DISCUSSION: CRITICAL REALISM AND C2C BEHAVIOUR

This paper presented an outline of an emerging epistemology that is having a significant impact on a variety of social sciences. In this instance it has been employed to explore a single case of an actor involved in a system of C2C exchange.

Much of consuming behaviour is rightly seen as taking place within a dominant socio-economic framework with a particular set of values, aspirations and pre-ordained behaviours. This case has provided an insight onto how individuals behave economically when such a control structure is removed. Most significantly in the context of current debates within consumer research relating to resistance of the market economy, this paper demonstrates the difficulty of such resistance beyond existing social, cultural, economic and political structures. In order to explore this effect in greater detail further cases and a different event focus will be required. This will be the subject of further papers arising from this research project. Such contributions will go some way towards resolving the challenge to consumer researchers set by DiMaggio and Louch (1998) who pointed out that the deficiency of knowledge regarding the social organisation of exchange in C2C markets. Finally, we can suggest that the ability of critical realism to offer an alternative to linear additive approaches to explanation of social phenomenon is worthy of some further attention amongst consumer researchers.

Social Influence on Post Purchase Brand Attitudes

Kirk L. Wakefield, Baylor University

George W. Stone, Georgia College & State University

ABSTRACT

Self-determination and attribution theory form the basis for examining differences in brand attitudes following purchase decisions for a university education (Study 1) and an automobile (Study 2). In the first study, we examine differences in attitudes in those who recently entered the university (freshmen) vs. those whose entry is more distant (sophomores), testing for differences based on whether family or peers influenced the decision to enter the university. In Study 2, we test for differences in post purchase brand attitudes due to recent/distant purchase time, family and peer influence and consumption purpose (functional/hedonic). Brand attitudes remain highest for those who independently purchased an automobile for hedonic reasons. The worst-case brand attitude scenario occurs for distant functional purchases heavily influenced by family and friends. Implications for personal selling and advertising management, social persuasion theory and marketing pedagogy, and future research conclude the paper.

POST-PURCHASE BRAND ATTITUDES AND SOCIAL INFLUENCE

Consumers purchasing expensive, high involvement products or services that are used or consumed over relatively long periods of time are likely to frequently revisit their purchase decision. With many products and services, the newness wears off and altered brand attitudes may lead to cognitive dissonance and subsequent switching behavior. As the consumer gains experience with the product or service, s/he becomes more intimately familiar with its benefits and drawbacks. Following a substantial investment in a new car, a university for an education, or membership in a private social club, an individual may acquire a different perception of the product or service after gaining experience with it.

Consumption decisions are frequently influenced by external sources, including market sources and personal sources. As individuals search for information that will either facilitate evaluation of alternatives leading to choice, or facilitate post-purchase evaluation of the alternative chosen, their perceptions may be colored by the opinions and input of others. While prior social influence research has focused principally on the initial purchase decision (information search, alternative evaluation, trial/purchase), little work has investigated the lasting influence of others on post-purchase evaluations of that decision. With respect to post-purchase evaluations, what differences in attitudes toward the product can be expected between individuals who make a relatively autonomous purchase decision and those whose initial purchase decision was heavily influenced by family or friends?

Social influence vs. Self-Determination

To persuade individuals to purchase their product or service, marketers frequently attempt to take advantage of social influences in personal selling, advertising and other promotional efforts. Using the opinions of others may provide an effective avenue to influence choice. Yet, self-determination theory (Deci and Ryan 1980) suggests that individuals are likely to ultimately be less satisfied when others direct brand choices. Borrowing theory from the growing stream of research regarding self-determination in the psychology literature, we contrast brand attitudes toward a given purchase between those who make brand choices influenced by family or peers and those whose decisions are more self-determined.

Specifically, in Study 1, we observe differences in attitudes toward a service currently being consumed by individuals who have recently made the purchase decision and those whose initial decision is less recent, contending that those whose initial decisions were largely determined by peers or family members are likely to have less positive post-purchase brand attitudes than will those whose initial decision was made with more autonomy.

Functional vs. Hedonic Consumption Purpose

In Study 2, we extend our examination of the role of initial peer and family influence in determining brand attitudes after purchase, while also accounting for the functional or hedonic purpose of the purchase. The functional/hedonic consumption context may affect the manner by which individuals evaluate the decision (O'Curry and Strahilevitz 2001). The interaction between consumption purpose (functional/hedonic) and social influence on brand attitudes has yet to be examined. For reasons of self-esteem and attributions made to protect one's self-esteem, we expect to find that individuals who make relatively autonomous purchase decisions (viz., with less social influence) for hedonic consumption purposes to hold more positive brand attitudes than individuals who make socially (family or peer) influenced purchase decisions for utilitarian consumption purposes.

Importance of Research

This research is important for three reasons. First, from a theoretical perspective, research related to post-purchase attitudes has focused on individual differences (e.g., involvement, Richins and Bloch 1986, 1991), and/or processes (e.g., need for cognition, Cacioppo, Petty, Kao and Rodriguez 1986) that may influence attitude consistency or dissonance, but has not examined the role of social influence. Although the role of social influence in brand preference and choice behavior is well established, little has been done to examine differential effects of social influence on post-purchase attitudes. Second, from a pedagogical perspective, this is critical since treatments of social influence in the marketing literature, particularly consumer behavior and marketing management texts, typically assign no valence to using social influence as a means to complete marketing exchanges. The use of social persuasion in personal selling (e.g., Cialdini 1994), advertising (e.g., Kamins, Brand, Stuart & Moe 1989), and brand choice (e.g., Rosen & Olshavsky 1987) is treated as an avenue of motivation with little risk of dangerous detours in route to building brand preference.

Third, from a marketing management perspective, post-purchase brand attitude is directly linked to repeat purchases of a brand. Consequently, situations or factors that might lead to an initial satisfactory transaction (i.e., via social influence on an individual's brand choice) but that also lead to deleterious effects on long term brand attitude are apt to be of concern to marketing managers. Specifically, personal sales approaches that use peer or family reinforcement to influence an individual's purchase of a minivan for its utilitarian benefits may lead the individual to subsequently hold a less positive attitude toward the brand purchased than that held by an individual who perceives that he autonomously purchased a minivan for the same utilitarian purpose.

For publicly consumed products or services, we compare the perceptions of individuals who make relatively autonomous decisions versus those who make decisions highly influenced by peers or family. While we expect that decisions reinforced by family or

friends to produce initially relatively positive attitudes toward the product chosen, we expect that individuals who make more autonomous decisions to hold more positive attitudes toward the product in post-purchase evaluations than those who made the decision more so due to social influence. We first examine these relationships within the context of an individual's decision to attend a specific university. We extend the analysis to the purchase of an automobile in Study 2.

STUDY 1

Attributions & Self-Determination

Attributions. Brand attitude research has long held that social norms are likely to influence purchase intentions and choice. Individuals may comply with the advice of others due to either normative or informational social influences. In the initial decision-making process for publicly consumed products, individuals make purchases that will provide social approval or negate disapproval (normative) or that are in agreement with others considered knowledgeable about the product category (informational). After the initial purchase, however, the user of the product gains information about the product that may or may not be in agreement with the normative and/or informational influence received at the point of purchase. To the extent that post-purchase dissonance occurs, an individual may attribute the difference between post-purchase attitude and purchase attitude to the influence of others who influenced the decision (i.e., Weiner 1986, 2000). Any notable shortcomings can be attributed to others in order to protect one's self-esteem ("I knew I shouldn't have listened to them. If I had done what I wanted I would have bought something else."). In the case of product or service failure, we can expect that those highly influenced by others to purchase a brand may hold less positive brand attitudes when compared to those who make more autonomous decisions, as we now explain.

For self-esteem reasons, individuals who make more autonomous or self-determined decisions are motivated to maintain relatively consistent and positive purchase and post-purchase attitudes—even when product failure occurs. An individual who autonomously gathers information and decides to purchase a vacation package has only himself to blame if negative results occur. Rather than admitting a bad decision, for ego-defense reasons, people will seek to maintain a relatively positive attitude toward the purchase ("It really wasn't such a bad cruise. It was fun spending an extra day in port."). Anecdotal evidence suggests that this phenomenon frequently occurs in marital contexts when one independently makes what would otherwise appear to be a bad decision.

Self-determination. Self-determination theory holds that individuals have an innate need for autonomy, competence, and relevance (Deci and Ryan 2000). Sheldon, et.al. (2001) finds that these three aspects of self-determination (autonomy, competence and relevance) are the most salient needs (compared to other fundamental needs) in determining an individual's "most satisfying events." An individual will be most satisfied when s/he autonomously (rather than jointly) makes a good purchase decision, as it reinforces feelings of competence and personal relevance. In short, we are most satisfied when we get to determine the outcome of an event. Conversely, having to seek or wait upon another's input or acquiescence may take some satisfaction out of what might otherwise be a relatively enjoyable purchase occasion.

Although social reinforcement of a purchase may lead to an initially high brand attitude, one can expect that in the post purchase evaluation stage individuals will have a more positive attitude toward a product purchase when they have not been swayed by family or peer influence to select a particular brand. Based upon

self-determination theory and attribution theory, we expect this effect to be most prominent after the passing of time, as the newness and accompanying purchase arousal wears off. Individuals begin with relatively positive brand attitudes at the point of purchase—or else they wouldn't be making the purchase. Over time, variance in brand attitudes is likely to increase as some individuals have positive and some have negative post-purchase outcomes.

Thus, it is anticipated that individuals who have made recent purchases of a given product are likely to have more favorable brand attitudes than those whose purchase decisions are more distant. However, brand attitudes of those individuals who report that decisions were heavily influenced by family or peers are expected to be significantly lower as time passes, compared to those who report that initial purchase decisions were subject to less social influence. Hence, a time (recent/distant) X social influence (low/high) should obtain. Formally:

- H1: Individuals whose purchase is more recent will have more positive brand attitudes than those whose purchase is more distant.
- H2: For more distant purchases, brand attitudes of individuals who report that the purchase decision was subject to high social influence will deteriorate more so than those who report little social influence.

Methodology

Data were collected from subjects as part of a university's annual student evaluation process at a medium-sized southern university. Overall, 419 freshmen and sophomores responded. Respondents were asked via a 5-point Likert scale (Disagree/Agree) the extent to which his/her decision to attend the university was due to family and friends ("I chose to attend *this university* because of my family." "I chose to attend *this university* because of my friends."). The reliability of single-item scales has been found to favorably compare with the use of multiple-item scales (Wanous, Reichers and Hudy 1997) when measuring constructs that are likely to be unambiguous to the respondent. Multiple-item scales are desirable for measuring more complex, multi-faceted constructs such as personality traits, attitudes and image perceptions.

Given the focus of this study, students' attitude toward the university was measured via a 13-item standardized university image scale (source: University of Texas; <http://www.utexas.edu/student/research/>) employing six-point semantic differentials ($\alpha=.909$):

Academically lax—	Services are unavailable—
Academically rigorous	Services are accessible
Impersonal—Friendly	Prejudiced—Tolerant
Bureaucratic—Streamlined	No sense of community—
	Great sense of community
Hostile—Caring	Arbitrary—Fair
Intellectually stifling—	Unrewarding—Rewarding
Intellectually stimulating	
Culturally stagnant—	Limited learning opportunities
Culturally enriching	—Variety of learning
	opportunities
Miserable—Enjoyable	

Summing the scores of the 13 items, student responses on this scale could range from 13 to 78. Subjects who intended to remain at the

TABLE 1
Results of Study 1 (N=242)

2-Way Interaction (F=5.17, p=.02, e ² =.042)	Low family influence	High family influence
Year One	65.2	67.7
Year Two	62.0	63.4
2-Way Interaction (F=6.30, p=.01, e ² =.018)	Low peer influence	High peer influence
Year One	67.1	65.7
Year Two	63.4	61.0
Main Effect		
	Low	High
Time since purchase (F=5.83, p=.02, e ² =.029)	66.7	62.6

university have significantly ($F=5.48, p=.005$) more positive attitudes toward the university (64.5) than do those who reported an intention to transfer (61.3) or were uncertain (61.7).

Since we are interested in examining those who have either high or low social influence, subjects who reported ambiguous social influences (e.g., "neutral" on the 5-point Likert scales) were removed. Thus, individuals reporting either low family or peer influence (e.g., "Strongly disagree," "Disagree") or high family or peer influence (e.g., "Agree," "Strongly Agree") were retained for analysis.

Observed differences in attitudes toward the service (university) over time between subjects may be due, in part, to factors not accounted for in this study. Further, we are relying upon respondents' reports of the degree of family or peer influence after the fact, rather than observing it at the point of purchase. *However, whether due to reality or selective/distorted perception, we are interested in the attributions and self-esteem maintenance processes individuals may employ in post-purchase evaluations.*

Results

Table 1 displays the analysis of variance results from Study 1. The dependent variable is the respondent's attitude toward the university. A 2 (year 1 vs. year 2) X 2 (low/high family influence) X 2 (low/high peer influence) three-factor design was employed in which the time since entering the university was a between-subjects factor and family and peer influences are within-subjects factors.

Main effects. As expected, subjects who recently entered the university (freshmen) have significantly more positive attitudes toward the university than do second-year students (66.7 vs. 62.6, $F=5.83, p=.02$), supporting H1.

While not explicitly hypothesized, additional main effects emerge from this data. Individuals who reported that their families strongly influenced their decision to attend this university had significantly more positive attitudes toward the university than did those whose families did not exert much influence on their decision to attend (64.7 vs. 62.5, $F=6.56, p=.01$). Individuals who were strongly influenced by their peers to attend the university had somewhat less positive attitudes toward the university than did those for whom peers had little influence (64.2 vs. 62.0, $F=3.53, p=.06$).

Interactions. As anticipated, a two-way interaction emerged with subjects' attitude toward the university between low/high family influence and recent/distant time passage since purchase

decision ($F=5.17, p=.02$), supporting H2. The interaction appears to be driven by the relatively greater drop in attitude toward the university between the first and second year by those who were heavily influenced by family members (67.7-63.4=4.3) than for those whose families did not strongly influence their initial decision to attend the university (65.2-62.0=3.2). A similar two-way interaction ($F=6.30, p=.01$) occurs for those who were heavily influenced by peers to attend the university compared to those who were not. The attitude toward the university by those who were highly influenced by peers to attend drops from year one (freshmen) to year two (sophomores) at a greater rate (65.7-61.0=4.7), than does the attitude toward the university of those who were not much influenced by peers to attend (67.1-63.4=3.7).

Interestingly, family influence plays a greater role in determining the choice of the university than did peer influence (2.93 vs. 2.67, $t_{417}=4.20, p=.000$).

Summary. The two-way interactions point to the finding that the individuals with the worst attitudes toward the university are those in their second year who reported being highly influenced by their peers to attend the university (61.0). While individuals heavily influenced to attend the university by their families have the highest initial attitude toward the university (67.7) in their first year, those in their second year who reported being heavily influenced by family members experience a substantially lower attitude (63.4), although this attitude is more positive than other second-year students whose family did not influence the choice (62.0). These numbers are not particularly surprising, given the recurring problem of student (customer) retention in this and other settings.

Given the nature of this study (between-subjects), these results mainly indicate that there is a difference between first and second year students' attitudes toward the university, and that increasingly negative attitudes are associated with individuals who initially had greater family and peer support to attend the university. Interestingly, it appears that individuals who did not attend due to peer influence have generally more positive attitudes (in year one or two) than those influenced by peers to attend. This is not the case with family influence.

A university education represents a relatively functional consumption context, although this may differ by individual and university. To the extent that the university experience was intended as more hedonic or functional might shed some light as to the relative role of family and peer influence. In the next study, we examine a different purchase context (automobile purchase) while

accounting for the purchase intent (functional/hedonic) and family/peer influence.

STUDY 2

Functional/Hedonic Context

Hedonic consumption refers to situations in which the product or service is experienced for fun, pleasure, arousal, or excitement (Hirschman and Holbrook 1982). Functional products or services provide utilitarian benefits. Although some products or services may hold functional or hedonic value in the same way for most people (e.g., auto repair vs. amusement parks), the functional/hedonic nature of a given product or service may differ based on (a) individual consumption preferences and purposes, (b) situations, and (c) the role of buyer/user.

First, individual consumption preferences and purposes may differ such that one individual seeks functional rewards while another seeks hedonic rewards for the same product, as when one member of the family desires reliability, safety, and value from an automobile and another seeks speed, power, and status. Second, the consumption situation or context may lead an individual to at one time prefer functional benefits (comfortable and durable jeans) and at another time prefer hedonic benefits (fashionable, name-brand/status jeans) for a specific product. Third, individuals may assume different roles in purchase situations (e.g., computer) such that as a user one may seek more hedonic features (game ports, videogame graphics, soundcard, TV monitor compatibility, etc.), while as a buyer one may care more about functional aspects (price, repair record, etc.). Most consumption situations are unlikely to be purely functional or hedonic. Rather, individual purposes and preferences, situations, and the buyer/user role may lead an individual to seek primarily functional or hedonic benefits from the consumption experience. In sum, not all individuals will perceive a given product or service purchase as functional or hedonic. Instead, variance is likely to exist across individuals for a specific product purchase.

The functional or hedonic consumption purchase may serve to moderate the effects of family or peer influence on one's brand attitude for two reasons. First, situational purchase involvement may provide some arousal for even functional purchases. Compared to hedonic purchases, functional purchases that are dictated by family and friends may take away whatever pleasure one might derive from the shopping experience. In contrast, one's attitude toward the brand is likely to be most positive when the outcome is self-determined and when the purchase is hedonic, as when an individual makes an independent purchase of a sports car, athletic equipment, apparel, or other products/services consumed for personal pleasure. In short, in terms of brand attitude, the worst-case scenario is a functional purchase heavily influenced by friends and family and the best-case scenario is a hedonic purchase self-determined without friends or family influence. Second, in varying degrees, a shopper's self-esteem is connected to the efficacy of the shopping experience (Hanley and Wilhem 1992). In the hedonic, autonomous purchase context, the purchase is likely to be of personal importance to the individual (e.g., purchase of an expensive tennis racquet). In order to protect one's self-esteem, individuals in this context are apt to maintain a relatively positive brand attitude. Conversely, in the functional, socially-influenced purchase context, the purchase does not have high personal relevance ("It wasn't that important to me anyway.") and the buyer is able to attribute a poor decision to the influence of others ("If they hadn't told me to buy that brand, I wouldn't have.").

Thus, a three-way interaction between purpose (functional/hedonic), family influence (low/high) and peer influence (low/high) is anticipated:

- H1: Brand attitudes will be higher for hedonic purchases made with low family or peer influence than for functional purchases made with high family or peer influence.

Time Influence

As in Study 1, individuals who have made more recent purchases are expected to have more positive brand attitudes than do those whose decision is less recent. In keeping with self-determination and attribution theory, we expect that those who have made relatively independent recent purchase decisions will hold the most positive brand attitudes. Those with the poorest brand attitudes are expected to be individuals who were subject to heavy influence by family *and* friends to purchase a specific brand and where more time has passed since the purchase. Hence, a three-way interaction is expected between time (recent/distant), family influence (low/high) and peer influence (low/high). As time passes, the value of the brand opinions of others is likely to have deteriorated and any product defects attributed to *their* poor judgment.

- H2: For more distant purchases, individuals reporting that the purchase decision was subject to high social influence will have less positive brand attitudes than those reporting less social influence.

Methodology

For consistency with the sample drawn from Study 1, subjects (N=143) on a college campus who had purchased an automobile were surveyed. Respondents reported the brand of the automobile purchased, its original price, and the date (month/year) of the purchase, and whether family or friends were present at point of purchase. Subjects were asked the purpose of the automobile purchase: purely for practical purposes—purely for enjoyment (7-point semantic differential). Family influence and peer influence were each measured with items asking, "In this purchase, to what extent was your decision influenced by *family members* (friends) to buy the brand you selected?" Responses were recorded on 7-point "no influence—very much influence" scales.

Social influence validity check. The presence of family members or peers at the point of purchase increases the likelihood that individuals will report that family or peers influenced the purchase decision. Of course, the individual may disregard their input or the family members or peers may provide limited input. In general, however, we would expect that the presence of family members or peers is likely when their influence is reported. The data indicates that those who indicated that family members were present at the point of purchase reported higher family influence than those without family members present at the point of purchase (4.73 vs. 3.33; $F=3.03$, $p=.08$). Subjects who reported that friends were present at the point of purchase were more likely to report that friends influenced their brand decision than those without friends present at the point of purchase (3.32 vs. 2.21, $F=8.22$, $p=.005$).

As a second validity check on the sources of social influence, subjects were asked to indicate the extent to which they agreed (7-point Likert Scale) with the statement, "I chose this brand completely on my own." This response was negatively correlated with the extent of reported family influence ($r=-.42$, $p=.00$), but uncorrelated with peer influence ($r=.02$, $n.s.$).

Brand attitude. Attitude toward the brand was measured with an established scale developed by Maheswaran and Sternthal (1990). The seven-item scale (bad—good, outmoded—advanced, inferior—superior, not as good as competing brands—as good as competing brands, not useful—useful, a product I'll not try again—a product I'll try again, not a good value—a good value) produced acceptable reliability ($\alpha=.93$).

TABLE 2
Effects on Automobile Brand Image in Study 2 (N=143)

3-Way Interaction (F=4.40, p=.02, e ² =.03)	Low family influence	High family influence
Functional Purpose		
Low peer influence	41.1	40.3
High peer influence	40.5	34.0
Hedonic Purpose		
Low peer influence	43.3	39.5
High peer influence	39.9	41.4
	Main Effect	
	Low	High
Time since purchase (F=3.69, p=.03, e ² =.02)	43.4	38.3
	Covariate	
Price of automobile (F=17.7, p<.01, e ² =.09)	Price range: \$800-\$49,000, x = \$14,550	
3-Way Interaction (F=3.20, p=.05, e ² =.03)		
Year 1	Low family influence	High family influence
Low peer influence	45.8	41.6
High peer influence	42.7	44.0
Years 2-4		
Low peer influence	38.5	37.8
High peer influence	39.8	33.0

Results

Table 2 displays the results of the effects on brand attitude from a four-factor design utilizing a 2 (functional/hedonic) X 2 (recent/distant purchase) X 2 (low/high family influence) X 2 (low/high peer influence) ANCOVA, where the price of the vehicle purchased is the covariate. Using a median split, subjects were categorized as having a functional/hedonic purchase, low/high family influence and low/high peer influence. Since the actual purchase date of the vehicle was recorded, recent purchases were categorized as those within the past 12 months and distant purchases as those 13 months and greater. Given the likely price/quality relationship with brand attitude (e.g., \$40,000 Lexus vs. \$2000 Chevrolet), the price of the vehicle is included as a covariate control.

Main effects. As expected, subjects' brand attitudes were more positive for those who made recent purchases (43.4) than less recent purchases (38.3; F=3.69, p=.03). The price paid for the automobile, entered as a covariate, is positively related to attitude toward the brand (F=17.7, p<.01).

Interactions. As anticipated, a three-way interaction (F=4.4, p=.02) emerged between family influence (low/high), peer influence (low/high) and purpose (functional/hedonic), supporting H1 in this study. The interaction is driven primarily by the combined effects of high family influence and high peer influence on the purchase of automobiles used primarily for functional purposes, representing the poorest attitude (34.0) toward the brand of vehicle

owned. Conversely, individuals who bought vehicles primarily for hedonic purposes with little family or peer influence reported the most positive attitudes (43.3) toward the brand of car/truck that they owned.

Individuals who have negative brand attitudes are good candidates for trade-ins after their auto loan is paid off. Hence, those who keep their cars longer than four years are likely to have relatively positive brand attitudes. Consequently, a modified 2 X 2 X 2 model examining only those who made automobile purchases within the past four years reveals a three-way interaction (F=3.90, p=.05) between family influence (low/high), peer influence (low/high) and time since purchase (recent/distant). A dramatic difference exists between those who were subject to heavy family and peer influence in a recent (within past 12 months) purchase (45.8) and those whose purchase decision was more distant (13-48 months ago), but heavily influenced by family and peers (33.0).

Curvilinear analysis. Figure 1 represents the curvilinear relationship between brand attitude and time since purchase for those subjects whose last purchase was within the previous 72 months. Time since purchase is negatively related with brand attitude (t=-2.31, p=.02). The quadratic form of time since purchase is positively related to brand attitude (t=2.2, p=.03), as illustrated by the convex line in Figure 1. An interaction term (time x family x peer) is also negatively related to brand attitude (t=-2.3, p=.02). The three variables (time, time², time x family x peer) account for 11.4% of the variance in brand attitude in this regression model. Hence, brand

attitudes decrease at an increasing rate (exacerbated by the coincidence of family and peer influence) before increasing after four years from purchase.

Less variance exists in brand attitudes in the first few months following purchase within this sample, but brand attitudes become more dispersed after the first year. Thus, although subjects' initial brand attitudes are not equivalent, the data suggest that they are relatively similar (e.g., high) close to the point of purchase.

GENERAL DISCUSSION

The findings of the first and second study support the premise that family and peer influence may produce relatively positive initial brand attitudes, but that in many cases time appears to *wound all heels*. That is, as time passes since the initial purchase, individuals tend to have less positive brand attitudes than do those who made recent similar purchases. The findings suggest that the shortcomings of the brand and/or the shortcomings afforded by the informational or normative social influence of family or friends are assessed over the passing of time and may lead to deteriorating brand attitudes. At the same time, individuals may be apt to attribute poor decisions to the presence or influence of others. In any case, comparing the attitudes of those heavily influenced by family and peers in a purchase decision with those who report making more independent decisions reveals more positive brand attitudes held by the latter.

Pedagogy. Treatments of social influence in marketing literature, particularly consumer behavior and marketing management texts, typically assign no valence to using social influence as a means to complete marketing exchanges. The findings of these studies indicate that a long-term risk may exist in using this route of persuasion. In keeping with self-determination theory, the data suggest that the brand is most likely to be enhanced in the mind of an individual when s/he believes the purchase decision was made based on his or her own will and competency. From a relationship marketing standpoint, the seller's appeal to one's family or peers to influence or reinforce a purchase decision could potentially harm the relationship. Given that brand attitude is strongly related to purchase behavior, a weakened brand attitude will lead to a weaker seller-buyer relationship.

Buying cycle and post-purchase attitudes. The relationship between passing of time since purchase and brand attitude found in Study 2 offers interesting context-specific implications. As Figure 1 shows, $time^2$ intersects $time$ just after 48 months, or at the time when a typical car loan expires. Buyers' brand attitudes appear to decline up until the point of deciding if they are going to get a new car or not after paying off their loan. This data shows that those who have kept their cars beyond 48 months have more positive brand attitudes than those whose car purchases were within the past 12-48 months, and begin to approach the level of brand attitudes of those whose purchases were made within the past 12 months. An obvious explanation for the curvilinear effect seen here is that those who decide to keep their vehicle beyond 4 years are those who have maintained relatively positive attitudes. Alternately, some individuals may conclude that they cannot afford (or prefer not) to purchase a new vehicle and then compensate to reduce cognitive tension by upgrading their opinion of the vehicle they are still driving ("This car isn't so bad after all. At least it's paid for.").

From a broader perspective, marketers must recognize the typical customer buying cycle for a product/service and seek to build brand equity that will lead to repatronage during that time. Information systems that collect customer-specific data regarding purchase decision criteria to be used in follow-up marketing communications to (a) reinforce key product/service characteristics and (b) determine quality expectation gaps in need of remedy would be

an avenue of maintaining positive brand attitudes. For those individuals who were heavily influenced by family and friends to make a purchase, follow-up communications that seek to convert the buyer may be necessary to achieve repatronage. From a segmentation standpoint, it may be useful for sellers to recognize that a segment of their current customers (if brand selection was heavily influenced by family and friends) may have attitudes more similar to non-customers.

Functional vs. Hedonic Selling Contexts. The findings of the second study indicate that the selling situation may dictate the most effective means to building and keeping brand preference. High family and peer influence in the more hedonic purchase resulted in a relatively high brand attitude (41.4) compared to high family and peer influence for a more functional purchase (34.0). Interestingly, those who make functional brand choices influenced by family or friends have nominally lower brand attitudes (40.3 and 40.5, respectively) than that held by those who report being influenced by neither family nor friends. The same pattern is seen in the 3-way interaction with time, family, and peer influence. Thus, it may be that such purchases represent brand selections that were meant to please family and friends, but that ultimately please no one—or at least not the buyer. Brand choices meant to please one group (family or friends) may produce less conflict and relatively less internal conflict.

In general, sellers of functional products and services may do best to steer the individual to choices that s/he personally prefers, with less deference to family and friends. Appeals relative to "this [car] has what you wanted" and "you've made a good choice" rather than "others will approve" and "your spouse and kids will like it" are apt to generate stronger brand attitudes since they enhance feelings of autonomy and competency.

Reframing purchase decisions. In Study 2, those who made hedonic purchases and reported little influence by family or friends hold the most positive brand attitudes. Some purchases may be more functional than hedonic for most individuals (e.g., oil change). Yet, in more ambiguous person/product/situations, persuasive attempts to frame the decision for the individual to independently recognize hedonic benefits ("This family sedan has 282 horsepower and goes 0-60 in 6.8 seconds.") in what might otherwise be a more functional purchase may lead to more positive brand attitudes. Further, even in the most functional of purchases, the purchase context may be repositioned to offer hedonic benefits that help maintain brand attitudes (viz., O'Curry and Strahilevitz 2001). An express lube operator may offer spacious waiting areas with comfortable chairs, television, and quality snacks while customers get their oil change that makes the visit pleasant to the individual, even if the individual is carrying out the functional purchase under the influence of his/her spouse. In sum, generating hedonic brand benefits to the individual buyer is likely to result in relatively lasting, positive brand attitudes.

Limitations and Future Research

We relied upon individuals' reports of social influence at the initial purchase, inferring attribution behavior in a between-subjects design. The subjects were primarily young (under 30 years old) and within a single region or subculture, such that we are unable to extrapolate these findings across age groups and cultures. Within-subjects extensions of this research would benefit from a longitudinal design across a wider typology of subjects. Gathering brand attitude data at the point of purchase would provide a benchmark to measure deviations from initial brand attitudes over time. Examining the role of social influence in other sample frames covering a broader cross-section of individuals (viz., age, culture, gender, etc.) would aid in the generalizability of these results.

FIGURE 1
The relationship between time and brand attitude

Future research examining the role of group influences (e.g., identification) may offer insight into social situations where that influence helps to maintain brand attitudes over time. Research that compares and contrasts the role of different sources of social influence (informational, normative, group identification) for different product purchases (e.g., functional/hedonic) may shed light on appropriate methods of persuasion in different contexts.

Creativity and Innovation: Consumer Research and Scenario Building

Laurel Anderson, Arizona State University

Paul Rothstein, Arizona State University

INTRODUCTION

If you want innovation... "Never ask the customer what they want!" That is Rule #1 at Ziba (2002), a multi-disciplinary product development firm. Many people don't know what they want and are poor reporters of their own behavior. According to Ziba, they usually want what their neighbor has. Sherry (1995) also states that much consumer behavior is habit and consumers don't think to tell you about it. Zaltman (2002) discusses the need to get at what "people don't know they don't know." And, especially with regard to innovation, consumers may not know what is possible. Many types of innovation may not even be within their frame of reference. So how do we use consumer research to understand the consumer without asking them directly? And then, how do we use the research to generate innovative ideas for consumer experience?

Creativity and innovation are necessities in today's Era of Consumer Experience. Consumers are seeking experience and use this to differentiate between the products that they chose. Tom Peters (Hirasuna, O'Leary and Lawrence 2000), among others, sees the present as the Era of Consumer Experience. He says that quality has been commoditized and no longer serves to differentiate products. Consumer experience now serves that function.

In today's marketplace, designing consumer experiences has become a common and critical challenge for researchers and development teams in all types of markets and industries. Like never before, it has become vital to connect with consumers in significant and memorable ways. "Recognizing experiences as a distinct economic offering," note Joseph Pine and James Gilmore, authors of *The Experience Economy* (1999), "provides the key to future economic growth," which they define as an offering that focuses on engaging individual consumers in unique, personal and memorable ways (Pine and Gilmore 1999). Citing examples like Disney, the contemporary "coffee experience," and staged birthday parties, Pine and Gilmore assert that experience has become a major source of economic value in the new economy. "Experience," they note, "represents an existing but previously unarticulated genre of economic output. Decoupling experiences from services in accounting for what businesses create opens up possibilities for extraordinary economic expansion—just as recognizing services as a distinct and legitimate offering led to a vibrant economic foundation in the face of a declining industrial base" (Pine and Gilmore 1999, p. x).

To be able to innovate and develop products that lead to the fulfilling, compelling experiences for consumers, we need to have a deep, holistic and contextual understanding of the consumer. This paper addresses the question: how do we generate innovative, creative, impactful ideas for new product experiences for consumers? There is a paucity of consumer research on creativity and innovation and on using consumer research descriptively and then generatively to produce creative, innovative ideas for consumer experience. This paper presents one consumer research method that does this.

One of the authors of this paper observed and interviewed people in very creative organizations (IDEO, Hewlett Packard, Ziba, GVO, Patagonia, 3Com, Fish, Idea Factory, etc.), observing ways that they generate ideas and design products and services that create consumer experiences. A couple of themes pertinent to this paper were repeated numerous times. First, there is a whole group of people doing innovative consumer research that has not been

well represented in the consumer research literature—industrial designers. Second most of these creative firms are expert and creative at ethnographic consumer research. And third, storytelling/scenario building was extensively used. Through scenarios, the character (consumer) lives and we have a deep understanding of the consumer's activities, needs and expectations. It also enables us to identify opportunities and visualize new and innovative consumer experience ideas. Dorothy Leonard (1997) talks about this as "empathic design" in her *Harvard Business Review* article.

Ethnographic methods and frameworks provide a way to both understand (*describe*) the consumer and *generate* ideas. Ethnographic methods fit particularly well with experience (thick description, contextual) and also with idea generation. There is also increasing discussion in the literature of storytelling and scenario building (c.f. Denning 2001, Kotter 1996, Nakamae 1999, Swap et al 2001, Boyce 1996). Suri and Marsh (2000) define scenario building as "... the development of a series of alternative fictional portrayals—stories—involving specific characters, events, products and environments, which allow us to explore product ideas or issues in the context of a realistic future" (152).

The objective of this paper is to present and utilize an ethnographic consumer research framework developed by Rothstein (2002, 2001) and user centered consumer research of teens (Anderson 2002) that will creatively and innovatively build scenarios that lead to a deep understanding of consumers (*descriptive*) and scenarios that are *generative/prescriptive* of new ideas for new product experiences for these consumers. This method's focus is on extending ethnography; including its descriptive aspect and then moving to its generative aspects. It is one answer to the question, how do we generate ideas for new products for consumers. Tangently, ethnographic research has always been an analysis challenge. This method provides a way to meet that challenge by organizing and relating the messy data that results from ethnographic work.

A (X 4): A METHOD FOR UNDERSTANDING, EXPLORING AND DESIGNING EXPERIENCE

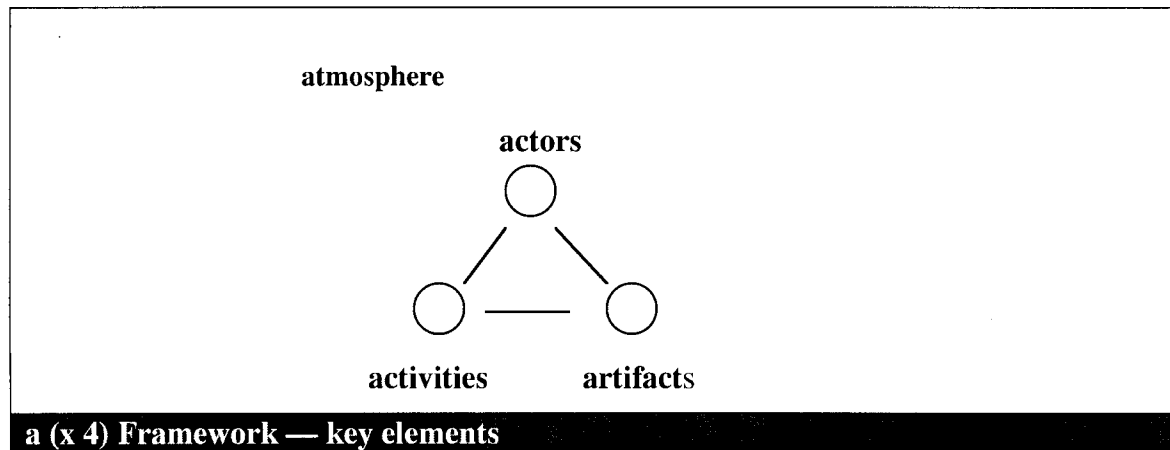

We need to look at our business as more than simply the building and selling of personal computers (that is, goods). Our business is the delivery of information (that is, services) and lifelike interactive experiences."

Andrew Grove, Intel Chairman (1996)

The next section presents a new method for researching, exploring and communicating scenarios about new consumer experiences. Called *a (x 4)*, the method is structured around the four key factors—actors, activities, artifacts and atmosphere—that animate experiences with new products, communications, environments and services. By closely examining the interaction of these factors, researchers and development teams can gain insight and inspiration for the development of new consumer experiences (Figure 1).

a (x 4) borrows and combines strategies and techniques typically found in consumer research, ethnography and design. As a multipurpose and multidisciplinary framework, it is used as a tool for data collection (i.e., consumer research), analysis and scenario-building. It features four phases:

FIGURE 1

Facts & Observations

During this phase, *a(x4)* is used like an ethnographic coding scheme to collect contextual information about consumers and their everyday experiences. The immersion in field work has been clearly identified by many experts as critical in the scenario-building process (e.g., Suri and Marsh 2000; Couch, Sanders and Welker 1997; Ireland and Johnson 1995). The *Facts and Observations* that researchers collect result in a robust, targeted and highly useful ‘information database’ about the actors, activities, atmosphere and artifacts that relate to a project or study (Figure 2).

Snapshots

With an ‘information database’ established, *a(x4)* is next used to create sets of *Snapshots* (organized according to the four factors) to illustrate and communicate key insights, relationships and conclusions. The *Snapshots* involve summarizing essential information gleaned from field studies and often includes highly visual representations using photos, video, drawings and diagrams. As a semi-structured visual exercise that intentionally taps into intuition and imagination, the *Snapshots* compel researchers and development teams to focus on communicating information that relates directly to the key factors that influence new experiences. These are the *descriptive scenarios*.

Visualizations

The third phase involves using the four key factors to create a highly visual, speculative image (or set of images) about a proposed consumer experience. *Visualizations* are fundamentally a precursor to more specific and defined scenarios. This preparatory step is important because it helps researchers and designers remain free from project-specific constraints and limitations which, if imposed too early, tend to stifle and suffocate innovation and creativity.

Scenarios

With all of the previous phases completed, detailed *prescriptive scenarios* about new consumer experiences can be developed. The development team proceeds with substantial knowledge about actors, activities, artifacts and the context (i.e., atmosphere) in which these all interact. The form of the scenarios varies greatly, including: text-based narratives, storyboards, play-acting and, increasingly, highly effective multimedia videos.

Thus, the *a(x4)* demonstrates how a combination of ethnographic approaches and creative exercises can be used to generate ‘real-world’ data and fuel speculations about the future of consumer experiences (Figure 3).

TEEN CASE

This research utilizes the user-centered methodologies of photo essays, metaphor development, textual and collage analysis to gain an understanding of teens (Gen Nets) and their computers. These methods are used to get at what teens “don’t know they know.” The focus is on the descriptive and generative scenarios created while using the *a(x4)* framework and including actors, activities, artifacts and atmosphere data.

At their peak, this Gen Net group will exceed the number of baby boomers (Tapscott 2000). They are important for us to understand. This research aims to add to that understanding by seeking to understand at a level that these teens may not be aware. According to Jerry Zaltman (2002), “A lot goes on in our minds that we’re not aware of...Most of what influences what we say and do occurs below the level of awareness. That’s why we need new techniques: to get at hidden knowledge—to get at what people don’t know they know.”

This data is used here to first illustrate the development of descriptive scenarios. Analysis of the data from this research reveals different groups of teens (Anderson 2002). Utilizing Rothstein’s *a(x4)* framework, data from one of the groups of teens is analyzed and used to develop descriptive and then *generative scenarios*. The data will be examined using the four components: actor, atmosphere, activities and artifacts. The *a(x4)* phases of facts and observations, snapshots, visualization and synthesis are followed.

Research

The research was conducted in collaboration with eighth grade Language Arts teachers in middle school. The concept of metaphor was taught in the teens’ Language Art classes. Then the teens were asked to develop a metaphor for their computer, create a collage that depicts their metaphor, and describe this metaphor. They were also asked to write a “wish list” that completes the sentence... “I wish my computer could...” And lastly, they constructed photo essays that showed what their computer meant to them. There were 150 teen participants in this user-centered research.

Snapshots

Analysis of the data found different groups of teens. The data from one of these groups will be utilized in the subsequent phases. The snapshot phase provides a thick description (Geertz 1973) of the group studied. A *Snapshot* is effective in analyzing the collected data. *Snapshots* involve organizing, summarizing and communi-

a(x4) scenarios	facts and observations	snapshots	visualizations
Process	research →	analysis →	synthesis →

cating data that has been obtained about the four key elements: actors, artifacts, activities and atmosphere.

Data from the metaphors, wish lists and photographs from the teens in this group (which we later called Toolman) was employed in this phase. In the Toolman group, the participants used the following metaphors for their computer among others: bookshelf, scrapbook, mothers, parents, diary, toy box, dog, friends, food, ant hills, malls, flashlight, superman, teacher, etc.

The following are a few illustrative examples of the paragraphs written by the teens describing their metaphors:

“There are lots of things computers can be described as. A metaphor for my computer is, computers are malls. They’ve got so much in common. They’re both places where you can relax, shop and talk. Both are great inventions. Why do you think malls and computers are alike? Both are places where you can relax. You relax in malls by walking around and relax by sitting and typing on the computer. You

can shop both at the mall and on the computer logging on to store websites or visiting the stores at the mall. Talking is a major part of shopping with friends and talking online for fun. Can you think of any more reasons why malls are computer?”

“My computer is my parents. They both make me look good. They make all my papers look professional. They correct my spelling, check my grammar, and keep things neatly filed. Both my parents and my computer introduce me to new people from different places. My computer and my parents give me interesting facts on many different cultures. They guide me when I am trying something new, or installing something new. My computer is a parent because it is never too busy when I need help, unless someone else is using the computer or my sister is bugging my parents.”

“My computer and my parents also try to make things as easy as possible for me and don’t try to overwhelm me. They can

both entertain me when I am bored, and neither one will ever turn its back on me. My parents are getting older, and so is my computer as technology improves. My computer and my parents are always teaching me new things. The one bad thing my computer and my parents have in common is that they can both give me a headache after awhile. Those are some of the things I can think of that my computer and my parents have in common.”

“My computer is Superman because of all the great things that they can do! First of all Superman can fly, shoot laser out of his eyes, has super strength, and great intelligence. I believe that these traits compare with what my computer can do...almost! What is so great about my computer? Let me tell you what my computer can do and how much it rally means to me.

Alright, so like I said, my computer is Superman, well it does a lot of awesome things that I think compare with the good deeds that Superman does. For example, my computer allows me to talk to people using the Internet. I can type essays with it like I'm doing now. On my computer, I can play music, not to mention also playing DVD's and video games! That equals five different reasons that I love my computer. In my opinion, that's enough reasons that my computer is just as great as Superman, in fact, it is Superman!”

“I said that my computer was a tool. This was my metaphor because my computer helps me do all sorts of things. My computer lets me go places in the internet. I can check my email so I can keep in touch with my friends that don't live in Arizona.

I can play games on my computer to keep me busy when I'm bored. I can do reports by typing on my computer to make it look more nice. For my reports I can also get research off the internet. It also helps me if I can't buy something at stores I can go to the stores website and order it. Basically if I didn't have a computer things would be harder, like school and socially it would be harder.”

The Snapshots phase involves descriptions of the patterns of each of the $a(x4)$ factors. For this Toolman group we found the following:

With regard to the *atmosphere* or context most of the students had computers in their bedrooms. They had the computer on in the background almost all of the time that they were in their rooms. Music was also often on. And frequently friends were there. Most often one was on the computer and one playing video games. For some, less than the above context, the computer was in a public area of the house, most often the family room. This area was not as private. And the computer was then frequently seen as an intrusion with other activities going on—television, talking, meals, etc. And more often in this case, more people were vying for the use of the computer, which created more tension.

The *actors* in this research were a group of 13–14 year old teenagers. They were middle school students taking Language Arts (a required subject). They lived in a city in southwestern United States. They saw and used their computers in a positive, very functional way. (As illustrated by the metaphors above and the description of activities below). There were sometimes other actors in their environments. They frequently had friends around using their computers. And there were sometimes family members around. This group did not talk about the presence of family members as much as other groups who often saw family members as a source of

tension with regard to the computer. This group saw the computer as helpful and positive.

The teens in this group are the multitaskers. One of the main computer *activities* that this group was involved in was communicating, mainly through instant messaging. In fact, in most cases, the computer was on in the background most of the time that the students were home. They were also heavily involved in shopping, learning, researching, entertaining games, and word processing activities. This functional use of the computer led to the title for this group, Toolman.

In the most common context of the teen's bedroom, the most frequent *artifacts* that existed were a table or desk for the computer, chair, television, video game equipment, stereo, CD's, disks, book bags and beds (on which the teen or friends were often lying) (Figure 4).

Visualization

Visualization starts the generative, prescriptive phase. The third part of $a(x4)$ involves speculating about the future of user experience by creating a highly descriptive image or set of images. Created before the development of more specific and highly defined scenarios and concepts, *Visualizations* help individuals and groups break free from overly restrictive constraints and limitations. If done properly, *Visualizations* create a broad, somewhat abstract image from which specific scenarios and concepts about user experience can later be constructed. The importance of this step should not be underestimated. As noted by Bill Moggridge (1993), effective scenario-building is based on a willingness to suspend real world concerns, free from constraints that often limit creativity.

In this Toolman teen case, we have a multitasking, heavy communicator where the computer is a constant part of their life. Interaction with their friends also is much of a constant, either in person or over the computer. With the computer there is always an open communication channel that is on. Additionally there are other major activities going on at the same time ranging from school work and learning to entertainment to shopping. It is easy to envision that, in addition to communicating, these teens become very accustomed to the constant access to the other functions of the computer. And that as they are multitasking, their friends are often a part of all their other activities. These other activities become more collaborative—either in person or virtually through the computer. So their friends also become more of a constant and are involved in their video games (witness the virtual playing of video games with participants from all over the world), school work, shopping, learning, etc. at any time that the teen is involved in these activities. The computer provides the opportunity for this activity to happen in a more constant and a more visual mode than in the past. These teens become more visual thinkers because of this constant access.

Scenarios

With the previous steps completed, specific and detailed scenarios about user experience can be developed. Researchers and designers start this activity with considerable knowledge and insight about actors, activities, artifacts and the context (atmosphere) in which these all interact. They will have conducted field research, created detailed profiles or *Snapshots*, and developed a visionary, speculative image (or set of images) about a new experience. The form of the scenario can vary greatly depending on circumstances, time constraints and/or other needs and expectations. Common types include: written stories, illustrated stories, comics, storyboards, plays and, increasingly, multimedia productions.

FIGURE 4

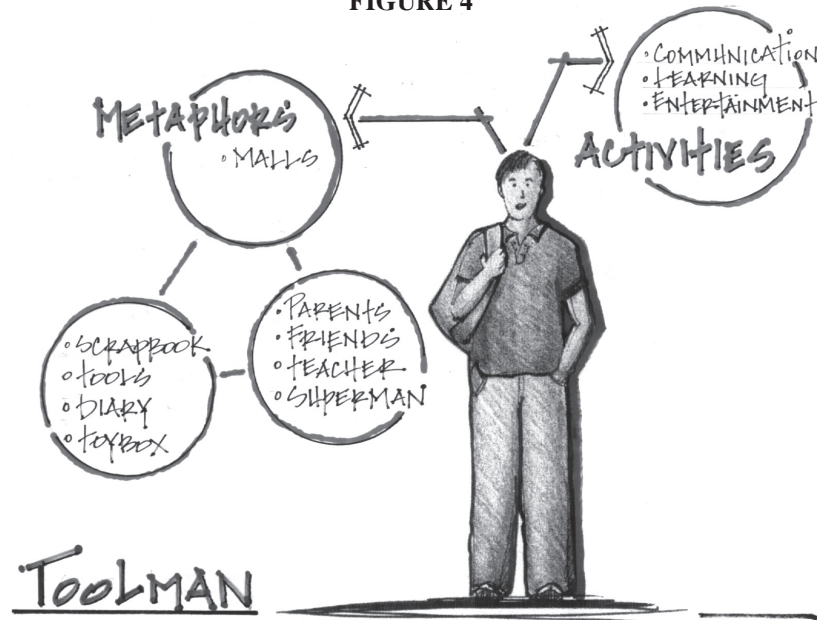

FIGURE 5

For the teen Toolman group, a new computer product (adapted from a concept originally developed by Ryan Brown, a 2002 graduate of Arizona State University's product design program) might be envisioned to support experiences like learning, collaboration with friends, visual communication with friends and mobility—all of great importance to this teen consumer group. As such, the product concept might feature a portable, lightweight PC with an integrated scanner and removable flexible displays. For the Toolman user group, a computer like this would allow them to learn, create and collaborate with friends in a wide variety of environments and circumstances. It would be easy to take this PC with them. The mobility of the product allows the teen the access that they have become accustomed to with the multiple functions of the computer. Also, the scanner and visual displays are highly compatible with the

visual thinkers that these Toolman teens have become. This PC is the mobile tool that allows the teens constant access to the many different functions of the computer, most especially those that increase visual capabilities (Figure 5).

Delight-As-Magic: Refining the Conceptual Domain of Customer Delight

Yannik St-James, Queen's University
Shirley Taylor, Queen's University

ABSTRACT

This paper explores consumers' experience of delight and investigates the role of surprise in this process. These questions are examined through an interpretation of five consumers' own accounts of delight in the context of travel experiences, informed by literature from the fields of psychology, aesthetics, and consumer research. The exercise contributes to our understanding of customer delight by identifying two distinct modes of delight: delight-as-pleasant-surprise and delight-as-magic. Delight-as-magic refers to the effertent emotional arousal individuals derive from consumption experiences they imbue with a subjective, symbolic meaning associated with themes of interpersonal warmth, aesthetic experiences, or leisure experiences.

"What is man before beauty cajoles from him a delight in things for their own sake, or the serenity of form tempers the savagery of life?"—Johann Christoph Friedrich von Schiller

Customer delight has gained considerable popularity among marketing practitioners in the last decade and has more recently attracted the attention of marketing researchers. Deming (1986) introduced the concept of customer delight as the true source of competitive advantage in an era where customer satisfaction has become a competitive necessity. Consultants and managers rapidly espoused this philosophy, and customer delight has been substituted for customer satisfaction as a strategic objective in several firms, including Eastman Kodak, National Semiconductor Corporation, AT&T, and Sun Microsystems (Chandler 1989; Hines 1995; Trader 1995). In support of this trend, research findings have indicated that customer delight may contribute to enhanced customer satisfaction, word-of-mouth communication, repurchase intentions, and more positive evaluations of brand extensions (Kumar 1996; Oliver, Rust and Varki 1997; Westbrook and Oliver 1991).

Little agreement exists, however, regarding the meaning of 'delight'. Indeed, firms that adopt a customer delight strategy interpret this concept differently to signify exceeding customer expectations, providing superior quality through the service encounter, or creating a "wow" factor by providing customers with unexpected attention and service features (Chandler 1989; Cohen 1997; Hines 1995).

Similarly, efforts by psychology and consumer researchers to define the concept of delight have yielded various conceptualizations. One conceptualization construes customer delight as extreme satisfaction, suggesting that delight occurs when customer expectations are highly exceeded (Estalami 2000; Ngobo 1999). More popular conceptualizations of delight involve various combinations of positive affect, arousal, and surprise (Oliver et al. 1997; Plutchik 1980; Russell 1980; Westbrook and Oliver 1991). Adopting a prototypical approach of emotion, a third group of researchers have depicted delight as a type of joy or happiness (Richins 1997; Shaver et al. 1987). Finally, studies eliciting consumers' own descriptions of delight have associated this emotion to feelings of excitement, effervescence, warmth, well-being, joy, exuberance, thrill, exhilaration, elation, surprise, joy, relaxation, and comfort (Davitz 1969; Kumar 1996; Menon and Dubé 1999).

Discrepancies among various conceptualizations of the construct and empirical findings suggest that certain issues remain unresolved. In particular, the role of surprise in the experience of

delight needs to be clarified. While Oliver et al. (1997) posited surprise as a necessary antecedent of delight, some empirical investigations have suggested that consumers sometimes experience delight in the absence of surprise (Kumar 1996; Oliver et al. 1997). The purpose of the present study is to explore the role of surprise in consumers' experience of delight. Specifically, the experiential dimensions of delight, the underlying meanings of those experiences, and the conditions under which delight emerges are examined through an interpretation of consumers' own accounts of delight in the context of travel experiences. The interpretation is embedded in an experiential view of consumer research (Holbrook and Hirschman 1982) and it is informed by literature in the areas of psychology, aesthetics theory, and consumer behavior.

METHOD

Study Design and Data Collection

Phenomenological interviewing (Thompson, Locander, and Pollio 1989) was well suited to the study's discovery-oriented goal (Wells 1993) of understanding the meanings of delight for consumers. Five informants participated in a series of two interviews—averaging a total of two hours of interview per participant—in addition to a subsequent member check. Interviews, which were conducted either in the informant's home or in a University office, were recorded and subsequently transcribed.

The investigation was situated in the context of travel experiences. This context was chosen because it potentially includes consumption experiences covering a broad spectrum of consumer involvement and affective content, that is, various levels of emotional arousal (Price, Arnould, and Tierney 1995). Consequently, a broad definition of the term "travel" was adopted, as informants were encouraged to describe various activities (transportation, lodging, sight-seeing, etc.) they may have engaged in while traveling for any purpose (business, leisure, adventure, etc.).

Informants were selected purposively, to maximize the variety and richness of travel experiences. Preliminary interviews suggested that a discussion of emotions associated with traveling was more forthcoming in women. Hence, the sample consisted of five women recruited through a network of personal acquaintances and selected to represent a broad range of age, background, and travel experiences: Sarah and Christina, two 21-year-old students; Susan, a 47-year-old physical education teacher; Claire, a 57-year-old retired secretary; Elisabeth, a 62-year-old retired grade school teacher.

The first interview was designed to yield information about informants' travel history, their motives for engaging in these trips, and the emotions associated with them. This insight was important to allow the findings regarding delight to be judged in the context of informants' broader experiences and how they understood these experiences. The first interview was also intended as an evaluation of the extent to which the concept of delight emerged naturally in consumers' account of their consumption experiences. While several pleasant and joyous stories were described in these interviews, none of the informants explicitly employed the word 'delight' in relating those events. Consequently, the second interview was designed to first explicitly ask informants to identify experiences of delight while traveling, if any, and then to elicit a description of those experiences. Although the second interview was slightly

more directive, in that informants were asked about a particular type of experience, both interviews were formulated to allow informants to freely describe their experience in detail.

Finally, informants were contacted a third time to conduct member checks, a procedure that assesses the credibility of the author's interpretation against the informants' view of their experiences. Informants corrected certain minor chronological errors, but they generally found that the interpretation was interesting and reflected their own experience.

Data Analysis

The process of defining the conceptual domain of customer delight rested on the general procedures of grounded theory (Strauss and Corbin 1998). The objective of this interpretation was to identify the experiential dimensions of delight, to understand the underlying meanings of those experiences, and to gain insight into the conditions under which delight emerges. An idiographic analysis of the text transcribed from the interviews was first conducted, where the experiences of informants were considered individually. This involved a reconstruction of each informant's travel history, as well as an impressionistic reading of transcripts to identify themes emerging from informants' travel experiences. The number of delight episodes identified by each participant ranged from none at all to eight cases, for a total of twenty episodes of delight. A procedure of open coding broke these episodes down into various categories of information (e.g., physical responses to delight, related emotions, context, etc.). These experiences were then aggregated in a cross-case analysis using axial and selective coding (Strauss and Corbin 1998). Axial coding involved connecting the basic categories into more general conceptual classes composed of sub-categories. Selective coding then mapped relationships between the larger conceptual classes. Thus the interpretation process increasingly moved towards a more abstract level of analysis. It is important to note that this process was not linear, however, and it often entailed moving back and forth between the various coding operations as the interpretation developed. In fact, the analysis progressed through a hermeneutical process (Arnold and Fisher 1994), with successive iteration between individual experiences, emerging global themes, and the literature that informed the interpretation, with the goal of removing contradictions from the developing interpretation.

DELIGHT-AS-MAGIC: EMERGING THEMES

An analysis of the interviews revealed episodes of delight as pleasant surprise, converging with Oliver et al.'s (1997) definition of delight. However, and more importantly, a second type of delight also emerged which did not involve pleasant surprise. These episodes constitute the focus of the present analysis. In lieu of positive affect and surprise, these episodes of delight appeared to be endowed with a magical quality that eludes rationalization. In the words of one informant, these episodes consist of:

[...] little *special* moments that you kind of remember. You get a flash, sort of. You're not really sure why or how... why it's there, but... you're just delighted and that's it, I guess.-Susan

Similarly, these delight episodes were also associated with situations that informants viewed as "just right" or "perfect":

[...] and I remember telling my husband "Ah... This is just *perfect*". It was like time was standing still, also, because it was so peaceful and quiet, and we were just standing there and... I was, like, totally delighted and out of it [laughs].-Claire

The object of delight in these instances appears to possess a quintessential nature, a "rare and mysterious capacity to be just exactly what they ought to be... unequivocally right" (Cornfield and Edwards 1983, in Belk, Wallendorf, and Sherry 1989, p. 16). Indeed, Cornfield and Edwards' characterization of the pleasure quintessential objects ignite in us is reminiscent of the childlike experience of delight depicted by some informants, and suggests that this pleasure arises from the meaning bestowed upon the object: "The pleasure such things offer us is wonderful and illogical; it is very like the pure joy a child feels when he unexpectedly comes into possession of something magically desirable" (p.16).

The delight that emanates from these magical moments will be referred to as 'delight-as-magic'. Understanding the nature of delight-as-magic requires that we dissect the sources of meaning that imbue some experiences with a quintessential quality and hence renders them delightful. The interviews suggest three sources of meaning leading to episodes of delight-as-magic—interpersonal warmth, leisure experience, and aesthetic experience—which are described next.

Interpersonal Warmth

Participants recalled several delight episodes that occurred in the context of close, comfortable interpersonal interactions. Andersen and Guerrero's (1998) construct of 'interpersonal warmth' captures the essence of this context. Interpersonal warmth refers to the "pleasant, contented, intimate feeling that occurs during positive interactions with friends, family, colleagues, and romantic partners" (Andersen and Guerrero 1998, p.304). For instance, Christina's experience of delight during her trip to San Francisco was in part associated with her interactions with close high school friends ("they're all, like, on the same wave length as me"). Similarly, harmonious interactions between family members were constitutive of her experience of delight while sitting outside a restaurant in Quebec City:

Sometimes my family fights when we're on holidays but I think that that time maybe we weren't, for once [laughs]. [...] just sitting there and totally being relaxed, having no responsibilities, and being with my family and not arguing.

These findings converge with previous observations that, compared to less intimate relationships, close relationships contain significantly more positive emotions such as delight (Bersheid, Snyder, and Omato 1989).

Interpersonal warmth was also a source of delight when informants were reunited with friends or family members after being separated from some time.

I guess, like, walking into my house and, like, having the house smell, and seeing my cats, and seeing my mom and dad [...] I love them so much, and being away from them for months, even for short periods....-Laura

This experience evokes Saint Thomas Aquinas' characterization of delight as a situation where "we are not without the good we love, but are at rest in its possession" (in Drost 1995, p.47). Hence, while desire represents the movement towards an object that is loved, delight lies in the repose we find in the presence or possession of that object, so that delight "is to the emotions what coming to rest is to physical things" (in Drost 1995, p.51).

At other times, interpersonal warmth engendered delight when informants met new people with whom they felt spontaneous bonding (Andersen and Guerrero 1998). In Susan's words, this

occurs upon “meeting people with whom you... it’s just *easy*, you know... just easy communication; you almost feel as if you’ve known them forever, and you barely know them.”

While interpersonal warmth stimulates the experience of delight, its absence may inhibit the emotion. This is illustrated when comparing Christina’s delight situations characterized by interpersonal warmth—interacting with her friends in San Francisco and with her family in Quebec City—with the emotions she felt during what she described as the best memory of her trip to Helsinki. Christina spent the last evening of that trip with schoolmates and professors at a local bar located on top of a building. Although she reports feelings of happiness, delight eluded this evening, a situation in part attributable to the absence of interpersonal warmth:

People that I was with, I wouldn’t say that I’m a hundred percent comfortable with, not that I wasn’t comfortable with them but, just not like they were my friends or my family, people I’ve known for ever and ever. They became friends, but we didn’t... it’s not like they are the people that know everything about me. [...] Sometimes there were things that normally I would say, that I wouldn’t say. You’re a bit more reserved when you’re with people that you don’t... you know. You’re on a different level, kind of.—Christina

Delight in the context of interpersonal warmth is associated with both cognitive and emotional goals. Indeed, informants described these interactions as founded on mutual understanding, shared interests, easy communication, comfort and love. The concept of validation subsumes these goals, as it encompasses “experiences of understanding, acceptance and warmth” (Praeger 1995, p.47).

Leisure experience

Some delight episodes were consistent with three elements Unger and Kernan (1983) identified as characteristics of the concept of leisure: intrinsic motivation, perceived freedom, and involvement.

For the ancient Greeks, leisure (*schole*) referred to “a contemplative activity pursued for its own sake or to its own end.” (Unger and Kernan 1983, p. 382.). In this view, leisure is intrinsically motivated—an activity that is undertaken as an end in itself. Several delight episodes occurred when informants were engaged in seemingly mundane activities undertaken for no other purpose than the immediate pleasure they procured. For instance, some of Christina’s delight episodes took place as she was simply walking through the streets of Quebec City, Helsinki, or San Francisco, enjoying her surroundings, the music and activity around her, or the company of her friends. In these examples, delight stemmed from the pleasure of engaging in the activity itself and entailed a special type of involvement characterized by a spontaneous letting-be and a deep absorption in the process (Arnould and Price 1993; Unger and Kernan 1983). This observation offers insight into the case of Elisabeth, who did not report any delight episode while traveling. Indeed, while she travels, Elisabeth is entirely focused on a dominant goal of learning:

I just want to remember so much. I can’t remember half of the things that the people are telling me, and that bothers me [laughs]. Because when you go on a tour and you are traveling from A to B, the tour leader is telling you the history of everything going by, and you think “Oh, I’m gonna remember that, I’m gonna remember that”, but you don’t remember three quarters of it. It’s *really* difficult. [...] So I’m standing there,

listening, and listening, and listening, and not having time to be... bumping around [laughs]. Like I say, it’s been more of a learning experience. I go because I’m interested and I want to find out.

Hence, Elisabeth is so cognitively engaged in the situation that the level of effort and concentration she exerts in trying to learn leaves little room for spontaneous hedonic experiences to wash over her.

Unger and Kernan’s (1983) second characteristic of leisure, perceived freedom, was present in all delight episodes; informants engaged in these activities willingly and with great enthusiasm. No feelings of delight were reported during activities informants felt obliged to participate in. On some occasions, the absence of perceived freedom even detracted from the experience of delight. As explained previously, the lack of interpersonal warmth precluded feelings of delight for Christina during her last evening in Helsinki. However, the pressure to follow a schedule imposed by the group also played a role:

[...] also, we weren’t really... We were still in the, like, tourist mode, like, see this, go here... like, we were there, but then we could only stay there for a few hours and then we had to go to this bar, and then... so it wasn’t so much like I’m just sitting back and enjoying the view.

Lastly, delight episodes in the context of leisure experiences often contained a dimension of escape from external pressure or responsibility. Christina’s feelings of delight while walking in the streets of Helsinki were partly due to the fact that she was away from the stress of competition. Likewise, her delightful stroll in the streets of Quebec City took place while she was released from her responsibility as supervisor of a group of students. Sarah experiences a similar feeling every time she goes home for a brief vacation from school and from the responsibilities of living on her own:

It’s just the home, like, comfort. I’m really happy to be home and not have to worry about... your own house, cooking, things like that. It’s just like a relief, just to have that home, I guess.

This concurs with previous observations that leisure constitutes an “interlude from the ordinary” or even a “fantastic escape from reality” (Unger and Kernan 1983). Although the interviews were situated in a travel context conducive to leisure, the three characteristics of intrinsic motivation, perceived freedom, and escape from the ordinary transcend the travel context and apply to other service settings.

Aesthetic Experience

Delight was also associated with the contemplation of beauty in one’s surroundings. For Susan, beauty in nature corresponds to a very specific type of coastal landscape, which she spontaneously referred to upon recalling a number of delight episodes:

I think that probably all the moments I spend on cliffs, you know, with the wind blowing, along the ocean. I think delight is there, along the ocean. [...] It’s a really nice feeling to be out there... that feeling of, you know, openness around you. [...] It’s so beautiful! It’s just *amazingly* beautiful.

The idea that delight may emanate from the contemplation of a beautiful object—and specifically of nature as an object—was

acknowledged in Kant's aesthetic theory (Budd 1998b). Kant proposed that a person will delight in an object he or she finds beautiful, due to the existence of a certain harmony between that person's *imagination*—the perception process which transforms sensory input into a perceptual representation of the object—and his or her *understanding*—the perceptual process of assigning the object to a specific type or category of objects. For Kant, delight thus occurs when the object perceived corresponds to the object conceived, that is the object the imagination would have produced if its only aim was to please itself. Accordingly, one could posit that a person will see an object as quintessential when that person's perception of the object is isomorphic to an idealized mental imagery or schema he or she holds.

French sociologist Pierre Bourdieu asserted that a one's tastes are grounded in one's habitus, that is, the socially constructed system of schema a person gains through his or her upbringing, education, and experience through life (Holt 1998). The influence of Susan's habitus can be seen in the delight she felt while visiting friends in Kenya, and relishing in a certain '*art de vivre*':

[...] the house, the garden, the life you're having there... I think that was delightful as well, you know... the nice meals, she had nice things, nice cutlery, nice china, things from all over the world, you know.

Delight in aesthetic experiences thus occurs when, in the contemplation of an object, a person's perception of that object is harmonious with an idealized mental representation of that object developed through that person's socialization process and life experiences.

In some instances, informants recounted memories of stunning landscapes that left a strong impression on them, but did not elicit delight. Consider, for instance, Sarah's account of her best memory from her trip to Africa:

They took us out to the Grey Cliff Valley and we were just sitting on the edge of it and it was *amazing*, like, the view was *amazing*. It was, like, out of a movie or something. [...] I was really, like *marveled*. I don't know... I don't know what the word is, like... in *awe* that I was actually there, like, I was standing right there on a huge cliff overlooking Africa [laughs]. You could see, like, volcanoes in the distance and you could see all the villages down there, and... and feeling sick because it was so high [laughs].

Sarah's dominant emotions in this situation were awe and amazement. Kant's distinction between the beautiful and the sublime (Budd 1998a) enlightens this observation. Whereas the sentiment of beauty immerses the mind in restful and pleasurable contemplation as there is a sense of harmony between nature and our faculties, the sentiment of the sublime stimulates agitation in the mind as fear looms in an overwhelming recognition of the infinite greatness of the world. Supporting Kant's propositions, the informants' experiences suggest that delight is associated with the sentiment of beauty, while awe dominates the experience of the sublime.

Finally, several accounts of delight in the beautiful were described in the context of a first time experience, such as Claire's first view from the top of a mountain in Austria, and Susan's first glimpse of a luxurious tent during her safari in Africa. Although it might appear that surprise triggers delight in such instances, it is unlikely the most significant factor giving rise to the emotion. According to Kant, the pleasure one derives from seeing an object

for the first time and finding that object beautiful has two sources: the awareness that one is experiencing the object for the first time and the inherent pleasure in contemplating the object itself. (Budd 1998b). This allows for the possibility of seeking and finding delight again in the object beyond that initial contact. In support of this proposition, informants expressed the desire to experience other similar situations and intentions to return to a specific destination that created delight. For example:

I've been to Austria and, to me, that's the most beautiful country I've ever been to. Switzerland is something quite similar, so I want to go there. [...] I prefer hills than big, big mountains, and Austria reminded me of here. Actually, we're planning to go back to Austria. [...] we want to go to that *same* place where we went hiking.-Claire

Hirschman and Holbrook (1982) note that aesthetic products "may be consumed in anticipation of the pleasure they provide" (p.96), and the interviews suggest that consumers may seek reenactment of this pleasure over time. In this context, the hypothesized link between surprise and delight (Oliver et al. 1997) appears tenuous at best. When delight emerged from aesthetic contemplation, it was associated less with surprise than with the materialization of an anticipated and desired experience.

Synchronicity of themes

Three themes underlie the experience of delight-as-magic: interpersonal warmth, aesthetic experience, and leisure experience. While one theme often dominates a specific delight episode, they do not necessarily constitute distinct and mutually exclusive experiences. In fact, these themes often work synergistically to accelerate the experience of delight. For instance, Sarah's delight in coming home stems from the pleasure of seeing her parents after a long separation (interpersonal warmth) and from the escape it represents from her daily responsibilities (leisure experience). This synergy contributes to the magical quality of delight episodes by instilling a sense of synchronicity (Rook 1987) where informants felt that "they were in the right place at the right time, the beneficiaries of a unique and fortuitous convergence of events" (p.194): "You know, the timing, if you feel like going somewhere else, or if the timing is not... But, you know, if you just feel 'This is where I want to be now', you know."—Susan. These moments are spontaneous and attributed to chance, a gift that informants feel lucky and privileged to receive (Belk 1996).

CONCLUSION

The present study refined our understanding of the conceptual domain of customer delight through an interpretation of consumers' travel experiences. This interpretation suggests that, in addition to delight arising from pleasant surprise, there is also delight that could be labeled delight-as-magic. Delight-as-magic refers to the efferent emotional arousal individuals derive from consumption experiences they imbue with a subjective, symbolic meaning. Specifically, interpersonal warmth, aesthetic experiences, and leisure experiences were identified as fertile ground from which delight can be cultivated. Contrary to delight-as-pleasant-surprise, delight-as-magic does not necessitate the presence of surprise and novelty and may be repeated over time as individuals continue to engage in activities that entail a strong hedonic motivation. This idea expands the Rust and Oliver's (2000) concept of "reenacted delight", which posits that the experience of delight may be transformed into a pleasant memory where delighting features are recognized as truly unique and therefore will not expected in future

service encounters. However, the concept of delight-as-magic rests on a slightly different proposition where the memory of delight creates a desire for repeated reenactment, as delighting experiences are actively sought again. This process is due to the presence of delighting features that resonate in a particular way with the customer and sustain a certain aura of meaning that prevents them from becoming perceived as commonplace. Future research should investigate the evolution of delight-as-magic over time. What contributes to maintaining, enhancing, or reducing the occurrence of delight in an object over time? Under which circumstances does the delighting consumption experience lose its aura of pleasure and become trivial?

The concept of delight-as-magic is also appealing for the potential explanation it offers in reconciling Oliver et al.'s (1997) findings regarding the nature of customer delight in different contexts. Indeed, in their survey of symphony concertgoers—decidedly an aesthetic consumption experience—delight was associated with positive affect but not with surprise. According to the conceptualization of delight-as-magic, these findings may be attributable to the fact that it was the very pleasure of rejoicing in the anticipated aesthetic experience that created delight.

The delight episodes reported in the present study resulted from explicit prompts from the researcher who asked informants to identify, if they could, such occurrences in their travel experience. This approach was judged necessary since no informant used the word 'delight' during the first interview. Two questions arise from this procedure. First, could the concept of delight be of little importance in consumers' experiences? This appears unlikely since delight episodes were easily recalled by informants and were described as particularly meaningful to them. Furthermore, the prototype perspective on emotion offers one possible explanation for the absence of the word 'delight' in the first interviews. According to this approach, individuals consider certain emotions as general categories that supersede more narrowly defined emotions that, in a sense, represent facets of prototype emotions (Fehr and Russell 1984). Several episodes of delight were described in the first interview as being characterized by feelings of joy and happiness, two emotions that are hierarchically superior to delight (Richins 1997; Shaver et al. 1987). The second question pertains to the possible bias introduced by directly asking informants to identify delight episodes. While this approach may stimulate acquiescence or impose a concept on the informant's experiences, accounts from the second interviews suggest that this was not the case. Indeed, informants clearly distinguished what they considered to be delight episodes from other experiences. At the end of the second interview, each informant was probed explicitly about their emotions during events discussed in the first interview that were not identified in the second interview as delightful. None of them agreed that delight could have been present in those events, even when asked directly. Nevertheless, the notion that delight may not be a forthcoming concept in consumers' descriptions of their consumption experiences is an intriguing finding that deserves attention in future research.

Finally, the narrow scope of this study needs to be recognized as a limitation. Further insight into the concept of customer delight would be gained from examining the proposed model in other consumption environments. For instance, it would be useful to contrast the experience of delight in contexts that appear to be conducive to delight-as-magic, such as aesthetic products and services, versus contexts that are more mundane and endowed with a lower affective content (Price et al. 1995). The small size of the sample also impedes more in-depth analysis of interesting issues that arose. For example, differences were observed in the experience of delight based on informants' age, with younger informants

reporting more delight episodes in the context of leisure and older informants more frequently taking delight in aesthetic experiences. Likewise, the finding that one informant did not report any delight episode during the numerous trips she has taken over the last fifty years is intriguing and indicative that personal characteristics may intervene in the experience of delight. A larger-scale investigation would permit more attention to such differences.

In summary, this study suggests that customer delight may usefully be construed as a multi-modal construct where delight-as-magic is experientially distinct from delight-as-pleasant-surprise. As such, customer delight is a more complex and perhaps more powerful construct than what extant conceptualizations in the marketing and psychology literature propose. For marketers, this study suggests that there may be more paths to delighting customers than offering pleasant surprises. Fostering interpersonal warmth, creating aesthetically pleasurable experiences, and orchestrating events conducive to leisure experiences may stimulate recurring encounters of delight-as-magic. Future research is needed to build on this exploratory study to determine how the outcomes of these types of delight differ.

Forewarning & Debriefing as Remedies to Deception in Consumer Research: An Empirical Study

Jill Gabrielle Klein, INSEAD
N. Craig Smith, London Business School

ABSTRACT

This research examines the effectiveness of forewarning and debriefing as measures to mitigate the use of deception in consumer research. Findings from an exploratory study suggest that these remedial measures may not only improve practice, but also lower respondent concern and increase the likelihood of research participation. Implications for researchers are discussed.

INTRODUCTION

Unethical practices have been blamed for reduced consumer willingness to participate in research (e.g., Bearden, Madden and Uscategui 1998). While some of these practices are clearly avoidable, other practices are arguably unavoidable, particularly some deceptive practices. Forewarning and debriefing have been proposed as remedial measures to mitigate the use of deception, but doubts have been raised about the extent and adequacy of their use by consumer researchers (Toy, Wright and Olson 2001) and respondent reactions to these measures are largely unexplored. In this paper, we examine the effectiveness of forewarning and debriefing as measures to mitigate the use of deception. First, we look at how deception is addressed in psychology as a basis for proposing appropriate remedial measures. We then report an exploratory study where respondents evaluated four common deceptive practices in a market research context that researchers might consider justifiable (primarily to eliminate demand characteristics).

REMEDIAL MEASURES TO MITIGATE DECEPTION

Ethical principles governing psychological research originated with the Nuremberg trials of 1947 and the Nuremberg Code can be seen as the basis of all subsequent guidelines governing experimentation with human participants (Schuler 1982). Voluntary participation and informed consent are fundamental prerequisites. The first American Psychological Association (APA) code was approved in 1953 and made substantially more stringent in the 1973 and subsequent revisions, particularly in light of controversy over the Milgram obedience experiments (Baumrind 1964). The guiding principles are perceived to be exacting, though they are to be applied within a cost-benefit framework, resulting in debates about the code's interpretation and implementation (Kimmel 1996).

The distinction we have made between avoidable and apparently unavoidable but problematic practices in consumer research is consistent with the APA approach to deception. The current version of the code (APA 1992; under revision for 2002) requires that deception not be used if it is avoidable. If an alternative procedure is not feasible, the use of deceptive techniques must be justified by the study's prospective scientific, educational, or applied value. A weakness of this approach is that psychologists might be too quick to anticipate significant scientific output, though Institutional Review Boards (IRBs) provide a partial check.

The APA code also states that participants must not be deceived about a significant aspect of the study that would affect their willingness to participate, perhaps because of physical risks, discomfort, or unpleasant emotional experiences. It is important to consider the form and effects of the deception. Commercial and academic consumer research generally uses only "mild decep-

tions"—deceptions that are not targeted at respondents' fundamental, self-related beliefs or values and unlikely to affect their willingness to participate—instead, respondents are deceived about "peripheral factors such as the research sponsor, why a procedure or measure is used, or the purpose of the study" (Toy, Olson and Wright 1989, p. 72). However, while the risk of harm to the individual by or as a result of the deception might be less or negligible, even mild deceptions are morally problematic (Kimmel and Smith 2001).

Deception is widely used in psychology, notwithstanding the provisions of the APA code and critics who charge that any use of deception is an unacceptable violation of the individual's right to voluntarily choose to participate in research (Adair, Dushenko and Lindsay 1985). Proponents of allowing deception argue that it is essential in many studies. Broder (1998), for example, cites memory research and studies of incidental learning and of cognitive illusions that could not have been conducted without deception. Under these circumstances, it is argued, the decision to be made is not whether to use deception, but whether the research is necessary (Kimmel 1996).

The APA code stipulates that deception must be explained promptly to participants within a debriefing to correct any misconceptions. However, it may not be sufficient simply to tell respondents that they were deceived and to provide correct information; effective debriefing may require "dehoaxing" and "desensitizing" (Toy, et al. 1989). Providing an educational benefit is often viewed as an important part of debriefing, particularly if the participants are students (Schuler 1982). This does not lessen the possible harm from deception, but it may partially compensate and be included in the researcher's assessment of the benefits and costs of research participation.

Forewarning is a more uncertain remedy to deception. Under informed consent provisions of the APA code (1992), researchers are obligated to brief participants beforehand about the study and explain that, should they choose to participate, they might withdraw at any time. However, the participant's decision relies upon the information provided by the researcher. Clearly, if fully informed about the study, there can be no deception. Under forewarning, subjects in a deception experiment may be "informed in advance that some information may have to be withheld and that full disclosure of the purpose and procedures will be made at the end of the experiment" (Adair, et al., p. 60). However, if deceit is used to obtain consent, by definition it cannot be informed (Baumrind 1985). Further, reliance is placed on the researcher's estimate of the risk to the respondent (Schuler 1982). One solution to these problems is to pretest the experiment to establish whether subjects would give consent, absent the deception (Kimmel 1996). A similar approach is adopted in the study reported below.

A case can be made that intentional deception is never permissible (Bok 1978). However, a more balanced view would argue that some deception in consumer research is morally justifiable (Kimmel and Smith 2001). In keeping with the treatment of deception in psychological research, we propose treating deception in consumer research as permissible under conditions where the researcher has no alternative procedure available, the deception is mild, and appropriate remedial measures are used. We recognize that this

position is not uncontroversial and note that our focus is on the use of remedial measures to mitigate the use of deception, rather than the ethics of deception, per se.

The appropriateness of remedial measures can be subject to empirical inquiry. The purpose of the study reported below was to illustrate in an exploratory study how possible remedial measures for deception in consumer research might be investigated and to demonstrate their effectiveness. Drawing on psychology, as discussed, the remedial measures examined are forewarning, debriefing, and the use of monetary and other forms of compensation. In addition, we explored the implications of a non-deceptive approach, i.e., telling the truth. Remedial measures were examined within a market research context, drawing upon industry codes of conduct to establish that the practice is considered problematic.

STUDY OF CONSUMER RESPONSES TO DECEPTIVE PRACTICES

Overview

Respondents evaluated four deceptive practices that might be considered unavoidable and justifiable (subject to the above criteria): study purpose and sponsor deception, undisclosed taping, and interview length deception. Benefits from research participation were also explored, consistent with Schuler's (1982) observations on the importance of assessing research costs and benefits for participants. Scenarios were manipulated in an attempt to determine whether the remedial measures we have identified may reduce respondent concern about deceptive practices and increase the likelihood of future participation in research. We sought ethical evaluations and emotional reactions of consumers as well as measures of the impact of these practices and of possible remedial measures on research participation.

Development of Scenarios

Pilot study. In a mall-intercept study, 352 adult consumers were asked to imagine that they were a participant in a given market research scenario and to indicate their response to the described event. In total, the pilot study examined consumer reactions to 35 scenarios (each respondent rated 3 unrelated scenarios). The practices found to be most egregious to consumers were: study sponsor deception, breach of confidentiality, frugging (fundraising under the guise of research), videotaping without consent, and the non-disclosure of a follow-up interview. Some remedial measures were tested; for example, warning people of a follow-up interview led to more positive ratings.

The criteria for selection of scenarios for the current study were whether the deceptive practice was ethically suspect (relative to industry codes), perceived to be relatively frequent, and arguably unavoidable. Accordingly, practices included in the pilot study that are clearly avoidable were dropped from the main study, including frugging and the non-disclosure of a follow-up interview. A further consideration was the scope for remedial measures that lessen the potential for harm and reduce negative reactions to the research experience. In addition to the pilot study, the development of the main study scenarios was informed by a separate investigation of practitioner and consumer respondent experiences of market research.¹ Following pretests, the final set of 23 scenarios was adopted. Below, we describe the scenarios used and our rationale for their selection.

1. Length of Interview. Interview length deception often occurs because interviewers fear respondents would decline to participate if given an accurate estimate of the time needed, perhaps because they have overlong and poorly constructed questionnaires.

It is widely regarded as frequent and problematic. We regard deception by commission, where interviewers lie about the interview length, as unethical and clearly avoidable. This is consistent with industry codes that prohibit deception to secure cooperation (e.g., ICC/ESOMAR 1986) or specify that "respondents must not be enticed into an interview by a misrepresentation of the length of the interview" (CASRO 1995, p. 5). Deception by omission is more troubling. Some recent industry initiatives require interviewers to state the likely duration of the interview (MRA CAC 1993). However, for some studies, length may vary substantially, according to consumer responses and interest (Laroche, McGown, and Rainville 1986). Accordingly, five scenarios involving interview length were tested: (1) the interview is said to last 15 minutes and it does last 15 minutes; (2) the interview is said to last 15 minutes and it takes 30; (3) the interview is said to last 30 minutes and it does take 30; (4) the respondent is not told the interview length and it takes 15 minutes; (5) the respondent is not told the interview length and it takes 30 minutes.

2. Taping. Undisclosed taping of an interview would be deception by omission. Researchers may not wish to disclose taping because it might bias responses or influence participation rates. The CMOR (1999) Respondent Bill of Rights states that respondents will be told in advance if an interview is to be recorded, consistent with CASRO (1995) and PMRS (1984). However, ICC/ESOMAR (1999), in a change to its code, permits recording without advance notice if it would otherwise result in "atypical behavior". However, respondents must be told about the recording at the end of the interview. Accordingly, two possible remedial measures for audiotaping were examined: debriefing and forewarning. There were three scenarios: (1) a control scenario in which the respondent becomes suspicious of taping (due to "clicking" heard on the phone line) but the respondent is never informed of the taping by the interviewer; (2) the respondent is informed at the end of the survey that the interview was taped; (3) the respondent is forewarned (during solicitation) that the interview will be taped.

3. Deception Concerning Purpose of Study. Revealing the purpose of a study may bias responses. CMOR's (1999) Respondent Bill of Rights commits researchers to disclosing the nature of the survey. The MRA CAC (1993) guidelines suggest that this need only note the general topic of discussion. Particularly troubling are instances of deception by omission where a different purpose is implied though unstated. For example, Tessar (1994) reported consumer frustration at being asked to do one thing (watch television programs) and then being questioned on something else (advertising). Accordingly, a typical advertising effectiveness research scenario was utilized to examine purpose deception. The respondent in the scenario is asked to watch a television program, even though the purpose of the study is to test advertisements aired during the program. Five remedial measures (or combinations thereof) for this deception were examined: (1) forewarning that the purpose cannot be revealed; (2) debriefing about purpose; (3) providing a benefit to compensate for the deception (a quiz about the program, with the possibility of winning a prize); (4) forewarn-

¹Two separate studies were helpful in developing the scenarios used here. A survey of American Marketing Association (AMA) practitioners provided confirmation of prior research on the prevalence of specific suspect practices and suggestions for alternative approaches and perceived justifications for practices considered unavoidable. Secondly, a mall-intercept study improved our understanding of consumers' positive and negative feelings toward research and of the context within which ethically problematic practices may arise.

ing and debriefing; (5) forewarning, debriefing, and providing the benefit.

4. Deception Concerning Sponsor of Study. Revealing the sponsor of a study also might bias responses. Moreover, it can conflict with an obligation of research companies to protect client confidentiality that is specified in most industry codes. CMOR's (1999) Respondent Bill of Rights, the MRA CAC (1993) guidelines, and some other codes, commit researchers to disclosing the name of the interviewer and the research company. This disclosure is unlikely to produce biased responses because it does not reveal the study sponsor. The problem is more difficult for in-house researchers where nondisclosure or deception may seem unavoidable (Sudman 1998). Accordingly, five scenarios were tested: (1) control condition in which sponsor is not mentioned; (2) sponsor of research (client) is revealed; (3) respondent forewarned that sponsor cannot be revealed; (4) research firm identified and respondent forewarned that sponsor cannot be revealed; (5) respondent forewarned that sponsor cannot be revealed in advance, then is debriefed about sponsor identity.

5. Benefits. The effects of research participation benefits were examined, in keeping with our earlier discussion of compensation in psychological research. Monetary incentives are recommended (e.g., Bearden, Madden, and Usategui 1998) and the American Association for Public Opinion Research (AAPOR 1999) advocates incentives as a "best practice" for maximizing response rates. One of CMOR's earliest initiatives was the development of "thank you" cards for mailing to survey respondents that explained the benefits of market research. We tested four scenarios: (1) a control condition in which no benefits or incentives were given (same as control condition in study sponsor deception), (2) indirect benefits of research ("participation in research helps produce products that people would like to see in the stores"), provided during solicitation; (3) indirect benefits of research provided at the conclusion of the interview; (4) \$5 voucher incentive; and (5) \$20 voucher incentive.

Method

Data were collected in mall-intercept interviews in a middle class mall in Jacksonville, Florida. Potential participants were stopped as they shopped and were asked to participate in the study. Each respondent saw one scenario only, to minimize possible demand effects. Respondents were asked to read the scenario and then answer 3 sets of questions on the following two pages. The first two sets of questions asked for reactions to the scenario, the third asked respondents for demographic information and their level of participation in market research studies. When they were finished, respondents were thanked for their participation and given a written debriefing. A sample scenario (undisclosed study purpose with forewarning) is provided below:

Imagine that one afternoon you are at home and the phone rings. The person on the other end of the phone says:

"Hello, I'm with a national marketing research firm and we are calling consumers to ask whether they would be willing to participate in a study by watching a new TV program airing on network TV this evening. We will call you after the show to discuss your reactions. We would like you to watch this program as you would any other program, therefore we cannot say anything more about the specific questions you will be asked. Would you be willing to participate?"

You agree. After the show the research firm calls. The first few questions are about the TV program, the remainder of the 15 minute interview is about the advertising that appeared during the program.

Dependent measures. Our dependent measures were primarily intended to establish whether consumers would respond more favorably to research practices that include remedial measures to mitigate deception. Two sets of dependent measures were used, presented to the respondents as questions 1 and 2 (rotated within each scenario type to minimize possible order effects). One set measured respondents' ethical evaluation of the market research company's action described in the scenario. The set comprised the eight items of the Reidenbach and Robin (1990) multidimensional ethics scale (MES) and a single unidimensional measure of ethical evaluation (very ethical/not at all ethical). It should be noted that these measures are of respondents' perceptions of the ethics of the research practices. Many deceptive practices could still be unethical regardless of how they might be evaluated by research respondents.

The second set of dependent measures comprised 7 items measuring emotional reactions to the scenario, its effects on research participation, and whether respondents felt deceived. More specifically, respondents were asked to indicate on a 7-point scale the extent to which they agreed or disagreed with seven statements relating to participation in the study described (where appropriate), future participation in market research, and whether they would feel upset, angry, happy, irritated, or deceived by the experience. Our assessment of emotional reactions to research practices is in contrast to previous studies. While practitioners and academics may discuss questionable practices in terms of whether or not they are ethical, it is quite possible that consumers themselves may evaluate practices in terms of how irritating or upsetting they are. Again, our purpose is to establish the effectiveness of remedial measures. We expect consumers to respond more favorably to the more effective remedial measures on one or more of our dependent measures.

Sample. Four hundred and six individuals agreed to participate in the study (a 24.5% participation rate).² The sample was 50.5% female and median household income was \$30,000-44,999. Relative to the U.S. population, minorities were overrepresented (25.9% of respondents were black, 60.2% were white) and the sample was skewed toward the young (66% were 37 or younger), and was better educated (65.3% had one year of college or more). Respondents were familiar with market research; two-thirds had been asked to participate in a marketing research study in the previous 12 months, 27.8% reported having been asked to participate 3 or more times in the past year (the mean value for prior research participation was 2.41).

RESULTS

Table 1 shows mean values for respondent ratings of the different scenarios. Below, we discuss the analysis of each group of

²The contract research firm reported a refusal rate (percentage of people who said no when asked to participate) of less than 1%. However, this is after "wave-offs", people who, when passing the interviewer, indicate that they are not interested in participating in a research study. The research firm reported a wave-off rate of 75.5%, consistent with other studies it has conducted in this mall. Hence, the participation rate for this study was 24.5%.

TABLE 1
Respondent Ratings of Scenarios (N=406)¹

Scenario	Participate	Future	Negative	Deceived	Happy	Unethical
1. Length of Interview						
told 15/actually 15	N/A	4.28	2.32	2.33	4.35	3.72
told 15/actually 30	N/A	3.76	3.51	3.59	4.12	3.59

¹Approximately 18 respondents per scenario.

scenarios in turn. ANOVA's and contrast tests were conducted to analyze differences in responses across scenarios. Because the dependent measures "irritated," "upset," and "angry" were highly correlated, they were averaged as an index of negative reactions (Cronbach's $\alpha=.87$). Ethical evaluations reported in the table and analyzed below reflect the unidimensional measure only.³

1. Length of Interview. In examining interview length, we are interested in: (1) whether deception about length led to a more negative reaction than did the truth (or no information) about

length; (2) whether the actual length of the interview would have an impact on respondents' reactions; and, (3) whether telling versus not telling respondents about the length of the interview would influence responses. As Table 1 shows, respondents had the greatest negative reaction when they were deceived about the length of time the interview would take. Respondents who read the scenario in which there was deception about the length of the interview ("told 15/actually 30") had significantly higher negative reactions ($t(84)=2.93, p<.01$) and felt significantly more deceived ($t(84)=3.52, p<.01$) than respondents who saw the other scenarios. Deception about length did not significantly affect how happy respondents would feel ($t(84)=.47, n.s.$), or how ethical they judged the research to be ($t(84)=.65, n.s.$).

The two scenarios in which the interview lasted 15 minutes were contrasted against the two scenarios in which the interview lasted 30 minutes (the deception scenario was excluded). The length of the interview did not affect responses to scenarios: the t-

³We conducted exploratory and confirmatory factor analysis to test the dimensionality of the MES in this study. This revealed a two-factor structure rather than the three dimensions of the scale, suggesting that attempts to understand the underlying rationale for respondents' ethical judgments, based on the MES, would not be reliable in this context.

scores for contrasts for all seven of the dependent measures were non-significant. There were also no differences in reaction between scenarios in which the length of the interview was disclosed during solicitation and when the length was not disclosed (the deception scenario was again excluded from this analysis). Those who were not told the length of a 30 minute interview were more likely to participate in the future ($t(84)=2.91, p<.01$), had less of a negative reaction ($t(84)=3.09, p<.01$) and felt less deceived ($t(84)=2.95, p<.01$) than did those who were deceived about interview length.

In summary, respondents appear to be most sensitive to being deceived about the length of the interview. The actual length of the interview (15 or 30 minutes) did not affect ratings nor did the disclosure of the interview length at the commencement of the interview. However, participation in future research would appear to be more likely if people are not told the length of a 30 minute interview, rather than told that it will be 15 minutes and it takes 30 minutes.

2. Taping. Two possible remedial measures for audiotaping were examined: debriefing and forewarning. These two procedures were contrasted against a control scenario in which the respondent becomes suspicious of taping. Debriefing respondents at the end of the interview did not affect reactions relative to the control (all t values were *n.s.*). Forewarning, however, did prove to be a successful remedial measure. Forewarned respondents were significantly happier with their participation, felt less deceived, and judged that the procedure was significantly less unethical than respondents in the other two taping conditions ($t(47)=2.28, p<.05, t(48)=2.19, p<.05$ and $t(48)=2.82, p<.01$, respectively). Forewarning produced no significant differences in negative emotional reactions or willingness to participate in the future.

3. Deception Concerning Purpose of Study. Five remedial measures (or combinations thereof) for study purpose deception were examined. Forewarning respondents that they would not be told the purpose of the study (as opposed to simply deceiving them) led respondents to be significantly more likely to participate in the future, and significantly more likely to be happy with the experience ($t(100)=2.48, p<.05$ and $t(100)=2.46, p<.05$, respectively). Debriefing respondents (relative to the control group) had a diverse impact on reactions to the scenario: debriefed respondents were significantly more willing to participate in the future and were happier with the research experience ($t(100)=3.82, p<.001$ and $t(101)=2.46, p<.05$, respectively). But they also felt more deceived and had more of a negative reaction to the scenario than did the control respondents ($t(100)=3.22, p<.01$ and $t(100)=2.77, p<.01$, respectively). The other remedial measures (incentive; forewarning and debriefing; and forewarning, debriefing and incentive) did not have any significant effect on reactions and no remedial measure had any significant effect on ethical judgments relative to the control condition (all t values were *n.s.*). Thus, while forewarning produced some positive reactions, debriefing produced both positive and negative reactions, perhaps because it reveals the deception. Accordingly, in combining forewarning and deception, the positive effects of the forewarning appear to be canceled out by telling respondents they were deceived. In addition, offering an incentive did not ameliorate the effects of the deception.

4. Deception Concerning Sponsor of Study. Methods of protecting against bias due to respondent awareness of the study sponsor were examined by comparing a control scenario in which the sponsor is identified with three alternative practices. As Table 1 shows, the means across the different scenarios are quite similar. There were no significant differences between the control scenario and the alternative strategies (with the exception of a single significant finding: respondents felt more deceived when they were

forewarned that they would not be told the study sponsor compared to when the sponsor was identified). However, when contrasted against a generic control, where there was no identification of the study sponsor, all four of these remedial measure scenarios evoked less negative reactions. There were significant differences on the negative reactions measure between the control and forewarning ($t(83)=3.03, p<.01$), research firm/forewarning ($t(83)=2.25, p<.05$), and forewarning/debriefing ($t(83)=2.18, p<.05$), though not for the other dependent measures (all t values *n.s.*). Thus, the findings suggest that not identifying the study sponsor can be problematic and show that remedial measures can reduce respondent concerns, but they do not speak to the superiority of any one remedial measure.

5. Benefits. The effects of explaining indirect benefits of research to consumers and of offering a voucher incentive were examined. The explanation of indirect benefits during solicitation did not significantly affect reactions relative to the control (in which respondents were simply asked to participate). The explanation of indirect benefits at the end of the interview, however, did leave respondents feeling significantly less deceived than respondents in the control ($t(84)=2.08, p<.05$). The vouchers did not have any effect on respondents relative to the control, except for the finding that the \$20 voucher led to significantly lower negative reactions compared to the control ($t(84)=2.80, p<.01$). Thus, there is some indication that the incentives for participation in research need to be reasonably substantial. However, there were no significant differences on any of the measures between the \$20 voucher scenario and the indirect benefits scenarios, suggesting monetary incentives may not be needed if respondents can be persuaded the research is worthwhile.

DISCUSSION

Overall, we found that remedial measures did reduce perceived negative consequences and mitigate the use of deceptive practices. Consistent with prior industry research (e.g., Humbaugh 1998), we also confirmed that deceptive practices (specifically, interview length deception and study purpose deception) appear likely to reduce future participation, at least relative to remedial measures. Our study points to the potential effectiveness of remedial measures in market research, at least for the deceptive practices investigated. Subject to our study limitations, research industry efforts to promote development of these measures might well be warranted, as well as their more widespread adoption by academic researchers. Below, we comment on each measure in turn.

Telling the truth is more of an alternative to deception than a remedial measure. Clearly, from an ethical standpoint, it is preferable to avoidable deception. However, researchers may be uncertain when a deception is avoidable. Our study suggests that it is possible to test when a deception can be avoided without compromising research integrity or participation rates. For example, we found that disclosure in advance of the actual length of even a 30-minute interview did not result in more negative evaluations relative to nondisclosure or relative to disclosure of a 15-minute interview. Also, we found that disclosure of the research firm in combination with forewarning (that sponsor identity could not be revealed) was no different to forewarning alone.

The results of our study suggest that forewarning has considerable potential in mitigating adverse consequences of deception in market research. Forewarning about taping led respondents to feel happier with the research experience, to feel less deceived by the research, and to judge it as more ethical than did debriefing or failing to disclose that the interview was being taped. Likewise, forewarning respondents that they would not be told the purpose of

the study made them happier with the experience and more likely to participate in the future. Forewarning also reduced negative reactions to study sponsor deception. Thus, telling respondents ahead of time that they will be taped, or that they will not be told the sponsor or the purpose of a study, appears to be an effective remedial measure.

Debriefing was less effective in reducing respondent concern about deceptive practices. In some cases, debriefing generated negative reactions, including feeling deceived—perhaps because the deception is revealed and its effects are not fully assuaged as a result of the debriefing. However, from an ethical standpoint, this may not make it any less necessary as a way of redressing a deception, at least in the absence of forewarning. Nonetheless, forewarning alone may suffice for much commercial research, given our findings on forewarning. In particular, it may be sufficient in most studies to forewarn respondents that a study sponsor cannot be revealed for reasons of client confidentiality. One test to be applied is whether advance knowledge of the identity of a research sponsor would have influenced the respondent's decision to participate.

Compensation also appears to be effective, though perhaps it need not be monetary. Explaining the benefits of research participation at the end of an interview appeared to be advantageous. While not significantly affecting willingness to participate in the future, or positive or negative feelings about the research relative to a control condition, telling respondents why their participation is worthwhile reduced feelings of deception, and was generally as effective as providing a \$20 voucher.

Turning more specifically to implications for academic research, we note that Toy, et al. (1989) found that many academic marketing studies employ deception, though less than 40% reported conducting a debriefing. While the proportion of debriefings that actually took place was likely higher, it's very possible that many researchers are not sufficiently familiar with debriefing techniques or the ethical obligations that go with the use of deception (Toy et al. 2001). Our discussion of deception shows that there may be good reasons for journal editors to require that the use of debriefings be reported and, perhaps, the rationale for the deception (Adair, et al. 1985). A further consideration is the obligation of an educational compensation to academic research participants, who are often students.

Limitations

Interpretation of our results must be tempered by the study limitations. First, although our findings for remedial measures overall are relatively robust, this was a broad and inevitably exploratory study and this limits claims that can be made about the relative merits of different remedial measures or their most appropriate levels. A more complete design would extend to a greater number of treatments and levels for each treatment and with more scope for analysis across issues. Second, there are inevitable trade-offs between control and richness in the use of an experimental design. More specifically, respondents read descriptions of research situations, and were not subject to the questionable practices directly. While we considered the latter approach, we concluded that to deliberately engage in unethical practices in order to test their effects would not be appropriate. Third, it is likely that there is some degree of non-response bias influencing our findings. We had only respondents willing to participate in the mall-intercept. In many respects, however, the participants in our study represent the segment of greatest interest to research practitioners: those who are willing to participate in research and comprise the pool of available respondents for market research. Fourth, although administered as a mall-intercept, all the scenarios in our study questionnaire re-

ferred to phone research. Finally, the scenarios were set in a market research context, though we believe they are applicable to academic consumer research as well as commercial research. Problematic practices and remedial measures could be explored within the context of academic research, perhaps with researchers testing different approaches as part of other studies (e.g., changes in respondent satisfaction with short or long debriefings).

CONCLUSION

In sum, we argue that deception in commercial and academic consumer research may be avoidable because alternatives are often available. Academic researchers are well advised to anticipate IRBs drawing their attention to possible alternative non-deceptive approaches. Where alternative procedures are not available, the researcher must consider whether an intentional deception is warranted by the possible benefits of the study, even if the deception is mild. If the deception is considered justifiable, its effects may be mitigated by the use of forewarning and debriefing. This approach may make research participation less aversive in addition to being less potentially unethical and reducing any harm that might otherwise be perpetrated.
