Non-consequential Reasoning in Hedonic and Utilitarian Consumption Decisions

Laura Smarandescu, University of South Carolina

This work investigates the effects of pursuing non-instrumental information on non-consequential reasoning in the context of hedonic and utilitarian product purchases. Individuals did not differ in their willingness to pursue non-instrumental information in the two purchase contexts; however, once they pursued the non-instrumental information they were more likely to rely on it in hedonic than in utilitarian purchase decisions. This research suggests that individuals feel more accountable for hedonic than for utilitarian purchases and thus, they are more likely to weight non-instrumental information to avoid feelings of guilt.

Is It the Luxury Car or the Super Model that Tempts Him?: The Possibility of Misattributed Arousal

Xiuping Li, University of Toronto

Research in consumer impulsivity has documented the effect of hedonic stimuli (e.g., dessert) on related behaviors (eating). We extend this line of research in the direction of whether the induced craving towards one hedonic stimulus category (dessert) can be carried over (or misattributed) to intertemporal choices in ostensibly unrelated behavioral domains (investing). In a series of experiments, we found that cues of hedonic stimuli (pictures or scents) led to (1) more choices of vices, (2) impatience in waiting for larger monetary gains, and (3) unplanned purchases.

Goal Abstraction Compatibility and Lexical Fit in Consumer Choice

Ryan Hamilton, Northwestern University

Objects can be described by either their concrete, feature-level attributes or by more abstract, benefit-level attributes. Likewise, a consumer may have a relatively more abstract or concrete mindset in approaching a decision. In a series of studies, we find that choice is a function of consumer mindset such that individuals with an abstract mindset tend to prefer products that dominate on abstract benefits and individuals with a concrete mindset tend to prefer products that dominate on concrete features.

Differential Impact of What is Available and What is Inferred: Promotional Element Salience Effect in Reference Price Promotions

Igor Makienko, Louisiana State University

Conceptual Background

In reference price promotions, consumers are usually exposed to a sale price and a reference price or to a reference price and a discount (we do not investigate situations with all three elements). Thus, savings are presented either directly, in the form of an explicit discount,

or indirectly, by stating the sale price along with the reference price. In the first case consumers infer the sale price. In the second case, they infer the size of discount. Though these two formats may represent economically identical deals, consumers' evaluations are likely to vary depending on the salience of promotional elements.

Levin and Gaeth (1988) found that when ground beef was presented as '75% lean', respondents displayed significantly better evaluations than when it was presented as '25% fat'. Evaluations were different despite the fact that information on the salient attribute automatically provided information about the absent attribute. Salient stimuli have a disproportionate influence on people's judgments (Slovic, Fischhoff and Lichtenstein, 1982). Hence, the first research question is whether promotion format will have a differential impact on consumers' deal evaluations and price estimates. Building on prior findings that consumers prefer to see their gains separately rather than integrated into a price of the product (Thaler, 1985; Diamond and Campbell, 1989), it is expected that consumers' evaluations will be higher for discount present conditions than for sale price present conditions.

The second factor investigated in the study is reference price level. Extant research showed that reference prices have a significant impact on consumers' buying behavior (Kalyanaram and Winer, 1995). For example, it was found that high implausible reference prices substantially increased perceived value of the offer despite decreasing believability of such claims (Urbany, Bearden and Weillbaker, 1988; Mobley et al., 1988). Urbany et al. (1988) suggest that consumers do not reject high implausible reference prices but instead discount them to the level deemed more reasonable. However, this reference price effect may only be true when a high implausible reference price is presented along with a sale price. Compeau and Grewal (1998) suggest that believability of reference prices is of little concern since consumers know that the retailer must sell the product at the advertised sale price. Presenting a discount instead of a sale price in advertisement may inhibit consumers' abilities to estimate the actual sale price and may result in under- or overestimation of the sale price. Moreover, with a high implausible reference price the size of the discount should be large enough to make the sale price (inferred) attractive to consumers. Large discounts will also be perceived with skepticism (along with high implausible reference prices) and are also likely to be discounted to a more reasonable level (Gupta and Cooper, 1992). In this situation consumers may engage in a double discounting that may lead to deal evaluations lower than those in a 'high implausible reference price and sale price' format. Therefore, there may be preference reversal. At plausible levels of reference prices, consumers will have higher deal evaluations when a discount is present than when a sale price is present. However, at high implausible levels of reference prices, consumers will value sales promotions providing information about sale price significantly higher than those providing information about a discount.

Methodology

A 2 (plausible reference price vs. high implausible reference price) x 2 (discount is present vs. discount is absent) between-subjects design was employed to investigate how the level of reference price and the salience of promotional elements affect consumers' deal perceptions. Respondents were exposed to a hypothetical advertisement of a Philips TV set and then were asked to answer a questionnaire. Manipulation checks were conducted to ensure that respondents remembered their treatment conditions and were significantly different in their perceptions of advertised reference prices. Data was analyzed by MANOVA.

Major Findings

A significant interaction between reference price level and salience of promotional elements ($p=0.016$) was found using MANOVA. Upon further investigation, it was found that the interaction was significant only for source credibility ($p=0.031$).

Results of the analysis partially support findings of Urbany et al. (1988). Respondents exposed to advertisement with high implausible reference prices had significantly higher attitude toward the deal (but not perceived value of the offer as in the original study), significantly higher market price estimates, and exhibited significantly lower believability toward claimed savings than those exposed to plausible reference prices. Quality perceptions of stimuli did not differ across groups. Main effect of the salience of promotional elements was significant. When advertisement contained reference price and sale price, respondents' attitudes toward the deal and their perceived value of the deal were significantly higher than when advertisement contained reference price and discount. One interesting and unexpected finding refers to retailer (advertiser) credibility. While credibility of the advertiser was not different at the plausible reference price level, it was significantly higher for the discount present condition than for the discount absent condition at the high implausible reference price level, meaning that double discounting somehow improved the retailer credibility.

Contrary to the hypotheses salience of promotional elements did not have any effect at the plausible reference price level. However, in line with the hypotheses, presenting a discount instead of a sale price in a high implausible reference price condition resulted in significantly lower attitude toward the deal and perceived value of the offer. At high implausible reference price level, salient discount had detrimental effect on respondents' deal perceptions and at the same time significantly enhanced retailer credibility.

Too Good to be True vs. Too High to be Good: The Role of Product's Price and Form of Incentive in Sales Promotion Evaluations

Igor Makienko, Louisiana State University

Conceptual Background

According to the perceived value concept (Monroe and Chapman, 1987), consumers evaluate market offers based on the ratio of perceived quality to perceived sacrifice. In a sales promotion context, this means that deal evaluations should be positively related to the size of incentive because an incentive would decrease a consumer's perceived sacrifice and, as a result, enhance the perceived value of the offer. However, there are some limits on the size of discounts that retailers can offer during sales promotions. One way to increase the size of an incentive while keeping the sale price of a deal constant is to show a higher regular (reference) price. Blair and Landon (1981) note that consumers can be skeptical of implausible reference prices, and at the same time, be influenced by them. Indeed, Urbany, Bearden and Weilbaker (1988) found that after exposure to implausible reference prices, consumers update their internal reference standards upward. This adjustment leads to a substantial increase in the perceived value of the offer despite decreasing believability of such claims. Therefore, it is expected that when consumers are exposed to overpriced products and bigger incentives, they will have higher evaluations than when they are exposed to normally priced products and respectively lower incentives. However, there will be an interaction if the second factor—the form of incentive is taken into account.

One major difference between the two forms of incentives is that with a monetary incentive consumers do not need to pay the regular (reference) price for the offer, while with a nonmonetary incentive, they do. (For the sake of simplicity the study is limited only to instant sales promotions). Situations where consumers pay only sale price for the offer are identical to reference price advertising, and consumers are likely to have higher evaluations for the overpriced condition. However, when consumers have to pay regular price and get a nonmonetary incentive with the purchase, a high regular price of the offer may result in a perceived unfairness and trigger negative feelings toward the retailer (Xia, Monroe and Cox, 2004; Martins and Monroe, 1994). In this case, consumers' evaluations in the normally priced condition are likely to be higher than those in the overpriced condition (despite greater nonmonetary incentives in the overpriced condition).

Therefore, it is hypothesized that consumers' evaluations and purchase intentions toward instant monetary promotions will be higher when the promoted product is overpriced than when it is normally priced. Conversely, consumers' evaluations and purchase intentions toward nonmonetary promotions will be higher when the promoted product is normally priced than when it is overpriced.

Methodology

Respondents in a 2 (normally priced vs. overpriced product) x 2 (monetary vs. nonmonetary incentive) between-subjects design experiment were exposed to a hypothetical sales promotion advertisement of a Kodak one-time-use color camera and then were asked to answer a questionnaire. Sale prices (either actual or inferred—by subtracting the value of the nonmonetary incentive from the regular price) for all four conditions were identical (\$2). The Kodak brand was used to prevent inferences about low product quality that respondents may make based on a low sale price of the offer. To control for consumers' preference heterogeneity in the nonmonetary condition, a free film processing coupon was chosen as a clear complement to the camera. Data were analyzed using MANOVA.

Major Findings

Contrary to the hypotheses, no significant interaction was found between the product price level and the form of incentive for both deal evaluations ($p=0.603$) and purchase intentions ($p=0.863$). Upon further investigation it was found that respondents did not significantly vary in their deal evaluations ($p=0.502$) and purchase intentions ($p=0.296$) across the two forms of incentives. The only significant main effect found was for the price of promoted product ($p<0.001$). Contrary to Urbany et al. (1988) overpriced condition did not improve evaluations of the deal and purchase intentions. When a product was overpriced, respondents' evaluations of a deal and their purchase intentions were significantly lower than when it was normally priced.

One plausible explanation of those findings is based on consumers' belief that a marketer's goal is to make a profit. When a discount appears to be too high, consumers may engage in attributional processing to account for the behavior and may make some inferences about the quality of a product or the motive of a retailer (Friestad and Wright, 1994). With high offer prices consumers may completely switch their focus from product quality to retailer's motivation and infer that the retailer wants to look good by stating inflated regular prices first and then offering bigger discounts. As people pay greater attention to disadvantages (Sen and Johnson, 1997) and negative stimuli get a greater weight in consumer decision making (negativity bias), sales promotions with overpriced products are likely to result in lower evaluations than those with normally priced products.

The Role of Meta-cognitive Experiences in Reason-based Choices for the Self vs. Others

Hyejeung Cho, University of Michigan
Christina Brown, University of Michigan

Extended Abstract

Prior studies have shown that people sometimes base judgments on the subjective meta-cognitive experience, for example, the ease or difficulty with which relevant information comes to mind (referred to as "ease-of-retrieval" by Schwarz et al. 1991). For instance, Wänke et al. (1997) have shown that consumers evaluate a BMW less favorably after generating ten reasons to choose a BMW over a Mercedes than with only one self-generated reason. Our research ultimately intends to look into three possible mechanisms for this "ease-of-reasoning" effect. The first two explanations have been offered by prior studies, but there seem to be mixed findings in the literature (see Haddock 2000 and Wänke & Bless 2000 for reviews).

Three possible mechanisms for the ease-of-reasoning effect

The first possible mechanism suggested by prior studies is the 'availability heuristic' based processing. This heuristic-based account suggests that people infer a scarcity of good reasons from the experienced difficulty of generating reasons. According to this explanation, people are more likely to rely on this ease effect under low-elaboration conditions than high-elaboration conditions. If this availability heuristic mechanism operates in the reason-based choice contexts, then the experienced difficulty of generating reasons should have a negative impact on the predicted choices of others as well as the choices made for the self only under low elaboration conditions (or at least the ease effects should be more pronounced under low, rather than high, elaboration conditions). The second possible mechanism involves the perceived validity (or quality) of reasons. According to this explanation, people are more likely to rely on the ease effect under high-elaboration conditions, because subjective difficulty of generating reasons undermines the perceived validity or compellingness of the reasons (Wänke & Bless 2000, Tormala et al. 2002). If this 'reason validity' mechanism operates, then the subjective difficulty of generating reasons should have a negative impact on the predicted choices of others as well as the choices for the self only under high elaboration conditions. In the current study, we suggest another possible explanation that the subjective experience of difficulty tells the person something about his/her preferences directly (i.e., "I can't think of many good reasons, so this tells me something about my own preferences" rather than "I can't think of reasons, so this tells me something about the reasons themselves"). In other words, the consumer may believe that it is inconsistency with his/her own preferences, rather than the validity of the reasons themselves, that makes reason-generation difficult. If this 'preference diagnosticity' mechanism operates, then one's subjective difficulty of generating reasons should be limited to decisions made on one's own behalf. We further argue that only under high-elaboration conditions people would be motivated and make a distinction between one's own feelings and the feelings that others might be likely to have. Therefore, under high-elaboration conditions, when a person makes a choice for the self, the target option will more likely be chosen after only a couple of (vs. many) reasons are generated. On the other hand, when the person predicts others' choices, the person would predict that the others will more likely choose the target option after many (vs. a couple of) reasons are generated, supposedly because the subjective difficulty of generating reasons is no longer diagnostic for others' choices.

Experiment design

Allowing people to generate reasons *then* asking them to make choices on behalf of themselves or predict others' choices will allow us to disentangle these mechanisms. Seventy-nine undergraduate students participated in our experiment with a 2 (reasons: 2 vs. 8 pro reasons) x (NFC: high vs. low) x 2 (choice type: self vs. others) mixed-design where 'reasons' and 'NFC' were treated as between-subjects factors and 'choice type' was treated as a within-subjects factor. Each participant generated either 2 or 8 reasons for choosing New York over Las Vegas as a vacation destination. NFC was measured using the 18-item scale (Cacioppo, Petty, and Kao 1984) and participants were divided into two groups based on a median split for data analysis. After reading a choice scenario and generating reasons, participants were asked which destination they would most likely choose and which destination they thought other students most likely choose (the two choice questions were given in a counter-balanced order). At the end, participants were asked how difficult it was to generate the 2 or 8 reasons (on a 7-point scale) for manipulation check.

Major findings

First of all, our manipulation check on the experienced difficulty of generating reasons revealed only a main effect of the number of reasons as expected: participants in the 8-reason condition reported that it was more difficult to generate the reasons than those in the 2-reason condition. Our analysis of the main data revealed a significant three-way within subjects interaction among 'the number of

reasons,' 'NFC,' and 'choice type' showing that depending on the choice perspective (self or others), the ease effect on the choice outcome differs. This three-way interaction was the only significant effect. In specific, when people made a choice for themselves, those with high NFC relied primarily on their subjective ease experience. They were more likely to choose N.Y. over L.V. after generating 2 (vs. 8) reasons to go to N.Y. However, when they predicted similar others' choices, they relied more on the number of reasons they generated. They were more likely to choose N.Y. over L.V. after generating 8, rather than 2, reasons. On the other hand, those with low NFC, when making a choice for themselves, were more likely to choose N.Y. after generating 8 reasons than 2, suggesting that they did not make use of subjective difficulty in making their decision and simply relied on the number heuristic (i.e., "more reasons are better"). However, when predicting others' choices, they were more likely to choose N.Y. after generating 2 reasons than 8, consistent with the possibility that taking others' perspective generated more cognitive effort. For high NFC people, our results replicate the previous finding that people sometimes use the ease or difficulty of generating reasons as a guide to their choices; however, according to our data, what their subjective difficulty of generating reasons informs may be neither about the scarcity of good reasons nor about the validity of the reasons themselves. It seems to be rather about their diagnosticity for the person's own preferences. Our future study will look more closely into the mechanisms for low NFC people.

When Behaving Bad is Good: Self-Regulatory Enhancement by Strategic Goal Deviation in Consumption

Rita Coelho do Vale, Tilburg University

Rik Pieters, Tilburg University

Marcel Zeelenberg, Tilburg University

Extended Abstract

Most important goals cannot be attained without considerable self-regulation and effort (Cantor and Blanton, 1996). During the process to attain the desirable end state that the personal goal focuses on, consumers need to choose between multiple goals (Kruglanski, Shah, Fishbach, Friedman, Chun and Sleeth-Keppler, 2002), to restrain "irresistible" impulses (Baumeister, 2002), and need commitment to persistently pursue the current goals (Brunstein, 1993; Locke and Latham, 2002). Altogether, the process of goal striving can be quite exhausting leading many times to interruptions of current goal-pursuit (Baumeister, Heatherton and Tice, 1994).

A common assumption in the literature is that in order to reach a specific goal, consumers need to progress through some sequence of steps when making a choice (Bettman, 1979), consistently regulating their activities in alignment with their focal goals (Hacker, 1985). For example, Bettman (1979) proposed that in order to reach goals, a set of sub-goals must be defined, defining a plan to reach the specific goal. Analogously, Kruglanski and colleagues (2002) proposed that each goal can be depicted as a goal-system, where the super-ordinate goal is cognitively connected to its various sub-goals or way-stations en route to that goal. Hacker (1985) considered that any activity that is not organized towards the goal should typically be characterized as trial and error.

Clearly, the systematic pursuit of goals over time can be quite exhausting since cognitive and other resources are spent over time to keep commitment and focus on the current long-term goal (Kruglanski et al., 2002). Thus, controlling self-behavior requires the expenditure of resources that become depleted during the self-regulation process, resembling a muscle's ability (Muraven and Baumeister, 2000; Schmeichel and Baumeister, 2004). And, if the muscle metaphor of willpower generalizes, then because the muscle needs periods of rest and relaxation to recuperate and to strengthen, willpower will also require its moments in the sun. This is the thesis that we examine in the present research.

Many goals that consumers pursue, such as dieting, saving, and exercising, entail inhibitory behaviors that need to be executed over extended periods of time, involving effort and need for high self-regulation. Such inhibitory activity strains willpower, and it does so progressively when the inhibition needs to be maintained over extended periods of time. Long-term projects on which consumers work repeatedly, sometimes with little optimism for a quick or easy finish, strain the limits of self-regulation for practically everyone (Mischel, Cantor and Feldman, 1996). Thus, it is likely that consumers, when pursuing goals that involve inhibitory behaviors for extended periods of time, may need periods of rest and relaxation to recuperate and to strengthen self-regulatory resources.

The issue then is if we always need to perform the behaviors that bring the desired end-state closer, in order to eventually attain it? Or, if there are conditions that is good to temporarily deviate strategically from direct goal pursuit, in order to eventually attain the goal?

For goals that require inhibitory behaviors over extended periods of time, such as in dieting, exercising, saving and so forth, it may be beneficial to temporarily not only abstain from goal pursuit, but actually to perform behavior that runs counter to the overarching focal goal, but which allows the replenishment of self-regulatory resources. Therefore, in the spirit of the muscle metaphor of willpower, we propose that the temporary pursuit of non-regulatory behaviors, even when counter productive to the overarching goal, can act as a mechanism to deal with immediate self-regulatory depletion, can contribute to willpower enhancement, increasing likelihood of goal-pursuit and contributing to eventual long-term goal-attainment.

We hypothesize that in goal-pursuit processes where individuals foresee that high self-regulatory behaviors will be needed to attain the focal goal, intermittent goal-striving processes (i.e., goal-focused activities with goal-relaxation moments) will be preferred, leading to lower levels of ego-depletion and increasing likelihood of goal attainment. By exerting goal-relaxation moments, we also predict an enhancement of motivation to proceed with self-regulatory tasks, as well as an increase in consumers' ability to cope with self-regulatory demands.

Results from five experimental studies demonstrate that the inclusion of *a priori* moments of goal-relaxation in self-regulatory processes, when counter productive to *immediate* goal-attainment, increase the likelihood of long-term focal goal attainment. The findings demonstrate the importance that goal-rest periods are defined *before* initiating self-regulatory activities, i.e., *a priori*. This prior knowledge that goal-rest periods will take place during self-regulation leads to lower rates of ego depletion than when consumers do not have *a priori* knowledge about the occurrence of such goal-relaxation periods. Furthermore, the inclusion of goal-relaxation moments, in which inhibitory self-regulatory processes do not take place (e.g., interruption of dieting behavior to eat "normally" for one day), increases motivation to attain the goal, enhances action likelihood of proceeding with self-regulatory activities, leads to lower depletion, and increases ability to develop coping strategies to deal with self-regulatory issues. Consumers also clearly showed preference for engaging in self-regulatory activities where goal-relaxation periods are included. Taken together, these results provide support that for goals requiring inhibitory behaviors over extended periods of time, the likelihood of eventual goal-attainment is higher when consumers engage in an intermittent goal-striving process, where relaxation-goal activities are entailed, than when they engage in a straight goal process, where all the activities are aligned with focal goal.

Overall, this research contributes to a better understanding of self-regulatory behavior for goal-attainment, emphasizing the importance of temporal activity/planning in goal-striving. Because goals play an essential role in consumer behavior (Bagozzi and Dholakia, 1999), are present in most behaviors of daily life (Cantor and Blanton, 1996), and its pursuit involves coping with challenges, temptations and frustrations (Mischel, Cantor and Feldman, 1996), this research sheds some light on when it is good in the long run to be sometimes bad in the short run.

Improving Consumer Quality-Efficiency By Using Simple Adaptive Feedback in a Choice Setting

Anjala Krishen, Virginia Tech
 Pushkin Kachroo, Virginia Tech
 Kent Nakamoto, Virginia Tech
 Steven Suhr, Virginia Tech

This paper proposes a feedback control based adaptive scheme for providing choices for users in a web setting. We hypothesize that using this scheme for updating the number of choices presented produces an efficient method of user interaction. We conducted an experiment with seventy-five subjects who had to choose a computer they would buy, given monetary constraints from a large choice set. We used various algorithms for number of choices to be presented to the users in a time-sequential manner. One algorithm was the proposed Simple Feedback Algorithm, which was proven by the data collected to be the most quality-efficient.

The Negative Stigma of Coupon Redemption

Jennifer J. Argo, University of Alberta
 Kelley J. Main, York University

The present research explores the possibility that the positive act of redeeming coupons to save money is a socially stigmatized behavior. Further, we suggest that not only does a stigma exist for the consumer who redeems a coupon but that the negative stigma extends to influence other shoppers in close proximity to the consumer. The results of a laboratory and a field investigation confirm that coupon redemption is a negatively stigmatized behavior and that its negative implications extend to impact other non-involved bystanders.

Relationship Stages and Consumption Patterns: Variations in Object Attachment and Importance of the Brand

Maria Sääksjärvi, HANKEN–Swedish School of Economics and Business Administration
 Ryszard Kedzior, HANKEN–Swedish School of Economics and Business Administration

Consumers' interpersonal relationships have often been excluded as explanatory variables in consumption behavior (Richins, 2001), despite their ability to affect consumption practices (Johnson and Thomson, 2003). As intimate interpersonal relationships relate to consumers' happiness, feelings of self-esteem, fulfillment, goal achievement, and general well-being (e.g., Leary, 1999; Leary and Downs, 1995; Peplau and Perlman, 1982; Mikulincer, *et al.* 2003) they are likely to influence both the type and the volume of products consumed.

We propose that the effect of interpersonal relationships on consumption behavior can be observed by taking into account different relationship stages. For example, research has shown that divorced men and women dine out more often than their married counterparts, and women spend more money on shoes and hair care if they are divorced rather than married (Silverstein and Fiske, 2003).

If consumption patterns differ across stages of the relationship cycle, marketers could approach consumers with more targeted advertising messages when their relationship stage could be identified. Similarly, consumers could better protect themselves from persuasive messages by recognizing that a particular relationship stage might leave them vulnerable to such claims.

The purpose of this paper is to present a framework of consumption patterns across relationship cycle stages. We propose four different relationship cycle stages—single life, infatuation, committed relationship, and dissolution—and relate them to object attachment and the importance of brands. Each stage is signified by a distinct combination of object attachment and brand importance, in which brand importance can be high or low and object attachment broad or narrow, and deep or shallow. Breadth of attachment denotes the volume of objects that the consumer is attached to, whereas depth signifies the meaningfulness of the attachment. Brands are separated from objects, as they are vehicles of self-expression used for the creation of an ideal-self (Hogg *et al.*, 2000).

Consumer lifecycle stages and consumption

In the *single life* stage consumers are seeking to define their self-identity. An identity is effectively communicated through the brands the consumer chooses. For example, a woman can choose to be a sporty Esprit girl, or a classy Armani woman. Product categories that are often used for the purpose of communicating one's identity are those that are highly observable in nature, such as clothing, beauty products, and services, which can communicate the status and attractiveness of the owner. Therefore, we predict the importance of brands, as well as the object attachment to increase. More specifically, we predict that the object attachment increases both in breadth (as there are many objects the consumer is likely to be attached to) and in depth (as the meaning the consumer attaches to objects is likely to be very elaborate).

In the *infatuation stage*, a consumer has found a potential partner that s/he is infatuated with. To maintain harmony and ensure the success of the relationship, consumers often try to communicate their ideal self-identity to their partner. As a result, the importance of brands (as they signal status and quality) is likely to remain high. However, the breadth of the attachment to objects is likely to decrease. With the advent of the new partner, the objects no longer play such a central role they used to do. Thus, as compared to the single life stage,

in which object attachment was broad and deep and brands important, the broadness of the attachment as well as the importance of brands, is likely to decrease in the infatuation stage.

In the *committed relationship* stage consumers focus their attention on the relationship they have. In this stage, the breadth of object attachment decreases, as consumers are shifting their attention from objects to the relationship, and no longer feel the need to communicate a distinct identity. In contrast, the depth of object attachment increases, since the objects acquire bring additional symbolic meaning that is likely to be linked to the relationship (e.g., romantic dinners or holidays). Similarly, the importance of brands decreases, since consumers no longer need brands as much to reinforce their ideal-self.

During the *relationship decline and dissolution* stage consumers begin to separate themselves from the relationship identity, and start seeking a new individual identity. As a consequence, the breadth of their attachment to objects grows in view of the fact that consumers begin to experiment with new products. At the same time, the depth of the attachment decreases, as the objects are just trials, i.e. not meaningful *per se*. Simultaneously, brands are increasing their importance, since consumers start paying more attention to what brands can signal about their identity and use it for creating a new identity.

The existence of a link between a consumer relationship stage and his or her consumption pattern has several implications for both marketers and consumers. Consumers are likely to be more influenced by certain types of persuasive messages in particular stages of their relationships. Marketers could use this information to their advantage to better target those consumers who are likely to be most receptive towards the message. For example, consumers in the decline stage are more likely to be receptive towards innovations and products that involve excitement. As they seek for a new identity they are willing to experiment with a variety of products. Brands of the products, on the other hand, should be communicated to single consumers or those in the beginning of a relationship, as they are more susceptible to use a brand as a signal of status and quality.

Consumers, on the other hand, could overcome vulnerability associated with particular stages (such the decline stage), if they can link their feelings to a particular stage. Recognizing that consumption might be a reflection of a particular relationship stage that might leave the consumer insecure can help the consumer limit or control excessive spending.

Attributional Processes during Product Failures—The Role of the Corporate Brand as Buffer

Sabine Einwiller, University of St. Gallen

Michaela Waenke, University of Basel

Andreas Herrmann, University of St. Gallen

Jakub Samochowiec, University of Basel

Information about product failures is expected to deteriorate brand attitudes. However, our research indicates that the harmful impact is attenuated if the responsibility for the failure can be assigned to a superordinate brand. We found a significant interaction between the favorability of product information and the strength by which a product brand is endorsed by a corporate brand. Negative information reduced attitudes towards the product brand but only when the product brand was not strongly endorsed by a corporate brand. These findings call for the incorporation of the corporate brand's function as buffer into the models of brand architecture.

People We Love to Love and People We Love to Hate: Predicting Desired Outcomes of Reality TV Scenarios

Jennifer L. Young, University of Texas, Austin

Julie Irwin, University of Texas, Austin

This study seeks to uncover the qualities of participants that people look for when deciding on a reality TV contestant to root for or root against. We examine the relationship between a number of respondent ratings (e.g., similarity to self, attractiveness, intelligence) and the respondents' desire to see the contestant win or lose. We expected, and found, that preference for contestant success depended on the type of reality show (we tested four basic types: relationship drama, sadism, trickery and glamour).

The Sphere of Pure Consumption: Outsourcing the Production of Sacred Commodities

Teresa Davis, University of Sydney

Olga Kravets, University of Sydney

This paper explores the phenomenon of outsourcing of production of sacred 'commodities'. The example of the international markets for adoption is examined as one manifestation of such outsourcing. The creation of distance and separation between the 'production' and 'consumption' cycles is offered as one of the ways consumer markets seek an utopian market where production does not taint consumption. The industrialised late capitalist economies are seen as becoming a sphere of pure consumption, while the less industrialised economies in transition are seen more and more as bearing the lion's share of production of these 'products'.

Market Agents' Roles in the Maintenance and Transformation of Rituals

Behice Ece Ilhan, Bilkent University
 Ozlem Sandikci, Bilkent University

Extended Abstract

Following Rook's (1985) seminal work on ritualistic dimensions of consumption, numerous studies investigating the content, context, and major elements of different rituals appeared in the marketing literature (e.g. Lowrey and Otnes, 1994; Sherry and McGrath, 1989; Wallendorf and Arnould, 1991). These studies demonstrated symbolic significance of rituals and reported their dynamic nature. However, while it is noted that "the marketplace significance of rituals ... is striking" (Rook 2004, p.315), very few studies to date examined the role of market agents in the maintenance and transformation of rituals. The exceptions include the studies looking at the role of retailers (McGrath 1990; Otnes 1998; Sherry and McGrath 1989) and the relationship between advertising and consumption rituals (Otnes and Scott 1996). Motivated by this gap, this study seeks to identify the market agents and explore their roles in reproduction and transformation of rituals, using dowry practice—a form of marriage payment—in Turkey as a case study.

There are two reasons for our focus on the dowry practice. First, dowry is a long-standing and commonly performed wedding-related ritual in Turkey and many other Asian countries, including India and China (e.g. Tambiah, 1973; Croll 1984; Siu 1993; Bhopal, 1997). While the content of dowry varies from culture to culture, in general, it involves the gifts given to the bride, the groom, and the groom's family by the bride's parents. Irrespective of its content, it is a highly symbolic ritual that marks the transition from childhood to adulthood and from being a daughter/son to a wife/husband. Second, several studies report major transformations in the nature and content of dowry ritual in different cultures it is practiced (e.g. Rao, 1993; Caldwell et al., 1983; Banarjee 1999; Yan 1996). A recent study demonstrates that Turkish marriage dowries have undergone major changes as a result of the country's economic development and urbanization (Sandikci and Ilhan 2004).

Traditionally, Turkish dowry is confined to the textile products such as embroidery, clothing, bed linen, and carpets that are manually manufactured by the bride-to-be (e.g., Çelik, 1987, Tezcan, 1997, Öztürk, 1983). However, as a result of the changes in the social roles of women, the weakening of traditional lifestyles, and the emergence of independent manufacturers, more and more daughters and their mothers began to either buy ready-made dowry pieces or outsource the artifacts. Today, a prolific and expansive dowry market, composed of different agents producing various dowry pieces exists in Turkey. Our analysis indicates that there are several players in this market, including independent women, retailers, schools and institutes, collective exhibitions, and media that have the power and the means to both reproduce and transform dowry ritual through their design, production, and marketing activities.

So far, we collected data through a series of semi-structured, "long interviews" (McCracken 1988), observations, photographs, and supplemental materials such as newspapers, web pages, and business flyers. Depth interviews were conducted with four dowry shop owners and four independent women who work as freelance manufacturers in Ankara. The informants vary in terms of the size of the businesses, type of dowry preparation service they provide, and number of years in the dowry market. We have also visited dowry and marriage planning fairs both in Ankara (May 2003, 2004) and in Istanbul (February 2005) where we had the chance to observe different players in the market.

Preliminary analysis suggests that the market agents play three different roles: to mediate, consult, and innovate. The market agents assumed the role of the mediator as a result of the proliferation of dowry meanings. Traditionally, dowry included a pre-determined, fixed set of artifacts. However, as a result of urbanization and changing lifestyles dowry preparation became increasingly subject to negotiation (Sandikci and Ilhan 2004). While market agents transform the rituals through new or modified artifacts, scripts, and performances, they also reproduce the ritual through marketing 'classic' pieces. Overall, our study indicates that market agents have the ability to transform the dowry ritual and also the means to control the rate and extent of the diffusion of new artifacts, scripts and performances.

Spiraling Downward: An Illustration of Social Breakdown Theory and Its Relationship with Self-Concept

Brian P. Brown, Georgia State University
George P. Moschis, Georgia State University

Extended Abstract

Social breakdown theory (SBT) suggests that an individual's sense of self, his/her ability to mediate between self and society, and his/her orientation to personal mastery are functions of the kinds of social labeling experienced in life (Kuypers and Bengtson 1973). It contends that the media can be instrumental in creating negative social labels that adversely affect the self-concept of susceptible older adults. The result is a downward spiral that finds victims accepting the view that they are incompetent, ailing, and useless to society and subsequently believing and behaving accordingly. Kuypers and Bengtson (1973) argue that the elderly are more vulnerable to social labeling because of the "nature of social reorganization in late life" (i.e., role loss, vague or inappropriate normative information, and a lack of reference groups). Thus, the model has the potential to clarify why older individual's self-concepts may change in later life and the consumption related consequences of such changes (Moschis 1994).

While SBT is yet to be empirically tested in its entirety due to its dynamic nature, specific relationships between variables lend themselves to falsification. Our efforts were in a similar vein, testing specific relationships and the moderating effects of select variables.

Conceptualization

Over their life course, older adults are likely to face a variety of life transitions that require the acquisition of new norms, behaviors, and roles. SBT addresses the issue of how one's changing social world might result in changes in one's self-concept (Moschis 1994). The SBT model acknowledges that one's social system is in constant flux as it reflects new roles, norms, reference groups, and statuses characterized by different stages in one's life (Kuypers and Bengtson 1973).

Social roles are sets of expectations or guidelines for people who occupy given social positions, such as those of a widow(er), grandfather, and retiree. Yet, there appears to be little evidence of clearly-defined expectations concerning what the growing number of older people should do during their later years, as a result of transitions into various types of roles. The difficulty in determining the socially appropriate cognitions and behaviors for older adults is likely due to a number of factors. The transition to "old age" tends to be vague, amorphous, and unregulated, as the scarcity of rites of passage ceremonies that benefit children and younger adults reflects (e.g., graduation, marriage) (Rosow 1974). Additionally, the heterogeneity of older adults adds to the complexity of defining their social roles.

Kuypers and Bengtson (1973) assert that when certain social reorganizations occur in late life, the individual is deprived of feedback concerning "... who he is, what roles and behavior he can perform, and, in general, what value he is to his social world" (p. 182), due to a lack of normative guidance, role loss, and a lack of appropriate reference groups. As a result of the subsequent "feedback vacuum," the elderly are vulnerable to, and dependent on, external sources of self-labeling (e.g., the mass media). Moreover, these external cues tend to communicate negative, stereotypical messages of the elderly as useless and obsolete. In short, Kuypers and Bengtson (1973) contend that the effects of ambiguous role conditions leave older adults susceptible to the negative cycle of social breakdown syndrome because they rely on negative, external labeling that gradually erodes their self-concepts; ultimately, they accept a self-concept of a person who is useless, obsolete, and inadequate. Kuypers and Bengtson (1973) predict that the consequence of this pattern is an atrophy of coping skills. However, they contend that SBT's downward cycle can be broken and even reconstructed through certain personal circumstances and/or interventions (e.g., his/her health, financial resources, and housing situation).

The present study considers the basic foundation of the SBT model within the context of the life course framework. It proposes that various unexpected and anticipated life events that older adults encounter require transitions to new and not well-defined roles. Resulting feelings of role loss or discontinuity will lead to a susceptibility to negative labeling (i.e., via media messages) that weakens one's self-concept and results in the initiation or intensification of emotion-focused coping strategies (Folkman and Lazarus (1980). This progression may be moderated by one's financial status, health, and education.

Method

The data used in this study was based on a national mail survey of 695 U.S. consumers who were part of a panel. Because SBT applies only to elderly individuals, this number was reduced to 314, by limiting analysis to only those respondents 60 years or older.

Regression analysis was utilized to test the relationships between role discontinuity events, declining self concept, and emotion-focused coping strategies. The moderation effects of media, education, income, and health were also tested.

Major Findings

The hypothesis that the relationship between one's self-concept and emotion-focused coping strategies was supported. The mass media measure did not emerge as a significant moderator of the relationship between role discontinuities and declining self-concept. A key finding of this study was the moderating effects of health and education as they relate to anticipated life discontinuities and one's self-concept. Apparently, the impact these factors might have on the elderly's stability of their self-concept due to role discontinuities in later life has important societal implications.

Developing and Testing the Cultural Embeddedness of Products (CEP) scale

Alexander Jakubanecs, Norwegian School of Economics and Business Administration

Magne Supphellen, Norwegian School of Economics and Business Administration

Extended abstract

Background

National culture seems to be an increasingly important variable in consumer behavior research. First, the variety of products from all over the world is growing in most Western markets. At the same time, there is now stronger political pressure to display the origin of products, especially within the European Union. Moreover, previous speculations about convergence of national cultures (e.g. Levitt 1983), are countered by recent evidence showing that many cultures are in fact diverging along several dimensions (de Mooij 2000; de Mooij 1998).

Research on cultural meaning of products has typically adopted a qualitative anthropological approach (Applbaum and Jordt 1996; Thompson and Haytko 1997). Past research has provided useful insights of how consumers ascribe cultural meanings to specific products. However, in order to study larger numbers of products and exploit the advantages of multivariate statistical analyses, we need quantitative measures of focal concepts. In this research we develop a scale for measuring the type- and extent of national cultural meaning embedded in products, the CEP-scale.

Defining the CEP construct

CEP is an individual level variable and refers to the degree to which a product category (e.g., pizza, meatballs, orange juice, TV, jeans, etc.) is perceived to be embedded in a given national or ethnic culture. The dimensionality of the construct was uncertain ex ante. Our research strategy was to develop a broad set of scale items and look for different dimensions by means of factor analysis.

We used three theoretical frameworks in developing the scale items: theories on transferal of cultural meaning to products (McCracken 1986), theories on symbolic interactionism (Solomon 1983), and social identity theory (Kleine et al. 1993). Furthermore, we consulted two experts on national culture and consumer behavior, one academic and a marketing director of a multinational consumer goods company. The items were developed to capture the interaction of meaning in consumer products with the culturally-constituted world and consumers' self-concepts. The initial list included 17 items, such as "when consuming this product, I feel that I am part of the national tradition" and "this product is probably found in some folk tales, songs, or jokes (of this nation)".

Method and major findings

The CEP Scale was tested on two non-student samples in Moscow, Russia (N= 201 and 238). Five products were included in both tests. Products were selected systematically to provide variation in the expected level of cultural embeddedness: ketchup (low), soft drink (low), vodka (high), mors (a special kind of juice based on berries; high CEP), and pelmeni (a special kind of meatball; high CEP).

Based on the first dataset we performed exploratory factor analyses in order to explore the dimensionality of the scale. Regardless of extraction- or rotation schemes, the analyses tended to converge in two factors, but with some sign of a third factor (explained variance, all factors: about 65%). The two major factors seemed to represent a descriptive CEP dimension (items such as: "This product could be

used by foreigners, e.g. in movies or stories about Russia, in order to describe something typical Russian”), and a personal CEP dimension (items such as: “as a Russian, I probably have other thoughts and feelings for this product than other people”). One or two items, though, tended to load on a third factor. These items referred to a public aspect of CEP (item: “If other Russian were to see me using this product, he or she would perceive me as a typical Russian”). This third factor was interesting from a theoretical viewpoint, because previous research has shown that the self-concept has a private and a public dimension (e.g. Richins 1994).

Hence, we developed three more items in order to cover a potential public aspect of CEP. In a new study of Russian consumers (N=238) involving the same five products (ketchup, soft drink, vodka, mors and pelmeni), the revised scale was tested for both a two-factor and three-factor structure via LISREL.

The results tended to support a three-dimensional structure for the CEP Scale. There was a better fit for the three-dimensional model, in particular for two product categories-vodka and mors. The fit indicators for the three-dimensional model were CMIN/df=2.445, NFI=0.859, CFI=0.910, RMSEA=0.078 for vodka and CMIN/df=1.747, NFI=0.876, CFI=0.942, RMSEA=0.092 for mors. Preliminary evidence of discriminant and nomological validity was found by correlating the three CEP dimensions with related constructs such as the CETSCALE (descriptive CEP: $r = .044$, $p = .544$; private CEP: $r = .281$, $p < .01$; public CEP: $r = 0.246$, $p < .01$) and age (descriptive CEP: $r = -.05$, $p = .488$; private CEP: $r = -.168$, $p < .022$; public CEP: $r = -.106$, $p < .138$).

Moreover, the three dimensions of the CEP-scale correlated differently with these other variables. This finding supports the validity of a multidimensional definition of the construct.

Implications

The CEP-scale may prove to be a very useful scale for cross-cultural consumer research. In addition to measuring the extent of cultural embeddedness of a given category, researchers may use the scale to identify the *type* of embeddedness involved: descriptive, personal or public. Future research should validate the scale on other samples in other countries and in other product categories. Most important, research is needed on the effects of the different CEP-dimensions on information search and processing, attitude formation and choice.

Self-Gifting vs. Gifting to Others: An Examination of Psychological Orientation Differences in the Domain of Gift Giving

Suri Weisfeld-Spolter, Baruch College

Stephen Gould, Baruch College

Maneesh Thakkar, Baruch College

Extended Abstract

In the past, gift giving theory and research had typically been dyadic or interpersonal in nature (e.g. Belk, 1979). Nonetheless, it was acknowledged that people may sometimes give gifts to themselves, and in 1990 the first empirical investigation on the topic of giving gifts to oneself was conducted and self-gifts were conceptualized as (1) personally symbolic self-communication through (2) special indulgences that tend to be (3) premeditated and (4) highly context bound (Mick and DeMoss 1990b, p.328).

Since its inception into the marketing research domain, it has been suggested that the self-gift phenomenon may be widely occurring in American society (Mick and DeMoss 1990a, 1990b) and two predominant contexts of self-gift behavior have been identified: reward and therapy (Mick and DeMoss 1990a, 1990b, 1992). Other research has substantiated the notion that self-gifts are a fairly common and important phenomenon particularly in western consumer behavior. According to social researchers, Western individuals have become increasingly self-oriented in their purchases and consumption behavior (Mick et al. 1992). Similarly, McKeage et al. (1993) believe that people have been giving gifts to themselves since the early beginnings of self-indulgence. Mick et al. (1992) advise that if self-gifts are as prominent in American society as some past research has suggested, then it’s a phenomenon marketers cannot afford to ignore or misunderstand.

Specifically, McKeage et al. (1993) suggest that future research might examine affective responses to self-gifts versus gifts-to-others. Additionally, Mick and Faure (1998) suggest that therapeutic self-gifts may result from a different type of psychological process than reward self-gifts. Extending Gould and Weil’s (1991) study of gender differences in buying gifts for same sex friends versus opposite ones, (they found that males described themselves differently in terms of masculine and feminine traits when buying gifts for same sex friends

as opposed to for opposite-sex friends, while females tended to be more consistent across these two situations,) we predict that psychological gender orientation will be triggered differently based on the gifting scenario (self-gift vs. interpersonal gift) and such psychological differences will have affective and cognitive implications for consumer decision making in gift buying situations. Further, we hypothesize that these differences will exist between the two contexts of self-gifts as well (reward and therapy).

When measuring gender orientation, prior research has suggested that people who score high on the feminine dimension are said to be nurturing whereas people who score high on the masculinity dimension are said to be more instrumental. Similarly, we would like to add to the self-gifting literature by examining affective differences (nurturing vs. instrumental) that may exist between the two self-gifting contexts and interpersonal gift giving situations by measuring individual's gender orientation in these different contexts. Psychological gender orientations have been shown to substantially mediate many of the gender differences in a range of behaviors in that the more women resemble men along gender dimensions, such as masculinity and femininity, the more similar their behavior (Helgeson, 1994). Models of psychological androgyny have supplanted the prior bipolar models of gender, in the sense that both sexes are viewed as capable of having both masculine and feminine qualities (e.g. Bem, 1974)

Therefore, we hypothesize that when gifting to a friend, individuals will feel more nurturing and score higher on the feminine dimension, and when self-gifting, they will feel more instrumental and score higher on the male dimension. Additionally, between the two self-gifting scenarios we predict that the therapeutic (reward) situation will result in higher feminine (masculine) scores than in the reward (therapeutic) situation. To test our hypotheses that gender orientation changes depending on the gift-giving scenario, we conducted a pretest with 34 subjects and found strong support for our predictions. In the pretest we also observed that subjects seemed fatigued filling out the full BEM Scale (60 items) three times. Thus, we ran the ANOVA with a reduced 20 item BEM scale (Barak and Stern, 1986) and still found significant results. We then used this reduced BEM scale, confirmed by a Factor Analysis, in our main study with 85 new subjects. The method was similar to the one used by Gould and Weil (1991). A within subjects design was used where subjects randomly received counterbalanced questionnaires and were assigned to three gift giving scenarios: self-gift reward (SGR), self-gift therapy (SGT) and interpersonal gift (IG). Subjects were told to imagine a certain gift-giving scenario and then asked to fill out the BEM scale; they repeated this task for each of the three gift scenarios. Subjects were also asked a number of items designed to assess subjects' feelings when comparing the different gift giving experiences.

A one-way ANOVA with scenario condition (SGR, SGT and IG) was run on the measure of gender-orientation based on the BEM scale inventory score. The analysis produced significant results ($M_{SGR}=-0.88$ vs. $M_{SGT}=5.61$ vs. $M_{IG}=14.27$, $F(2,230)=31.808$, $p<.001$). The means support our predictions, as the gender orientation is significantly different in all three situations and more feminine in the self-gift therapy situation as compared to the self-gift reward situation (in which it is more masculine and not feminine at all). Further, we also ran a one-way ANOVA with scenario condition split at two levels (self gift (SG) and interpersonal gift (IG)), the results support our prediction that gender orientation of the individuals varies based on the gift context an individual faces ($M_{SG}=2.36<M_{IG}=14.27$, $F(1,230)=49.716$, $p<.001$). Additionally, as predicted, in the interpersonal gift situation, individuals' gender orientation is more feminine than in that of the self gift situation where it is more masculine.

Our study makes two important contributions. First, it adds to the self-gifting literature by proposing that psychological gender is one aspect that differentiates the two main contexts of self-gifting. Second, this is a pioneering study that directly compares self-gifting and interpersonal gift giving and shows how they differ with regards to individuals' psychological states. Future studies should examine other affective and cognitive differences that may exist in this domain.

Perceptions of Counterfeit Consumers

Stephanie Oneto, University of Houston

Jill M. Sundie, University of Houston

Counterfeit products, such as fake Luis Vuitton handbags and Oakley sunglasses have become widely available in the marketplace to consumers worldwide. The international trade of counterfeit products has been estimated at over \$100 billion per year, or 3-6% of sales overall. As a result, it is estimated that corporations have experienced a global loss of \$200 billion both through lost sales and damage to brand equity (Review of Business 2001). Although the magnitude of this phenomenon is staggering, consumer research in this area has remained sparse. The current research aims to be filling this gap.

Consumers often purchase luxury or prestige products for their ability to communicate information regarding their social class, or to indicate their membership in a valued reference group. Previous research has shown that consumers who purchase expensive luxury items often place greater importance on the status or image associated with the product than with the product itself (Dubois and Duequesne 1993). Some consumers of counterfeit luxury products may be attempting to capitalize on the symbolic nature of a prestige brand without paying the premium price. If luxury products and prestige brands convey information about the owners' social status to others, consumers of authentic looking counterfeit products are sending inaccurate information about their social status. Social Identity Theory (SIT) holds

that people will form negative impressions of individuals deliberately attempting to misrepresent their social status to others. The current research applies SIT to investigate perceptions of individuals that choose to purchase and display counterfeit products.

Social identity theory (Tajfel and Turner 1979) focuses on explaining the dynamics of intergroup relations, and has been applied to better understand the strategies members of low status groups use to increase their status both individually and collectively. According to this theory, people gain self esteem from their membership in social groups, and will pursue goals they believe will increase or maintain the status of their social groups. According to SIT, one way this is manifested is in the evaluations people make of in-group vs. out-group members. Individuals tend to favor or make more positive evaluations of members within their social group (in-group members) than members of other groups. Although the misrepresentation of one's social status through the purchase of counterfeit products violates social norms, people's judgments about counterfeit consumers, according to SIT, will depend on whether those counterfeit consumers are in-group or out-group members. This study tested the hypothesis that individuals will make less favorable evaluations of counterfeit consumers when those consumers are members of an out-group, compared to an in-group.

The sample consisted of 304 undergraduate students from a large Southeastern university. Respondents were asked to complete a survey, ostensibly about an online dating service, and evaluate an online dating profile containing a photo of either a Caucasian or African-American male target and information about his hobbies, likes/dislikes, and income. In addition, the passage also contained information about one of three possible products that the target had recently purchased (high status: Rolex watch, lower status: Seiko watch or counterfeit: replica of a Rolex watch). After reading the passage, respondents were asked to evaluate the target on a number of attributes: desirability as a date, desirability as a marriage partner, physical attractiveness, social status and trustworthiness.

As expected, MANOVA revealed a significant main effect of product status, such that targets portrayed as having recently purchased, and wearing, a counterfeit Rolex watch were rated significantly less favorably on all five dependent variables than those wearing either a Seiko or authentic Rolex watch. Consistent with our main hypothesis, a significant three-way interaction of participant race x target race x product type was observed when analyzing Caucasian and African-American respondents. In other words, when the subject's race matched that of the target, respondents rated the target wearing the counterfeit product more favorably than when the race of the target differed from their own. Results were similar for both the Rolex and Seiko watch. Now tell the reader in words what the three-way means. The results provide support for the efficacy of Social Identity Theory in understanding status consumption, and the hypothesis that perceptions of consumers of counterfeit products depend on the respective group memberships of the consumer and the observer. This study also suggests that consumers of counterfeit products are actually not acquiring the prestige and status they are seeking. In fact, their choice of counterfeit products may actually negatively influence the image these consumers project to others.

The Tiger Roars: Tribalism in a Non-traditional Australian Sport

Catherine Sutton-Brady, University of Sydney

Extended Abstract

The decline individualism and the rise of tribalism have now been noted by many researchers, (Maffesoli, 1996; Cova, 1997; Cova and Cova, 2001; Muniz and O'Guinn, 2001). Tribes according to Maffesoli (1996) are held together through shared emotions, life styles, moral beliefs and consumption practices. Additionally there has been much research, building on the idea of the "subculture of consumption" as defined by Schouten and McAlexander, (1995) as "a distinct subgroup of society that self selects on the basis of a shared commitment to a particular product class, brand or consumption activity". The definition was further expanded by Kozinets (2001) to groups whose members define themselves within a broader cultural context, finding meaning and community largely in terms of holding contrasting positions against that cultural background.

The traditional idea of community has also been challenged in today's world with increasing geographical mobility (Thompson and Holt, 1996) in a sense blurring the boundaries. What we are now seeing is the tribes or community being formed with no geographical boundaries (Tambyah, 1996). Many tribes today are based on sport and other leisure pursuits. Belk and Costa (1998) refer to these as transient consumption communities which result from serious leisure pursuits and are defined by shared experiences objects and actions.

This paper explores tribalism in the martial art of karate. Shotokan Karate a traditional Japanese martial art form has been practiced in Australia for less than 30 years, therefore is not considered a traditional Australian sport, but does have a significant following. Using ethnographic evidence gathered at the last World Championships in Durban South Africa, this paper introduces and showcases elements of tribalism and of the subculture of consumption which are evidenced by following the Australian team over three days of competition. Over the three days of competition we see evidence not only of tribalism in karate in general but clearly see it manifesting in the behavior of the national teams of various countries. These competitors and spectators share a passion for the sport. It gives them a sense of identity. The spectacle of the sport is enhanced by the opening ceremony. We see evidence of rituals, flags, chants setting the tribes apart, but conversely we see the shared meanings in rules of competition, karate gi (uniform) and an overall passion for the way of life.

The importance of karate as a way of life for the karateka was further evidenced in post competition interviews that were carried out, which reaffirm Maffesoli (1996) idea that "the accent is on that which unites, not that which separates". So while we clearly find differences between nations in their pursuit of competitive success they still define themselves based on their sport, showing a shared commitment to the sport. Many respondents spoke of their karate family, which for most was a global family, crossing many national boundaries.

Experiencing Motherhood: The Importance of Possible Selves to New Mothers

Emma N. Banister, Lancaster University Management School

Margaret K. Hogg, Lancaster University Management School

Long Abstract

Background

We report a small-scale exploratory study that investigated the interrelationships between consumption, identity and choice using the theoretical lens of *possible selves*. Mothers-to-be and new mothers are faced with important choices, as consumers, at a major transitional stage in their lives. We examine the impact that women's experiences of consumption choices had on the processes of their identity formation and stabilization as mothers ('the kind of mother I want to be', 'the kind of mother I don't want to be').

The transition to motherhood (Goldberg 1988:2) is a time when women learn about their new role and identity as mothers, experience changes in patterns of consumption as well as significant changes in their work/life balance (e.g. Fursman 2002). Identities may be challenged as different roles are experienced in competition (e.g. Fursman 2002), along with changes in women's relationship with others (Smith 1999a;b) and difficult consumption decisions (Prothero 2002).

New motherhood as a transitional stage can be linked to 'possible selves', which describe future possibilities not central to our current identity (Antonucci and Mikus 1988:69-73). Possible selves provide consumers with goals, aspirations, motives, fears and threats and the self-relevant information that individuals need to organize and give direction to their lives (Markus and Nurius, 1986). Women may have preconceived ideas about their 'possible selves' (Antonucci and Mikus 1988: 69-73) as they approach pregnancy and motherhood-'what kind of mother do I want to be?' and just as importantly, 'what kind of mother do I not want to be?' This study provided an opportunity to explore how women's choices in the early stages of motherhood are used to manage this process.

Method

Women were recruited for a small-scale pilot study on the basis that they had recently given birth to their first child. We used semi-structured interviews to identify the main themes and patterns of interest, and explore the choices made by our participants and the context in which these decisions were made.

We plan to develop our methodology on the basis of this pilot study and use a quasi-longitudinal approach. We hope to recruit twenty-four expectant new mothers and interview them at key stages in the transition to motherhood. Our qualitative approach will also incorporate diaries and projective techniques. Using a quasi-longitudinal approach will capture experiences of maternity and support services, as well as evolving experiences of mothering linked to consumption and identity as they are made, rather than relying on retrospective accounts, which could provide inaccurate accounts of pregnancy.

Findings

Our preliminary findings identify some of the key ways in which women's hopes, fears and expectations of mothering (possible selves) have impacted on the choices and decisions they made. We identify some of the key choices that our participants made at certain stages of their pregnancy/motherhood and identify the role of possible selves: in terms of the mother/parent that they wanted to be (ideal), their thoughts about the kind of mother they did not want to be (negative self), balanced with the pressure to fit with others' expectations (ought self).

The issues explored included pregnancy, birth, breastfeeding, attitudes towards immunization, specific consumption activities (for baby and/or for mother) and the interplay of actual experiences relating to new mothers prior attitudes and beliefs in the form of possible selves. New mothers' hopes and fears were exhibited in consumption decisions such as whether to purchase particular products (e.g. dummies/pacifiers), and whether to fit in with society's expectations (e.g. gendered products and colors) but also key experiences associated with motherhood such as the wish to breastfeed, yet the experience of difficulties in establishing breast-feeding. Our participants found themselves balancing their needs and expectations with those from a variety of sources (e.g. friends, family, work colleagues, health service professionals) and this was particularly challenging in some circumstances.

Discussion

The concept of possible selves provided a useful means to explore our first time mothers' experiences and the way in which they negotiated their way around some key decisions associated with new motherhood. This approach provides the potential to highlight women's expectations and the sources from which they take advice. Our research could demonstrate how women cope when their actual experiences of mothering (actual self) do not align with their hopes and expectations of mothering (ideal self), or the kind of mother I think I should be (ought self), and sometimes involve aspects of mothering they had originally hoped to avoid or reject (undesired self). These

hopes and fears can include consumption decisions such as whether to purchase particular products (e.g. pacifiers), and whether to fit in with society's expectations (e.g. gendered products and colors) but also the kinds of experiences highlighted within this paper such as the wish to breastfeed, yet the experience of difficulties in establishing breast-feeding.

Many of the decisions which women face at this time are likely to be influenced by the 'ought self' which are informed by discourses generated by social networks and public policy campaigns/ health care professionals about what constitutes 'a good mother' as well as family members and the social networks of new mothers. The discrepancies and psychological distances between a range of selves (e.g. ideal/actual; ought/actual and undesired/actual self—see Higgins et al. 1987) clearly had an influence on the consumption experiences of our mothers as well as their overall well being. The research contributes, theoretically, to our understanding of possible selves relating this concept to consumption choices into public services. It also contributes to our understanding of identity formation processes amongst new mothers—how identities are acquired or imposed; and the consumption practices in daily life (Reckwitz 2002; Warde 2003) which underpin the acquisition of the identity of mother.

Beauty, Brains, or Brawn: Idealized Male Images in Advertising

Patricia T. Warrington, Purdue University

Anna Gourgova, Purdue University

Extended Abstract

A number of researchers have examined the influence of the media, particularly advertising, on American perceptions of physical attractiveness and beauty, and the implications of that relationship on attitudes and self-perceptions. Most agree that advertising presents idealized images of individuals and the American lifestyle (Richins 1995). Enhanced by special effects capable of minimizing the least imperfection, many models and actors project virtually unattainable levels of beauty and physical attractiveness. Some even suggest that the thin and beautiful female model so pervasive in cosmetic and apparel advertising contributes to the development of eating disorders such as anorexia nervosa and bulimia (Richins 1991; Cattarin, Thompson, Thomas, and Williams 2000).

Social comparison theory (Festinger 1954) has been used to investigate the process by which people compare themselves with individuals in ads. Festinger (1954) proposed that humans have a drive to evaluate themselves through comparisons with others. Negative effects may occur when comparisons are made with others perceived as superior on a dimension of interest (upward comparisons) (Major, Testa, and Bylsma 1991), and these comparisons may be primarily automatic (Lyubomirsky and Ross 1997). Research indicates that for women, comparisons to idealized advertising images result in lower satisfaction with physical attractiveness (Cattarin et al. 2000; Richins 1991), decreases in self-esteem (Martin and Gentry 1997), and increases in moods such as depression and anger (Cattarin et al. 2000).

It appears that men as well as women make social comparisons to advertising imagery and that these comparisons impact male self-perceptions. Gulas and McKeage (2000) demonstrated that idealized images of financial success negatively reduced male subjects' level of self-esteem whereas idealized images of physical attractiveness had no significant effect. It may be then that men are subject to upward comparisons when idealized images reflect relevant features other than physical attractiveness. For example, media images that portray desirable characteristics such as athleticism or intellect may be influential in affecting male self-perceptions. The present study represents an exploratory effort to identify the types of idealized male images prevalent in contemporary print advertising from the perspective of the individual consumer, both male and female.

Method

Male fashion photos were chosen randomly by the researchers from recent issues of men's lifestyle magazines and retail catalogues. The selected photographs featured full-color, full-body shots of a single model (no other people or animals). All commercial text and graphics, including background and brand names, were removed using photo editing software. Eighty-six pictures were included in the final set. Participants were asked to sort the photographs into as many piles as they deemed appropriate on the basis of similarity of

appearance and to select the single photograph from each pile that best represented all of the photographs placed in that group. The participants were then asked to provide a word or short phrase of their own that best described the type of look depicted by each group of photos. Finally, each exemplar was rated in terms of overall attractiveness and a list of adjective descriptors (e.g., handsome, attractive, powerful) using a 5-point scale ranging from low (1) to high (5).

Results

Five distinctive clusters emerged from multidimensional scaling analysis.

Classic/ Elegant: This category portrayed male models who were elegantly dressed, very well groomed, and with serious facial expressions. These images were rated high on descriptors such as sophisticated, intellectual, classy, confident and intellectual.

European/Fashion Forward: This cluster of images was described as stylish and bold in their commitment to make a fashion statement. The reference to Europe may indicate that the models were considered less typically American-as though coming from the old continent of high fashion and extravagance. The images rated high on sophistication, mysteriousness, and intelligence.

Trendy/Casual: These images scored high on descriptors such as athletic, healthy, casual, outgoing, and rugged. This look was perceived as youthful and highly attractive.

Guy Next Door/Athletic: The guy next door appears to be the antithesis to the Classical/Elegant Look. These male images ranked high on friendliness, strength, and masculinity. On average, the models were perceived as attractive, but somewhat ordinary and regular.

Machol/Masculine/Sporty: Participants described this group as macho, strong, outdoorsy, healthy, yet more stylish than the Guy Next Door. The models in this group were closely linked to sex appeal, power, good health and an outdoor lifestyle.

Implications for Future Research

The results of this analysis suggest that consumers tend to categorize idealized print images of men in terms of types of attractiveness that emphasize lifestyle characteristics. As such, men may compare dimensions other than overall physical attractiveness with that of the models depicted in advertising directed toward them. Further research is needed to better understand which comparison dimensions are most relevant in eliciting upward and downward comparisons for men and under what conditions. It may be particularly worthwhile to study the extent to which idealized male images negatively impact self-esteem for pre-adolescent and adolescent males.

Image Consumption: The Study of Bridal Photography, Semiotic, and Feminine

Jin-Tsann Yeh, Vanung University

Chyong-Ling Lin, Lunghwa University of Science & Technology

ABSTRACT

The growth of the bridal photography industry could be a miniature of Taiwanese anthrop-sociology development records. In the past, the conservative bridal photography showed exaggerative make-up and bridal costumes that represented a semiotic of contemporary fashion. However, along with the import of Western information a new aesthetic awoke and educated Taiwanese women to reach an ideal state of self-confidence and autonomy. The research was drawn on the premise that the awareness of feminism was an effect of media exposure to women of new images and an overall development of anthrop-sociology as well. A researcher developed survey instrument and a visiting survey were designed and used to collect data from 550 randomly selected customers from the cluster of bridal photography salons. The finding revealed that modern Taiwanese women thought that they could be independent decision makers and were keen-witted and capable. They would ask for bridal photography based on the value of commemoration and self-expression and agreed that bridal photography represented beauty, romance, and happiness. Also, bridal magazines and friends'/relatives' recommendations were the best information resources.

INTRODUCTION

In preindustrial society, bridal photography was not a must-have commodity when two families prepared a wedding ceremony for the new couple-to-be. During that time, bridal photography was only taken at a groom's front yard on the formal wedding day. However, along with anthrop-sociology development and the economic boom, the modern couple-to-be sees bridal photography as one important step of the wedding ritual; they view bridal photography as their own business rather than old people's. They visit many bridal photography salons to try on the most fashionable wedding gowns, check the samples, discuss their preferred style with sales representatives, and pick a date prior to the formal wedding ceremony to take shots—it usually is an all-day long and very complex process. All they wanted to pursue was an ideal look for a day that could preserve and fulfill a romantic affair. Lewis (1997) indicated that “wedding photographs are powerful because they are traditional, professional, personal, and seemingly accurate renditions of reality as they help couples remember a key period in their social and personal lives” (p168).

Miller (1995) indicated that consumption could reflect cultural diversity, meaning, and value. Bridal photography consumption and popularization was just an angle which reflected the historical record of the growth of Taiwan society that our people gradually awoke along with the social-economic developing; they were aware of personal meaning and value in the material culture. Also, while foreign media such as modern art, movies, TV shows, and advertisement were introduced, they were disciplined to have different perspectives defining their own values of wedding photography as well as feminine social meaning.

The research draws on many researchers' premise that how consumers create meaning in their lives toward aesthetic, body image, and design operates interdependently along with anthrop-sociology development and advertising. The purpose of the study was to explore the interaction among the awareness of feminine self-esteem and self-actualization, semiotic, and bridal photography which might affect the new generation to abandon traditional concepts of the burden of marriage and create a new wedding ritual practice of creating an atmosphere of happiness.

LITERATURE REVIEW

The Development of the Bridal Photography Industry

Once, taking pictures was luxury and seldom happened, in the preindustrial era, only wealthy families could have the chance to take snap shots for fun or even possess a camera. However, most middle-low income families might invite a photographer to take shots for very formal and important situations to record family events such as births, weddings, and funeral ceremonies...etc. The purpose was to prolong a family memory and to unify the sentimental power of the family or a clan to the next generation (Bourdieu, 1990). Hence, it could be understood that photography, in the past, served only a social function instead of satisfying individual demand.

Adrian (1999) indicated that, before 1980, bridal photography salons did not provide full service but only rented white gowns. After several years, some bridal salons such as Lao Mai and Chongshi set the full wedding service package that included photography, head-to-toe styling, florists, and white gowns. Through a successful marketing strategy with advertising and promotion, the bridal industry soon developed their business. The sudden changed was unavoidable for those old-fashioned photo studios that became aware that proper weddings could not be achieved without an integral service package. Based on the demand, the number of full service bridal salons had rapidly grown to over 200 in the Taipei metropolitan district by 1997.

The minimal full package that the modern bridal photography salons provide usually includes at least 20 sheets of 12-15 inch enlargement pictures in an album, plus one additional 36-40 inch enlargement photo with frame which can be displayed on the formal wedding day. However, the price was not very easily met by the new couple-to-be; usually the bridal salons charge at least NT\$30,000 for the minimal full package in Taipei. The price was a little bit lower outside of the region.

New Feminism

The social status of women was very low historically in Taiwanese society. The economic boom, that caused feminine involved into working position, led an overall social-economic upgrade in education, income, entertainment, and cultural business. The development modified personal value to pursue higher self-esteem and self-actualization. Moreover, the import of foreign media such as movies, TV shows, magazines, and advertisements exposed people to different perspectives of feminine value, visual communication, and aesthetics (Figure 1 & 2). The women were introduced to a new feminism that changed their sense of aesthetics and their eyes fell on personal appearance and performance. Swinth (2002) pointed out that women in the media were both symbols and icons which helped create a new modern social order and set a new image for women to achieve and imitate.

McCracken (1986) indicated that when a viewer/reader glimpsed an object, a process of transfer would happen to the person. Hence, when the bridal photography industry emerged women became visualizations of ideology, and because of the Cinderella factor, women invested themselves to achieve the ideal beauty and self-realizing image in the bridal photographs as portrayed in public media (Figure 3 & Figure 4). The forming process of the new feminism was socially produced by the new image in the media. It involved a relationship of sharing meaning between people and objects via the power of symbols to communicate images and ideas which would be considered as cultural conventions (Kang, 1997).

Semiotics and Bridal Photography

Otnes and Scott (1996) declared that ritual semiotics were expressions that were designed to identify and transfer metaphors, moods, and arguments for products' image in particular motifs and for different occasions. Also, the identities and transfers could evaporate into our social constructions which would shift the audiences' capabilities and preferences to interpret products' image (Christensen & Askegaard, 2001). Therefore, the traditional bridal appearance was gradually changed when the new bridal image was introduced to us through bridal photography in bridal salons, along with the progress of Taiwan society.

According to bridal yearbooks, the traditional bridal photography was composed of black-and-white pictures, which did not have many poses and gestures. The new couple, in the past, was required to stand straight without any close touching (Figure 5) because marriage

meant a turning point for the two persons with new social responsibilities. The heavy and ugly bridal make-up style represented the idea that the woman had a new responsibility to take care of the whole family after removing the mask. However, in the new era, of the new feminism, the bride would like the emphasis to be on showing her inner beauty (double eyelids were no longer a standard of beauty in 21st century of Taiwan) (Figure 6) and her determination to look after a romantic and happy marriage. Their postures and gestures were no longer conservative (Figure 7, 8, 9, 10, 11, & 12), they particularly imitated models in the Western media because they wanted to show that they were sexy and confident. Furthermore, the new semiotic of bridal photography have revealed a reality that women had announced their autonomy from male dominance.

METHODOLOGY

The purpose of the study was to discuss the moving of the modern Taiwanese's perspective towards aesthetics, body image, design, as well as feminine awareness that could be told through modern wedding photography. Questionnaires and visiting surveys given to both consumers and bridal salons' managers were adopted as survey instruments to collect data. The survey's instruments consisted of demographic data, motivations to have wedding photography taken, brand images, senses of beauty, perspectives towards feminism, photography styles, product values, and symbolic meanings of bridal photography. Fifty consumers, ages 18-35, were chosen to do the visiting survey on the streets; five professional bridal salons' manager accepted our invitation to complete the visiting survey. Moreover, a sample of 500 visitors was randomly selected to fill in the survey from Aug. 29 to Sept. 11, 2003. The data from the questionnaires was analyzed by using procedures of the SPSS 10.0.

Findings of Visiting Survey

The Visiting Survey of Bridal Salons' Managers

The motivation to take bridal photography. According to Fand-Yu Lin, the Tia bridal salon's manager, *bridal photography represented and public ritual more than a personal demand because it meant a man and a woman decided to join hand in hand for the rest of their lives.* Vanessa bridal salon manager, Su-Ching Chiou, said that *bridal photography meant a lot for a couple because it represented that fact that they stepped into another phase in the journey of their life. That kind of joy, happiness, and excitement, which they strongly wanted to share with their relatives and friends, existed only in that moment and would not return forever. A groom might be deeply touched suddenly and feel his responsibility to his bride when he saw his lady appearing in a stunning dress. Hence, we would seriously undertake to provide the best service for each new couple.*

With regards to preserving the traditional custom, Mei-Lin bridal salon manager Xuan-Min Huang shared her personal experience that *some new couples would not dare to disobey their seniors and not have bridal photography done because their seniors seriously considered it to be a public ritual that proved the joining of two families. However, some new couples chose not to prove their marriage by having bridal photography done; they omitted the complicated process because they believed that the happy marriages need to be carefully cultivated and are not guaranteed by stunning wedding gowns or a series of delicately designed bridal pictures..*

Marketing of aesthetics. Most bridal salons' managers held quite similar perspectives in that they totally agreed that aesthetics was interdependent with anthrop-sociology development and advertising. According to Vanessa bridal salon manager Su-Ching Chiou *both staffs and consumers' sense of beauty could be informed from outside resources such as Western magazines or contemporary artworks. For example, she suggested that a bride could hold a silver tray or a designed basket with candies in it instead of the traditional wooden tea tray which was not quite in harmony with the stunning bridal style, to thank their guests at the end of the wedding.* She insisted on providing a different wedding to her customers by adding small changes that created a new aesthetics.

Moreover, Bazaar bridal salon manager, Che-Ming Lin intimated that most customers would hand him newspaper or magazine clippings that they wanted to imitate. He would further communicate with his consumers to shape a neat style which matched the current fashions and revealed their personalities as well. The most important thing was for the customer to not blindly chase the fashion; a good style also had to give a sense of the customer's individuality.

The new feminism. Most brides-to-be would gather many information before they took shots, and also they would positively participate to discuss their make-up, decorations, poses, and angles with the bridal salon staff. It was totally different from the tradition that women could not have any opinions for her marriage. Taipei Fashion bridal salon manager Mon-Yang Lu shared his experience that *grooms-to-be would express an attitude of indifference toward bridal photography. Nevertheless, brides-to-be show a determined attitude to announce their authority to direct the production of bridal photographs.* Vanessa bridal salon manager Su-Ching Chiou expressed that *the new women possessed a better ability to earn money; they could afford ideal bridal photographs. Modern women would ignore their future parents-in-law suggestions because they did not want to pretend they were satisfied with their arrangements.*

With regards to make-up and dress, Mei-Lin bridal salon manager Xuan-Min Huang pointed out *the modern bride did not like the bridal fashion of the past because it was a ridiculous custom where by the bride was packaged into a different person with heavy make-up, exaggerative decorations and gown. She indicated that light make-up and simplified gowns were the current trend. Brides especially like to show their backs in backless gowns which was not allowed in the past.* And Tia bridal salon manager Fang-Yu Lin said that *modern bridal photography reflected the new feminism in that brides were willing to show their attractive figures with décolleté gowns and that they were eager to show their beauty, character, and thought. They disagreed that "a woman without talent was the highest virtue" but they wanted to pursue self-esteem, self-actualization, and self autonomy.*

The Visiting Survey of the Consumers

The motivation to have bridal photography done. Most people agreed that taking bridal photography was a ritual to record a romance of two persons. "I want to capture a record of my beautiful appearance when I am still young. Bridal photography can help me to reach an ideal state where I will wear a gorgeous gown and delicate make-up. I feel very happy and proud when I see that I can be as beautiful as a superstars" (visitor#10). However, some people were concerned that bridal photography was a necessity although it would cost them a hefty expense. They thought "If I did not have to worry too much about the expense, I think I would feel more positively about bridal

Figure 1

Figure 2

Figure 3

Figure 6

Figure 7

Figure 8

Figure 9

Figure 10

Figure 11

Figure 12

photography. But it usually takes at least twenty-five thousands dollars or more for a package service; it is a great amount for me" (visitor#9 & 13).

The male consumers saw the bridal photography as something for only women. However, they were willing to give it a chance if they were physically fit. One visitor said "I am willing to have wedding photography taken to keep my handsome appearance as a memorial gift if I lose my weight" (visitor#4). However, some visitors did not like bridal photography because they thought the pictures were not very natural. For example, "I saw a totally different person modified by Photoshop. I think those pictures were only a fiction" (visitor#11).

Marketing of aesthetics. Price usually was the main concern for consumers before they decided to sign a contract with a certain salon. However, besides pricing factors, brand image, the photographer's sense of beauty, and the skill of photographers were influential factors for the prospective customers. One visitor said that "I feel insecure choosing a salon with an unknown brand name. Besides this, I will check the styles they created because I worry they do not possess enough sense of beauty" (visitor # 17). They also concerned that "the photographer is able to communicate with me, he must figure out and sense what kinds of style will match me because I do not want to get pictures that show no feeling of me" (visitor#12).

Nevertheless, some consumers were hardly able to sense or to judge what image those salons wanted to transmit "My friend introduced 'France Paris' to me because that name sounds in very classy, but I did not see any difference compared to the others" (visitor #19). Or, "I do not have strong feelings about bridal photography, but I only know 'Hidden Love' is a very romantic name" (visitor#10).

The new feminism. Sex appeal and self-expression were two important subjects of concern for the modern bride-to-be. They did not like the conservatively composed bridal photographs that bride and groom standing up straight without any smiles. They thought "I want to wear the different styles because I usually only wear one style in my daily life" (visitor#20). Or, "I do not care how others will judge me, because I want to have a different style to express myself from others" (visitor#12). To express sex appeal could be a one way to obtain self-esteem and self-actualization for modern women, "I especially prefer décolleté gowns because they makes me look very sexy and modern" (visitor#14). However, some visitors asserted that they would not choose gowns for their shot because "when I put on wedding gowns I look much older than my real age; I would rather put on casual dress for bridal photography. Besides, if we can wear comfy clothes such as jeans with T's in bridal photographs, we can have a free and relaxed attitude for our marriage" (visitor#11 & 23).

RESULTS AND CONCLUSIONS

Results

According to the statistical testing for the 455 returned questionnaires, the following research results were noted:

The majority of the respondents were female (69.5%), 30.5% of respondents were male. The largest group of respondents were from Taipei city (66.6%) and the age grouping of respondents were between 19-25 years of age (55.4%), 26-30 years of age (15.6%), and 31-40 years of age (18.0%). In addition, regarding the respondents' educational background, 46.6% respondents held bachelor's degrees, college degrees 26.4%, and high school degrees 18.2%.

The marital status of most respondents was single (73.2%) and the motivation of need was the main reason to consult with bridal photography salon (59.3%). Professional expertise of a photographer was the major reason to choose a bridal salon (42.4%), recommendations from friends and relatives were the second (29.0%), and price was the least concern for the prospective consumers (4.8%). Most respondents passively collected information (23.3%) because it was not a necessity in daily life. The reliable resources were bridal magazines (47.9%), friends and relatives' recommendations (43.1%), bridal shows (31.6%), and consultation with sale clerks (30.3%).

The main reason to have bridal photography done was commemoration (89.2%). The consumers asked for photo albums (47.7%), designed greeting cards and wedding invitations (43.5%), and photo discs (43.7%). With regards to the Western brand image, the respondents thought it was romantic (53.2%), fashionable (45.7%), and elegant (46.6%).

Both males and females agreed that modern women were independent ($M=3.81$, $SD=0.77$), keen-witted and capable ($M=3.59$, $SD=0.75$), and major decision makers ($M=3.49$, $SD=0.80$); nevertheless, they disagreed that women were commander ($M=2.92$, $SD=0.85$). The men slightly disagreed and reached significant difference that women could be powerful people ($t=-3.08$, $p=0.002$), were independent ($t=-2.99$, $p=0.003$), and decision makers ($t=-4.03$, $p=0.000$). In the other hand, the women respondents disagreed that women enjoyed wearing less ($t=3.44$, $p=0.001$), had only a beautiful and gorgeous appearance ($t=2.80$, $p=0.005$), and attracted men by appearance ($t=2.56$, $p=0.11$).

Most respondents associated bridal photography with beauty and self-confidence ($M=4.11$, $SD=0.77$), marriage ($M=4.02$, $SD=0.72$), and romance ($M=3.89$, $SD=0.71$). The youthful respondents translated bridal photography into romance ($t=2.34$, $p=0.02$), and showed difference concerning price ($t=1.96$, $p=0.05$), service ($t=2.41$, $p=0.016$), and quality ($t=3.38$, $p=0.01$).

With regards to the pattern of bridal photography, most respondents preferred backgrounds featuring Western attractions ($M=3.93$, $SD=0.83$), Western-style gowns ($M=3.59$, $SD=0.83$), and realistic photo styles ($M=3.60$, $SD=0.77$). In the contrast, the respondents were least interested to nude bridal photography ($M=2.65$, $SD=0.89$). The single respondents had significantly different feelings toward backgrounds featuring Western attractions ($t=-2.82$, $p=0.005$), the Western-style gowns ($t=-3.11$, $p=0.002$), and Japanese Kimonos ($t=-2.97$, $p=0.003$).

Most respondents strongly agreed that bridal photography was beautiful ($M=4.07$, $SD=0.69$), delightful ($M=3.97$, $SD=0.72$), and attractive ($M=3.76$, $SD=0.70$). Moreover, they agreed that bridal photography was commemorative ($M=4.21$, $SD=0.70$) and self-expressive ($M=3.70$, $SD=0.81$), but they least agreed that it was ambiguous and alluring ($M=2.88$, $SD=0.91$). The youthful respondents revealed strong agreement and significant difference that bridal photography represented self-expression ($t=4.48$, $p=0.000$), commemoration ($t=4.05$, $p=0.000$), and association with location ($t=2.35$, $p=0.019$).

Conclusions

The following conclusions were drawn from the findings and results of the data analysis.

The typical respondents lived in Taipei city and Taipei County, were female, 19-40 years old, and possessed at least a college degree or higher.

Most respondents were single, were highly interested in consulting bridal photography salons and were not much concerned about the price because they valued the function of commemoration more than anything else. Also, they preferred bridal salons that offered photo albums, designed wallet-size greeting cards, and wedding invitations.

Professional wedding magazines, friends and relatives' recommendation, and wedding exhibitions were the main resources for the prospective consumers. Nevertheless, the prospective consumers would choose services in a certain salon based on the photographers' expertise.

Most respondents agreed that modern women were independent, keen-witted and capable to handle major tasks alone, but women respondents agreed least strongly that women retained their positions in the workplace by wearing sexy dresses and maintaining a good-looking appearance.

Most respondents said that bridal photography was gorgeous and romantic. They believed personal glamour shots could present their personalities and commemorate their marriage. The youthful respondents were less concerned about the price factor but more interested in well-decorated banquet halls. It could attribute to modern feminism that women were daring to pursue and satisfy their personal desires.

Framing the Negative: Consumers and Consumption

Margo Buchanan-Oliver, The University of Auckland

Tatum Savage, Sony

Consumer researchers have conventionally studied the link between self-concept and consumption choices within a positive frame (Grubb and Grathwohl 1967; Sirgy 1982; Solomon 1983; Belk 1988), thus generally neglecting the negative circumstances of consumption. Others have long recognized that consumption is more convoluted than a mere response to need, want, or desire as people are also motivated by negative emotions (Bourdieu 1984; Miller 1997; Wilk 1997). Consequently, consumer researchers must also understand those states of mind that negatively impact upon consumption practice.

Negative consumption, or anti-choice, depicts those products a consumer chooses not to buy (Hogg 1998) and researchers suggest that the conceptualised feared self (Markus and Nurius 1986; Ogilvie 1987), a negative possible self, is an effective concept to explore negative consumption (Patrick, MacInnis and Folkes 2002). However, no consumer research to date has employed the *actual* feared or undesired self in negative consumption.

Using an exploratory, emic research design this research sought an increased understanding of the role played by the feared self and, subsequently, the role played by negative product-user stereotypes (Hogg and Banister 2001), in negative consumption. In-depth interviews were employed to gain an understanding of negative consumption behaviour of beverages consumed within a social consumption context. The findings support previous assertions that choosing not to consume a product is just as relevant in shaping our self-identities as positive consumption, and that choosing to *not* consume those products associated with the feared self does play an integral part in shaping our social, public, and private self-identities.

However, this research also discovered a further significance of the feared self within the realm of negative consumption. The findings discovered that the role the feared self played was dependent on the experiential nature of the feared self, and that the conceptualised feared self is not as influential on negative consumption as previously considered.

Rather, it was those feared selves that were experience-based that played a greater role. Renamed as the *escaping self*, to differentiate from the conceptualised feared self, experience-based feared selves appear more powerful as indicators of negative consumption. Denoted by flights from both past and current selves considered unfavourable or undesirable by the respondent, the *escaping self* differed from that of a conceptual feared self because respondents became more involved in its suppression.

Furthermore, it appeared that the undesired *other*, or a negative product-user stereotype, emitted the greatest influence on negative consumption. Respondents commonly associated their avoided products with negative images of the typical product-user. Those beverages that were avoided due to a link with a negative stereotype produced a heightened emotional response and an enduring avoidance.

It was discovered that the negative image of appearing as someone that they are not, or someone perceived to have lesser qualities than themselves is, for these individuals, more fearful. Therefore, negative consumption appeared more influenced by the undesired *other* rather than the undesired self.

This research undertook a more dimensional analysis of the undesired self than previously employed, and in combination with an emic approach, allowed a deeper understanding of the feared self's influence on an individual's avoidance behaviour. This enabled a gained understanding of the role played by the undesired or feared self in negative consumption. It also discovered that conceptual feared selves differ from experiential feared selves (*escaped selves*) in their relative influence over negative consumption.

Additionally, this research provides an enriched comprehension of negative stereotypes, the role they play in negative consumption, and their relationship with the feared self, and suggests that the influence negative stereotypes exert over consumer avoidance behaviour operates at a higher level than that of the feared self.

Such increased understanding of how negative selves influence negative consumption will assist in marketers' positioning strategies. Marketers also need to be aware of the relative influence of the feared self, escaping self, and negative stereotypes in consumers' negative consumption behaviour. Identification of these negative selves or stereotypes would assist in implementing advertising and communication strategies well removed from representations of these undesired selves or others.

The contributions also extend to the consumer. This, and further exploration of negative consumption, will give consumers' confidence that the full scope of their consumption practices have been acknowledged, and that researchers recognise negative selves and their impact upon the preservation and enhancement of self-concept. Furthermore, this emic research highlights the relative impact of consumers' negative self-identities and negative stereotypes as perceived by them, and their relative impact upon their consumption choices.

SPECIAL SESSION SUMMARY

The McDonaldisation of Enchantment and Consumers Practices of Re-enchantment: A Dialectic View of Transformative Consumption

Craig J. Thompson, University of Wisconsin-Madison

We glide through contemporary shopping malls, our senses filled by a dazzlingly and dizzying array of sights, sounds, and seductive sales pitches. We choose our themed meals from a palette of standardized choices fortified with all kinds of differentiating symbolic additives. Our living spaces, conversations, and personal styles become increasingly interlinked with the ceaseless flow of calculated commercial images that promise an aura of mystery, sensuality, and authentic difference. In the midst of this consumer culture flux, lies Nietzsche's fabled myth of the eternal return: a perpetual repetition of unfulfilled quests and disappointing outcomes that are undertaken in hopes of attaining an elusive ideal. This session will place an analytic spotlight on this dialectical cycle of enchantment?rationalization?disenchantment?re-enchantment and the kinds of consumer desires and transformative consumption projects that it engenders. The papers in this session will analyze how this dialectic motivates particular forms of transformative consumption that are geared toward not only self-transformation but also to transformations in the very structure of market relationships.

This dialectic between disenchantment and enchantment has been a recurring analytic subtext of culturally oriented consumer research. Belk, Wallendorf, and Sherry (1989) chart the tensions and movements between sacred and profane consumption that animate everyday consumption and imbue special possessions with their invocative power. Arnould, Price, and Otnes (1999) reveal how natural servicescapes enable consumers to experience a magical transformation conspicuously absent from the rationalized flow of their everyday lives. Firat and Venkatesh (1995) trace out modernity's disenchanting and rationalizing trajectories and anticipate that the conditions of postmodernity will engender a new liberatory project of creative, playful, and enchanted consumption. Kozinets (2001) argues that ardent Star Trek fans (Trekkers) seek to align technological utopian promises of science with the emotionally charged realms of fantasy, myth, and mysticism. Kozinets (2002) analyzes the empowering and enchanting rituals that emancipate Burning Man participants from their usually distanced, prosaic, marketized social experiences. Brown, Kozinets, and Sherry (2003), find successful retro branding invoking the storied forms of myth that blend quests, nostalgic longing, and irresolvable mysteries into storied realms of enchantment whose delights draw from the past. Thompson (2004) argues that the natural health marketplace leverages the ideal of mystical enchantment through its mythological blending of Gnostic appeals to spiritual transcendence of the body and Romantic appeals to the magical and revitalizing properties of nature. Kozinets et al (2004) analyze ESPN Zone as a liminal and ludic space where consumers escape their routinized work lives by engaging in deep play; in this way, these consumers can see themselves as a part of a wondrous and transcendent spectacle, linked to fantasy, celebrity, and magical moments of athletic achievement. Muniz and Schau (2005) contend that the enduring loyalties and passions expressed by members of the abandoned Apple Newton community are steeped in an ethos of technomysticism and religiosity.

This family of studies can be parsed into two related but distinctive thematic categories. The first addresses how consumers rework and refashion the cultural/symbolic resources offered by the

marketplace to mitigate feelings of disenchantment. These studies emphasize the co-creation of meaning and suggest that consumers enchant consumption objects by situating them within layers of emotional and autobiographical significations. Consumers also actively created their own enchanted worlds of consumption through their participation in consumption communities and a multitude of liminal consuming spaces. The second set of studies analyze the ways in which the commercial market has responded and adapted to these ephemeral consumer desires for enchantment, via strategies such as retro branding (Brown et al 2002), using computer technology to create interactive domains for fantasy enactment (Davis 1998), and designing so-called "cathedrals of consumption," such as Las Vegas spectacles, themed shopping malls, theme parks, themed restaurants, cruise ships, magnificent high tech athletic stadiums, various forms of superstores, and state-of-the-art movies theaters (Ritzer 1998).

However, another turn of this dialectical cycle is now underway: a growing legion of consumers are expressing dissatisfaction with the pre-packaged experiences of enchantment that are made readily available within these cathedrals of consumption (e.g., Thompson and Arsel 2004) and are seeking out transcendent consumption experiences that convey the aura of magic and authenticity (Arnould, Price, and Otnes 1999; Kozinets 2002; Thompson and Tambyah 1999; Thompson and Arsel 2005). While specific studies have explored specific moments in this dialectic, little consideration has been given to the dialectic relationships that exist between these consumption modalities or discussed the transformative impulses that emerge from this cycle. The aim of this special session was to cast a theoretical spotlight on this broader set of dialectical relationships.

SESSION OVERVIEW

The dialectic between rationalization and enchantment can be traced to the formative stages of the modern capitalist system. From the outset, the rationalizing impulses of Fordism co-existed with the enchanting consumer dream worlds offered by department stores, arcades, and theme parks (Benjamin 2002; Leach 1993). This very tension also provides the genealogical and conceptual link between two of the more influential books ever written on the capitalist system: Max Weber's (1904/2001) *The Protestant Ethic and the Spirit of Capitalism* and Colin Campbell's (1987) *The Romantic Ethic and the Spirit of Modern Consumerism*.

Weber famously argued that the Protestant ethic, with its emphasis on hard work, delayed gratification, and rational self control, set the cultural stage for the high degree of capital accumulation and investment that capitalism required to flourish. Moreover, the Protestant ethic was highly compatible with the bureaucratic rationalization of production and economic relations that fueled the growth of the capitalist economy. Weber also laid the foundation for many contemporary cultural critiques of capitalism by warning that the expansionist tendencies of capitalism had the potential to create an iron cage of rationality that would disenchant the world and empty the human soul. Campbell's (1987) companion work argues that the Protestant ethic also demanded an intensive reflection on one's inner life and passions for the ostensible purposes of quelling any vestige of sinful thought. Campbell suggests

that this form of reflexive self-monitoring paradoxically stoked the imaginative hedonism and other forms of consumer fantasy that function as the cultural drivers of modern consumption.

George Ritzer (1993, 1998, 2001) further develops this dialectical relation by analyzing its contemporary manifestations in a postmodern economy oriented toward service (rather than manufacturing) and where lifestyle choices and consumption interests have become defining aspects of identity. According to Ritzer, the iron cage of rationality has taken the form of McDonaldization—that is, a process by which the principles of the fast-food industry—efficiency, predictability, calculability, and control through technology—are being applied, across the globe, to more and more sectors of social life. Across myriad contexts, Ritzer shows how these rationalizing principles have led to a high degree of cultural homogenization and also have transformed the very nature of work and consumption.

In his more recent work, Ritzer (2005) makes a dialectic turn by positing that McDonaldization also inspires consumer desires for enchantment, which the capitalist market then attempts to satisfy through a plethora of “cathedrals of consumption.” These consumption cathedrals are designed to attract and enchant consumers and thereby inspire purchases of the magical goods and experiences being proffered. Through this argument, Ritzer culls a postmodern synthesis from Weber and Campbell seminal explanations of rationalism and romanticism. The rationalizing tendencies of McDonaldization foster potent desires for experiences of enchantment. A staggering variety of themed servicescapes now stand ready to give consumers what the experiences of enchantment that they have been structurally predisposed to want. Paradoxically, these cathedrals of consumption adhere to the logic of McDonaldization by delivering commercialized and pre-packaged forms of enchantment and therein lay their most fundamental shortcoming.

Ritzer (2005) contends that enchantment emerges from moments of unpredictability and spontaneity but these qualities are antithetical to the imperatives for technological control and consistency that characterize branded servicescapes. As a result, these themed consumer environments can only offer rationalized simulations of enchantment and they consistently fail to deliver the feelings of awe, wonder, and surprise which are intrinsic to fully captivating experiences of magical consumption (see Arnould and Price 1993). The simulations of enchanting places are never quite authentic and never quite fill consumers’ experiential void. These conditions then set the cultural stage for a continuous cycle of consumer expectations and disappointments (a self-perpetuating cycle much like Campbell’s explanation of insatiable consumer desires). Trapped within the McDonaldized world of consumerism, individuals tend to see few ways out of the system and hence continue to pursue a futile project of enchantment through the paradoxically rationalized and predictable dream worlds produced by corporate capitalism. For Ritzer (1999) and many like-minded social critics (Lasn 1999), consumers are trapped in a resilient, multi-faceted, and hence pernicious iron cage of rationality.

This pessimistic account suggests that the dialectic between disenchantment and the quest for enchantment is a kind of closed loop that cycles through in perpetuity. Ritzer sees a glimmer of hope in an irrepressible impulse for creative self-expression. Ritzer, much like Lasn (1999), views creativity as the humanistic monkey wrench that can jam the system and open up venues for resistance and escape. In effect, consumers are seen as either being fully constrained with the iron cage of McDonaldization or they helplessly bang against its bars hoping to create an opening wide enough for an escape into some never quite specified Utopia. The papers in this session explore a different set of implications that follow from

this cycle of enchantment?rationalization?disenchantment?re-enchantment.

Ostergaard and Jantzen opened the session with a brief distillation of Ritzer’s “cathedrals of consumption” thesis. Next, they analyzed specific experience economy exemplars from a postmodern perspective to argue that Ritzer’s pessimistic view is premised on an outmoded modernist view of authenticity. Drawing from Baudrillard’s order of simulacra, they proposed that the very nature of enchantment has been transformed in ways that defy the assumptions of the Weberian tradition. Next, Thompson and Coskuner analyze an emerging form of marketing relationships- Community Supported Agriculture (CSA) through interviews with producers (e.g. farmers) and CSA members. Their analysis shows that CSA farmers and consumers are linked in a common project to create a new market form that forges an ethos of communal participation; that reintegrates consumers into the production process; and that rekindles connections with the magic of the land and food. Through the CSA model, farmers and consumers understand themselves as transforming the market system in a way that obviates the ills of corporate-dominated agri-business and more specifically the corporatization of organic farming. These same actions also imbue food consumption with an aura of magic that emerges through a symbolic contrast to the far more convenient and predictable world of processed foods and fast food chains. Sherry and Kozinets analyze the ways in which desires for spiritual epiphanies and sanctifying (and community building) experiences which traditionally have been fulfilled by organized religions are now actively constructed by consumers in spheres far removed from religious institutions. These re-enchanting practices map onto postmodern consumer trends by emphasizing a decentralized, grassroots, DIY participatory where there is no singular authority orchestrating the form that sacred experiences may take. Kozinets and Sherry argue that these consumer-centric actions are a re-enchantment of religious experiences and a means to reclaim experiences of the sacred from the rationalizing impulses of organized religion.

SHORT ABSTRACTS

“Is Re-Enchantment just Enchantment?: Towards an Understanding of a Second Order Enchantment”

Per Ostergaard and Christian Jantzen

Ritzer’s (2005) proposals for re-enchanting a disenchanted world are grounded in Weber’s (2001) arguments about the rationalization of the western world. Ritzer makes a direct comparison between the cathedrals of consumption and the cathedrals associated with organized religions. The enchantment in pre-capitalistic era is presumed to be quite similar to enchantment today. Is this comparison historically viable? We investigate this question through the lens of Baudrillard’s (1993) writings on simulation and simulacra.

“Politicized Consumption Community and Consumers’ Practices of Enchantment”

Craig Thompson and Gokcen Coskuner

This study analyzes a politicized form of consumption community in order to extend theoretical understanding of the enchantment-disenchantment dialectic. Community Supported Agriculture is a system of shared risk and consumer involvement (and commitment) quite distinct from conventional channels of food distribution. By vesting consumers in a specific organic farm and by encouraging consumers to get closer to the land, the CSA model immerses consumers in a world of unpredictability, surprise, and spontaneity that is quite conducive to experiences of re-enchantment.

“New Religions, Temple Burns, and the Reenchantment of Belief”

Robert V. Kozinets and John F. Sherry, Jr.

This study depicts the grassroots, themed, creative behavior of consumers at a popular American anti-market festival and analyzes them as ritualistic and touristic processes that decommo-
dify, resacralize, authenticate, and reenchant the processes of belief and meaning-making that have most commonly been provided by organized religions. Although the Burning Man festival has been explored as an autonomous zone of self-expressive communal and social regeneration, the significance of its sacred dimensions holds insights for consumer researchers interested in exploring meaning-making, authenticity, the sacred and reenchantment in contemporary religious expression.

SPECIAL SESSION SUMMARY

What's On Your Mind? Neuroscientific Approaches to Studying Consumer Choice

William Hedgcock, University of Minnesota

Akshay Rao, University of Minnesota

SESSION OVERVIEW

Consumers routinely make choices between multiple alternatives. There is a long tradition of research in several disciplines (i.e. Economics, Psychology, and Marketing) that provides normative and descriptive insight into how consumers should and do make these choices. Notably, the emergent literature on choice has veered away from standard expected utility theory and its associated axioms based on numerous observed violations of the predictions of the theory as well as the axioms. For instance, Prospect theory has now become the received view in much of marketing research on consumer choice.

Our session was designed to address a set of issues that derives from this perspective. Decision-making is a complex process that can involve emotional as well as computational elements. In particular, the assessment of risk, the making of tradeoffs, the role of social cognitive strategies, arousal due to anticipation and other aspects of a decision may play a role in the observed violations of expected utility theory, and are difficult to assess using traditional methods. The session featured three presentations that employ multiple methods including sophisticated functional imaging techniques to examine the processes employed by subjects as they are exposed to choice tasks.

The session accomplished three objectives: we provided insight into theoretical issues, particularly the role of emotion/arousal on decision-making; we highlighted the role of functional imaging and associated techniques that are quickly becoming important techniques to study brain processing; and we informed practitioners and public policy makers about how consumer choice is demonstrably contextual and labile, thus suggesting that extreme caution be employed in making generalizations about how consumers respond to choice sets.

ABSTRACTS

“Inferring the Role of Outcome Feedback on Choice using Neuroscientific Techniques”

John Dickhaut, University of Minnesota

Consumers face risky choices in a variety of settings, from purchasing financial securities to deciding on whether or not to purchase an extended warranty for a new car. We examine differences in the neural mechanisms that may occur in the evaluation of risky outcomes in the presence and absence of performance feedback. Employing behavioral and neuroscientific measures, we not only observe differences in performance quality but also observe differences in emotional response, depending on the presence and absence of feedback.

“The Neuroscience of Trust”

Kevin McCabe, George Mason University

Two settings in which consumers may employ trust are examined. In interpersonal exchanges in which the other player in the marketplace is known, the nature of brain activity is substantially different relative to exchanges with marketplace institutions (such as brand names). It appears that the anticipation associated with consuming a branded product may yield a different type of arousal as opposed to the system that has evolved to monitor inter-personal relationships.

“Brain Activation: Shedding Light on the Decoy Effect”

William Hedgcock, University of Minnesota

Akshay Rao, University of Minnesota

The decoy effect is a long-standing empirical observation of a violation of the regularity principle. According to this effect, the choice share of elements in a two-element choice set change upon the introduction of a third, irrelevant alternative. We observe and predict (based on behavioral as well as functional imaging studies) that the decoy effect occurs because trade-offs (between the original two elements) elicit negative emotion and the presence of the decoy makes the decision task easier and less laden with negative emotion.

A Holiday Loved and Loathed: A Consumer Perspective of Valentine's Day

Angeline Close, University of Georgia
George M. Zinkhan, University of Georgia¹

ABSTRACT

From a consumer perspective, we investigate the behaviors, rituals, meanings, and themes associated with Valentine's Day as it is "celebrated" in the U.S. The objective of our multi-method study is to provide insight into Valentine's-related rituals, themes, and meanings as a basis for understanding consumer behavior for this holiday. We seek to add to conventional thinking about the impact of Valentine's Day on various consumers in the U.S. We analyze consumer diaries, online postings, group interviews, surveys, and in-store observations to address three distinct research questions. Our research questions focus on: a) behaviors and rituals (both in-store and in the private sphere), b) key consumer meanings and emergent themes, and c) roles of marketing communications during this holiday. We report various behaviors and rituals and key meanings behind such actions. We find that this holiday is associated with extremes (e.g., consumers either love it or hate it). Commercialism and marketing communications contribute to consumers' reactions to this holiday by fostering materialism, togetherness, and gender roles. At the same time, there are strong anti-consumerism and anti-commercialism sentiments. We discuss consumers' perspectives on this holiday and suggest avenues for future consumer research on this unique holiday.

INTRODUCTION

Valentine's Day and the surrounding season is a time for rituals and romance in the U.S. This holiday is worthy of study due to the unique consumption, gift/card exchange, grooming, dating, and romance-based consumer behaviors associated with this holiday. Some of these Valentine's-related behaviors are ritualized to an extent. In a general sense, rituals organize life and give it meaning. Ritualized behaviors are important to study as they may propose consumer behavior principles, which in turn lend marketers to product and service positioning opportunities (Arnould, Price, and Zinkhan 2004, p. 93). Consumer rituals for this holiday are especially enacted by individuals in romantic relationships. Valentine's Day is generally known as the day for celebrating romantic relationships; yet, this day also celebrates other non-romantic relationships as well (e.g., familial, friendly).

For any type of relationship, however, this holiday celebrates commercialism and spending. This socially constructed, mass-marketed day and surrounding season is the stimulus for many consumers to purchase romantic goods (e.g., roses, chocolate, jewelry) and services (e.g., massage certificates, vacations) for both themselves and for their significant other. Furthermore, this holiday entices many to exchange "Valentines" or similar greeting cards for romantic partner(s), friends, and family members. In fact, over one-billion dollars worth of Valentine's Day cards sell annually in the U.S.

It is not to say that all consumers look forward to or even like this day of romance and rituals. For some, Valentine's Day serves as a somewhat unwelcome reminder of their "single status". For others, it is a time when society suggests that money should be spent as an indicator of affection. In fact, this holiday can be a source of obligation, self-loathing, and/or disgust for various segments of the

population. Such sentiments entail their own distinct rituals for this holiday (e.g., singles nights at clubs; self-gifts).

We believe that it is important to understand this commercial holiday from a consumer perspective. We focus on three research questions:

RQ1: What are the consumer behaviors and rituals associated with Valentine's Day?

RQ2: What are some key consumer meanings and emergent themes associated with the holiday?

RQ3: What roles do marketing communications play in shaping the holiday?

We address these questions via multiple methods of data collection, including: a) consumer diaries, b) online postings, c) surveys, d) group interviews, and e) in-store observations.

The following section reviews relevant social science research on rituals and gift exchange. Next, we describe our methods of data collection. We then report and discuss the findings.

LITERATURE REVIEW

Rituals and Valentine's Day

Rituals are sets of multiple, symbolic behaviors that: a) occur in a fixed sequence, and b) tend to be repeated periodically (Solomon 2002). We analyze the holiday further as it pertains to a variety of classifications of rituals. Valentine's Day is a holiday that is associated with a variety of cultural rituals. Cultural rituals are behaviors that occur in a relatively fixed sequence that are repeated periodically (Arnould, Price, and Zinkhan 2004). Other types of rituals that may be associated with this holiday are religious, magical, aesthetic, calenderical, and rites of passage (Arnould, Price, and Zinkhan 2004).

Such rituals may be further categorized as primarily personal rituals, ethological rituals, or consumer rituals. Personal rituals are those repeated behaviors that are performed via an individual's emotions and desires. Ethological (e.g., greeting, mating) rituals, however, are a component of biology (Rook 1985). Consumer rituals include possession, grooming, divestment, and exchange. Possession rituals occur when a product moves from the market to the place of consumption (e.g., home, workplace). Grooming rituals are often private behaviors that assist with transforming the private self to the public self and vice versa. Possession rituals may be grooming rituals, in the event that the individual is cleaning, polishing, or restoring the self or the extended self. Divestment rituals are performed as an individual dispossesses something (e.g., a grandmother's wedding ring). Exchange rituals (e.g., rites of passage) are often associated with gift giving and receiving. We note that rituals exist in cycles, which may be global consumption rituals (Rook 1985; Arnould et al. 2004). In any sense, rituals, often retail and market driven, organize life and give it meaning or purpose and may be apparent in various Valentine's-related behaviors.

Gift Giving and Exchange

A substantial portion of academic literature associated with Valentine's Day is devoted to the study of gift exchange (generally gift giving). For instance, the French anthropologist Marcel Mauss

¹Thank you to the informants who contributed to this study.

concludes that reciprocity motivates gift giving (1925). Since that time, pioneering insights have been added to that observation. Sherry (1983) combines anthropology (a social aspect) and consumer research (a psychological aspect), to create a macro-model of the gift exchange process. He recommends that the “reformulation” stage (the final stage of the gift giving process) should be studied thoroughly, as knowledge in this area is crucial to understanding the socio-psychological dynamics of gift giving (Sherry Jr. 1983, p.165). We consider these dynamics as important for understanding Valentine’s gift exchange and related rituals.

Goodwin, Swift, and Spiggle (1990) also examine motivations associated with gift-giving. They propose that gift giving is a product of either voluntary or obligatory motives; time, money restraint, and many consumer behaviors are affected by these motives. Belk and Coon (1991; 1993) explain how such motivations have traditionally been viewed from either an economic or a social model of exchange—inappropriate for romantic gift exchange.

Belk and Coon (1993) confirm that more emphasis should be placed on a modernized representation, such as the Model of Agapic Love. This model focuses on gift giving from a pure, unselfish, and altruistic viewpoint. Such a love-oriented model applies to a study by Huang and Yu (2000). Huang and Yu (2000) focus on a survival analysis for gift giving in a romantic relationship. They claim that links exist between gift consumption amongst partners and the length of the romantic relationship. Their findings apply to gift exchange for Valentine’s Day; however, their study is not specific to the holiday, as are the following studies.

Netemeyer, Andrews and Durvasula (1993) contribute a study entirely focused on Valentine’s gift giving. They show how three behavioral intention models may be applied to both planned and voluntary behavior. Otnes, Ruth, and Milbourne (1994) study attitudes toward Valentine’s gift exchange from the *male* perspective. They find that males have motives with respect to: purpose, gift/card giving, and the reasoning behind *why* males choose to engage in or opt out of the gift giving. Polonsky, Neal, Rugimbana, King, Bowd, and Porter (2000) follow the Otnes et al. (1994) study, and confirm the themes of obligation, self-interest, and altruism. In contrast, Polonsky et al. find that either obligation or self-interest is always present.

Few prior studies focus on non-gift rituals associated with this Valentine’s Day. Thus, one of our research questions focuses on exploring a more comprehensive account of consumer behaviors for this holiday. We will now discuss the methods we used to address the research questions.

METHODS

Table 1 summarizes our methods and informants, sample sizes, timeframe, and relevant details.

Method I: Diaries

Eighty-eight consumers kept diaries related to their thoughts and behaviors concerning the holiday. The age of diary authors ranged from 18–47, with a mode of 23 years-old. A relatively even distribution of males and females in various relationship statuses completed entries. Diary entries focused on the holiday’s: a) cultural rituals, b) male roles, c) female roles, d) enjoyment factor, and e) comparison to other holidays (e.g., meanings, associated marketing communications). Diary entries provide a personalized data source for this more intimate holiday.

To complement the offline diaries, we analyze online diary entries that have been published on the Internet. Online diary postings are often written under a non-recognizable screen name;

such anonymity provides for rich, truthful data concerning individuals’ sentiments and experiences with the holiday. While some individuals post with a first name and other information (e.g., age, city of residence), we are not always able to obtain the poster’s age or gender.

We used axial, open, and selective coding techniques for data analysis, and grouped similar entries into categories of meaning. Such contributed towards revealing the emergent patterns of each category (Wolcott 1990). The authors reviewed each other’s data interpretations until saturation.

Method II: Survey

For a supplementary perspective, we distributed a twelve-item exploratory survey on Valentine’s Day (2003) to college students. We administered one hundred surveys in order to gather insight from individuals in a romantic relationship. We included a screener question (i.e., Are you currently in a romantic relationship?). If the respondent reported to be in a relationship, they were directed to complete the survey. In total, we analyzed sixty-four surveys (thirty-two for each gender).

Survey items questioned the expectations, behaviors, perceptions, and the commercial aspects of this holiday. In addition, respondents indicated their age, gender, and whether they are in a “new relationship” (less than six months) or a more established relationship (six months or more) as suggested by Huang and Yu (2000).

Method III: Focus Group Interviews

Unlike the survey administered to both genders, we designed a focus group for female college students in a relationship, to encourage discussion without males present. We choose to focus on females for group interviews, as this is a more “female holiday” in the U.S. Furthermore, insight on male perspectives has been examined (e.g., Otnes et al. 1994; Polonsky et al. 2000) in extant literature. The focus group participants included six females (three in a new relationship and three in a more established relationship). An outside moderator served as the discussant. Two researchers took field notes during the session. The researchers debriefed the session and constructed overall themes and sub-themes.

Method IV: In-Store Observations

By conducting in-store observations, we witnessed aspects of commercial preparation for Valentine’s Day. The observations and fieldwork took place in floral departments of two large national grocery store chains and other retailers associated with the holiday. Observations took place at the first location, located in a southeastern city, during the week of and on Valentine’s Day 2003. A second round of observations took place at another grocer in a different town, on Valentine’s Day 2004. A final round of observations took place in a mid-size southwestern city the weekend before Valentine’s Day 2005.

At the outset of our study, we did not intend to focus on one specific kind of human relationship (e.g., heterosexual, homosexual). However, our informants tended to focus on heterosexual relationships or did not specify the type of romantic relationship.

FINDINGS

RQ1: WHAT ARE THE CONSUMER BEHAVIORS AND RITUALS ASSOCIATED WITH VALENTINE’S DAY?

A wide variety of rituals, often retail related, are associated with Valentine’s Day. We show five broad interrelated categories and their defining behaviors in Table 2. In light of our research

TABLE 1
Methods of the Study

Method	Informants	Time Frame	Details
Consumer Diaries (n=88)	Undergraduate Students Males and Females Ages 18-47; Mode Age=23 Any relationship status	2002-2004	Entries focused on the: a) cultural rituals, b) male roles, c) female roles, d) enjoyment factor, and e) comparison to other holidays.
Online Diaries/ Postings (n=22)	Anonymous posters to online diaries & message boards Males and Females All ages Any relationship status	2000-2004	Sources include: diaryland.com, opendiary.com, my-diary.org, pfft.com, diarist.net, mydeardiary.com, marketing science message board, various personal websites
Survey (n=64)	College students Males and Females Age 18-22 Currently in a romantic relationship	2003	Conducted on Valentine's Day
Focus Group Interviews (n=6)	College students Females Age 18-22 Currently in a romantic relationship	2003	Moderator's guide covered: rituals, meanings behind the holiday, traditions, reasons, and self-gift giving
In-Store Observations (n=41)	Customers at floral department and associated holiday retailers Males and Females All ages Any relationship status	2003-2005	Conducted on the week of and on Valentine's Days; field notes taken Conducted in the southeast and southwest

objectives, we will not discuss the meanings of *each* of these items; however, we focus on those that contribute to addressing our specified research questions.

Exchanging Gifts and Cards

Gift and card exchange is the most frequently mentioned behavior. One informant describes how she is just a *partial*-conformist to the American norm (Santino 1995, 1996):

Many people in America celebrate Valentine's Day by participating in the same rituals. The most common (gift giving and consumption) rituals are buying your loved one chocolate candy, red roses and wine. I also participate in these typical traditions, but I try and modify them for meaningful reasons. [F, Diary]

This informant, like others, partakes in traditional rituals, yet she maintains a sense of individualism on a day that is otherwise conforming to the consumption and/or exchange of specific products and brands. Valentine's is a day when many *speak of* giving personalized gifts in lieu of the "status quo" gifts of roses, chocolate, stuffed animal, and/or perfume. One way to optimize gift giving is to involve as many senses as possible. One informant describes her gift giving technique:

When I buy my Valentine's Days gifts, I also try to use all five senses. I will purchase some kind of candy for taste, flowers or cologne for smell, a nice dinner with candles so it looks nice, a winter shirt to feel warm in and I like to buy my loved ones a soft sound CD to listen to. [F, Diary]

Personalization is an important element of altruistic gift giving. She continues, as she discusses the importance of considering the preferences and tastes of the recipient:

I always try to put effort in my gift giving and personalize them too. For instance, my mom would prefer flowers and my dad would rather have cologne. So, whoever the person I am shopping for, whether it be my boyfriend, mom or dad I always try to be creative, use all five senses and most importantly show them my love. [F, Diary]

However, it is often more difficult and time intensive to select and purchase personalized gifts on this holiday due to the mass-production of Valentine's-related merchandise online and in on-ground retail locations.

Others view the entire idea of gift giving for this holiday as purely market-driven and store-bought. Many men have learned to "listen to the shelves" and to avoid certain gifts for romantic occasions (e.g., blenders, cleaning supplies). One man takes time to help other gift-givers by specifying what, in his experience, women *do* want for this holiday:

Any way, amigo, if you want her happy always remember: the gift has to shine or smell [good] or she should be able to wear it! Otherwise, you'll be doomed. [M, Posted 2-14-04]

This perspective is in stark contrast to many of the female posts, diaries, and discussions of appropriate gifts to give and to receive. Many females discuss how the gift exchanged should be meaningful to the couple, thoughtful, or unique.

TABLE 2
Valentine’s Holiday Consumer Behaviors & Rituals

Category	Specific Behaviors & Rituals Mentioned by Informants
Exchanging Gifts & Cards	Personalizing/non-conforming gifts, incorporating symbols (e.g., cupid, heart), decorating rooms/vehicles, incorporating senses, lighting candles, sharing chocolate anything, surprising loved ones with gifts or meaningful gestures, giving shiny or scented gifts, e-gift giving, preparing a special gift basket, giving specific items: red roses, flowers, concert tickets, teddy bear, pearls, diamond jewelry, engagement ring, chick-flicks, romantic movies or television shows lingerie, candy, diet candy, Spa Sydell half-day certificate, framed picture of the couple, car, new house, gifts for pets. Cards: personalizing, cutting out hearts, using artsy/crafty Valentine’ s, exchanging cheesy store-bought Valentine’ s, writing poetry, expressing true romantic feelings in a card, sending e-Valentine’ s, exchanging Valentine’ s with other singles, sending secret admirer cards, naming the “ Hallmark Holiday”
Showing Affection	Sex, kissing, making out, acting sensual, making loved ones feel special, slowing down, building a fire, cuddling on the couch, going on a date, romantic getaways, getting in the mood, love-making, celebrating love, spending time alone, enjoying each other’ s company, staying in together, avoiding the crowds, emphasizing commitment to one another, renewing vows, proposing, celebrating a romantic anniversary, getting married, snuggling, reading to each other, being grateful for each other, displaying affection, reminding friends and family they are loved, playing a game
Going Out	Nice restaurant, going to the ballet, parties, get-togethers, singles parties, fraternity date nights, hiring a sitter and escaping out, movies, theatre, concert, shopping, carriage rides, clubs, bars, spa getaways, weekend vacations, anti-Valentine’ s parties, going to virtual spaces: e-dating sites, singles chats, Valentine chat rooms, message boards
Preparing & Consuming Food/ Drink	Preparing romantic food, heart-shaped sandwiches, actually cooking in lieu of fast food, cooking surf-n-turf, aphrodisiacs, drinking expensive wine, drinking champagne, eating candy, candy hearts with messages, eating chocolate, avoiding cheap chocolate, eating alone, eating desserts, whip cream, avoiding overcrowded restaurants, having candle-light dinners on the back porch, picnics, expensive dinners
Grooming & Clothing	Wearing certain colors (i.e., red, pink) of lingerie and/or clothing, wearing pretty underwear, wearing heels, planning what to wear in advance, buying a new outfit, wearing sexy clothes, wearing a themed tie, putting on a cute outfit, getting dressed up to go meet singles, taking time off to groom, bikini and leg waxing, spending extra time on make-up, tanning, spray-tanning, getting a special hairdo, applying manicures/pedicures in pink or red, actually showering and brushing teeth, applying lotions and glitter, beautifying the entire body, looking better than other females, applying a temporary heart tattoo, wearing extra perfume, working out, shaving chest hair into a heart shape

Some males mention that the Internet makes it much easier to give feminine gifts (e.g., lingerie). These males share that they are uncomfortable spending time in a women’s lingerie store, such as Victoria’s Secret, aside from feeling that they make the women shoppers uncomfortable. One male reports that he actually enjoys giving lingerie—if it is purchased on the Internet:

Yeah, I enjoy the experience of buying a gift online. It makes it more efficient. Victoria’s Secret it is easier to go to online. Call me crazy. It is easier to do it online. [M, Diary]

Some informants also use the Internet to send online greeting cards for this holiday to friends and family members in certain situations. However, others choose to send an e-gift card:

I wouldn’t ever buy a card online and send it online (like an E-card), but I would buy a greeting card to have sent along with the gift. But if the gift card was a free E-card, then, yeah (I would send it), that’s not a problem. I don’t mind even just putting in a little note, five or so words in a message, that comes along with the gift when it is sent. I would even pay a couple dollars extra to make that message longer. [M, Diary]

To this informant, e-cards with gifts are an important part of the gift exchange and even worth paying a premium for; however e-cards should be free. Traditional, paper greeting cards (store-bought and homemade) are discussed as the more common form of card exchange among romantic partners. In general, these gifts and cards are a vehicle of showing affection.

Showing Affection

A key group of behaviors involves showing affection. Informants discuss relaxing with loved ones as a way of sharing affection. Whereas some individuals involve themselves with “holiday hype”, one young woman shares how she likes to slow down with loved ones on this holiday:

Even though Valentine’s Day is not necessarily about gift giving I enjoy the holiday every year just for the sole purpose that I get an extra chance during the busy year to let my loved ones know I care and have a nice dinner and celebrate each other’s love. My fondest memories of Valentine’s Day is every year building a warm fire after dinner and relaxing with each other. [F, Diary]

Kissing, making out, love-making, and sex are other behaviors informants commonly share as a way to show affection to loved one(s) for this holiday. This is one example of “celebrating” the holiday in the private sphere.

For those in and out of romantic relationships, more daring behaviors take place on Valentine's Day. This holiday makes it more appropriate to be direct with affection. This day is different:

There is a sense of magic, excitement, and romance. [F, Diary]

On this day, some take initiative to rekindle a relationship or connect with someone new:

It can be a day to try to find a loved one. It is a day when a secret admirer might emerge. [M, Diary]

It is the holiday that entices some to come forward with their romantic feelings.

Going Out

Although many celebrate the holiday intimately at home, a common Valentine's-related behavior entails “going out”. Many informants discuss going out on dates in the public sphere (e.g., movie theaters, parks, restaurants). Many singles choose to spend the holiday at singles events or with a group of other singles. This is one day where singles seek each other's company:

Singles might sit around in a group, watching movies or feeling sorry for themselves. Or, they might find a way to celebrate the day. [F, Diary]

One informant tells how this is the *one* night he is sure to go out to meet someone, because other singles are out celebrating, while the couples are home together.

Preparation and Consuming Food/Drink

Whereas many consumers go out and celebrate over dinner in a restaurant or café, others celebrate the holiday by preparing and consuming food and drink in the privacy of the home. Some consumers share that romantic dinners at home have the benefits of saving money, avoiding risks from drinking and driving, and have a comfortable and personal atmosphere.

Some of the more commonly exchanged and consumed items for this holiday are sweets and chocolates. Women often receive sweets on this day, and this consumption ritual is based on the assumption that women go weak for sweets (see Barthel 1989; Belk and Costa 1999). Some do not just like chocolate—they LOVE it. Such instances may explain why sweets are a common gift to women on Valentine's Day. As one woman explains:

It's not just candy. I have a fatal weakness for desserts. I love ice cream, cakes, pies, pastries, chocolate, fruit, and most other sweets with a passion. Whenever I go to a moderately nice restaurant, I'm mostly thinking about the dessert I could get at the end of the meal if I'm not too full. At Italian places, I dream of espresso pie and tiramisu, and most restaurants have good cheesecake. If it's homemade and comes in a pool of raspberry or chocolate sauce, I go weak at the knees. [F, Posted 2-14-03]

Such information may be of interest to men, as it appears that this woman would be pleased with gifts of chocolate just as much as expensive jewelry or roses. She is disappointed that her husband does not love sweets. It is not from the dieter's viewpoint (i.e., it is

unfair that he goes without sugar cravings), but from the pity-filled perspective that he is truly missing out on one of life's finer things:

It's a little disheartening that my husband doesn't share my love of sweets. He will happily eat ice cream or cheesecake or apple pie, but he doesn't seem to savor it, and really look forward to the next time the same way I do. The power sugar holds over me doesn't hold him. Some people in my situation would envy his self-control and lack of need of candy, but I just pity him, knowing he'll never understand what it's like to be in love with it. [F, Posted 2-14-03]

Just as chocolate and candy are frequently mentioned, red wine and champagne are the beverages many informants associate with the holiday. Wine is even a part of grooming rituals for some individuals on this holiday.

Grooming and Clothing

One grooming behavior of note is the act of “primping and priming”, or taking extra effort to look one's best. In the group interviews, the females discussed how grooming efforts on this day are much different from their everyday rituals. One woman spent hours beautifying herself for her new boyfriend:

I was so nervous getting ready for Valentine's Day when I first met my boyfriend, I literally attempted to calm my nerves by drinking a couple glasses of wine, and then beautified my entire body, from head to toe. [F, New; FGI]

Such a lavish grooming ritual may be more common for young women in new relationships. One woman, in a more established relationship explains that she no longer performs extraordinary grooming rituals:

I love my boyfriend dearly, but I don't think it is necessary to buy a new dress to wear for one night like I would have for the first Valentine's Day that we spent together! We tend to use the money that I would have spent getting my hair and nails done on something that we can both share together, like a really nice dinner. [F, Longer-term; FGI]

Unlike the young woman who shunned the need to buy a dress, another informant was proud of both her recent purchase and the way it complements her “purchased” skin tone:

I bought a new dress, but I had to make sure that it was classy but sexy at the same time. I made sure I had a nice color by going to the tanning bed a couple weeks prior to Valentine's Day. [F, New; FGI]

Such women in new relationships were *especially* eager to share their preparation rituals, and the session transformed into a “competition.” Many of the young women spoke at once, trying to surpass one another with their lavish doings. One woman in a new relationship seemed confident of her extra beauty efforts, as he took time out of her school and work schedule to groom:

I had to make sure that I had time to go to the spa to “fix” my body up for Valentine's Day. [F, New; FGI]

Some men may not believe (or desire to acknowledge) the preparation that some females go through; however, informants stated that their partners were extremely pleased with the final “product.”

Some of the ritualistic behaviors may seem unnecessary; however, these behaviors contribute to these females' individuality. Our informants (women in romantic relationships) do prepare for Valentine's Day in similar ways; however, the females in new relationships discuss going to greater lengths and monetary expenses for their partners.

We now consider the underlying meanings and emergent themes associated with these behaviors.

RQ2: WHAT ARE SOME KEY CONSUMER MEANINGS AND EMERGENT THEMES ASSOCIATED WITH THIS HOLIDAY?

The key meanings and themes we discuss here include: "love, affection and intimacy", "altruism", "mutual expectations", "self-gifts", and "negative feelings". Other themes (e.g., commercialism) are discussed in the section related to our third research question. We begin with the "positive themes" and then discuss more negative aspects of Valentine's Day.

Love, Affection and Intimacy

One key meaning of Valentine's Day is the showing of love, affection, sharing intimacy, and sex. In the public sphere, kisses, hugs, and hand-holding in public are more common on this day; public displays of affection are sightings that many have come to expect on February 14th. In the private sphere, this holiday celebrates romantic love and intimacy. For some, it is a time set aside for sex:

It is the holiday to stay in and share intimate times and sex. [F, Diary]

Valentine's means displays of love, affection, and care. [F, Diary]

Informants often associate the holiday with *all* loved ones (e.g., family, friends, significant-other):

Valentine's Day is a time for love and affection. I do not know anyone who wants to spend Valentine's Day alone. I love to spend my Valentine's Days with the person I am dating or my family. I love buying and giving gifts during this holiday but the most important thing is being with the people I care about and love. [F, Diary]

Family, specifically, is often mentioned as an important part of the holiday. Important family members include parents, siblings, and grandparents. Many phone calls and letters for this holiday are not just for romantic loved ones, but also for such family members.

Altruism

Altruism, or voluntary giving which is not directed at gain, is a key Valentine's Day theme. Motivations for gift giving in a romantic relationship change with time, and altruistic gifts may extend the relationship (Huang and Yu 2000). We find, for instance, that males in a longer-standing relationship have positive feelings for this holiday stemming from altruistic motives and love. Polonsky et al., however, find that "the altruism motive was rarely found to occur independently amongst young males, especially with relationships that have been established for periods longer than six months." (Polonsky et al. 2000, p.1003)

We find a similar phenomenon in responses from women. Women in a longer relationship were more likely to share selfless giving than the women who were involved in a fairly new relationship. Past studies (e.g., Huang and Yu 2000; Polonsky et al. 2000)

also found altruism is positively related to relationship length. However, those studies focused on males' gift-giving; our findings extend to women as well. Altruistic motives are apparent with males and females and underlie behavior for this holiday.

Mutual Expectations

Childhood experiences play a large role in shaping adult Valentine's expectations. Early memories of the day evoke images of elementary school and the parties, arts and crafts, candy, time off from schoolwork, and egalitarian exchange of Valentine's cards. Time off from schoolwork is more common on Valentine's Day in public elementary school, because of the secular association with the holiday, as compared to the policies that limit celebrations of religious holidays (e.g., Christmas, Easter) during class time. Because of such strong, early-rooted influences, consumers build up high expectations for the day. As a result, consumers enter their teenage years with high expectations. Such heightened expectations may lead to disappointment (e.g., by teenage females who expect uninformed young males to shower them with gifts and affection).

These expectations are mutual; over half (53%) of the males and 63% females in our survey expect a gift(s) from their significant other for the holiday. Heightened female expectations might be associated with the fact that women receive more gifts than they give on Valentine's Day (Goodwin et al. 1990). A further explanation may be that women see themselves to be gift-receivers more so than givers on this day. However, males do view the lack of gifts received as a negative factor associated with the holiday (Otnes et al. 1994).

Interestingly, a higher percentage of males and females in a new relationship expect gifts, as compared to those in a more established relationship. As the duration of the relationship increases, both men and women expect fewer gifts from their partners. As both partners may begin to feel comfortable and confident in the relationship, they may not feel the need to impress the other, as with self-gifts.

Self-Gifts

Self-gifts are gifts that are given to oneself to try and appear more attractive in their partners' eyes (Huang and Yu 2000). Examples of "self gifts" include perfume, cosmetics, and lingerie. We find that more of the women in a *new* relationship indulge in self-giving. This could be explained by the negative relation between relationship length and pressure to look "perfect". Valentine's Day is viewed as one of the most romantic times of year, and women who spend this day with someone special for the first time often go to greater lengths to "prepare themselves". Females speak of these self-gifts as a way to make themselves "absolutely irresistible" for their partner.

Negative Feelings

Not all informants hold the same warm feelings for the holiday; some consumers "can't stand this day of love." Past studies have suggested that men are primarily the ones with "anti-Valentine" feelings; however, there are expressive females speaking out and sharing their distaste for this love-oriented day. One woman turns to chat rooms and message boards when her misery needs company:

I've spent this valentines surfing the net, looking for sites about love sucking! My bou of 4 years broke up about 1 month ago, he is with someone right now...DEATH TO VALENTINES! [F, Posted 02-15-00]

Another young woman encourages others to send hate mail instead of “happy-grams”:

I want to urge everyone to join me in sending hate mail instead of Valentine's on this wonderful day. It makes you feel better. I promise. [F, Posted 02-15-00]

However, another woman shares her suggestion of getting rid of the day completely:

I always used to hate this holiday, and my friends told me I was weird- but now I know I'm not alone! Abolish Valentine's Day! [F, Posted 02-11-00]

Yet, some individuals just have problems in the way society interprets the holiday—or, they do not think it is a holiday at all:

I hate Valentine's Day because all those people in love think that it is a real holiday and it's not...it is a time of the year that everyone who is in love gets stupid and all mushy while the rest of us get left out yet again and we are forgotten about just because we haven't found the one...this sucks...! [M, Posted 02-04-00]

A theme we see often is that informants do not think that love is to be shown on “this day and this day only”. The following men seem to have more of a problem with it being *the* day for showing love:

I hate Valentine's Day, because...I don't know. I think, if you love someone, you don't need a special day to show it. Every day is suitable for this. [M, Posted 02-15-00]

Some of this dislike for the holiday (and what it represents) stems from unfulfilled expectations. Not getting a gift, “the right” gift, or desired attention often leads to disappointment. Self-esteem may fluctuate on Valentine's Day, as some get a boost or a threat to their self-esteem. We now consider the role of marketing communications on consumer expectations and experiences for this holiday.

RQ3: WHAT ROLES DO MARKETING COMMUNICATIONS PLAY IN SHAPING THE HOLIDAY?

Marketing communications play a role in shaping feelings of materialism on one hand, and togetherness on the other. Marketing communications also contribute to gender roles for this holiday. We begin by discussing some observations of in-store marketing communications practices, and then discuss some roles that various forms of marketing communications play in fostering materialism, togetherness, and gender roles for the Valentine's holiday.

In-store displays sometimes start appearing months prior to February 14th. Our observations in floral departments and retailers that cater to the holiday include: multiple red and pink displays, including balloons, a “Valentine's Day Gift Center” banner, and extra options for floral and gift-wrap arrangements. Such a promotional arrangement attracts mainly men, who often purchase flowers, a card, chocolates, a balloon, and/or another small gift all at once. In turn, we see that few females come seeking gifts. Interestingly, there were no masculine items in the area.

One of the most traditional gifts for this holiday is a dozen red roses. However, some specifically requested something different:

I need a really nice arrangement for my girlfriend—but rather than roses, can you use tulips instead? [M, Observation]

To further individualize the gift, the saleswoman asked:

Have you two been together for a while, or is this the first time you would be purchasing flowers for her? I need to know so I can pick the right colors for the arrangement. Normally, red symbolizes love... [F, Observation]

He jumped in:

Yes! (pointing to a peach shade) That would be perfect, since my girlfriend prefers softer colors instead. Also, I really don't have a limit on how much the flowers cost. This is the first time I'm buying flowers and I want it to be nice. [M, Observation]

Here, price is a proxy for quality. He was willing to pay for “the best”. He described his spending limit as:

As much as it takes to satisfy my girlfriend! [M, Observation]

Another observed customer described how he begins saving months in advance, because he expects a considerable financial burden for this holiday. Marketing efforts also entice women to spend, among other enticements:

Marketing gets me “in the mood”, and causes me to buy more stuff than I normally would. For example, I bought Valentine cards for everyone in my family and all of my friends. [F, Diary]

Fostering Materialism

Valentine's Day has a materialistic aspect that is reflected in the multitude of ads, public relations material, in-store displays, and e-communications that remind consumers to purchase something for their loved ones. Recall we found that both women and men expect to receive some sort of gift. Some consumers overtly trace these mutual expectations to marketing communications. Recall that some consumers express negative feelings toward this holiday. Some explicitly attempt to avoid marketers' influences. One way is via the exchange of non-marketed, “hand-made” gifts (e.g., home-made dinners, massages, original song lyrics, homemade cards). However, traditional store-bought goods or services (e.g., restaurant meals, massage certificates, CDs, greeting cards) are mentioned by the majority of informants. Some individuals aspire to share luxurious items and brands (e.g., Tiffany & Co., Godiva) with their loved one, as ad images suggest. However, not all informants associate Valentine's marketing communications with materialism. Instead, they notice the “togetherness” reflected in marketing communications.

Fostering Togetherness

Marketing communications foster a sense of togetherness for some. Images often depict lovers spending time together. One informant recognizes the meaning of showing such images, and how she now appreciates this holiday's meaning:

Having people around to share special occasions leaves a much stronger impact in one's life rather than receiving material things. Every year on Valentine's Day, I have a nice breakfast with my mother and father and then a romantic dinner with the person I am dating... that way I can spend a little time with everyone that I love. [F, Diary]

For some, the shared gifts, food, and drink, are a vehicle of spending quality time and showing affection with loved ones and non-materialistic in nature.

A formal engagement is a symbol of togetherness. Some ads suggest proposing on this day. One male even recalls the advertiser:

Every Valentine's Day this one jeweler, the Shane Company, I think, calls out for men who are in relationships and suggests we come to their store and buy a ring. I don't want some businessman telling me that it is time to propose! [M, Diary]

The Valentine's season is a popular time for advertising engagement rings and wedding goods. To some informants, a diamond ring (and the future marriage that it symbolizes) is the ideal exchange. One informant had a day to remember. She is happy to share her story, as well as glimpses of her solitaire:

We went down to Atlanta on Valentine's Day and checked into the Westin Hotel and went outside for a picnic that my boyfriend had planned. It was raining so we were carrying an umbrella. We went to a horse and buggy, to which I was very surprised, and rode around Atlanta. We got off at Centennial Olympic Park and sat under a pavilion and had a salad, heart-cut sandwiches, fruit, and strawberries dipped in chocolate. After lunch, my boyfriend had a velvet Godiva chocolate box (that I had asking to eat all day!) I finally go to open it, and at this point, I was thinking that he might have put a ring in there, since our day had been so extravagant. I opened it and it (a ring) was not in the box. I got some chocolate and put the box down (disappointedly). [F, Diary]

Her diary continues:

Later, he picked the box (of Godiva chocolate) back up and asked me to see what kind of chocolate was in the center. I opened it and the ring was in there! He asked me to stand, and he got down on one knee... and asked me to marry him! I was crying and, of course, it was one of the most exciting days of my life. [F, Diary]

Upon hearing that her friend received a ring, another female responded with a half-joking tone:

You got a diamond ring—I didn't even get a card. [F, Observation]

Such sentiments are not uncommon—especially from singles on this holiday that reportedly “discriminates against” single people. To those who have negative Valentines feelings, marketing communications overtly depicting togetherness and engagements are especially irritating.

Fostering Gender Roles

Marketing communications fosters gender roles for this holiday. For example, consumers state how marketing messages suggest, imply, or state that this is a day for females. Informants reference the ads and messages that suggest pampering the female with a gift, card, dinner, and other purchased signs of affection. In turn, a somewhat common female perspective is that it is a day for female attention:

Females are supposed to be pampered and spoiled on this day. [F, Diary]

Some males perceive their gender role as a day to cater to “the ladies”:

Valentine's Day is cool...since I'm a true ladies man 🍷 It is a great day. 🍷 [M, Posted 5-20-04]

Other male roles apparent in marketing communications include buying, buying enough, and finding romantic activities to do. One woman realizes the pressure the hype for this holiday seems to put on some males:

There is so much hype, I think it sucks even for people IN a relationship- what should they do/buy, are doing/buying too much (for women), are they doing/buying enough (enough)? I got married on Valentines day and I remember every man invited was all smiles, because it gave them something “romantic” to do on valentines day with their partners that didn't cost them anything, and took all the pressure of them! Its embarrassing to be a marketer when you see something so commercialized, isn't it? [F, Posted 2-15-2004]

Another female shares her perception of each gender role during this holiday:

The male is the wooer. The female role is to be wooed. [F, Diary]

Although some females are “wooed”, other females are anything but wooed.

This is a day for a female to have her heart broken or else have an absolutely wonderful day. [F, Diary]

It is apparent that Valentine's Day is a day of extremes—from euphoria to heartbreak.

DISCUSSION

On the surface, Valentine's Day is a simple holiday; nonetheless, there are a wide variety of behaviors, rituals, meanings, and commercial efforts associated with this day. Because this holiday is so rich in consumer meaning, we are just scratching the surface in this study. Valentine's Day rituals are constantly evolving. New traditions are added annually (e.g., e-Valentine's, speed dating).

Marketing expenditures and efforts are large, and often begin months before the holiday. Such marketing efforts often target males as potential buyers, and often make explicit suggestions or guidelines to assist them in the gift giving process. Such marketing efforts are a clever strategy, because (young) males are sometimes fertile ground—and confused about what is expected from them with respect to this holiday.

At the same time, we find evidence of consumer revolt. Many consumers go out of their way to avoid “stereotypical” rituals or the mass-commercialism associated with Valentine's Day. For some, Valentine's is a season to be reminded of one's “single status” or a time of self-reflection and evaluation. For some, this holiday can be a source of obligation, self-loathing, and/or disgust. Distinct rituals are enacted for this situation (e.g., singles nights at clubs; gossiping about couples, girls' night out, self-gifts).

Consistent themes emerge in our research. For instance, we find that males often feel obligated to make significant purchases. Females tend to focus more on grooming rituals and prepare to “be wooed”. Members of both sexes discuss themes of belongingness and romance. Males are inclined to use gifts as a form of nonverbal

communication, whereas females engage in self-gift behaviors. Females spend a considerable amount of time and money in preparation for "the day."

Limitations of our study include relatively small sample sizes and restricted geographic/demographic focus. Furthermore, most of our informants focused on heterosexual relationships. One direction for future research is to examine, in detail, other kinds of relationships. Another way to expand our focus would be to study Valentine's rituals in other cultures. For example, in South Korea, the gender roles are often reversed, and the holiday is a time for the female to provide a gift (e.g., and express her "hidden affections"). Culture and practices learned at an early age are large contributors to rituals and meanings associated with a holiday. Nonetheless, these ritual practices change and evolve over the course of a lifetime. In terms of future research, the following three questions are of interest: 1) In elementary school, Valentine's Day is an egalitarian holiday with equal exchanges of cards and gifts to both sexes. How is it, then, that all of this has changed by the adult years, which now focuses attention on the female?, 2) Why is it that females have such high expectations for this holiday?, and 3) Why is Valentine's a holiday that seems to befuddle males so much? Females seem to have firm expectations, but males (at all ages) find the "meaning" of the holiday to be elusive.

A Halloween Community: The Role of the Marketplace in Response to Social Isolation

Garth Harris, Queen's University

EXTENDED ABSTRACT

Our field's understanding of the marketplace has grown dramatically over the past few years. One line of research finds the market to be an authoritarian institution containing amoral, or even immoral, totalizing logics based on self-interest leading to dehumanizing community fragmentation (Firat and Venkatesh 1995). In order to escape these dehumanizing logics, consumers must escape the hegemony of the market (Kozinets, 2002). Another perspective presents the marketplace as providing cultural capital upon which consumers draw to construct their lifestyle and identity projects (Holt 1998). However, a common point of both perspectives is that the marketplace, as constructed by marketers, is a dull, manipulative and an unreflective space void of family, community or religion (Holt 2002). Yet the marketplace remains an attractive, alluring and even growing dominant logic that many consumers come to actively embrace. The purpose of this study was to contribute to our understanding of the marketplace by exploring some of the dimensions underlying the allure of the market. One key finding in this investigation was that the very amorality of the marketplace attracts consumers and provides consumers with an opportunity to build social bonds.

An ethnographic study of Halloween was conducted from August to November 2004. I immersed myself in the festival. Observations and field notes were taken at multiple sites including retail outlets, community events, bars and dances. I conducted 20 unstructured interviews with different individuals/families before and after Halloween. These participants came from diverse backgrounds ranging in age from 6 to 80, and demonstrating various levels of involvement with Halloween from trick-or-treating to putting up elaborate yard displays. I also followed one family through the consumption experience from buying the costumes and decorations to following them around on Halloween weekend to a community dance and trick-or-treating. For the purpose of this current paper, I analyzed my field notes as well as 5 transcribed interviews involving 7 participants.

Three themes emerged from the data: social isolation, temporary community and the role of marketplace within a Halloween hypercommunity. In today's world of double-income families, urban sprawl and long commutes, people are feeling a time pressure which leaves them socially isolated from their families and communities (Putnam, 2000). Halloween gives consumers an opportunity to chat with neighbors and temporarily reduce their social isolation. Consumers in this study long for the past where life was simpler and people were closer to friends, families and neighbors.

In response to social isolation, Halloween gives consumers a chance to construct a temporary community. Halloween has many of the same characteristics of a hypercommunity (Kozinets, 2002). It is bound by both time and space and is an intense experience. Halloween decorations typically go up the night before Halloween and are dismantled as early as 9 P.M. on Halloween Night. The majority of activity happens quickly during an intense period between 5:30 and 8:30 P.M. and dies off just as quickly. During this time period it seems everyone is out of their houses on their porches chatting with kids and neighbors about Halloween and neighborhood news.

Like a hypercommunity there is a caring and sharing element to the Halloween community that manifests itself through families. Through the wonderment and excitement of the children, the community comes alive. Parents get a chance to step out of their

social isolation, experience the enjoyment of their childhood and reconnect with their families and neighbors. Halloween is a hypercommunity where consumers attempt to strengthen social ties but unlike the Burning Man hypercommunity, Halloween is created well within the marketplace.

In this study, consumers readily admit that commercialization is central to Halloween. They understand that items provided by the marketplace are in a sense "amoral" – void of social meaning other than the attempt by companies to sell more products and make a profit. It is this amorality that makes the rituals of Halloween safe and accessible to the masses. Halloween is widely advertised by companies, and likewise, Halloween decorations and other paraphernalia are accessible and convenient for busy consumers despite Halloween's marginalized past. The marketplace offers Halloween, a "safe-haven" in the sense that it is "amoral". The Halloween merchandise is safe, physically and creatively with store bought costumes, decorations and candy. The wide variety of ever changing Halloween merchandise is also a source of safe creativity that allows consumers to exact Halloween rituals of family and community.

Consumers are actively trying to escape the social isolation of their daily lives. But very few people can escape the marketplace because they do not have the financial or time resources to access events like Burning Man. On the other hand, almost everyone has access to the marketplace. The allure of the marketplace is that consumers have access to it and can temporarily create communities that are creative but at the same time safe like the ones seen on Halloween. The amorality of the marketplace, which is what many say is its fault, may ironically be the very characteristic and allure that provides the consumer the opportunity to achieve some of the communal and self-expression/ideals that were previously thought only achievable outside of the marketplace.

Authenticity at Gettysburg

Athinodoros Chronis, California State University-Stanislaus
Ronald D. Hampton, University of Nebraska-Lincoln

EXTENDED ABSTRACT

Authenticity in the marketplace is frequently met in multiple consumption expressions: art, museum artifacts, ethnic food and restaurants, old downtown renovations, collectibles, retro-style objects (Brown 2001), and leisure experiences (Arnould and Price 1993; Belk and Costa 1998; Costa and Bamossy 2001). As a theoretical concept, however, authenticity is still in the early stages of its conceptualization. A relatively small number of scholarly works has already appeared in anthropology, geography, and tourism. Nevertheless, academic work on authenticity remains vague both in terms of its definition and in its marketing relevance. As Bruner (1994) has noted, authenticity takes multiple forms and thus we can only unpack its meaning by analyzing the context and the specific instance it is used each time.

Consumer researchers have only recently started to investigate authenticity at a theoretical level, relevant to consumption practices. Nevertheless, it still remains a "problematic concept" (Costa and Bamossy 2001). The initial problem consumer researchers are facing is to define what meanings authenticity takes in different consumption contexts. Existing literature on authenticity underscores managerial concerns at the expense of a consumer perspective. With few exceptions (Bagnall 1966; Belk and Costa 1998; McIntosh and Prentice 1999), the majority of the existing studies overemphasize managerial strategies and the steps taken to offer an authentic product, ignoring consumer perceptions of authenticity. The present paper is focused on the concept of authenticity and its interplay with consumption in heritage sites. In this context, our study extends previous efforts to understand the meaning of authenticity from the consumer perspective (Chronis and Hampton 2005) by focusing on the theoretical relevance of perceived authenticity for the consumption payoff.

Ethnographic research was conducted at Gettysburg, Pennsylvania, one of the most significant and popular heritage sites in the United States, visited by almost two million people a year. Data collection was accomplished primarily through in-depth personal interviews with visitors at Gettysburg during the summer of 2002. This method was supported by photo-elicitation and personal observation. Visitors were asked to commend on both their experiential consumption benefits and on those aspects of the site that they found particularly involving, captivating, significant, or characteristic of the historical events. Overall, fieldwork at Gettysburg resulted in a total of 75 interviews, 238 photographs, and hundreds of hours of observation. Transcribed interviews offered more than 500 pages of verbal data.

As expected, authenticity was brought up by visitors in multiple occasions, articulating each time different meanings. In this paper we distinguish between authenticity as a characteristic of a heritage site or, in other words, as a "product" feature, and authenticity as an experience. First, as a product feature, authenticity takes one out of five types: object-related, factual, locational, personage, and environmental. Second, in terms of its reference to the consumption experience, authenticity illuminates our theoretical understanding of consumers' connection with the past. Indeed, the most outstanding experiential outcome for a great number of visitors at Gettysburg was a temporary but profoundly intense imaginary flight in the past. As our data show, all five types of site-authenticity bequeath value to the heritage experience at Gettysburg and they help visitors connect with the past.

In recent years, various scholars expressed a modernist anxiety in the form of "kitschy imitations" (Gable and Handler 1996), pseudo-events (Boorstin 1964), and "hyperreality" (Baudrillard 1983; Eco 1986), that underscores managerial effort to "stage" authenticity (MacCannell 1999) and consumers' drive to discover it. Our research shows that authenticity, indeed, might be a concern for consumers during their experiences in the marketplace. Instead of the consumers being preoccupied with authenticity though, our findings show that this is not the case. Rather than being actively engaged in a search for authenticity, visitors at Gettysburg appreciate authenticity as a means to an end: perceived site authenticity is a powerful time machine that connects consumers with the past. In this role, perceived authenticity functions as a mediating concept that triggers consumer imagination. The conceptualization that we offer provides a link between authenticity as a feature of the product and the intangible virtues resulting from the consumers' passionate engagement with an outstanding cultural narrative.

While existing literature suggests that people engage in acts of imagination and the "suspension of disbelief" in order to attain a certain level of authenticity for the whole or parts of the product offering (Costa and Bamossy 2001), our insight at Gettysburg suggests that the reverse can be also true. Instead of having acts of imagination being responsible for the product authentication, perceived authenticity of the product can trigger consumers' imagination and transport them in narrative worlds.

Our research also provides guidance for the appropriate "staging" of authentic sites in both substantive and communicative terms (Arnould, Price, and Tierney 1998). While object-related, locational, and environmental forms of authenticity can be used for the substantive staging of the built environment (authentic artifacts, actual locations, authentically-looking environments), all types of authenticity can be used for the appropriate communicative staging of a consumption experience (through their incorporation into the heritage narrative).

In short, our research shows that in Gettysburg's stimulating context, visitors employ authenticity in its multiple forms as a signifier of a heroic past and as a vehicle for their imaginative engagement in a holistic and multisensory hedonic consumption experience.

You-Can-Do-It-We-Can-Help: Emancipation Within the Marketplace?

Tiebing Shi, Queen's University
Jay M. Handelman, Queen's University

ABSTRACT

This paper examines the marketplace and its allure to consumers. Following the existential-phenomenological interview format, we conducted 11 depth interviews with both male and female consumers to examine their lived experience within the marketplace and in particular, their patronage of Home Depot. Based on Green's view of freedom as combining both negative and positive freedom centering on concepts of opportunity and ability, we find that consumers can potentially begin a perceived journey toward emancipation within the marketplace. We also find that Home Depot, a dominant marketplace player, can portray itself as a benevolent emancipator, empowering consumers to start this perceived emancipatory journey.

INTRODUCTION

The marketplace has gained the attention of many consumer researchers in recent years (Murray and Ozanne 1991; Bristor and Fischer 1993; Hetrick and Lozada 1994; Holt 2002; Kozinets and Handelman 2004; Thompson 2004). The traditional Marxist view portrays the marketplace as dehumanizing (Kozinets 2002) and totalizing (Firat and Venkatesh 1995) and proposes that emancipation occurs when the consumer escapes the marketplace (Hetrick and Lozada 1994) either on his or her own volition or through the urging of consumer activists (Kozinets and Handelman 2004).

Poststructuralists, on the other hand, regard the marketplace as an arena where consumers co-opt marketplace symbols to create their own symbolic resistance and thus work to redefine marketplace meanings. For example, Thompson and Haytko (1997) study how consumers use fashion discourse to recreate meanings and to resist the repressive fashion norms in the marketplace. Thompson (2004) notes the blurred distinction between inside and outside the marketplace and advocates for studying how consumers engage in various discourses of power rather than assessing whether emancipation occurs inside or outside the marketplace.

However, through the idea of "the critical imagination", Murray and Ozanne (1991) conceptually imply that while working well within marketplace ideology, some corporations could align their interests with consumers' interest by critically examining and improving their practices, thus possibly contributing to the allure of the marketplace for consumers. Drawing from this conceptual possibility, this study seeks to contribute to our understanding of the allure of the marketplace through an empirical examination of consumers' perceived liberatory experience within the marketplace.

In this study, we examine a dominant corporation—Home Depot. The premise of this paper is that Home Depot's market positioning enables their customers to begin a perceived journey toward emancipation previously considered to occur solely outside the marketplace. This paper seeks to examine this conceptual possibility introduced by Murray and Ozanne (1991) and thus explore one aspect of marketplace allure.

We draw on the freedom framework of T. H. Green, a British liberal philosopher from the 19th century, as the conceptual lens through which to examine the marketplace. According to Green, an understanding of emancipation can be realized only by integrating the ideas of both negative freedom (freedom from constraints) and positive freedom (freedom to achieve self-realization) (Simhony 1993).

In the next section of this paper, we develop our understanding of emancipation and how it has been applied in the study of marketplace phenomena. This is followed by a development of Green's philosophy of emancipation which serves as the conceptual lens for this paper. This conceptual development is followed by an explanation of our research method and the results that were found.

THEORY

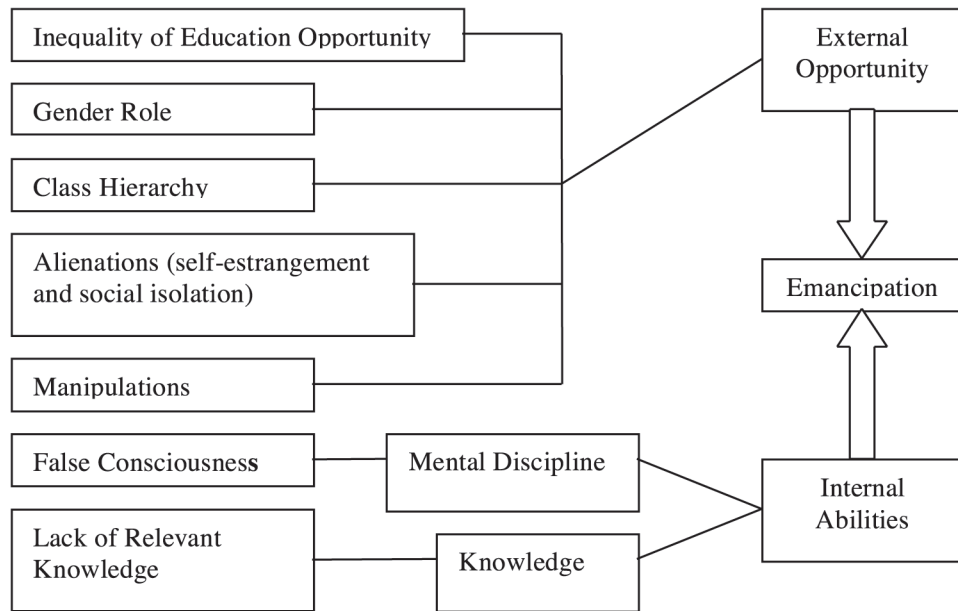

The Marketplace

Escaping the marketplace to be free from its ideology is advocated by the traditional Marxist view. This view argues that a logic of "self-interest" has increasingly undermined "the realization of the caring, sharing, communal ideal" and homogenizes consumers and suppresses their "self-expressive capabilities" (Kozinets 2002, p. 22). Firat (1994) finds that any countercultural ideas and practices could be co-opted by marketers and transformed for their own interests. As such, Firat and Venkatesh (1995) argue that consumers must find social spaces outside the marketplace to achieve emancipation. An example of such a social space is the Burning Man Festival whereby consumers escape the hegemony of the marketplace and its suppressive effects (Kozinets 2002). This is consistent with the view point of consumer activists who seek to awaken consumers from their false consciousness and blindness toward marketplace ideology and urge these consumers to escape its effects (Kozinets and Handelman 2004).

The poststructuralist view presents a slightly different view of the marketplace and emancipation. Consumer resistance occurs whereby consumers co-opt marketplace symbols to redefine meanings without differentiating inside or outside the marketplace. For example, sacred social spaces such as family and religion come to be inter-penetrated with marketplace ideology, so distinguishing between inside and outside the marketplace is difficult in contemporary capitalist society (Thompson 2004). From this perspective, consumers are never dominated by any singular hegemonic discourse (Thompson 2004). In a fragmented postmodern society, consumers use products and services in the marketplace to recreate their own discourses resisting potentially dominant ideologies of the marketplace. For example, Western natural health consumers construct their own microculture (Thompson and Troester 2002) and discourses (Thompson 2004) to challenge the medical authority and resist the dominant ideology. Instead of discussing emancipation inside or outside the marketplace, Thompson advocates understanding "the new opportunities for localized resistance that are produced in this matrix of overlapping discourses of power" (Thompson 2004, p. 173).

Different from the above-mentioned views, Murray and Ozanne (1991) imply the possible attractiveness of the marketplace. They propose an approach of critical imagination whereby consumers can "expose the social dysfunctions of marketing strategies in order to motivate regulation and change" (Murray and Ozanne 1991, p. 139). Similarly, private profit-oriented marketplace players can align their interest with public interests by critically examining their own practices, educating consumers, collaborating with progressive social groups, and thus building an attractive dimension to the marketplace that may potentially appear emancipatory in nature.

FIGURE 1
THE MODEL OF EMANCIPATION BASED ON GREEN'S VIEW OF FREEDOM

Green’s View of Freedom

To explore the allure of the marketplace and the possibility of emancipation, or freedom, this paper draws on Green’s theory of freedom as elaborated by Avital Simhony (1993). According to Green, emancipation (or freedom) occurs when *self-realization occurs*—that is, realizing one’s life themes and life projects that are free from false consciousness. Life themes are consumers’ “profound existential concerns” addressed in their daily life; life projects concern consumers’ self development and meaning systems relating to self and extended self (Mick and Buhl 1992, p. 318). To achieve freedom or self-realization, one needs a combination of internal ability (mental discipline and relevant knowledge) and external opportunity (Simhony 1993). Internal ability is “the ability to structure one’s desire into a coherent system” that is aligned with one’s well-being (Simhony 1993, p. 38). Achieving this internal ability requires mental discipline for breaking free from one’s false consciousness and the knowledge necessary for achieving self-realization. External opportunities include absence of manipulation and equal enabling opportunities to develop and to exercise one’s internal abilities. So, we frame the achievement of emancipation (and self-realization) as centering on internal abilities and external opportunities (refer to the figure 1).

For Green, complete emancipation occurs when both negative and positive freedom have been achieved. Negative freedom is freedom from constraints to self-realization. These constraints may be both external constraints (e.g., coercion, manipulation, lack of external opportunities) and internal constraints (e.g., false consciousness, lack of knowledge necessary for achieving self-realization). Consumers must be free from manipulation and coercion and have equal and sufficient opportunities to learn knowledge and exercise their internal abilities to realize their life themes and life projects. However, being free from these constraints is not enough. Positive freedom, therefore, is the achievement of one’s life themes

and life projects through exercising one’s freedom from the internal and external constraints that may have existed. In this study, we reconceptualize Green’s Utopian ideal of freedom as not an all-or-nothing proposition (i.e., either free from all possible constraints or not free at all), but instead regard emancipation as a process, a journey without necessarily a guarantee of reaching the ideal Utopian state.

Recognizing the adaptability of the marketplace (Holt 2002), the theoretical possibility exists for consumers to start a perceived emancipatory journey (realizing their life themes and life projects) within the boundaries of an ever adapting marketplace. Corporations can potentially tear down *some* internal and external constraints (negative freedom) while aiding consumers in their pursuit of their life themes and projects (positive freedom), in other words, empowering consumers to start a perceived journey toward self-realization inside the marketplace.

Green’s view of freedom provides a useful framework to study the allure of marketplace and emancipation inside the marketplace. We propose that emancipation integrates both negative freedom (*freedom from* internal and external constraints) and positive freedom (*freedom to* realize one’s life themes and life projects by fully developing and exercising one’s internal abilities). Drawing on this framework, we analyze consumers’ own narratives about their experiences and interaction with Home Depot. We explore the following questions: Why is the marketplace alluring? Can consumers start an emancipatory journey inside the marketplace?

METHODOLOGY

For this investigation we sought a site within the marketplace to which consumers flock. Home Depot, founded in 1978, is the world’s biggest home improvement retailer with more than 1500 stores world wide. In growing numbers, consumers flock to Home Depot to “do it yourself” (DIY). The “DIY” theme resonates with

the concept of self-realization and prompted our choosing Home Depot for this investigation. One Canadian store was selected as the research site.

The informants selected were randomly approached in the store and asked for their willingness to participate in this study. They were told that they could select the interview place, refuse to reply to any questions, and stop the interview at any time, and that this study had been approved by the store manager and was independent from Home Depot's sponsorship. Six male consumers and six female consumers who all had at least one year of experience shopping at Home Depot agreed to participate in this study. In the end one female consumer retreated from this study for lack of time.

To understand individuals' lived world inside the marketplace, we followed the existential-phenomenological interview format (Thompson et al. 1989) to attain consumers' first-person description of their marketplace experience with Home Depot as the focus of discussion. This format allowed our informants to freely talk about their personal experience with Home Depot as a social space rich in cultural symbolism (Firat and Venkatesh 1995).

Interviews were conducted at various locations depending on the informant's preference: the informant's home, cafes, and a seminar room and a meeting room at a business school. Each interview began with an introduction of the aim of our study (to explore consumers' understanding of their experience with Home Depot) and then a grand tour question regarding their purchasing experience with Home Depot: "Please tell me something about your purchasing experience with Home Depot." Other questions emerged from the on-going dialogue. The time of the interviews ranged from 50 to 100 minutes.

The analysis of the data followed an iterative process whereby an interpretation of each single interview transcript as a whole unit was conducted, followed by a comparison between the transcripts. Three themes emerged.

FINDINGS

For our informants, Home Depot helps them start an emancipatory journey by tearing down some internal and external barriers while providing our informants an opportunity to achieve their life themes and life projects (self-realization). This apparent emancipatory role by a dominant marketplace player is now explored.

Theme One: A Marxist Arcadia

Ray, a 31 year old paramedic who describes his daily life routine of being on-call to respond to medical emergencies as a combination of "very boring" yet "upsetting", expresses a starkly different vision in his pursuit of life themes and projects. He said: "It's kind of my sanctuary area, my workshop. ... When I build, I just relax. I create and build things. ... I create, just create. I only make paddles. Three hours later, I have made a paddle. ... I love canoeing. I love the sky. So, I am just trying to make paddles to see if they could work properly, and how I could make them better. The hope is that you can make them aesthetic. ... You know what you are doing is interesting." Here, in contrast to his daily life marked by boredom and distress, Ray discusses what for him is the achievement of positive freedom—a life where the day is spent creating paddles that enable him to canoe under the open sky. The place where he "creates" these paddles is not only his "workshop" but also his "sanctuary"—his Arcadia—a social space set aside from his daily life reality where simple and pastoral pleasures, beauty, and creativity can be pursued. Ray is seeking freedom from self-estrangement, in other words, freedom from the inability to find intrinsic values in life's daily pursuits.

For Ray and our other informants, Home Depot provides not only the raw materials but also the moral guidance in the construction of their sanctuaries. Feila, a 48 year old single mother and high school teacher talked about her close familiarity with Home Depot employees as a result of her frequent visits to Home Depot. She said: "I prefer to go to one place [where] I know the people and I know who they are because I need, because I think it is not just a game. ... You know, there is a time when everybody knows everybody in the little community. ... I do think this is personal, hmm, in terms of knowing you as a friend or things like that. It [Home Depot] is just a friendly store."

The marketplace is often referred to as a place of social isolation, exploitation, and dehumanizing encounters to be escaped (Kozinets 2002). But for Feila, her life themes and projects are enhanced by the "little community" feeling she gets at this otherwise gigantic retailer. At Home Depot, she knows the employees and they know her as a "friend".

Feila continued her life story and said: "When I grew up ... we were not allowed to take mechanics and I wanted to do. My brother did the mechanical stuff, my father did the work, you know, the trade parts of a family. So when you think of that type of thing thirty or forty years ago, children would not be encouraged, if you were female, to do certain jobs because of the division of roles." In Feila's past, in another social space and time, there was gender inequality imposed upon her where her brother had the opportunity to learn a trade, but she was denied the opportunity simply because of her gender. This gender inequality meant that Feila, like so many women, lacked the necessary socialization to enable the attainment of equal opportunities later in life (Bristol and Fischer 1993).

Daphne, a 38 year old elementary school teacher elaborates on the hurdle that gender inequality creates in her pursuit of her life projects. When going to other home renovation stores with her husband, she notes, "They are almost talking down to me ... I hate that kind of thing. It bothers me. It bothers me because they judge me incorrectly based on the fact that I am a female." Her opportunity to learn and grow is stunted as employees of other stores look past her to speak to her husband. But when she refers to Home Depot, a very different chord is played. She said: "But I don't get the same feeling at Home Depot. ... That's one reason why I go there because I don't feel like they are looking at me and thinking 'Why are you (as a woman) doing this?'"

For Feila and Daphne, Home Depot transcends past and present gender injustices enacted by others, enabling our informants to pursue their life themes and life projects free from gender discrimination. In Feila's word, Home Depot is "sexless".

According to our informants, gender is not the only social issue associated with Home Depot. Byron, a 30 year old physician described his roaming experiences at Home Depot and said: "I like *dressing down*, putting on the purple jeans, maybe they are dirty, maybe they are greasy, or full of saw dust, going into Home Depot, drinking my coffee, shopping for stuff, [and] talking shopping with people who know shopping. This is something completely different from my career. I enjoy doing that." Byron, an upper income professional shares his experience of escaping the familiarity of his career by "*dressing down*" into clothes symbolic of a working class laborer and connecting with people as social equals—"drinking coffee" and "talking shopping". Byron seeks out Home Depot on his distinct (from his regular career) journey towards his life themes and projects. Unlike his work environment of clear social class distinctions and professional hierarchy, Byron seeks out the egalitarian atmosphere of Home Depot, actively playing the part of a laborer with his dirty, greasy, and saw dust filled jeans. Feila underscores this egalitarian atmosphere at Home Depot when she

describes it as a place where “people come together. It doesn’t matter who you are”. For these informants, Home Depot is an egalitarian, working class social space where all class barriers are removed.

In this first theme, we find that Home Depot is intricately tied to our informants’ pursuit of their life themes and projects—their Arcadias that are distinctly removed from the reality of their daily lives. For these informants, positive freedom is achieved in a social space where simple, aesthetic pursuits fill one’s days. But even more, Home Depot instills this social space with Marxist ideals of social interaction and familiarity, and gender and class equality. Home Depot presents a Marxist Arcadia where informants can achieve their life themes and projects, free from social, gender, and class constraints. What does Home Depot do to become so revered by these informants?

Theme Two: A Temple of Knowledge

Rather than just being a retailer that sells building supplies and provides functional product and price information, for our informants, Home Depot is where one goes to seek emancipatory knowledge—knowledge that empowers one to transcend the constraints of daily life.

When describing her interaction with Home Depot employees, Daphne said: “They are like my friends telling me about, you know, just like someone who happens to have a lot of work experience here, making fences or whatever. It is not that I am the stupid one. ‘This is (I am) a person that doesn’t know it at all.’ This is not teaching... You know, [it is] more sharing.” For her, Home Depot employees “share” their knowledge that they gained from their own hands-on experience (making fences, or whatever). But she is not left feeling inept or unworthy. She feels like one of the workers, engaging in a dialogue where experiences and knowledge are shared. Rene, a 60 year old retired teacher, goes further in describing her interaction with Home Depot employees. She said: “They will let you see [that] you don’t really need ceiling lights though you really want them.” In fact, Rene tried to buy a fancy ceiling light for her bedroom but one employee persuaded her not to buy it because he thought that she didn’t really need it according to her description of her bedroom. From our informants’ perspective, the information they gain from Home Depot employees is starkly contrasted with manipulating sales pitches. The employees don’t try to sell you what you don’t need. Instead, the informants feel they receive important knowledge—emancipatory knowledge that can guide them with their life projects.

In addition to the informal interactions between customers and employees, Home Depot also offers regular workshops for both adults and children. These workshops offer equal opportunities for men and women, and boys and girls to gain emancipatory knowledge. According to Feila, “they [workshop leaders] are *encouraging* everyone to make their own choices by teaching [participants] how to use certain things. And they make it sound easy... It allows, it *empowers* females to do more.”

These workshops provide information, guidance, and training that “empowers” our informants to transcend the barriers of their daily lives. The workshop leaders encourage women to do projects by themselves and so help them break the stereotype of gender role, *one* type of false consciousness which is initially imposed on women and then might be internalized by some of them. With the encouragement and education of Home Depot, Feila continually tries new projects and develops new skills which were considered to be men’s skills.

So enthralled with the emancipatory potential of these workshops, Feila is enthused to have her daughter attend the child workshops offered around holiday themes. She said: “They just

take that step [teaching children about structures and tool applications in the clinics] into our community, as a part of our community, basically allowing our kids to do it themselves. Dates like Christmas, March Break, Father’s Day and Mother’s Day. These kinds of dates are for kids, always the time for them to come together.” Home Depot emerges as a community elder, entrusted with imparting potentially emancipatory knowledge to the children “allowing our kids to do it themselves”. In a certain sense, as Feila hopes, Home Depot helps the young girls avoid accepting the stereotype of gender role, a historical product of the male-dominated society.

But Home Depot is not only a place where emancipatory knowledge is imparted. It is also a place where our informants can seek knowledge—roam and find their way. Byron related his experience in Home Depot compared to shopping malls and said: “I don’t know why, but I find that crowds stress me out. I find that in many shopping malls ... I find it very straining, stressful, and exhausting to be around a lot of people. But in Home Depot, I will definitely get a cup of coffee, go in, roam around, maybe just get a hamburger, go back in and roam around again, and I leave with what I need.” Compared to stores in malls, he feels free and comfortable to eat, drink, and roam—free from stress and sales pressure. Replete with food, drink, and the dirtiest working clothes he can find, he presents a vision of himself wandering, roaming carefree around Home Depot discovering knowledge that helps him transcend the constraints of his daily stressful life.

For our informants, Home Depot is a Temple of Knowledge where emancipatory knowledge is imparted and discovered by those willing to make a pilgrimage. It is where one can take a journey to roam, free from stress and judgment, to gain knowledge that can help its recipient to transcend the constraints of daily life. In this Temple of Knowledge, social constraints such as gender roles (both imposed-upon and internalized) and class hierarchy are collapsed and the lost community is re-established. It empowers its followers with opportunities and abilities to achieve freedom.

Theme Three: A Benevolent Emancipator

In summing up their experiences, our informants present Home Depot as a Benevolent Emancipator—the friendly wise sage who only has the students’ interest at heart. They perceive no manipulation at Home Depot. Byron noted that Home Depot does not “target our own vulnerabilities with deceptive ads” such as the ads of Marlboro which indicate “You will be cool if you smoke like a Marlboro Man.” He said: “I haven’t felt a strong marketing pull to Home Depot to buy anything I don’t need, to buy anything cool.” According to Fred, “They (Home Depot employees) are not pushy and that’s nice. You get a more genuine feeling that they are really there to help you... In my experience, they do try to minimize my cost too”. Home Depot is presented as a friend with no hidden self-interests, but only a genuine desire to help.

Symbolic of their trusted presence, Home Depot employees wear aprons symbolic of the shop floor worker whose concern is focused on his craft, not profit. The apron comes to embody the Home Depot employee’s focus on his trade. Further, this Home Depot employee, particularly compared to other stores, is considered “mature” (Fred) where employees of other stores are regarded as “kids” (Ray).

What emerges is a portrayal of the Home Depot employee as an experienced, mature craftsperson, focused on his trade, bereft of worldly possessions, but rich with knowledge, interested only in sharing knowledge that will benefit his pupils in their pursuit of their life projects. The Home Depot employee is not driven by greedy self-interest. The Home Depot employee is the benevolent, sagely, (grand) fatherly figure concerned only for the emancipation of his apprentices.

DISCUSSION

Faced with the perceived negative and positive freedom presented by a dominant marketplace player such as Home Depot, we gain some insight into why the marketplace is so alluring to consumers. It must be noted that Holt's (2002) argument that the marketplace is able to adapt to provide consumers with what they *think* they need, certainly resonates. In other words, the argument can well be made that our informants have not achieved "true" emancipation. However, while the marketplace has been described as a dehumanizing and totalizing space or as an arena full of discourse contests between consumers and marketers, our findings present a large marketplace player, Home Depot, helping consumers start a perceived journey toward emancipation by offering external opportunities (equality of gender and classes, freedom from social-isolation, and manipulation) and enhancing their internal abilities via transferring emancipatory knowledge. It is such knowledge that leads the way towards the realization of life themes (e.g., creativity, self-development, independence, and equality) and life projects, and thus, emancipation. This provides intriguing insight into the allure of the marketplace.

Our findings indicate that, as Murray and Ozanne (1991) imply, a perceived journey toward emancipation within the marketplace is possible and that corporations can play an active role in this process. How can other potential emancipators such as activists compete with the benevolence of a marketplace player like Home Depot? They might need to do the same things necessary for consumers to experience both negative and positive freedom: offering equal enabling opportunities and transferring emancipatory knowledge to enhance consumers' abilities.

When we use the phrase "a journey toward emancipation", we mean that emancipation is an ongoing process that occurs over time where some constraints are overcome, others still exist, and some new ones might be constructed at the same time or later. Here, emancipation is not conceived as an either-or issue whereby consumers are either emancipated by escaping the marketplace or still enslaved within the marketplace ideology.

This research has attempted at least a small look into the role that marketplace actors (such as Home Depot) can play in the emancipation of consumers (Murray and Ozanne 1991). Future research could also examine other forms of alienation—powerlessness, meaninglessness, normlessness, and cultural estrangement (Seeman 1975), and other types of false consciousness, and how they might possibly be overcome within the marketplace.

Brand Literacy: Consumers' Sense-Making of Brand Management

Anders Bengtsson, Suffolk University
A. Fuat Firat, University of Texas-Pan American

ABSTRACT

In cultures where brands play important roles for consumers' identity construction, people learn how to relate to and use brands 'knowingly.' Through the process of learning to consume brands in ways that are recognizable by the consumer culture, consumers develop brand literacy. Based on contemporary studies in literacy, this paper develops the concept of brand literacy. We trace the historical reasons why such literacy emerges and illustrate from a research study the different levels of brand literacy, and discuss the implications for consumers' engagement and experiences with contemporary consumption life and culture.

INTRODUCTION

Research in consumer culture has provided important insights into the role brands play in consumers' everyday lives (Fournier 1998; Kates 2004). Today, it is widely acknowledged that brands are not just differentiating marks that help consumers to choose one brand against another, but are also—and indeed more significantly—cultural signs that supply people with individual identities (Elliott and Wattanasuwan 1998), and collective identities through brand communities (McAlexander, Schouten, and Koenig 2002; Muniz and O'Guinn 2001). We have learned that brands are meaningful to consumers not just because they are strategically managed by companies, but because consumers incorporate them into their lives and add their own idiosyncratic stories to them (Brown, Kozinets, and Sherry Jr. 2003). In contrast to contemporary strategic brand management models (Kapferer 2004; Keller 2003), research on consumer brand cultures has illustrated how brands are co-constituted through a dialectical process between the consumer culture and the companies' branding efforts (Holt 2002). Brands, in effect, have acquired, with the changes in consumer culture (Lury 1996; Slater 1997), the status of cultural institution, signaling a constellation of cultures of brand, playing the role of signifying and communicating messages and images that are now often globally read, contested and navigated. As argued by some, while people across cultures are sometimes unable to communicate due to language differences, often understanding each other is possible when brand names, such as *Coca Cola* or *Kleenex* or *Levi's* or *Beckham*, are uttered (Hildebrand 1998; Holt, Quelch, and Taylor 2004).

In an iconic consumer culture where brands become important resources for social interaction, consumers develop knowledge and competences in the peculiarities of consuming brands 'knowingly' in a given social context. In this way, consumers develop something we call *brand literacy* and become increasingly skilled in relating to and using brands in a way that is recognizable by the consumer culture. We define brand literacy as *the ability of the consumer to decode the strategies used in marketing practices in introducing, maintaining and reformulating brands and brand images, which then, further enables the consumer to engage with these processes within their cultural settings.*

According to the literature on literacy (Bernardo 2000; Street 1999; White 1984), three degrees of literacy are needed for complete literacy. The first degree of literacy is the "reading," the ability to decipher the words (signs, in the broader meaning of literacy) in their systemic unity in order to make sense and understand their complete meaning. A second degree is the "writing," the ability to compose signs into a set that transmits the meaning intended. This

second degree of literacy is needed to improve the first degree, since by "writing" one gets to recognize the intricacies of composition, thus becoming more capable to recognize the strategies and methods employed by the "author" of what is being read and, thereby, having an improved capability to read analytically, in between and behind the "lines." Finally, a third degree of literacy is the ability to embed one's reading and writing in particular cultures. Thereby, the literate person can judge how and why novel reconstructions s/he may attempt are likely to be interpreted, decoded and understood by those s/he is trying to communicate with. When one has all three degrees mastered, then s/he is best able to become a participant in the design of signs and, thus, culture, and not simply a receiver.

LITERACY IN SOCIAL LIFE

Literacy is an important concept in many areas of social life. As discussed, in literacy studies, it refers not merely to the act of reading and writing printed language, but also to the ability to extract and process complex meanings in a sociocultural context (Bernardo 2000). While literacy traditionally was considered a cognitive process, isolated from social and cultural interaction, there is an increasing acknowledgement that literacy is embedded in activities and practices of a community. In this way, literacy is an active and creative process that allows the individual to participate in social and intellectual practices (White 1984). Literacy has come to embrace skills and competencies in a variety of areas of social life, such as computing, film and politics (Street 1999). The multifaceted employment of the concept makes it necessary to define it in the context where it is developed and put to use. For as Street (1999, p. 38) writes: "within a given cultural domain there may be many literacy practices, that is, not one culture, one literacy."

Theories of literacy have also been used in marketing and consumer research where *advertising literacy* has been introduced as a concept for understanding peoples' advertising experiences (O'Donohoe and Tynan 1998). Ritson and Elliott (1995) use literacy theory and propose a model of advertising literacy. Their model is based on a 'practice account of literacy' which involves meaning construction in the individual domain and an 'event accounts of literacy' which involves meaning construction of self and group identity in the social realm. Their model of advertising literacy emphasizes how readers of advertisements are active co-creators of advertising meanings that display an ability to read, co-create and act on polysemic meanings from ads (Ritson and Elliott 1995). While advertising literacy is an important concept addressing consumers' ability to read and make sense of *advertising*, it does not embrace the skills and competencies that are necessary for consuming *brands* 'knowingly' in a cultural context. Sense making of advertising can indeed be an important aspect of consumers' encounters with branded goods but is not the only facet of brands that people experience through their consumption.

Brand literacy is acquired in many ways; through everyday consumption of branded goods and advertising, through social interaction with other people, and through experiences in cultures in which brands are prominently displayed through multiple media. There are historical reasons why brand literacy has developed in contemporary culture. We shall first explore this history, then try to develop an understanding of brand literacy itself. Finally, we shall

discuss how brand literacy can be understood in the context of consumers' sense making of co-branding and the implications it has for consumers.

HISTORICAL REASONS FOR BRAND LITERACY

Different consumers develop knowledge about brands in different categories of products. Some consumers, for example, have a high degree of knowledge in automobile brands and others in brands of wine. Partially, such knowledge may depend upon the person's interests due to occupation or hobby or relations to someone in the "business." How brands work and the designing of strategies behind brands may thus be gained through such special interest in a product category. Of greatest interest to us in this paper, however, is the lay consumer's literacy of brands, gained for reasons of pure consumer interest; that is, literacy based not on obvious reasons, such as occupation, but on consumption experiences.

Why does such brand literacy develop? Why do so many people in our world today care to care about brands? The origins of these complex phenomena can be partially traced in the development of modernity, and specifically, in modern consumer culture. Modernity's project is one of emancipating the human being from all impositions; originally of nature and, then, also of all restrictions and oppressive obligations inscribed in erstwhile social orders (Russell 1972/1945). Through such emancipation, humanity can, with the use of scientific discoveries and technologies, take control of its own destiny to build a society that provides all the conditions enabling all individuals to fulfill their utmost potentials and visions (Habermas 1983). In effect, the modern project is to realize a grand future for humanity. Such a project required that all individuals be able to practice their own free will (Rorty 1979). The result of efforts to find and implement principles to make this project a reality, efforts in both the discursive and practical domains of human life and society, specifically in western cultures, has been the growth of *individualization*, *commoditization*, *consumerization*, and *marketization* (Slater 1997). These phenomena, in turn, have constituted the foundations of the institutionalization of brands.

The idea of the modern market has been integral to the quest of the modern project (Angus 1989). In modern thought, the market is envisioned as a *mechanism* (Slater 1997) that allows free sellers and buyers to come together and exchange their resources without any prior or subsequent obligations to each other. They need not know each other, be obliged or bound to each other in any way. Thus, the idea is that through this market mechanism, all individuals become free agents who can obtain what they want and can afford, according to their own free wills, not having to feel or have any obligations that could thwart their wills. With the growth of the market, then, that is through marketization of more and more human interactions, free agency of the human individual is enhanced.

With marketization comes the individualization of the modern human subject. By freeing the individual from all obligations that institutionally tie her/him to others and others' wills, individuality becomes more possible as does the capability to act as an individual. Thus, each individual is further enabled to act one's free will and constitute oneself as distinct and different from others; this emancipation of the individual being a principle inscribed deeply in the ideology of modern human rights.

This theoretically meritorious idea(l) of freeing the individual through the market requires the other two phenomena of commoditization and consumerization. Commoditization, that is the separation of the objects or items of use from their producers and the processes by which they are created (Marx 1976/1867), is necessary so that those who exchange for them can possess them without any linkages; the commodities stand on their own and are

considered to contain, in themselves, the qualities that their possessors seek in them. Thus, possessing and using them is an independent act that involves only the possessor and the commodity, and nothing or no one else.

Consumerization, that is the separation of the individual from the process of production of what is used, is, then, another necessity for the existence of modern markets. Consumerization enhances the freedom to have and use commodities of all kinds, which means non-reliance on solely one's own production, and provides the ability to consume what others produce and are willing to exchange. This separation from production of commodities consumed means that individuals relate to most of the items they consume in modern society simply as consumers. Thus, as people become consumers, acquiring what they use, the market expands its existence and individualization is furthered (Firat and Dholakia 1998; Slater 1997).

The above phenomena in modern culture are responsible for the development and institutionalization of brands and brand cultures as much as, if not more so than, the manufacturers' (marketers' in general) need to establish recognition and relations with their customers. Indeed, the principle of the individual's emancipation from all that did and could repress one's free will, and, thus, her/his ability to decide his/her own destiny, partaking in social choices, has been and is one of the most voiced and revered idea(l)s of our time. Much of this freedom of the will has come to focus on consumption choices (Dholakia and Dholakia 1985) thanks to marketization, individualization, commoditization and consumerization, along with the increased centrality of the economic in modern culture and, thereby, greater ability to consume increasingly coming to define improvement of human lives. Consumption has also become the locus of exhibiting individuality with greater rationalization of workplaces and, thus, increasingly routine and homogenized work-lives for the large majority of people during production.

Consequently, for people seeking to express their individuality in and through what they consume, brands, especially those that represent the categories of consumption they find expressive—for this can be different for different people—have provided the ground for articulating symbolic meanings, identities and, thus, individuality (Lears 1994). In a consumer culture where practically everyone has access to all product categories in a mass-market, distinguishing marks tend to be more easily found or inscribed in brands than in products.

When the history of brands is studied, certain patterns are recognized. First branded products appealed most to upper classes, thus becoming signs of distinction for the superordinate groups in society. Similar to fashion, brands exhibited a trickle-down process (Simmel 1904), where the upper classes first adopted premium brands that later diffused to subordinate groups. While the brand owners' original intention for brands may have mostly been to distinguish their products from others, brands fast became signs of distinction for consumers. Thus, the brand has always been a part of the symbolic consumption system. Specifically, the brand name or icon is a signifier that simultaneously becomes a sign—a union of the signifier and the signified a la Saussure (Barthes 1967)—for any recognition of the brand immediately conjures up associations. As a signifier, however, the brand is a free-floating expression, for at the same time or through time it may be associated with varying meanings (signified).

Given this history of development and institutionalization, what is a brand today? It is no longer simply a sign of ownership of the brand by those who manufacture or distribute it, but an *iconic sign* that constellates images that serve as a means by which people have life experiences and meanings, and through which these

cultural values and meanings are communicated. The construction of this sign is only partially controlled by the marketer who is the owner of the brand. The complete brand is the result of cultural processes whereby other players negotiate the meanings and contribute to its articulation (Holt 2004), which is, in effect, always in the process of being constructed however stable it may seem at times.

In contemporary times, the increasing prominence of brands in people's lives is also a sign(al) that an iconographic culture is on the rise—meaning that in the articulation of distinctions made and the hierarchical significance of these distinctions, iconic imagery plays an increasingly dominant role. In language, literature, films, in all cultural media, communication of what is what and who is who becomes most prominently and easily accomplished through elicitation of iconic brands (Friedman 1985). Iconic brands, of which there are now so many, used in this manner, also contribute to the growth of the iconographic culture, a culture where meanings are relayed less and less through sets of words (signs in general) constructed according to linguistic (or more generally, semiotic) rules of formulating analytically logical connections and, thus, sense making unit(ie)s, but more and more through iconic signs that at once conjure up images that transmit meanings and elicit senses that can be felt as well as cognitively processed.

This phenomenon further indicates the necessity of expanding the meaning of literacy as we discuss brand literacy, where “reading” (sensing) and “writing” (constructing/composing) in an iconographic culture require more than abilities related to understanding and using of words, where participating in brand cultures requires abilities related to a multiplicity of signs that impact on all senses—sight, hearing, smell, touch, and taste. Brand literacy requires, what has been called, (multi)signefficacy (Firat 1996).

Therefore, those who are most brand literate today are the ones who are privileged in having (multi)signefficacy. While this is a necessary condition for high brand literacy, it is not the only variable in acquiring brand literacy. Additionally, similar to distinctions between those who are fashion oriented, whose actions are informed by their concern for and reactions to fashion, and those who largely remain uninformed about fashion, there are distinctions between those who care about and those who remain uninformed about brands. Furthermore, there are different degrees and types of involvement with and literacy of brands. Therefore, the question arises as to whether the culture will favor those who care about brands or those who do not. In the case of the persistence of an iconographic culture, the use of iconic signs, thus of brands, and the influence of those who can make such use expertly is likely to increase.

BRAND CULTURES IN HISTORICAL RETROSPECT

While market exchanges have constituted a common characteristic of human life for several thousands of years, the culture of branded goods—especially as articulated in contemporary marketing literature—is a relatively recent phenomenon. Mass produced branded goods gradually became more readily available in the late Nineteenth Century in United States (Strasser 1989). The reason why manufacturer brands became a viable phenomenon, as well as desirable for their legal owners is generally explained by a number of macro-environmental changes, such as industrialization and urbanization that brought new innovations, improved transportation and, not the least, mass consumption (Low and Fullerton 1994).

An important aspect of consumer cultures is recognized to be that people desire a good not just because of the utilitarian value of the commodity, but also for its symbolic capacity, such as enabling the individual to express social status or to construct and maintain

self identity (Belk 1988). In this symbolic market (Levy 1959), the availability of branded goods is not a prerequisite for such processes to occur. In the Eighteenth Century, when branded goods were still rare, consumption became increasingly complex as people were encouraged to select from a variety of styles and colors (Breen 1993). With the introduction of *branded* goods, however, distinctions among competing goods were intensified and, given the history of the market discussed earlier, consumers were encouraged to also consider the brand in their consumption decisions.

Since the early days of mass produced branded goods in the United States, a common feature of brands has been the claim and/or expectation of consistency. When branded food products gradually became available from around 1850 in United States, consumers learned that, unlike grocery products that could be bought in bulk by the merchant and then by the consumer, branded goods promised a consistent quality that should not vary from one purchase to another (Strasser 1989). As Miller's (1998, p 142) research illustrates, the issue of consistency and predictability (cf. Ritzer 1993) is, today, still an important feature of branded goods. In a world that is rapidly changing, where consumer identities are found to be fluid and constantly rearticulated (Bauman 2001), brands become powerful because they help consumers to anchor their identity projects (Elliott and Wattanasuwan 1998).

BRAND LITERACY

Consistent with contemporary viewpoints of literacy, brand literacy refers to the ability of the consumer to make sense of and compose the signs of a brand culture, and to understand the meaning systems that are at play. More specifically, this means that the consumer's understanding of the brand goes beyond the immediate surface meanings of the words and symbols associated with the brand. Consumers who exhibit literacy of a brand know that the brand name and the symbols associated with it are not just signs used to distinguish one manufacturer from another, but signs that carry complex cultural meanings. These cultural meanings are produced throughout the life of the brand where consumers and cultural intermediaries contribute to the cumulative (re)formulation of the brand. For instance, a person who demonstrates literacy of the Lacoste brand knows that this is the classical brand for polo shirts that was launched by the French tennis player René Lacoste in 1933. In addition to knowing the history of the brand, brand literacy also includes the ability of the consumer to relate to the brand's contemporary status in his/her imagined consumption context. For the Lacoste literate consumer, this ability can consist of a flair for effective use of the brand and sensitivity towards the connotation it may generate in his/her consumption context.

How does brand literacy relate to other concepts such as *brand awareness*, *brand image*, *brand loyalty*, *brand relationship*, and *involvement with branded goods* which deal with peoples' brand behaviors? Our argument is that these concepts are all important components of brand literacy, but they are not in themselves an indication whether or not the consumer has acquired brand literacy. In order to play a role in a specific brand culture—that is a context in which a particular brand is socially constructed—it is important that the consumer has an understanding of what other people think and feel about the brand. By definition, each and every consumer who has awareness of a brand has an image of the brand that may be influenced by certain associations. However, while a brand image generally refers to the perceptions of the brand held in consumer memory (Dobni and Zinkhan 1990) it does not take into account whether or not this image is cognizant of the cultural meanings the brand has in the particular consumption context. Because consumers oftentimes personalize the meaning of a brand through consumption rituals, a brand image can be more or less idiosyncratic.

TABLE 1
Levels of literacy

Levels of literacy		
Low	Medium	High
Consumer may buy and consume brands but has no or little knowledge of the symbolic meanings brands have acquired in the culture	Consumer has ability to read and understand the cultural meanings and strategies underlying brands	Ability to fully participate in the culture of brands. Consumer does not just follow the cultural meanings, but is able to reformulate and play with them

Our conception of a brand literate consumer is one that is able to articulate and spell out the culturally agreed meaning and to consume the brand in ways that, therefore, make him/her effective in the cultural context. Similar to that of a brand image, involvement with branded goods (cf. Coulter, Price, and Feick 2003), brand loyalty, and brand relationship are not in themselves evidences of brand literacy. Though it is likely that a consumer who has acquired brand literacy also shows signs of involvement with a brand, one can easily imagine a consumer who is heavily involved with a brand but has limited understanding of how the brand—according to the brand connoisseurs—can effectively be consumed. When it comes to loyalty and brand relationship, it is easy to envision that a consumer who continues to buy a brand from time to time and who has developed strong emotional attachments to a brand may nevertheless have little interest in getting acquainted with the brand's socially constructed meaning.

Furthermore, given that literacy is a multidimensional construct that emerges in specific social settings, it is appropriate to distinguish between various levels of literacy. In Table 1, we outline three levels of literacy, determined by skills of reading, writing, and ability to embed this reading and writing in the culture. As seen above, on the one hand, there are consumers who do not care to care about brands and remain outside of the iconographic culture in which brands play a major role. On the other hand, we have the brand connoisseurs who are heavily involved with brands and who know how to play effectively with brands in consumer cultures. In between these two extremes, we can identify a circumscribed level of brand literacy where consumers are able to read and follow the culture of brands, but have limited ability to formulate and articulate its meaning to become effective players in it. These different levels of brand literacy will result in different consumer relations with brands and, also, different forms of consumer engagement with the culture of brands (cf. Fournier 1998). We wish to explore these potential relations and forms of engagement in the rest of the paper.

UNMASKING BRANDING PROCESSES

One of the main goals of brand management has been to provide a basis for differentiation from competitors' products. In brand management literature, it is generally suggested that successful differentiation on product attributes is not a source of long term differentiation, since these attributes can easily be copied by competitors. In a market where competing firms have access to the same technological solutions, competition moves to the symbolic domain where brand owners seek to differentiate their brands through attributes that relate to consumers' emotional states. In this way, branding becomes a way to nurture perceived symbolic differences that speak to consumers' desires. Indeed, brands provide people with a variety of benefits. During shopping, well known brands help

consumers to make decisions instantly, where tried and trusted brands are oftentimes chosen without much consideration because of their record of consistent delivery in past experience. Hence, brands tend to display and inform consumers of certain features, whereas some other features of the product are hidden. When no obvious or important differences exist at the product level, branding becomes an important tool for managers who seek to relate their brands to symbolic differences perceived by consumers. In this context, brand literacy becomes an important skill. As companies execute their branding strategies, over time *some* consumers become more knowledgeable about the principles of and the techniques for branding processes partaking in the institution and constitution of brands. Sophisticated forms of brand literacy make consumers potent, for example, to unmask the processes that may be hidden behind the brand façade (Dholakia 2004).

Consumers with a high level of brand literacy are able to unmask the branding processes that may blur the properties of the product. For instance, in the food industry, many manufacturers supply their products to retailers not with their own brand but with the retailer's brand—the private brand. In the same grocery store, it is sometimes possible to find a product from the same manufacturer both under the manufacturer's brand name and in a version using the retailer's brand. Although the actual product may be identical, the similarities between the products are hidden through branding processes that add packaging and symbolic content. Some consumers are aware of the fact that many manufacturers also produce retailer brands and may therefore conclude that there is no point in paying a premium price for a manufacturer brand when basically the same product can be acquired at a lower price. Some manufacturers, for instance *Kellogg's*, go as far as advertising to consumers that they do not supply retailer brands. The fact that *Kellogg's* and others need to so advertise indicates that a not insignificant segment of consumers have acquired enough brand literacy in order to unmask this particular branding process. If people did not have the knowledge that sometimes two branded goods are manufactured by the same company, there would not have been a need for *Kellogg's* to run such advertisements. This is an example that indicates how brand management has to respond to brand literacy.

Consumers at different levels of brand literacy can also be expected to react differently and relate differently to brands. In a research conducted to understand how consumers relate to co-branded products—products where two or more brands are used in conjunction—at least three distinct orientations have been found in relation to levels of brand literacy.

RESEARCH AND FINDINGS

The goal of the research was to collect empirical accounts of consumers' sense-making of co-branded products. In this context, co-branded products refer to marketplace co-operations where two

or more brands are used as co-endorsers for the product (Askegaard and Bengtsson 2005). By exploring the ways in which consumers understand and relate to this particular form of marketplace cooperation we were able to demonstrate the different levels of brand literacy. An important goal for this study was to include consumers with first hand experience from consuming co-branded products. Consumers were recruited in two different grocery stores after they had been observed buying at least one co-branded product. Consumers who agreed to participate in the study were later contacted for in-home interviews. Phenomenological interviews (Thompson, Locander, and Pollio 1989) were conducted with each consumer at his/her home in order to elicit the lived experience of co-branded products. Each interviewee was interviewed for a total of four to six times, for one to two hours each time, over a six-month period. Through this multi-interview approach, it was possible to elicit how brand literacy was acquired. Thus, the data consist of interviews of seven consumers living in a large city in western United States. The selected interviewees represent a variety of ages, incomes, education levels, religions, and both sexes.

Our analysis of the data collected indicates that consumers at different levels of brand literacy construct at least three different categories of stories that justify or rationalize their relations to co-brands. There is an almost exact correspondence between the three levels of brand literacy and the three types of stories we elicited from the interviews. Consumers who showed a low level of brand literacy produced, what we call, *production stories* about co-brands. In these stories, the interviewees understood co-branding primarily as a way of sourcing primary products, where one of the brands is portrayed as supplier of a product that is bought by the other brand (or the company behind this brand) in order to be used as an ingredient in the product which the consumer is buying. For instance, a recently retired woman expressed that she thought the visual display of the chocolate brand Hershey's in a Betty Crocker brownie mix had to do with supply of the chocolate ingredient. She thought Betty Crocker bought the chocolate from Hershey's and then put the brand name on the package. In her opinion this procedure was a good solution where Hershey could sell their chocolate through another brand. As this example illustrates, production stories reflects a low level of brand literacy where co-branding is understood as a way for companies to manage their sourcing of primary products whereas understanding of the marketing logic that drives companies to initiate co-branding agreements is very limited. Consumers who had brand literacy at the medium level produced, what we call, *strategic stories*. Here the consumers provide analytical interpretations of co-branding activities by companies, explaining why and how their practices may or may not make sense and how it may influence their idea about the brands. For instance, a woman expressed her thoughts about the Betty Crocker brownie mix with Hershey's syrup and concluded that her idea of Betty Crocker had changed because of the kind of business co-operation the brand has with Hershey's through the co-branding activity. She had always thought of Betty Crocker as a homespun brand but now when it seems to be fairly business oriented, entering partnerships with other brands to improve profits, the warm, fuzzy feelings she associated with the brand changed. Finally, consumers with high levels of literacy produced, what we call, *critical stories*. Here, consumers exhibit an ability to critically question companies' co-branding efforts. In the research, consumers at this level of literacy indicated an understanding that co-branding has marketing implications but rejected or criticized this practice as a symbolic game that intended to make the products more appealing to consumers. Related to this rejection was the understanding that behind many brands there are multinational conglomerates that control

many of the brands in the marketplace. Co-branding was therefore seen as an opportunistic display of two brand symbols when it made sense from a marketing perspective. The reason co-branding is seen as opportunistic is that when such display is not favorable—such as the example of a display of Philip Morris on Kraft Foods—the link is kept secret so that consumer do not make a connection between the two companies and their brands. Other examples of critical stories occur when consumers critically evaluate a marketing organization's policies, offering strategies to better articulate or improve the brand.

IMPLICATIONS OF BRAND LITERACY

As literacy in general influences the individual's relations to/ in society, brand literacy affects the relationships consumers have with brands and with consumption in general. In a growing iconographic culture, consumers' brand literacy influences their degree of effective involvement in the images, strategies, and use of brands, and the degree to which they can impact on companies' policies. We see from the research on co-branding, for example, that consumers at different levels of brand literacy employ different levels of interpretation strategies. Interpretation, in dealing with understanding brands involves processes of juxtaposition (matching, comparing and contrasting of the values and beliefs of consumer's culture with the perceived signs from the marketer, resulting in temporary or longer-term co-existence of meanings), resistance (intended ignoring or critical refutation of perceived meanings of the signs), and transformation (intentional or unintentional reconfiguration of the signs or their intended meanings), similar to consumers' involvement in fashion (Thompson and Haytko 1997). Consumers at higher levels of brand literacy, as they move from production to strategic to critical stories about brands, also tend to employ more of the interpretation strategies and with greater depth. With increasing brand literacy, the consumers' reactions in terms of appropriating, interpreting, negotiating, and constructing signs and their attached meanings regarding the co-brand take different forms. Consumers encountering the stories emanating from the marketing organization's promotional efforts for the brand tend to juxtapose these to stories from other brand cultures, transform them in the process of appropriation, or resist them with greater intensity as their brand literacy grows.

Brand literacy is and will likely increasingly become a significant element in consumers' life experiences. Indeed, one can choose not to care to care about brands and let others acquire literacy about brands. However, in consumer cultures that are permeated with brands and where brands are important vehicles for social interaction, it becomes apparent that brand literacy is an important skill in everyday life that becomes difficult to opt out of. We recommend, therefore, a focus on this construct, developing a greater understanding of it through further articulation of its dimensions and, also, measures or scales of it, in order to appreciate fully its role in contemporary consumers' lives.

How Do Consumers Interpret Market Leadership Claims in Direct-to-Consumer Advertising of Prescription Drugs?

Anu Mitra, American University

Jack Swasy, American University

Kathryn Aikin, Food and Drug Administration*

ABSTRACT

Claims such as “most prescribed” are commonly made by top-selling prescription drug brands in their direct-to-consumer (DTC) advertising. Under the FDA’s current policy, sponsors may present “market leadership claims” (MLCs) with only sales data to support the claim. This paper examines how MLCs might affect consumers’ product judgments and whether such claims evoke unwarranted inferences and beliefs about the superiority of the leading brand.

Results of two studies suggest that market leadership claims in DTC advertising signal greater trust of the brand among prescribing doctors and imply superior product effectiveness under conditions when supporting survey and clinical data to support such inferences have not been provided.

ADVERTISING OF PRESCRIPTION DRUGS?

Prescription drug advertising has become increasingly consumer-directed in recent years, and the industry spent \$4.2 billion on “direct to consumer” (DTC) advertising in 2004 in the U.S.—an increase of nearly 30% from 3.2 billion in 2003 (Boston Globe, March 2, 2005). Market Leadership claims (MLCs) are commonly used in DTC prescription drug advertising; many of the top-selling brands in several categories (e.g., Celebrex, Zolof, Avandia, and others) make claims of market leadership to differentiate themselves from competition. (For example, Celebrex has used the claim “The #1 selling prescription arthritis medicine.”) We note two characteristics of MLCs that may have important implications when such claims are used in the advertising of prescription drugs. These claims are comparative in nature and may lead consumers to make inferences regarding the leader’s superiority on important product attributes. (c.f., Barone and Miniard 1999; Shimp 1978). In addition, a MLC for a prescription drug may lead consumers to draw inferences about the brand’s market acceptance, i.e., its relative standing among health care professionals.

The advertising of prescription drugs is regulated by the Food and Drug Administration (FDA), and under current FDA regulations, claims of product superiority or market acceptance must be supported by relevant clinical or market evidence. Therefore, if a company has clinical data to support the claim that its brand is “more effective” than competition, it could differentiate itself from competition based on this explicit claim of superior performance. However, if actual superiority in performance or doctor preference is difficult to document, MLCs that suggest *perceived* superiority may be used by the sales leader to differentiate itself from challenger brands. Under current FDA regulations, such MLCs are permitted as long as they are supported by sales data, such as that provided by the IMS Health National Prescription Audit. This research investigates how consumers interpret a MLC in the context of DTC prescription drug advertising, and examines the potential of such claims to evoke unwarranted inferences about relative effec-

tiveness of the leader and/or its superior standing among physicians or patients.

BACKGROUND LITERATURE

In one of the few papers in marketing that have examined market share, Hellofs and Jacobson (1999) identified conditions under which a high brand market share would lead to perceptions of higher quality. In the economics literature, Caminal and Vives (1996) suggest that a brand’s market share, which reflects the relative preference for the brand aggregated across dispersed individual buyers, could be used by consumers to make inferences about unobservable product quality. Based on this logic, prescription drug marketers could use various tactics to gain sales leadership (e.g., deep price discounts to selected formularies, aggressive sampling, and intensive detailing, etc.), and then use MLCs to shape consumer judgments. These strategies are likely to be effective, since research in marketing suggests that consumers are more likely to use extrinsic cues in their evaluation of experience/credence products such as prescription drugs (see Ziethaml 1988).

While Hellofs and Jacobson’s (1999) research offers initial empirical evidence on the effects of market share information, their study did not examine consumer responses to a brand’s *leadership* claim presented *within* an advertisement. Furthermore, this research does not offer an understanding of the nature of consumer inferences made from MLCs for prescription drugs, in particular, whether they may lead to unwarranted conclusions about specific attributes of the sales leader. Additionally, consumers may interpret share of prescription drug brands as indicative of the brands’ endorsement by physicians, who are experts, and may draw meaningful inferences about doctors’ preferences and brand beliefs. These may, in turn, influence consumer evaluations of the product. Two studies described below address these issues. Study 1, adopts an open-ended questioning approach to explore the nature of inferences evoked by a MLC. Study 2 examines how MLCs affect beliefs about the brand’s effectiveness and its standing among doctors (relative to competing brands).

STUDY 1

Although economic signaling theory suggests that market share will be used by consumers to make inferences about relative quality (see Caminal and Vives 1996), it offers little detail on the psychological mechanism for how judgments of other consumers might affect an individual’s perceptions. But support for such a mechanism can be found in studies in consumer psychology that have examined the issue of how social influence in general, affects consumer judgments. This stream of research has shown that even for familiar products in which personal taste was the sole criterion for evaluation, individual judgments can be modified by the perceived evaluations of others. This modification in judgment occurred despite the fact that no attempt was made to encourage subjects to believe that the information conveyed by others was accurate or reliable (c.f., Price and Feich 1984). Cohen and Golden (1972) note the importance of the “informational” value of social influence—“influence to accept information provided by others which is taken as evidence about reality” (p. 54). Social psycholo-

*The views expressed here are solely those of the authors and do not necessarily reflect the policies of the Food and Drug Administration.

gists use the term “social validation” to describe this influence. “We use actions (of others) as a means of social validation, as an interpersonal way to locate and validate the correct choice (Festinger, 1954).” This implies that a brand’s leadership position, which reflects a strong preference for the brand across numerous decision makers, is likely to influence consumer judgments about the brand’s market acceptance.

Since doctors are the primary decision makers in the selection of prescription drugs, which have risks associated with usage, research in social validation suggests that the prescribing behavior of doctors (reflected in the MLC) can significantly affect consumer judgments (Burnkrant and Cousineau 1975). Note that a *moderate* MLC (“most prescribed) can be made stronger by providing additional factual information (e.g., “4 million more than the next leading brand”). Thus we predict:

H1a. A MLC will evoke more inferences about the brand’s acceptance among doctors than a non MLC; more of such inferences will be evoked with a *strong* (vs. *moderate*) MLC.

Consumer research suggests that consumers use extrinsic cues such as price, warranty or brand name in judging the quality of a product (Rao and Monroe 1989; Srivastava and Mitra 1998), and that reliance on such cues to judge unobservable product quality is greatest when product attributes are difficult to evaluate prior to purchase (Ziethaml 1988). Consumer expertise in the prescription drug category is low. This suggests that a MLC, if interpreted as brand preference of numerous experts, i.e., doctors, is likely to evoke inferences about attributes of the drug. Thus we predict:

H1b. A MLC will evoke more inferences about product effectiveness than a non MLC; more of such inferences will be evoked with a *strong* MLC, compared to a *moderate* MLC.

Furthermore, a MLC such as “Celebrex is the brand most prescribed by doctors” does not draw an explicit conclusion nor does it provide an explicit argument structure (Sawyer 1988; Kardes 1993). Yet, the “open-ness” of the MLC makes it an effective persuasion tactic for two reasons: (a) involved audience members construct their own syllogistic reasoning and self-generate a desired conclusion; and (b) the audience attributes ‘less bias’ in the message (c.f., Sawyer 1988, p 168). Instead of directly asserting performance superiority, the ad that reports the behavior of doctors may generate fewer counterarguments and resistance to the source of the message. This further enhances the likelihood of self-generated inferences about the superiority of the market leader, especially under a *strong* MLC. Thus:

H2a. A MLC will evoke more *comparative* product quality inferences than a non MLC; more of such inferences will be evoked with a *strong* (vs. *moderate*) MLC.

H2b. A MLC will evoke more *comparative* market acceptance inferences than a non MLC; a greater number of such inferences will be evoked with a *strong* (vs. *moderate*) MLC.

Method

The overall research approach was consistent with suggestions by Graeff and Olson (1994) on the best methods to get a deeper understanding of consumer inferences, and similar It is also similar to other studies of comparative advertising (Manning, Miniard,

Barone, and Rose 2001). We employed a non-directive, thought-listing approach to investigate the nature of consumer inferences evoked by MLCs.

Subjects and Procedure. One hundred twenty undergraduate female students at a private university participated in the study. They were randomly assigned to see one (of three) versions of an ad for a hypothetical brand of prescription pain reliever.

Stimuli. Advertising claim condition was manipulated at three levels: (a) moderate leadership, (b) strong leadership, and (c) control. The layout and composition of the ads were modeled after an actual advertisement for a leading brand. In the “moderate” market leadership condition, the first claim featured in the ad was: “PRIDON. #1! The Most Prescribed Treatment for Acute Pain ***” In the “strong” market leadership condition, the leadership claim was supplemented with the sentence “Over 4 Million More Prescriptions Than The Next Leading Brand.” Both leadership claims were accompanied by a referencing footnote (“*** Data from IMS HEALTH, National Prescription Audit. Based on total dispensed prescriptions for the period 5/01 through 1/02”), and a “#1 Prescribed” banner that was placed in the upper right-hand corner of the ad. In the control condition, the first claim featured in the ad was: “PRIDON. Prescription Medicine For The Treatment of Acute Pain.” Other parts of the advertisement (major statement of side effects and warnings, etc.) were held constant across the three ad conditions.

Dependent Measures. After reading the ad, subjects answered two key open-ended questions: “What does this ad claim mean to you?” and, “What, if anything, about Pridon is suggested by this statement.” They also responded to a the manipulation check measure

Results

Manipulation check. Subjects’ responses showed that overall, MLC claim manipulations were successful in increasing subjects’ perceptions of relative prescription frequency. Average prescription frequency for the control and two market leadership versions were 2.5, 3.2 and 3.4 respectively ($F(2,117)=10.1$; $p<0.001$). While prescription frequency was perceived to be significantly different between the control and the MLC conditions, the perceived difference between the *moderate* and *strong* MLC conditions were not significant.

Findings. The 440 separate responses elicited by the thought listing task were content analyzed by two judges to classify the nature of the elaboration indicated by each response. A third judge was used to resolve discrepancies ($\kappa=.815$). A response was classified as a simple “ad restatement” if it was a verbatim or near verbatim restatement of the ad claim with little or no elaboration (“you can get it only from a doctor”). Responses indicating elaboration about the product were labeled Inferences and were classified under: (a) “product attributes,” if the response mentioned a specific attribute (e.g., “it’s effective”, “it is strong”), or (b) “market acceptance,” if the response addressed the brand’s relationship with doctors (“it’s popular”, “doctors trust it”). Finally, responses were classified as comparative (e.g., it’s more effective”) versus noncomparative (e.g., “it’s effective”). Subjects reported an average of 4.0 responses to the two questions. See Table 1.

Results for the three ad claim conditions are presented in Table 2. We observe strong support for H1a, that MLCs evoke more market acceptance inferences relative to the control claim ($\hat{u}_{\text{control}}=0.02$, $\hat{u}_{\text{mod}}=1.08$, $\hat{u}_{\text{str}}=1.45$; $F(2,117)=25.1$; $p<.001$). The difference between the *moderate* and *strong* ML conditions was not statistically significant ($F(1,78)=2.18$; $n.s$). However, contrary to H1b, MLCs did not evoke more product attribute inferences com-

pared to the control claim ($\hat{u}_{control}=2.10$, $\hat{u}_{mod}=1.60$, $\hat{u}_{str}=1.60$, $F(2,117)=1.41$, n.s.).

MLCs also evoked comparative inferences. About 30% of inferences about product attributes were comparative in nature.

Comparative product inferences were higher under the MLC conditions ($\hat{u}_{control}=.25$, $\hat{u}_{mod}=0.58$, $\hat{u}_{str}=0.75$; $F(2,117)=3.0$; $p=.054$), providing support for H2a. There was partial support for H2b. Comparative market acceptance inferences, which were not

observed in the control condition, represented about 39% of the market acceptance inferences in the MLC conditions. However, although more comparative inferences were observed in the *strong* than *moderate* MLC condition ($\hat{u}_{mod}=0.38$, $\hat{u}_{str}=0.60$), the difference was not statistically significant ($F(1,78)=2.14$; $p=0.15$).

Study 1 demonstrated that MLCs have the potential to evoke inferences about comparative product effectiveness and market acceptance of the market share leader. In the next study, we examine if MLCs affect specific brand beliefs.

STUDY 2

Consumer researchers have noted that inference plays an important role in persuasion, and may influence persuasion even more than the advertising message. (Chattopadhyay and Alba 1988; Greenwald 1968; and Petty, Cacioppo and Schumann 1983). Results of Study 1 showed that MLCs evoke inferences about the attributes of the market leader. In Study 2, we examine more specifically the issue of belief formation after exposure to a market leadership claim in DTC advertising. We make the following predictions:

- H3. Compared to a non MLC, a MLC will enhance beliefs about: (a) product effectiveness and (b) comparative product effectiveness. A *strong* MLC will enhance beliefs more than a *moderate* MLC.
- H4. Compared to a non MLC, a MLC will enhance beliefs about doctor-brand acceptance. A *strong* MLC will enhance beliefs about doctor-brand acceptance more than a *moderate* MLC.

Method

Subjects and Procedure. Seventy-seven undergraduate students participated in the study and were randomly assigned to one of ad claim conditions for a prescription pain reliever. The procedure used in this experiment was similar to that used in Study 1.

Stimuli. As in Study 1, advertising claim condition was manipulated at three levels: The layout and composition of the ad was adapted from that of a leading brand and included elements common to prescription drug print advertisements. The level of market leadership—*strong* and *moderate*—was manipulated using length of time (six months vs. five years). Thus, the *moderate* (*strong*) MLC featured in the ad was: “In 2002 (over the last five years), doctors prescribed PRIDON more than any other brand of prescription pain reliever.” The MLC was supported with a footnoted reference to data from an IMS audit for the appropriate time period (i.e., five-year time period vs. first six months of 2002). In the *control* condition, the claim featured in the ad was “Prescription medicine for the treatment of severe pain.” All other portions of the advertisement were held constant across all three conditions.

Dependent measures. Beliefs about product effectiveness were measured on three 7-point likelihood scales (effective/“relieves pain”/unreliable”). Comparative effectiveness was assessed using the same items posed in a comparative context (e.g., “more effective than other prescription pain relievers”). Beliefs about the relative preferences of doctors were assessed using a series of six questions about relative preference, trust and effectiveness (e.g., “How likely is it that doctors prefer PRIDON over other prescription pain relievers?”/“... like PRIDON less than ...?”/“... think PRIDON is more effective than other prescription pain relievers”: Very unlikely=1; Very likely=7). Subjects’ perception of relative sales was assessed on two 5-point scales. These measures served as the manipulation check.

Results

Manipulation check. Results showed that MLCs were successful in affecting perceptions of relative sales. Cell means for the two relative sales measures are in the appropriate direction across the three conditions (See Table 3). A factor score for “relative sales” was created based on the two items (see item loadings in Table 3). GLM analyses with planned comparisons revealed that the differences across the three claim conditions approached conventional levels of statistical significance ($\hat{u}_{control}=-.36$, $\hat{u}_{mod}=-.02$, $\hat{u}_{str}=.29$; $F(2,74)=3.02$, $p<.06$). Perceived sales level in response to the *strong* MLC was significantly higher than the control ($d=0.65$, $t=2.45$ ($p<.05$)), but the difference between the *moderate* and control conditions, was not statistically significant ($d=0.34$, $t=1.18$, (n.s.)).

Beliefs. Means for the brand belief items are displayed in Table 3. Factor scores for each construct were created (item loadings are displayed in Table 3). A summary of the GLM and contrast analyses is shown in Table 4.

Effectiveness. Consistent with H3a, consumer beliefs about product effectiveness were higher in the MLC conditions ($\hat{u}_{control}=-.41$, $\hat{u}_{mod}=-.01$, $\hat{u}_{str}=.32$; $F(2,74)=3.91$; $p<.05$). Contrasts reveal a significant difference between the control vs. the *strong* MLC condition ($d=.75$, $t=2.85$, ($p<.01$)), but not for the control vs. *moderate* MLC condition ($d=.43$, $t=1.50$, (n.s.)). A similar pattern was observed for comparative effectiveness ($\hat{u}_{control}=-.36$, $\hat{u}_{mod}=.11$, and $\hat{u}_{str}=.20$; $F(2,74)=2.33$; $p=.10$), providing marginal support for H3b. Contrasts reveal a significant difference for the control vs. the *strong* MLC condition ($d=.55$, $t=2.06$, ($p<.05$)), but not for the *moderate* vs. control ($d=.47$, $t=1.62$ (n.s.)).

Doctor-Brand Acceptance. Results also showed support for significant MLC effects on consumer beliefs about the doctor’s acceptance of the brand. Consumer beliefs about doctors’ relative trust in market leader brands were affected by MLCs ($\hat{u}_{control}=-.52$, $\hat{u}_{mod}=.24$, and $\hat{u}_{str}=.23$; $F(2,74)=5.33$ ($p<.01$)). Doctors were thought to trust the leader brand more in both the *moderate* ($d=.767$, $t=2.74$, ($p<.01$)) and *strong* ($d=.757$, $t=2.93$, ($p<.01$)) MLC conditions. Beliefs about doctors’ brand preference or liking for a market leader were similarly affected by MLCs ($\hat{u}_{control}=-.49$, $\hat{u}_{mod}=.15$, and $\hat{u}_{str}=.27$; $F(2,74)=4.74$ ($p<.05$)). Contrasts showed that doctors were thought to prefer the leader brand more in both the *moderate* ($d=.646$, $t=2.29$, ($p<.05$)) and *strong* ($d=.765$, $t=2.95$, ($p<.01$)) MLC conditions. These results provide support for H4.

MLCs affected consumer beliefs about doctors’ judgments of relative effectiveness in a similar manner, but to a lesser degree. Doctors were thought to judge a market leader brand as being more effective than other brands ($\hat{u}_{control}=-.40$, $\hat{u}_{mod}=.15$, and $\hat{u}_{str}=.20$; $F(2,91)=4.74$ ($p=.051$)). Contrasts revealed significant differences between the control and the *strong* MLC condition ($d=.60$, $t=2.26$, ($p<.05$)), but not for the *moderate* vs. control ($d=.54$, $t=1.89$ ($p<.10$)) at the $\alpha=.05$ level.

DISCUSSION

This paper extends previous research in economics and marketing on the role of market share information to understand the effects of leadership claims, specifically, MLCs used in prescription drug advertising. Our study provides preliminary evidence that an ad featuring an MLC for a prescription drug can enhance consumer beliefs about effectiveness, both in absolute and relative terms. We also observed that MLCs resulted in beliefs about the doctors’ *comparative* judgments about the market leader. In particular, presentation of a MLC resulted in consumers believing that doctors judged the product to be more effective, more preferable and more trustworthy than other brands. An interesting finding was

TABLE 3

^bScale: very unlikely=1; very likely=7 ^c Scale item reversed

that even with a “moderate” leadership claim (six months share leader), the brand was seen as being trusted more and preferred more by physicians. This suggests that a brand which can achieve sales leadership, for as few as six months, can advertise the fact and reap potential benefits in terms of consumer beliefs about doctor preference and trust.

While more research is needed to extend and test whether the results are generalizable, several implications are suggested about

market leadership claims in DTC advertisements. First, MLCs may create a “difficult-to-correct” bias against competitor brands that may not be clinically different in terms of clinical effectiveness or doctors’ comparative evaluations. Consider the claim a challenger brand might (accurately) use in a counter-attack—“No other brand is proven more effective than *ProPill*.” The likelihood that such a claim may be able to correct misperceptions may be low, especially if the challenger cannot support the claim with a well-controlled

TABLE 4

comparative efficacy study. Even with such a study and consumer acceptance of the challenger's claim, the counter-claim may result in, at best, a belief of competitive-parity.

Will consumers "self-correct" this bias? Previous research shows that consumer experience with products is often ambiguous, and in such cases, experience is often interpreted in line with prior expectations (Hoch and Ha 1986; Hoch and Deighton 1989). In some categories, consumers who are "new-to-the-market" may find their experience with a prescription drug especially hard to evaluate even with guidance from a healthcare professional. Therefore, we might hypothesize that expectations created by MLC advertising will influence how consumers form their consideration set and how consumers interpret subsequent product experience. Those who are prescribed the leader brand might experience a stronger placebo effect or may be more reluctant to switch to another brand in spite of a less than optimal product experience. Conversely, patients using a smaller share brand may switch unnecessarily because of the tendency to interpret the current performance of the brand as potentially inferior to that promised by a leader. Also, because of expectations, caregivers, who are now often the target of prescription drug advertising, may be similarly affected by leadership claims. They may be more inclined to ask about a market leader. Left uncorrected, the bias created by MLCs will result in effects similar to the concept of "double jeopardy"—the statistical observation that in many competitive markets, small market share brands generally evidence less "loyalty" among their buyers than large brands (leaders) do among theirs (Ehrenberg, Goodhardt, and Barwise 1990).

Consumers, unlike physicians and pharmacists, do not have a proper context for evaluating MLCs. Physicians and pharmacists understand that prescribing behavior may be affected by marketing practices (pricing and detailing) and that aggregate sales data are

not a substitute for well-controlled clinical tests of comparative effectiveness. Normally, skepticism about an advertiser's motives may protect consumers from being misled. Since doctors serve as the learned intermediaries, consumers may assume that doctors' prescribing patterns represent expressions of (unconstrained) choice among available medications, and that the brand selected in each case is the one that is "best" for the patient. If so, the market leadership position (achieved through the prescriptions written by numerous individual doctors acting independently.) would appear to the consumer as a true reflection of relative superiority. Ironically, the more strongly consumers believe that physicians act in the patients' best interest, independent of external influence, the more susceptible they may become to the effects of MLCs. Those most skeptical of their physician's motives (and/or DTC advertising) may be the least affected by MLCs.

If MLCs cause consumers to believe that a brand is superior, the incentive for pharmaceutical manufacturers to do comparative brand (as opposed to placebo) efficacy studies may be reduced. Under current FDA regulations, a brand would be allowed to make a direct claim about its superior effectiveness or doctor preference only when supported by market surveys or clinical data. We argue that MLCs in DTC advertising offer the brand an *indirect* way to make a claim of relative superiority without presenting such evidence. Our studies show that consumers make MLC-based inferences about relative effectiveness of prescription drugs, consistent with predictions of signaling theory (Caminal and Vives 1996). Caminal and Vives note that firms would attempt to gain market share by lowering prices and promoting the product heavily. The implication is that if a MLC can be used to shape beliefs about relative effectiveness as suggested by our data, then drug companies may have fewer incentives to do well-controlled clinical studies to assess comparative effectiveness. An advertising strategy

based on post-marketing data (such as IMS), may be less risky and less costly, even though post-marketing sales data are obviously not designed to assess comparative effectiveness.

Our studies provide initial evidence to suggest that market leadership claims in DTC advertising may serve as an indirect method of making a statement about the comparative superiority of a brand under conditions in which clinical or market evidence to support such claims are not available. Future research might examine potential boundary conditions on the extent to which MLCs affect consumer inferences. For example, researchers might examine the effects of using explicit share percentages to support the MLC, and if providing such information would result in fewer inferences about the relative superiority of the share leader. Without *specific* market share figures for the major brands in the category to clarify the leader's claim, consumers are left to form their own impressions about market structure. Consumers exposed to a MLC may overestimate the leader's relative market share (either the ratio of the leader's share to next largest challenger's, or the incremental difference between them). These assumptions about relative market share might affect whether the leader is viewed as better than "all other brands," "most other brands," or "some other brands" (c.f., Johar 1995). Research may also investigate the effectiveness of a disclosure in the advertisement stating that sales data (leadership) are not suitable evidence for judgments of comparative brand efficacy or safety.

Investigating Impulse Buying and Variety Seeking: Towards a General Theory of Hedonic Purchase Behaviors

Piyush Sharma, Nanyang Business School
Bharadhwaj Sivakumaran, Indian Institute of Technology
Roger Marshall, Nanyang Business School

INTRODUCTION

Impulse buying (IB) and variety seeking (VS) are classified as hedonic purchase behaviors associated with feelings and psychosocial motivations rather than thinking and functional benefits (Baumgartner 2002) and shown as examples of low-effort feeling-based decision-making, associated more with feelings rather than cognitive processing and with a strong affective component (Hoyer and Macinnis 2001). However, despite these motivational and behavioral similarities, there is no common conceptual framework or general theory to explain the socio-psychological processes underlying these two behaviors. This paper addressed this gap by exploring similarities and differences between these behaviors using a conceptual framework incorporating three relevant consumer traits—consumer impulsiveness, optimum stimulation level and self-monitoring.

CONCEPTUAL FRAMEWORK

Most of the consumer traits associated with IB and VS can be traced back to a single personality measure, namely trait impulsivity in the Psychology literature (Eysenck and Eysenck 1977; 1978; Zuckerman 1979; Cloninger et al. 1991; Eysenck 1993; Zuckerman et al. 1993; Zuckerman 2000; Whiteside and Lynam 2001). Individuals with high optimum stimulation level (OSL) are chronically lower in their arousal level making them indulge in sensation seeking activities to achieve their desired (optimum) stimulation level (Raju 1980; Steenkamp and Baumgartner 1992). Such individuals are also more likely to indulge in IB and VS behaviors to reach their optimum stimulation level. On the other hand, high self-monitors are expected to be more motivated to control their impulses (or, urges) due to their desire to appear rational and prudent (Becherer and Richard 1978; Rook and Fisher 1995; Dholakia 2000).

In this paper, it is specifically argued that consumer impulsiveness and optimum stimulation level influence both IB and VS behaviors positively, whereas self-monitoring influences IB negatively and VS positively. Moreover, self-monitoring is also hypothesized to moderate the influence of consumer impulsiveness and optimum stimulation level on purchase decisions, negatively for IB and positively for VS. Specifically, high impulsives who were high self-monitors indulged in less IB compared to low self-monitors and low variety-seekers sought more variety if they were high self-monitors.

METHODOLOGY

Two studies were conducted to test these hypotheses, one with 160 undergraduate students and the other with 309 retail shoppers. Questionnaires were developed using established scales to measure the consumer traits and level of impulsiveness/variety seeking in purchase decisions. In the first study, participants were exposed to two different purchase scenarios and their purchase intentions were recorded using single-item five-point scales (adapted from Rook and Fisher 1995). To improve the generalizability, retail shoppers were intercepted and interviewed about the items bought by them. Levels of impulse buying/variety seeking were estimated based on

their actual purchase decisions. Only pure impulse and variety seeking purchases were considered and the others were discarded (e.g. reminder impulse etc.).

RESULTS AND DISCUSSION

Using multiple moderated regression analysis, it was found in both the studies that consumers with high scores on CI and OSL indulged in more IB as well as VS compared to those with low scores on these two traits. High self-monitors indulged in less IB but more VS. Moreover, self-monitoring moderated the relationship between CI and OSL with level of impulsiveness or variety seeking in purchase decisions.

In this paper, IB and VS are shown to be similar to each other for the first time empirically based on a common conceptual framework incorporating three relevant consumer traits. It also highlights some key differences in the normative aspects of these two behaviors by showing the opposite influence of trait self-monitoring on these two behaviors. High self-monitors are shown to indulge in less IB but more VS. Moreover, the association of the other two traits i.e. consumer impulsiveness and OSL with VS is shown to be moderated positively by self-monitoring but negatively for IB. The conceptual framework used in this research paves the way for a better understanding of these two common but complex consumer behaviors.

LIMITATIONS AND FUTURE RESEARCH

However, this research also has a few limitations. It explored only the influence of consumer traits on both the behaviors. Future research may include some relevant situational factors such as mood, time and money availability and involvement level. It also used only one scenario for each behavior in the first study (i.e. using jacket and ice-cream). However, there could be a significant difference between the involvement level in the two scenarios used by us e.g. price difference between the jacket (IB) and the ice-cream (VS). Future research may use different scenarios to study these behaviors. Finally, future researchers could test more complex conceptual models by including some possible mediators for these behaviors such as browsing, impulsive urge, attitude towards impulse purchase, cognitive evaluation and resistance strategies.

Binge Drinking—Do They Mean Us? Living Life to the Full in Students' Own Words¹

Emma N. Banister, Lancaster University Management School

Maria G. Piacentini, Lancaster University Management School

ABSTRACT

This paper attempts to further understanding about young people and their excessive alcohol consumption, focusing particularly on students. The study aimed to identify and explore the role and position of alcohol in students' lives, and the perceived benefits that alcohol offered. Undergraduate student researchers were recruited and trained to conduct focus groups. Major findings focused on the way participants consumed alcohol, the language they used to talk about their behavior, the means by which they rationalized their behavior, and the perceived benefits they gained from drinking alcohol. The implications of this research for consumers and policy makers are discussed.

INTRODUCTION

The discussion and analysis of young peoples' drinking habits has captured the interest of academic researchers from a range of disciplines. The underlying assumption of much research has been that excessive alcohol consumption is problematic or deviant behavior, and the focus is often on examining the negative impacts of alcohol consumption. This study attempts to explore the area of young people and their alcohol consumption using young peoples' voices to present the findings, focusing particularly on students. Rather than judging students' alcohol consumption or approaching it as a problem-solving exercise, in this primarily exploratory study we attempted to progress towards identifying and understanding: firstly the role and position of alcohol in the lives of students, and secondly the perceived *benefits* that alcohol offered. Taking this approach should facilitate a better understanding of the attractions of excessive alcohol consumption, and hence its importance in students' lives.

LITERATURE OVERVIEW

Excessive alcohol consumption amongst young people has been recognized as a major problem for Western countries. Binge drinking is of particular concern in the UK and is prevalent among people between the ages of 16 and 24 (Strategy Unit 2004). It is acknowledged that alcohol plays a key role in the lives of many undergraduate students (e.g. Ardenekan 2005; Christie et al. 2001; Gill 2002; Gofton 1990; Webb et al 1996) with recent research suggesting that half the UK student population regularly binge drink (see Ardenekan 2005) and students' alcohol expenditure was nearly £1 billion in 2004, £300 million more than on food (Curtis 2004).

Gill (2002) provides a very useful review of the past 25 years of research looking at drinking behavior focusing on undergraduate students and based in the UK. However, all 18 of these studies used questionnaires as their main method of data collection and the majority of studies have focused on identifying the amounts of alcohol consumed and the negative effects of alcohol consumption. It is generally agreed that many university students tend to drink above what the government defines as sensible limits² (Webb et al. 1996) and are more likely to do so than the general population (Gill 2002). Webb et al. (1996) identify pleasure; habit; to increase confidence; anxiety/stress and social pleasure as the key reasons for students' consumption of alcohol (on a methodological point these choices were researcher-generated, although respondents were given the option to cite self-generated responses under the 'other' category). Questions left unanswered by this research, and other

related studies, are that in spite of focusing exclusively on student respondents, the studies do not identify factors associated with excessive alcohol consumption other than those that could be true for the *population as a whole*. Although one might conclude from these findings that the student sub-group of the population is no different from the wider population in its drinking behaviour, it is likely that the research methods used (researcher-generated closed options, a focus on negative aspects of drinking) skewed the findings away from developing a valid and reliable picture of the role of alcohol in students' lives.

In any attempt to understand the so-called binge-drinking culture, it is important to examine the context specific aspects of student drinking culture. Gill (2002) suggests that factors such as 'student demographics' need to be explored in more detail and Dowdall and Wechsler (2002) argue that a major shortcoming is the failure of studies to understand or communicate the broader context or the 'alcohol environment' of students' lives. It is important to appreciate those aspects of students' lives that make them distinct and therefore worth studying. For example, any discussion of students and alcohol should discuss students' access to bars and the existence of alcohol promotions that can be found on and off campus. This leaves us with the following question: what is it about being a student that leads to a tendency to drink excessive amounts of alcohol whilst at university?

Another potential obstacle to forming a clear picture of alcohol consumption is the terminology employed by alcohol researchers and policy makers. In recent years the term 'binge drinking' has assumed common usage. However, there exists confusion regarding this terminology—i.e. whether it refers to alcohol consumption over a prolonged period or whether it refers to the specific amounts drunk in a particular session (and associated with this, there exist differences in the amounts classified as worthy of the term) (Gill 2002). This confusion of terminology serves to cloud our understanding as researchers (Measham 2004) and also understanding by the population under study (of how their own behavior would be classified). Further, it is argued that the commonly understood definitions of binge drinking result in the majority of young people becoming included in the definition (see Measham 2004) in essence promoting the normalization of binge drinking as a behavior. Researchers have encouraged the use of less emotive and loaded language—for example 'heavy sessional drinking' (Measham 1996; 2004)—but the term 'binge drinking' continues to be used by the UK government, media and commentators, making the issue of terminology difficult and confusing for researchers and consumers alike.

Therefore a number of characteristics associated with previous studies help make our contribution to research in this field innovative, timely and ultimately important. There is a lack of research focusing on understanding the positive aspects of alcohol consumption, which is essential if we hope to fully understand

¹With special thanks to our 'student researchers' who let us into their world and ultimately helped us to explore this topic.

²The UK government's 'sensible drinking guidelines' recommend limiting alcohol consumption at 14 units of alcohol for women and 21 units for men. Since 1995 there has been a move towards changing the message focus to daily recommendations of 2-3 units for women and 3-4 units for men (Strategy Unit 2004)

young peoples' or students' high levels of alcohol intake. By starting from a different standpoint to the majority of studies, we have tried to be less judgmental in our approach, seeking to understand young peoples' behavior in their own terms. This approach should help encourage students' understanding of (and in some cases change) their behavior and public policy or university welfare departments to tackle excessive consumption through an approach that is centered in an understanding of why the experience of being a student may encourage alcohol consumption.

Our paper also contributes methodologically. We argue that research needs to ensure greater engagement with the population under scrutiny. In order to understand the behavior of young people—particularly with regards to activities that are considered deviant in some way—we need to find means by which to 'enter' their culture. By enlisting the help of members of the population under study, academic researchers are able to understand more about the context in which much public policy is situated. This kind of approach mirrors trends within other areas—for example studies of childhood and young consumers (e.g. Banister and Booth 2005; Pole, Mizen and Bolton 1999). Further, Dowdall and Wechsler (2002) have identified the need for more studies featuring 'thick description' in order to gain insight "into how the participants view their own conduct" (p17). We argue that by enlisting the voices of our participants to present and discuss our findings that we can hope for a 'truer', more authentic account of the role of alcohol in students' lives.

RESEARCH DESIGN:

Our research aimed to discover more about the drinking habits of undergraduate students, by exploring the *role* that alcohol plays in their lives and the *benefits* that alcohol consumption offers. Our experience with students is primarily restricted to the academic context of lectures and tutorials, but we wanted to use methods that would allow us to take our understanding beyond this context. We considered it important to enlist the help of experts within the area who would be able to aid our quest and ultimately provide us with a fuller range of insights and findings—undergraduate students.

Our research was based in a campus university in the North West of England. Picking up on the criticism of many student-focused studies (made by Dowdall and Wechsler 2002³), the university campus has nine bars. Most of the university's undergraduate students live on campus during their first year and in the nearby city (approximately three miles from the campus) in their second year, with some students choosing to return to campus living arrangements in their final year. Alcohol prices on campus tend to be low, and there are high numbers of drinks promotions in the city centre. The university has its own university nightclub in the city centre, which has recently stopped offering drinks promotions, presumably following government efforts to curb excessive alcohol consumption.

Five undergraduate second year student researchers were recruited on the basis of their competence in running focus group discussions as part of a practical workshop on a marketing research module. We specifically recruited second year student researchers as previous studies have suggested second year students tend to be adjusted to university life yet free from the stresses of final year study (Webb et al. 1996). These student researchers were invited to a training session, where proposed methods were discussed and students were invited to contribute to the research design. The student researchers suggested changes to the focus group guide and also the style of language to be used within the research. The final discussion guide was circulated to all student researchers and agreed by them.

The student researchers were asked to recruit participants from their friendship groups for a discussion about alcohol consumption and students' social lives whilst at university. The researchers were not asked to select on the basis of age or gender or amounts of alcohol consumed, but instead to select a group of their friends who enjoyed each other's company. The researchers were told that the discussions should be between 1 hour and 1.5 hours long and they should be based around the guided but informal discussion schedule. Although there were topics and lines of questioning that we wanted included in all discussions, the student researchers were advised to manage the discussion in such a way that it resembled 'normal' social interaction. Our researchers received a gratuity payment for their part in this research procedure, which included a sum for the transcription of the discussion.

Our student researchers were given consent forms, which explained to participants the broad aims of the research and our ethical responsibilities towards them. A key aspect of our approach was that all respondents were granted anonymity. In practice this meant that although consent forms were collected, the student researchers were requested to keep hold of these. The researchers changed all participants' names, and were asked to ensure that there was nothing to identify the participants within the transcripts. Table 1 gives the key information that was collected from participants along with their pseudonyms for the purposes of this study. As you will see the majority of students were 19 and 20 years old, there was a mixture of males and females and a mixture of courses studied, reflecting the friendship groups of our researchers. Each group had between 4 and 7 participants (researchers were asked to aim for approximately 6 participants).

Our data were analyzed through a process of initially reading and rereading the transcripts and two academic researchers independently identified key themes and patterns to emerge from the data. We then compared insights and looked for alternative explanations from the ones that were identified. There was also an instance where we contacted the group moderator to check our understanding of one aspect of the discussion, again to ensure that we had interpreted the conversations as accurately as possible.

Student researchers were employed in order to capture the authentic voice of our participants. As a consequence it is important to note that the language used and stories told were more explicit in nature than those we heard in our earlier research with this population (Piacentini and Banister 2006). Notably, the student data collected for this study contains swearing and reference to illicit behaviors (e.g. drug taking, sexual behaviour), which have been retained and reported, in the interests of preserving the authentic student voice.⁴

FINDINGS

We aim to shed light on two aspects: firstly the *role(s)* alcohol plays in the lives of our participants; and secondly *why* does it play this role? We structure the first part of our findings around firstly the *language and rituals* of alcohol consumption in an attempt to find out more about the role or position of alcohol in students' lives. We then explore the means by which our participants explained or

³See literature review—Dowdall and Wechsler called for more explanation of the factors (and context) associated with student life.

⁴Please note that we have followed our reviewers' advice and left in place the language used, in order to reflect the 'voices' of our participants, and hope this language is not viewed as offensive or problematic.

¹All participants were second year undergraduates except where indicated (i.e. 1 student).

rationalized their high levels of alcohol consumption, typically referring to expectations of student life, the temporary nature of student life and the key benefits of alcohol—particularly as a social facilitator.

Language and rituals of alcohol consumption

In any attempt to hear and understand the voices of research participants, it is important to first become acquainted with and then form a shared understanding of, the language used (Banister and Booth 2005). It became immediately clear that the term binge drinking had assumed common usage by our participants. Ironically, rather than using it as a loaded or negative term, our participants seemed to accept its applicability to their particular situation, using it as a kind of 'standard' or term of reference. The following exchange was fairly typical of its usage.

- Justin *I consider myself a medium binge drinker, cos when I go out I get wrecked, but I probably go out once a week so....*
- Laura *Yeah*
- Tina *I Guess I'm a medium drinker because (Group laughter) I do drink every night, I do drink every night, but I don't binge drink every week.*

It was important to recognise the shared culture in which our participants consumed alcohol. In each discussion group there was at least one mention of an activity that could be considered a key ritual involving alcohol, and in some cases rites of passage marking entrance into particular friendship groups. These ritualistic activities were then explained 'to the tape' demonstrating the extent to which our participants (and our researchers) saw themselves as a somewhat exclusive group, utilizing practices and rituals which could be unfamiliar to 'outsiders' of the student culture.

- Des- *Can you just tell me about the dirty pint, obviously I know but the tape doesn't*
- Rhys- *Well a dirty pint is where you have a pint full of spirits. Think about downing a pint of spirits, you aren't going to be well afterwards.*
- Harry- *The alcohol is worth about £25. Literally you've got to accept that you will be sick when you do a dirty pint. You drink it, raise your glass to the crowd then go to the bathroom and then just vomit like a bastard*

- Rhys- *You get wasted, absolutely wasted. Whenever I feel like being sick I hold it in, I hate being sick.*

The 'dirty pint' was also referred to within another group (although not by this name). It seemed to be a fairly masculine activity. The assumption by both groups was that this was something in which to participate and endure, not necessarily something to be enjoyed.

- Mark: *For your birthday Jack, what did we put in your drink?*
- Jake: *That was really nice... [said sarcastically]*
- Mark: *Didn't we spend twelve quid on it, put 12 shots in? that Baileys curdled...*
- Jake: *It was fucking horrible*
- John: *But he knew what was in it...*
- Mark: *Yeah. It wasn't like we only put a few shots in ha ha ha*

In addition ritualistic drinking games were discussed whereby the forfeit involved drinking copious amounts of alcohol.

- Brian- *Actually I've a good example of this, there was a few of us, I don't think everyone here was there, maybe not, but we were drinking Absinthe.*
- Des- *Just for the tape what's Absinthe?*
- Brian- *Absinthe is... What percentage is it?*
- Rhys- *70%*
- Brian- *Yeah 70%. We were playing a drinking game of darts and it involved pretty much everyone every few minutes downing either a shot of absinthe or whisky. And we were drinking beer at the same time. We drunk a lot. And a few days afterwards my head felt genuinely not right, I was genuinely worried and other people that were there said the same thing, for a few days, my head really wasn't in the right place*
- Brian- *When something like that happens you realize that alcohol can be quite nasty*

We played alcoholic Screw-Ball-Scramble. It was awesome... It was well funny, we tricked you [directed at the moderator], because, because, we were really masters at screw-ball, and we played a game

basically, who ever wins gets furthest and then whoever gets least furthest has to drink. We started off, and we like "oh we can't do it, we can't do it" and then kept fucking up on purpose, and he fucked up on the first one, and I finished it, jack finished it, and he had to drink seven fingers. [Chris]⁵

Some participants talked specifically about initiation practices that were specific to their social group; again the discussion suggested this to be a fairly masculine activity. The female members of the groups seemed to be 'in the know' about the particulars of the practice but did not acknowledge participating.

- Dean: *There's like an initiation thing for the new members of the club [i.e. his group of friends] where you have to down a flaming Drambuie so we were showing them how to do it (laughter)*
- Lisa: *That sounds a good one*
- Alison: *oh my god!*
- Mark: *I know, within this group, the 'Beer Bong' is quite important part of our social group*
- Mark: *how important do you feel this Beer Bong is, and how did you feel after it got stolen.*
- Vicky: *Have you got it back?*
- Mark: *Can you just explain what the Beer Bong is?*
- Jack: *I couldn't sleep...*
- Des: *The Beer Bong basically is an aquarium tube, which is see through err, approximately 3/4 of an inch in diameter, two meters long and with a funnel⁶*
- Mark: *And do you find that's good for social, and it's a good laugh yeah?*
- Des: *It's a good laugh yeah while you do it, it's not just to get drunk, well it is to get drunk but...*
- Vicky: *It's also quite funny*
- Des: *We sing a song... and it's like a drinking game*

Drinking games, and special drinks fulfilled a means to gain initiation into a social group, but seemed to be a primarily masculine activity. Female group members also discussed rituals associated with alcohol consumption, but these predominantly concerned night-out preparations and discussions the following morning. For female participants these pre and post night out rituals seemed an important aspect of the drinking occasion and also functioned as a bonding activity, providing key aspects of group membership.

- Penny: (laughs) *Started getting ready about three hours before we went out. Took me 40 mins to have a shower, shave and wash and dry my hair!*
- Suzy: *The four s's!*
- Penny: *Didn't have a clue what to wear so everyone is like a panel and they have to judge, and if they can't make a decision we don't get out any quicker! There's a lot of enjoyment in getting ready though, I quite like, it kind of prolongs the evening...*

In the following exchange, female group members talked about their habit of discussing the previous night's proceedings. The male group members rarely mentioned their pre-night preparations (typically claiming to take 10 minutes) yet there was agreement by both sexes concerning the need for post-night-out 'hangover foods'.

- Claire: *We have one [discussion] in the bedrooms in the morning don't we? Where everyone will go into*

someone's bedroom and sit on the bed and chat about what we did the night before

- Lisa: *Dean do you do that?*
- Dean: *Oh yeah all the time! [said sarcastically]*
- Leanne: *So what do you do Dean?*
- Dean: *I just go to sleep on Alison's bed all day*
- Leanne: *Would you take anything maybe take a hair of the dog and have another beer?*
- Dean: *You have to eat bacon*
- Claire: *Oh no a McDonalds*
- Anna: *Coke and a Kit Kat*
- Lisa: *Yeah that's what Sally Clarke says!*
- Liz: *And these aspects of the whole process of sorting yourself out talking to your friends about it, are they as important as the night before do you enjoy them to some extent?*
- Anna: *Yeah*
- Lisa: *Yeah they are a good laugh especially if someone can't remember what happened and you can just make up stuff that's really funny*

Explaining and rationalizing excessive alcohol consumption

In seeking to understand some students' tendency to consume excessive amounts of alcohol, it is useful to explore their rationalizations for behaviour, particularly in the context of widespread knowledge regarding the potentially destructive nature of alcohol consumption. The key themes here related to student expectations regarding their current and future lives. Students felt it was almost expected of them to consume excessive amounts of alcohol, with these expectations existing both within and outside the student community. This rationalization for consumption was also supported by their (primarily negative) experiences when not drinking in alcohol type situations. Most of our participants seemed fairly clear that their alcohol consumption would subside once they left university, and they used this as a means by which to rationalize any current excesses.

Fulfillment of expectations

One of the key themes to emerge builds on the expected student identity also discussed in Piacentini and Banister (2006). Participants tended to think that high levels of alcohol consumption were a key aspect of being a student.

[Discussing whether drinking is expected of him] *Definitely, definitely, football bar crawls, peer pressure, you get abused if you don't drink, you're forced to do things you know you shouldn't do like the 'dirty pint'.⁷ Potentially they have the power to kill you. [Rhys]*

- Lisa: *You have to really because I don't think you would have the proper uni life if you didn't drink*
- Alison: *Yeah.. (Claire: yeah ..Anna: yeah)*
- Lisa: *because you wouldn't get as many friends you wouldn't get the whole uni experience (Suzy: social thing) unless you were friends with other people who drank but there's not that many people at uni who don't drink*

⁵Chris refers to a game named 'screw ball scramble' which involves moving a ball bearing from one end of a course to the other. In this version whoever loses (ie does not get their ball bearing as far) had to face the forfeit of drinking lots of beer.

⁶In this example the 'beer bong' is used as a social means by which to consume alcohol.

⁷Please see previous explanation of the 'dirty pint'

- Alison: *I don't know anyone actually*
 Lisa: *I don't*
 Claire: *No well when I've gone out and not drank I usually end up having a crap night because everyone else is pissed and not making sense and you just get pissed off with them well I do anyway I'm just like I want to go home*
- Vicky: *When you subscribe to uni, part of the course is going out and getting pissed with your mates*
 Jake: *If someone said you can go out tonight and everything is free, you can't drink you would be like urgh no.*

These discussions hint at the potential for students to become 'segregated' within universities according to their behavior and attitudes toward alcohol. There are certainly undergraduate students within the university who do not drink yet our participants seldom mentioned these non-drinking students and did not seem to socialize with them.

Key benefits of alcohol consumption

There are a number of key benefits that were associated with excessive alcohol consumption, and these are explored in this section. As the previous discussions demonstrated, a number of activities surrounded alcohol consumption and facilitated group cohesion. However, the social value of alcohol to students did not stop here, and we now move on to talk about the role of alcohol in facilitating social interaction.

Provision of social facilitation

It quickly became clear that for many of our participants alcohol provided a clear social function and constituted a key aspect of students' social lives at university, reflecting the findings from our previous research (Piacentini and Banister 2006). There were two aspects to its role of social facilitation, which are neatly summed up by the following exchange. Firstly alcohol, and more specifically getting drunk, provided a means by which to meet new people and secondly it provided a social bond within the social group (as mentioned previously).

- Justin *I think especially to meet new people in the start of uni and stuff, like, all going out and getting drunk is the best way to get to know each other, in a relaxed atmosphere.*
- Tina *Like whenever you go out in a group it's always to drink, it's never go out as a group to go to the cinema or anything like that (Group agreement)*
- Laura *It's things like getting, if you get totally wrecked then it's a sign of a good night (laughter)*

Alcohol was also perceived to facilitate social interaction via its effect on individuals' personality characteristics. There was the belief that consuming alcohol allowed participants to enact (both positive and negative) aspects of their characters, which remained hidden or subdued while sober. Therefore participants used alcohol as a tool with which to enact positive possible selves, primarily a more confident and outgoing possible self.

"... it gives you confidence when you try to meet new people"
 [Sarah]

"... Yeah drink does give you that bit extra confidence. Well I wouldn't have met my girlfriend now, if I hadn't been drunk, it gave me confidence to go and talk to her" [Rhys]

However, participants also balanced these positive selves with the potential enactment of negative possible selves. Many participants—both male and females—identified aggression as a characteristic associated with alcohol consumption, which had negative connotations.

I think it [alcohol] definitely gives me more confidence and sometimes it makes me a bit more aggressive depends on the situation where and when I drink [Justin]

- Ryan *Basically Sarah hit me once and then it didn't really hurt that much*
 Carl *Yeah?*
 Ryan *No and she said can I hit you again and I said yes and she absolutely fucking pummelled me*

I reckon it causes a lot of arguments too. [Harry] will know about this. My ex-girlfriend used to drink quite a lot, get really, really pissed, have so many arguments. Ruined my night all the time, hated it. That's one of the reasons why I don't drink. [Rhys]⁸

There was also concern exhibited by some participants (particularly males) that they would not be perceived as being aggressive. In the following exchange the participants are looking at a photograph of Rhys (taken while drunk) on the wall.

- Brian- *Look at his face!*
 Rhys- *Not violent, it's not violent!*
 Brian- *I didn't say it was violent*
 Rhys- *Disgraceful behavior yeah but not violent*

One participant saw the potential for what was normally perceived to be a positive characteristic—confidence—as interpreted negatively when exhibited in excess.

The thing is I see myself as quite a confident person I think that alcohol can sometimes make me a bit irritating and I can go a bit too far and people can be like "fuck off" [Tina]

Therefore it is generally acknowledged that alcohol consumption could have both positive and negative effects on social facilitation, despite this providing a key rationale for alcohol consumption. Participants managed the risk of enacting aspects of their undesired/negative self, necessitating balancing the positive effects (e.g. social facilitation) with possible negative effects (e.g. hangovers and embarrassing situations).

Achieving an altered state—drinking to get drunk

The overall picture that emerged was one of students drinking primarily to get drunk. Our participants liked being drunk and deliberately sought to achieve this 'altered state'. They rationalized their behavior as temporary and this allowed them to disregard the particular dangers and risks involved with high levels of alcohol consumption. Alcohol consumption helped them to achieve some

⁸Rhys' comment here appears contradictory in the sense that he has talked openly about consuming alcohol and then says he doesn't drink. This kind of claim was noticed with quite a few participants in the sense that if they felt they did not drink heavily, they would classify themselves as non-drinkers, but often this *lighter* drinking was classified as such in comparison with others who might be very heavy drinkers.

of the aspects associated with student life, traditionally a time to study hard whilst playing hard, utilizing drink to lose inhibitions and bond socially.

The findings supported previous studies that claim a significant proportion of students drink with the sole intention of getting drunk (e.g. in the US, a figure of 48% has been identified [Marklein 2004]) There were numerous unprompted discussions in which students noted the extent to which they drank with this outcome in mind. In the excerpt below the participants talk about the tendency to drink to get drunk, and Laura draws a comparison with three of the group participants—Tina, Dennis and Ryan—who she views as drinking for alternative reasons—primarily to relax. She hints that their motivations for alcohol consumption are at odds with her motivations and those of many of her friendship group.

- Justin *I don't see the point personally of going out and having a couple of drinks*
 Ryan *Yeah*
 Justin *And not*
 Ryan *See all or nothing*
 Justin *Yeah*
 Laura *Unless you're a steady drinker yeah*
 Justin *Yeah I wouldn't go out and have two or three pints and come home and go to bed*
 Laura *Yeah like Tina and Dennis and Ryan will drink cos it's like something that you do in your evening to have a relax or whatever? It's not like a lot of people probably... I don't know about you Sarah but if you go out, then, we'll go out and get totally drunk cos that's the only time you properly drink alcohol*
 Jason: *Do they put the percentage on the drink to stop you drinking it because...*
 Chris: *No...*
 Jason: *I go for the higher...*
 Chris: *Yeah*
 Jason: *The more pissed it gets the more I'll buy it...but why?*
 Vicky: *Its not the case of how much alcohol is there, its how the alcohol affects you...*

Participants continuously discussed the cost of drinks, and the challenge of maximizing their expenditure to achieve the 'best' result. This represented a kind of cost-benefit analysis, using limited funds to achieve tangible results (drunkenness) from their expenditure.

- Tina *When we went for a drink with you guys in the Friary before you went to that house party like we had two drinks each and it was a tenner, so you do start to realize that we could've had like four bottles of wine for that...*
 Laura *You could've bought a CD or something or a DVD or could have bought a present for a loved one (group laughs)*

However, this attitude was not universal, with some students acknowledging that sometimes they would drink smaller amounts of alcohol to enjoy the taste.

- Rhys- *If you don't want to drink, then you shouldn't drink at all. If you think about it, you go into a pub, you drink three pints, that's six quid on average, and*

unless you're Ben three pints isn't going to get you pissed, so there's no point in drinking. Then you just need a wee....

- Rhys- *No it is, if you think about it, it's just pissing away money. I'd rather just have one coke or something*
 Brian- *Yeah but I can buy a bottle of wine, drink it throughout the evening, not to get drunk, just because I enjoy it....*
 Rhys- *The taste of the wine yeah. Food, wine goes well with food.*
 Brian- *Yeah. I do the same with beers. I'll just get a couple in and drink them slowly through the night just to enjoy them rather than to get really drunk.*

However, the comments made by Rhys and Brian provided the exception rather than the rule. The indication was given that few of the participants would drink solely because of a liking for the taste of alcohol. In fact few of them drank when there was no intention to go out and socialize. However, they acknowledged that this was a pastime that they might enjoy in the future and many of them talked about drinking wine with their meal at their parents' house (i.e. away from the student context).

Relief from boredom

There was also an element of rationalizing alcohol consumption because it was considered to provide relief from boredom. Many of our participants mentioned this. We should pick up on Dowdall and Wechsler's (2002) point regarding the importance of understanding our participants' context. The university the students attend is positioned just outside a small city. Undoubtedly there are fewer activities to keep the students entertained than might be the case in other non-campus universities based in larger livelier cities.

- Laura *Sobriety is boring*
 Ryan *I got bored to death by just sitting in my room sort of thing so I think alcohol could make it more fun (Dennis laughs)*
 [And later in the same discussion]
 Ryan *Do you know what I think if I had like an X-box*
 Laura *The internet you need the internet*
 Ryan *Yeah if I had the internet or an X-box I wouldn't drink that much I'm just bored like I've watched all the DVDs we've got I've got nothing to do*
 Tina *Actually that's true*
 Ryan *I wish this was actually a group session instead of this*
 Dean *Time just goes quicker if you're drinking*
 Ryan *Yeah definitely*

However, one participant felt negatively about the assumption that students tend to drink excessively; and pointed out that he had other things in his life, inferring that this limited his 'need' for alcohol (again suggestive that boredom encouraged students to drink excessively).

[Group 4]

- John: *I find great pleasures. I find other pleasure in life not just alcohol consumption like some students... [Chris laughs]*
 John: *I have some hobbies...*
 Mark: *What pleasures? [Background noise of laughter]*
 John: *mmm...*
 Chris: *Not too graphic please Andrew*
 John: *I quite like soccer and bedroom sports*

- Mark: [laughs] *so have you found since you got a girlfriend you drink less?*
- John: *Probably, like first term was getting wrecked all the time. The second term a lot of people sort of paired off...*

Experiences of not drinking in alcohol type situations'

As part of their discussions about drinking to get drunk, participants talked about 'drinking situations' where they had specifically remained sober. Their responses illustrate the challenges associated with the 'drink sensibly' message.⁹

[Group1]

- Jack *Tried it once [not drinking] and then about halfway through the night I just thought fuck it and started drinking*
- Carl *And if you and if you have gone to these situations and haven't drank how did this effect your night?*
- Ryan *I actually went in a nightclub when I hadn't drunk before it was really crap [group agreement]*
- Jack *You notice how dodgy all the clubs are and how minging¹⁰ everything is [group agreement]*
- Tina *And the sleazy sorts of people that are there*
- Jack *Yeah you just notice more and things and things you don't normally see basically when you're sober*
- Laura *And also when everyone else is drunk and they all seem to be having a really good time and you just want to be in that place yeah*

Experiences like this tended to rationalize students' alcohol consumption. In addition it led many of our participants to avoid socializing in 'alcohol type situations' (i.e. particularly clubs and late night bars) if they did not intend to consume alcohol.

The future...life after university

The 'alternative boundaries'¹¹ that students experienced were clearly viewed as temporary. Participants' alcohol consumption and positive attitudes towards excessive intake seemed to be justified on this basis. There was an assumption they would make the most of their years at university and their consumption would become more 'normalized' on leaving university and would begin to conform with the boundaries common to the rest of society.

- Dean *Cos I feel like I feel like I should be making the most of my time here I try and make sure that I do go out for a big night a week once or twice a week once a week once every fortnight trying to make sure I do go out*
- Ryan *The thing is you're only gonna be at university for three years or four years for some people and for those three years it's an experience you gotta I mean I wouldn't want to like look back and say at university I had a proper flat time like and it was shit*

After you have left uni you won't go out during the week as much and you will probably go out one night at the weekend not both [Lisa G3]

The key justification here is that by consuming high levels of alcohol, students are only doing what students do and they will cease once they become 'full working adults'. However, for one of our participants the reputation of students as big drinkers was something that she viewed negatively.

- Laura *The thing is though you are a student and like I find that people don't take you seriously ohhh they are like students they get pissed every night and do fuck all and I actually don't*
- Ryan *Well that's you're saying something's inherently wrong with that? Just*
- Laura *Well yeah there is in that you want to be taken seriously*
- Ryan *Well while we're young why don't you just get on with it*
- Laura *Well yeah cos the thing is like we're in the top 15% of the country and people take the piss out of us*

Participants' discussions of the temporary nature of their behavior seemed to revolve around the expectation that their drinking habits would change once they left university. Some participants predicted alcohol would maintain a socialization function—particularly for workplace networking—but the majority of discussions indicated an expectation that alcohol would take on more of a relaxant role, no longer functioning as a key social aid.

- Dennis *If I've got a stressful job I'll probably still be drinking in the evenings*
- Justin *I think I think I'll be more likely to have a relaxing drink a relaxational beer if I wanted my wife to open it and pour it into a glass for me*
- Tina *That's it you'll be more likely to be in as well*
- Justin *Yeah you won't have time or the energy to go out*
- Laura *Although it depends where you live, say if you live in cosmopolitan London and like you went out to like nice swishy bars and stuff*
- Dennis *I'd rather go to a village pub*
- Mark: *What about when you get a job?*
- Vicky: *Yeah. I don't intend to drink as much*
- Des: *It depends on money... which could affect it*
- John: *I want a job like Scouse Dave, who is a beer sampler*
- Mark: *So you think when you get more money you will drink better drinks?*
- Peter: *You will drink to enjoy it, and not get drunk*
- Mark: *So you will buy Budweiser, Peter?*
- Jake: *That's why I don't worry about drinking hardly now, if I drank as much as I drink now for the rest of my life I would probably have liver problems.*

⁹The main UK alcohol promotion messages focus on slogans such as 'don't do drunk' 'drink in moderation'

¹⁰Colloquialism meaning horrible or disgusting

¹¹See Measham (2004:319) who talks about calculated hedonism operating within the boundaries of time (typically the weekend), space (club bar etc), company (supportive friends) and intensity. We can recognise that the boundaries for students are not the same as for the general population, perhaps facilitating opportunities for heavier drinking.

DISCUSSION AND CONCLUDING COMMENTS

Our choice of methods provided an extremely successful means by which to encourage our participants to 'open up' and discuss their alcohol consumption habits in a frank manner. We are confident that our use of student researchers and friendship groups enriched both the range and depth of our findings. Students were able to talk about their alcohol consumption in comfortable surroundings (generally the home of the student researcher) and the

transcripts reflected the researchers' success in engaging in discussion that focused on core themes of interest yet resembling everyday conversations for the participants. However, it should also be noted that the use of relatively untrained qualitative researchers provided one of the study's major weaknesses with students perhaps failing to reach sufficient depth in certain areas, which in parts made the task of analysis and interpretation difficult. There were some instances when meanings and language were checked with the student researchers—thus helping to bridge potential gaps between informants' stories and the authors' analysis and interpretation.

Our major findings focused on the way participants consumed alcohol (e.g. rituals), the language they used to talk about their behavior, the means by which they rationalized their behavior, and ultimately the enjoyment and perceived benefits they gained from drinking alcohol and being drunk. Alcohol provided an important social facilitator, a kind of social fuel and confidence booster that helped our participants to meet new people and have fun.

Owing to our focus and space limitations we have not been able to report the negative experiences associated with alcohol that students discussed. However, suffice to say that our participants felt so strongly about the importance of alcohol in their lives that despite negative experiences—e.g. hangovers or doing something they later regretted whilst drunk—any reduction in consumption was temporary (e.g. students might take one night off alcohol). Participants reconciled their behavior with widespread knowledge concerning the health effects of high levels of alcohol consumption by emphasizing that their drinking habits would change on leaving university, and this provided a key rationalization of what they saw as a temporarily excessive intake. On this note it would be extremely interesting to track students' alcohol consumption on leaving university and identify whether their behavior does in fact change in the way they have predicted or whether alternative rationalizations are sought.

It must be acknowledged that some issues could be restricted to the particular context of our study. A different university, city and of course different participants might have led to a different range of discussions and findings. It would be useful to conduct further studies specifically talking to students who do not drink alcohol (or drink very low levels of alcohol) and identify how they experience life as a student and deal with what our participants might consider a void left through not drinking or drinking in lesser amounts.

In terms of the implications of our study for policy makers and university welfare departments, a number of key issues emerged. Despite being aware of the dangers associated with high levels of alcohol consumption, our participants perceived these dangers as primarily concerned with long-term alcohol abuse (dependency) and so were able to rationalize their behavior as temporary and less worrying. In this sense students saw themselves as a 'special population' and to some extent beyond the health promotion messages concerning alcohol, as post-university they would settle down with alcohol assuming a role as a relaxant rather than specifically a social tool. This has important public policy implications because it suggests that alcohol campaigns focusing on students would need to use different approaches and messages. It would be useful for alcohol health campaigns to pick up on some of the rituals which accompany alcohol consumption—so for example the preparation, post-episode and day after socialization—recognizing that for many young people, their enjoyment of drinking is not just about the alcohol but also the wider environment which accompanies this. It was also interesting to see how our participants had taken on the terminology used by media, researchers and health professionals, but using it in a primarily positive way, with the sense that a binge session reflected a good night out. This suggests that the

use of more formal language might be helpful and less likely to be adopted by young people, serving to normalize the activity and therefore lessen the impact of the message.

Consumers and specifically students can take away from this study an improved understanding of how they use alcohol to facilitate social interaction and bonding and may feel encouraged to question their need for such high levels of consumption. Policy makers and health professionals can begin to build a more detailed and in depth understanding of the importance of alcohol in students' lives. Any recommendations or alcohol reduction messages need to start from this premise—i.e. situated in an understanding of the particular context of students' lives—the primary social activities, the bars and drinks promotions, the rituals and language and ultimately the perceived benefits that alcohol offers. However, students could be provided with more advice and information to help them recognize when alcohol has taken on a role beyond that which seems to be the norm (e.g. signs to look out for in friends), how to drink and socialize safely (e.g. organizing transport home at the beginning of the night) as well as ensuring that universities facilitate plenty of social activities in order to ensure that students do not need to drink in order to have a good social life while studying.

When Temptation Hits You: The Influence of Weak versus Strong Food Temptations

Kelly Geyskens K.U.Leuven
Siegfried Dewitte K.U.Leuven
Mario Pandelaere K.U.Leuven
Luk Warlop K.U.Leuven

EXTENDED ABSTRACT

Food temptations are common in everyday life, in ads, in stores, on coffee tables during social visits, or in one's own refrigerator... Such temptations constitute a permanent threat to the accomplishment of consumers' long term goals of looking attractive. Resisting these food temptations requires self-control, and fails on some occasions. This happens when attention is diverted from inhibitory restrictions, and narrowed to the most salient available cues, which -ironically- are often the food itself (Ward & Mann, 2000). However, salient temptations might also remind consumers of their objectives (Fishbach et al., 2003), and facilitate self-control. In this paper we study when temptations (weak versus strong) prevent and when they facilitate reaching food-intake control objectives. We distinguish two levels of temptation: weak and strong. According to the 'inoculation' theory (McGuire & Papageorgis 1961), a weak temptation should strengthen self-control because it activates defensive mechanisms that are helpful in warding off subsequent strong temptations. Contrary to this theory, Gilbert, Lieberman, Morewedge, & Wilson (2004) state that a strong temptation should strengthen self-control because it activates inhibitory goals. Weak temptations are not threatening enough to do so. The present research explored the effects of different temptation levels (no versus weak versus strong temptation) on the self-regulation of food intake.

In a first study, one hundred and ninety female undergraduate students were randomly assigned to one of three manipulated temptation levels. Participants were told that the manufacturer of a well-known candy brand, 'Quality Street®', was interested in consumer inferences of the relationship between flavors and wrapper colors and shapes. Participants in the Weak Temptation condition were asked to associate twelve pictures of the candies (of different colors and shapes) with the corresponding flavor of each candy (e.g. 'chocolate with strawberry cream'). Participants in the Strong Temptation-condition were given the same task while a bowl filled with about 50 'Quality Street' candies was present next to them. Participants in the No Temptation-condition were asked to associate ten colors with ten words (e.g. 'white' and 'elephant'). Then, participants were given two bowls of the same volume, one with regular M&Ms® (400 grams), and the other with the 'new' crispy M&Ms (300 grams). They were allowed to sample as many of the M&Ms as they needed to complete a comparison taste test of both types of M&Ms. After the taste test, the remaining M&Ms in both bowls were weighed to assess the amount consumed. The main effect of Temptation seemed significant, indicating that the weak temptation seemed to increase consumption compared to the No Temptation and the Strong Temptation-condition. The strong temptation seemed to help participants in resisting the M&Ms. These results imply that the weak temptation leads to increased consumption in female eaters, whereas strong food temptations seem to help female eaters in exerting food-intake control.

In a second study, we directly measured concept/goal activation resulting from temptation manipulations. One hundred twenty one female undergraduate students participated. Temptation level was manipulated as in study 1, except that the 'Quality Street' candy was replaced by 'Cote d'Or®' mini-chocolates that exist in five different flavors. Then, participants were given a lexical decision

task in which they were asked to respond as quickly and accurately as possible whether the stimulus was a word ('W') or a pseudo-word ('N'). Response times and accuracy were recorded. The test consisted of one hundred trials, including 30 words related to food, dieting and temptation, 20 neutral words, and 50 pseudo-words. Of the 30 goal-related words, half were related to inhibitory goals like dieting and health, and half were related to the taste of food and consumption. A repeated measures ANOVA with Goal Type (food versus diet) as within subject variable, Temptation as between subject variable, and the average reaction time of the neutral words as a covariate, revealed a significant interaction between Goal Type and Temptation. In comparison with the no temptation condition, the food-consumption goal was more activated in the Weak Temptation-condition and less in the Strong Temptation-condition. These results show that a weak temptation arouses positive feelings related to food consumption. The strong temptation, on the other hand, inhibits these positive food-related thoughts.

In a third study, we examined the viability of the causal role of goal activation as suggested in study 2. We tested whether the strong temptation condition was able to inhibit the appetizing effects of an olfactory cue. The results of the third study showed that in the No Temptation-condition, participants in the Scent-condition ate more than in the No Scent-condition. Moreover, in the Scent-condition, the strongly tempted participants consumed fewer M&Ms than the participants that were not tempted. These results imply that the strong temptation seems to inhibit the consumption increasing effect of the scent on consumption. This supports the causal role of the food goal activation.

In summary, the results of study 1 show that weak food temptations might lead to overconsumption while strong food temptations might help consumers in controlling their food-intake, offering support for Gilbert et al.'s (2004) theory. Hence, advertisements featuring food temptations might be more detrimental for overconsumption than placing food right in front of consumers. As study 2 shows, weak temptations arouse positive feelings related to food consumption. The strong temptation, on the other hand, inhibits these positive thoughts related to food and, in this way, strong temptations seem to facilitate self-control. Study 3 showed that the activation of the eating goal by the scent of freshly baked brownies leads participants to increase consumption. However, the strong temptation inhibits this effect, again indicating that strong temptations seem to facilitate self-control by the inhibition of the desire for food.

Excessive Buying: Conceptual Typology and Scale Development

Lan Wu, Georgia Institute of Technology
Naresh K. Malhotra, Georgia Institute of Technology
Koert van Ittersum, Georgia Institute of Technology

MOTIVATION

Excessive buying is suggested to be responsible for increases in personal debt and the number of people filing for personal bankruptcy in the U.S. However, academic research on excessive buying is limited. The contributions of this paper are threefold. First, we propose a conceptual definition of excessive buying. Second, building on the “time-inconsistent preferences” and automaticity theory, we propose a typology of excessive buying that captures the complexity of its occurrence. Third, using the proposed typology, a psychometric scale to measure the different types of excessive buying is developed and validated.

DEFINITION OF EXCESSIVE BUYING

We define excessive buying as “an *inappropriate individual* type of buying behavior whereby consumers *repetitively* spend more than what (they think) they can afford”. Two reasons lead us to define excessive buying as a perception-based construct. First, a perception-based definition rules out the influences of external factors (e.g., socioeconomic status) on consumers’ buying behavior. Second, in terms of measurement, a perception-based definition can be easily operationalized by a psychometric scale.

IDENTIFYING THE DIFFERENT TYPES OF EXCESSIVE BUYING

We propose that there are five different types of excessive buying: 1) aspirational, 2) rewarding, 3) remedial, 4) out-of-control, and 5) habitual excessive buying. Excessive buying can be a conscious or unconscious behavior. Based on the “time-inconsistent preferences” theory, conscious excessive buying behaviors is conceptualized as a result of either strong desires or self-control failures. Bargh’s automaticity theory explains why excessive buying might also be a result of unconscious mental processes.

The first three types of excessive buying are motivated by strong desires. Hoch and Loewenstein (1991) imply that a consumer’s desire for owning an object is a summation of: 1) the satisfaction the consumer derives from owning the object and, 2) the deprivation a consumer derives from not owning the object. Sometimes deprivation, induced by adaptation (imagining oneself possessing the object), intensifies desire and the motivation to purchase.

Due to the shift of desire reference point from no-adaptation to adaptation, consumers engage in excessive buying. It is proposed that excessive buying occurs as a result of desire reference point shift induced by social comparisons, positive emotions, or negative emotions.

American consumers constantly make “upward” monetary possession comparisons. When consumers feel that a product may win admiration or status for them, they cannot resist the temptation to buy it at the expense of their long-term economic interests. When consumers are in a positive emotion, they are highly motivated to prolong the positive emotion. As a result, they engage in excessive buying to reward themselves. When consumers are in a negative emotion, they tend to adapt to the notion of possessing surrounding objects so that the negative emotional responses can be alleviated. Consequently, consumers involve themselves in excessive buying. We refer to excessive buying behaviors driven by social comparisons, positive emotions, and negative emotions as “*aspirational*”, “*rewarding*”, and “*remedial*” excessive buying respectively.

A fourth type of excessive buying is induced by self-control failures. Self-control is a significant determinant of people’s consumption behavior. Excessive buyers often report experiencing self-control failures in a shopping context (Hirschman 1992). Why consumers lose self-control helps us to understand the occurrence of excessive buying. Effective self-control is determined by three ingredients (Baumeister 2002). The first ingredient is “standard”. Standards refer to “goals, ideals, norms, and other guidelines that specify the desired response”. Uncertainty or conflicts in goals make people more susceptible to self-control failures. The second ingredient is the process of monitoring. Self-control is jeopardized when people fail to keep track of their expenses. The third ingredient is whether consumers possess sufficient resources to exercise self-control. Consumers cannot overcome temptation when there is a lack of such resources. We refer to excessive buying driven by self-control failures as “*out-of-control*” excessive buying.

Finally, a fifth type of excessive buying is induced by habits. We propose that a considerable portion of excessive buying is the result of unconscious mental processes. Consumption goals can be activated and then operated all outside of awareness (Bargh 2002). Especially, similar or familiar features of environment can automatically activate goals associated with the features in the past, leading individuals to act in accordance with the same goals. In a shopping context, when consumers enter familiar stores where they used to commit excessive buying, the same consumption goals that drive consumers to buy excessively will be activated automatically and guide consumers’ buying behavior. We refer to excessive buying driven by habits as “*habitual*” excessive buying.

SCALE DEVELOPMENT

Based on the proposed typology, a psychometric scale to measure excessive buying is developed and validated by using 2 studies and 233 respondents. Items are generated based on our theoretical typology and qualitative data from a survey research (Richins and Dawson 1992). Items are purified and examined by using confirmatory factor analysis. The analysis results in a 20-item five factor excessive buying scale. The five factors correspond to the five different types of excessive buying. A 9-item scale is also developed to measure the economic and emotional consequences of excessive buying. Reliability and convergent and discriminant validity of the scales are tested. Nomological validity of the excessive buying scale is tested by examining the relationship between the different types of excessive buying and the economic and emotional consequences. Specifically, the model suggests that “habitual” and “out-of-control” excessive buying result in significant economic consequences, while both “remedial” and “rewarding” excessive buying behaviors result in significant emotional consequences. No significant relationship is found between aspirational excessive buying and the economic or emotional consequences.

CONCLUSION

The current research proposes a perception-based definition for excessive buying. This research also suggests that there are five different types of excessive buying. Based on the typology, a psychological scale to measure excessive buying is developed and validated. Future research is needed to refine the current scale.

SPECIAL SESSION SUMMARY

Psychological Processes in Financial Decision-making: A Consumer Perspective

Eric M. Eisenstein, Cornell University

ABSTRACTS

“Intuitive Compounding: Framing, Temporal Perspective, and Expertise”

Eric M. Eisenstein, Cornell University

Stephen J. Hoch, University of Pennsylvania

Many important financial decisions hinge on a proper understanding of compound interest. For example, decisions on how much and when to invest in a 401(k) plan, whether to refinance a loan, or how to trade off various attributes of a loan instrument (rate, points up front, duration, etc.), cannot be made without a proper understanding of compounding. Furthermore, some judgments that enter into assessments of well-being and happiness, such as whether prices or wages are fair (cf., Bolton, Warlop, and Alba 2003), also depend on a proper understanding of compounding.

When consumers approach such decisions, however, their understanding of this critical concept is frequently quite poor. This problem is exacerbated because the geometric nature of compounding is counter-intuitive even to those who are intellectually familiar with the underlying theory. Furthermore, to accurately choose an option in many of the financial domains outlined above would require substantially greater spreadsheet modeling expertise than is possessed by the vast majority of consumers, which means that there will frequently be a substantial intuitive component to consumer decision-making in these domains.

A limited number of studies (e.g., Wagenaar and Sagaria 1975; Wagenaar and Timmers 1979) have investigated people's ability to intuitively predict the outcome of an exponential growth process. Most of these experiments were conducted in unfamiliar domains (such as the growth of duckweed on a pond) rather than in the more familiar financial domain. An unfamiliar domain is likely to reduce the ability of participants to transfer any expertise that they might possess—an effect that has been demonstrated repeatedly in other tasks (e.g., the Wason 1968 card task). Furthermore, previous studies have not specifically looked for expertise effects or examined heterogeneity in the psychological process used to make decisions.

In three experiments, we explored the psychological underpinnings of consumer estimation of compound interest in a heterogeneous population. In particular, we examined differences in processing arising from negative vs. positive framing (e.g., debt, loans, and inflation vs. interest, raises, stocks), and in differences between retrospective and prospective compounding estimation (i.e., what was the cost of a TV in 1970? vs. what will be the cost of a TV in 2030?). Furthermore, we examined the effects of expertise and training on accuracy. The normative theory is simple: given an interest rate, i , and a time horizon, n , the formula governing compound interest is $FV = PV(1 + i)^n$, where FV and PV are, respectively, the future value and present value of the investment, i is the interest rate, and t is the term.

Results demonstrated that the vast majority of people anchor on simple interest (i.e., $FV = PV[1 + it]$), and then adjust their answer upwards. Reliance on simple interest was demonstrated both by analysis of participants' open-ended responses and by the pattern of coefficients of individual-level models that were fit to respondents' estimates. Anchoring on simple interest yielded acceptable accuracy for short time periods and for low interest rates, however,

massive underestimation resulted for longer time horizons and for higher rates. Most of the major financial decisions that people make during their lives involve either long time periods (e.g., retirement saving, mortgages) or high interest rates (e.g., taking on credit card debt), which makes anchoring on simple interest a pernicious bias. Additional results demonstrated that all respondents found retrospective estimation (i.e., if there are FV dollars in the account today, what PV was invested n years ago at a constant interest rate, i ?) more difficult than prospective estimation.

Although most participants used simple interest as an anchor and were very inaccurate, a small minority were very accurate in their estimates. Open-ended responses and individual level coefficient estimates revealed that these subjects used a completely different estimation process, the “rule of 72.” The rule of 72 is an accurate approximation of the correct financial formula, the core of which is the realization that $y = 72/i$, where y is the number of years that it takes for money invested (or loaned) at an interest rate of i to double in value. If the time horizon is known, the rule of 72 can be used to approximate the effects of compounding by computing the number of doublings implied by (i, t) , and then doubling the principle that number of times. For example, if $PV = \$1,000$, $i = 9\%$, $t = 24$ years, then an exact computation shows $FV = \$7,911$. To use the rule of 72, compute $72/9 = 8$, which demonstrates that money at 9% will double in approximately 8 years. Since the time horizon is 24 years, this represents $24/8 = 3$ doublings, which will result in a $FV_{72} = 2^3 * \$1,000 = \$8,000$ (error = 1%). Note that simple interest would provide an anchor of $FV_{SI} = \$1,000 * 9\% * 24 = \$2,160$ (error = 72%).

In Experiment 3, we trained participants to use the rule of 72. Compared to an untrained control group, the trained condition realized enormous improvements in accuracy, with no increase in time spent on the task.

Expertise in estimating compound interest is strongly linked to the use of the rule of 72. If consumers anchor on simple interest, they are likely to make errors that have massive impact on their financial well being, including underestimating the cost of long-term loans (such as mortgages), saving too little and too late for retirement, and allowing credit card debt to revolve, rather than aggressively paying it down. Furthermore, the results shed light on the difficulty of learning nonlinear functions, even for those with substantial experience with them. Consumers can be taught to be considerably more accurate in their understanding of compounding in a very short amount of time.

“Choosing for the Long Run: Making Tradeoffs in Multi-period Borrowing”

Suzanne B. Shu, Southern Methodist University

Both basic economics and popular wisdom imply that consumers should be sensitive to interest rates when making decisions about borrowing and saving. Consumers assume that lower interest rates are always better, all other things held equal. For example, credit cards regularly compete for business by advertising that they charge interest rates below other cards that the consumer might currently hold. However, examples abound in which consumers choose loans with unreasonably high interest rates, such as products at payday loan stores that can charge interest at annual rates of several hundred percent. Public concern about this tendency for making unwise borrowing choices has resulted in Truth in Lending laws, which require lenders to explicitly state annual interest rates (APRs) for loans regardless of the length of the loan. Yet even with these corrective measures in place, consumers continue to borrow at rates which seem inconsistent with rational behavior.

These inconsistencies may lead us to wonder whether consumers really do pay attention to interest rates when making borrowing decisions. Although borrowers may believe that lower rates are better, their final loan choice may be inconsistent with this belief when other aspects of the loan, such as time schedule and per period payment amount, are changed. One explanation for this inconsistency between beliefs and actual choice is that consumers choose between loans based on attributes other than interest rates, such as the total payment amount, the length of the loan, or the size of the individual payments (even when controlling for budget constraints). This could imply that consumers' sensitivity to interest rates can be exaggerated or muted by the extent to which a change in rates affects these other attributes, such as the total payment amount.

In this paper, I hypothesize that consumers often choose between loans in a way that is inconsistent with both the normative economic model and the behavioral model of discounting. To test this hypothesis, a series of three studies is conducted that asks participants to choose between hypothetical loan schedules. The first study asked participants to repeatedly choose between pairs of loan schedules which differed in length, monthly payment, and annual percentage rate (APR). Since potential borrowers may be using one of several rules of thumb in choosing between loans (e.g., choosing based on total payment, timeframe, per period payment, or APR), pairs of choices were constructed to check for each alternative heuristic. Participants' responses were categorized based on these possible choice heuristics; results indicate that most subjects are consistently choosing the loan schedule with the lowest total payment amount. The second study involved a ranking task, in which participants order a set of eight different loans; the results of this study give us insight into how the various attributes of each loan are traded off. An ordered logit analysis of the data suggests that participants are using a model that puts weight on the rank (and not the absolute value) of several attributes other than interest rate. The third study mirrors Study 1 for positive outcomes (lottery winnings) rather than payments, to investigate whether the attributes that characterized the loan choices would receive similar weight in a gain situation. Results suggest that subjects do switch their emphasis to a different attribute (i.e., to monthly amount rather than total amount) when considering positive streams of payments.

Taken together, these three studies show that, when choosing between loan options, decision makers focus on loan attributes other than APR. This approach differs from previous work in this area since it suggests that people are not using any model of discounting (normative or behavioral), but are instead using sim-

pler decision strategies (and yet not as simple as just choosing based on lowest APR, which may be the simplest strategy of all). Explanations for the use of these decisions strategies may center on a combination of salience, reference points, and temporal bracketing. For example, a theory of reference points predicts that people will react differently when total interest cost is large relative to the original price (as it is in the case of a long loan, such as a mortgage) versus when interest cost is small relative to the original price (as it is for a payday loan). This focus on total payment (or, equivalently, amount of interest) may be stronger than the focus on interest rates for some consumers because the concept of an interest rate is intangible for many consumers. They may interpret interest costs as a penalty assessed by the lender rather than as a way of calculating the time value of money. Thus, even in cases where a consumer can directly compare loans based on APR, interest rates may have some influence, but the total payment amount will also still be taken into account (as the results of Study 2 demonstrate).

An additional implication of this work is its predictions for demand elasticities of interest rates. If consumers are indeed more sensitive to attributes other than APR when considering loans (such as total payment amount), then this will result in a greater sensitivity to interest rates on long term loans, such as mortgages. In other words, the elasticity of demand for rates will be higher for long term loans than for short term loans. Empirical work on loan choices has already noted this result. For example, Attanasio (1994) studied vehicle loans and tried to determine what factors influence borrowing. His empirical findings are consistent with the hypothesis of this paper, in that attributes other than interest rate influence loan choice. Determining these behavioral influences on consumption and savings patterns remains a rich area of future work.

“Bursting Another Financial Bubble: The Influence of Ability Perception on Choice Satisfaction”

*Katherine A. Burson, University of Michigan
Simona Botti, Cornell University*

Prior research has shown that consumers prefer to make a personal choice rather than having the same choice dictated to them even when they are not more satisfied as a result of their own choice (Botti and Iyengar 2004). How can we explain consumers' preference for choosing in spite of their subsequent satisfaction? It has been found that people generally believe that they will outperform others (Alba and Hutchinson 2000). For example, most investors view their ability to select investments as superior to the average investor's ability (Moore, Kurtzberg, Fox, and Bazerman 1999; Wood 1997). The same positivity bias may therefore cause consumers to believe that they can make better choices than anybody else, explaining their general aversion to relinquish choice. This positivity bias extends even to judgments made about others (Klar and Giladi 1997), suggesting that, when estimating someone else's ability to make good choices, people will overestimate their performance as well.

Although this positivity bias in estimates of relative abilities has proven to be quite robust, prior findings suggest that people may be unable to maintain optimistic self-assessments given information about the context of their performance. Research shows that people are likely to apply situational explanations to their own outcomes (Jones and Nisbett 1972). However, people have been also shown to ignore situational information in favor of disposi-

tional explanations for others' outcomes (Jones and Nisbett 1972). Hence, it might be hypothesized that in decision-making contexts in which consumers have access to situational feedback about the quality of their decision outcomes, assessments about one's own comparative abilities are more prone to positive illusions than assessments about others' comparative abilities. In this paper, we investigate the impact of situational feedback on estimates of relative investing abilities in a context where situational feedback is often available—investment decisions. For example, newspapers provide investors with information about the valence and degree of their own investment outcome, about how this performance compares to those of other investors, and about the performance of the market as a whole. Because people tend to incorporate this type of feedback only into evaluations of their own outcomes, we suspect that people's evaluations of their own comparative investing abilities, but not of another's, will be reduced.

We investigate the impact of situational feedback on estimates of relative investing abilities by comparing a situation in which the performance of a selected mutual fund was positive to one in which the performance was negative. Each investment outcome was carefully framed within a set of alternatives that also went up [down], on average, the same amount as the selected fund. Thus, each outcome was always an average outcome. Nevertheless, we predicted that, when the investment was chosen for participants by a third party (e.g., a broker), consumers would attribute the decision outcome to the skills of that broker—a dispositional explanation; conversely, when the investment was chosen by themselves, consumers would attribute the decision outcome to the situational factors (the market). As a result, in a bull market, investors would assess their relative ability following a gain as less stellar than the broker's relative ability. However, in a bear market, investors would judge themselves as less incompetent after a loss than the broker.

We tested this hypothesis in a 2 (self-choice/broker-choice) by 2 (positive outcome/negative outcome) between subject experiment. Participants evaluated the results of a mutual fund that they had either personally chosen or that has been chosen for them by a broker. In the positive outcome condition the mutual fund gained value along with all 3 alternative funds. In the negative outcome condition the fund lost value along with all 3 alternative funds. Results show that participants wanted to choose their mutual fund even though they were on average more dissatisfied with the funds' performance in the self-choice than in the broker-choice condition. When the selected mutual fund gained value, self-choosers' preoccupation with the situation prevented them from inflating their relative investing ability. Because both the selected and the alternative funds went up, on average, the same amount, choosers considering all the information provided could not maintain an optimistic view of their ability relative to average peers as they had not outperformed the market. However, the broker's choice was under much less scrutiny and as a result the broker was rated as more able than the average broker despite the fact that he had merely matched the average market performance. Participants were also most satisfied with the positive outcome that resulted from their broker's choice than with the same outcome when they chose it. A mediational analysis showed that this satisfaction was a direct result of the participants' perceptions of comparative abilities.

In conclusion, though consumers want to make their own choices, in those contexts that qualify decision outcomes with situational information, consumers' tendency to temper their own performance with situational information can lead them to view themselves as relatively unskilled choosers. However, consumers' attribution of dispositional factors to others' outcomes causes them

to perceive third parties making a choice on their behalf as relatively skilled. These disparate perceptions of ability have a direct consequence in outcome satisfaction: low perceptions of ability lead to low satisfaction while higher perceptions of ability lead to higher satisfaction. Thus, participants are ultimately more satisfied with positive results when they do not make their own choices. These results suggest that consumers' optimism about their own abilities can be tempered to an extent that they are actually unbiased in their self-assessments when situational information is available. Furthermore, these findings imply that consumers may not be sufficiently critical of the performance of experts. So, when evaluating the performance of an expert hired to make decisions such as a financial advisor, consumers may unnecessarily attribute positive performance to the skills of that expert.

Lost in the Story: Factors That Affect Narrative Transportation and Advertising

Jing Wang, Northwestern University

EXTENDED ABSTRACTS**“Narrative Transportation and Advertising Effectiveness”***Jing Wang, Northwestern University**Bobby J. Calder, Northwestern University*

Narrative transportation has recently been defined as “a convergent process, where all mental systems and capacities become focused on events occurring in the narrative” (Green and Brock 2000, p. 701). The authors show that high transportation leads to more change in story-related beliefs and evaluations than low transportation. Hence people’s attitudes toward whether individuals with violent mental disorders should be released without supervision change more if they are more transported by a story involving a murder by a disturbed individual.

From a more cognitive perspective, the work of Gerrig (1993; Polichak and Gerrig 2002) emphasizes that transportation should not be thought of as a passive process. This research indicates that transportation is characterized by “participatory responses” which are thoughts actively generated by the person in response to the narrative. Beyond merely paying attention to the story, a person produces her or his own cognitive responses, and this process is instrumental to the experience of transportation.

Based on previous research, we define transportation as a process of narrative information processing in which a person not only attends to information but he or she is absorbed into the flow of a story in a pleasurable and active way. Previous research has focused on how people react differently to a story if it involves high transportation versus low transportation. The present research focuses on how differences in transportation affect an ad that is presented in the context of the story (that is, where the story is the media context for the ad). We propose that these effects depend not only on the extent to which the audience is transported by the context, but they also depend on the relationship between the ad exposure and the transportation experience. Specifically, high transportation should enhance advertising effectiveness if the ad exposure does not interrupt the transportation experience. With high transportation, people are absorbed in the media context and experience it as a pleasurable activity. If an ad does not interfere with this process, say by occurring after the story is completed, the positive experience of transportation will be associated with the ad. This should lead to greater advertising effectiveness. However, if the ad does interrupt the transportation experience, this in itself creates a negative experience that is associated with the ad. This should lead to lower advertising effectiveness. Thus, we predict that the effect of media context transportation on advertising is moderated by the intrusiveness of the advertising. If an ad does not interrupt the transportation experience it benefits from association with the positive experience. If it does interrupt it, it suffers from the association with a negative experience. We conduct three studies to test these predictions.

The first study is designed to test the hypotheses that the effect of context transportation on product attitude is moderated by the intrusion of the ad. Participants are instructed to evaluate a new magazine by reading a sample story. We measure participants’ narrative transportation with Green and Brock’s (2000) transportation scale, and manipulate ad intrusion by inserting the ad either in the middle or at the end of the story. Consistent with our hypotheses, we find that highly transported participants have more favorable

attitudes toward the advertised product than less transported participants when the ad is inserted at the end of the story. However, when the ad is inserted in the middle of the story, highly transported participants have less favorable attitudes toward the product than less transported participants. Also consistent with our hypotheses, we find that highly transported participants perceive the ad inserted in the middle of the story to be more intrusive than less transported participants, and that the perceived intrusiveness of the ad mediates the effect of transportation on product attitude.

One alternative explanation of the results in the first study is that the effects could come from the position of the ad rather than the intrusion, because the time between ad exposure and evaluation is different across the conditions. The second study is designed to rule out this alternative hypothesis and to support our theorizing with a different operationalization of the construct. The ad is inserted in the middle of the story for all participants, but its intrusion to the transportation experience was manipulated by varying participants’ involvement with the advertised product. When participants are highly involved with the product, they are more likely to pay attention to it and process it deeply. As a result, the ad is more intrusive to the transportation experience and participants should have a less favorable attitude toward the advertised product because of the interrupted transportation experience. On the other hand, an uninvolved product should be less likely to interrupt the context transportation experience. Consequently, the product attitude should be less influenced by how transporting the context is. The results confirmed our hypotheses.

In the third study, we approach the theoretical link between the transportation experience and the processing of the ad from the flip side. Rather than manipulating the ad processing, we manipulate the degree of transportation itself by giving half participants a cognitive load. All participants read one of the two versions of the same story, one more transporting than the other. The ad is inserted in the middle of the story for all participants. We show that the effects of interrupted transportation are eliminated when the transportation experience is diminished by a resource-demanding task.

In summary, we show across three studies that transportation leads to a more favorable product attitude when the ad is not intrusive to the transportation experience, whereas transportation leads to a less favorable product attitude when it is interrupted by the ad. We also show the robustness of our results by operationalizing both transportation and ad intrusion in different ways.

“Narrative Self-Referencing”*Jennifer Edson Escalas, Vanderbilt University*

Self-referencing occurs when one processes information by relating it to one’s self or personal experiences (Burnkrant and Unnava 1995). Some consumer research has found that self-referencing serves to increase product feature and ad message elaboration, leading to enhanced persuasion when message arguments or product features are strong, but not when they are weak (e.g., Burnkrant and Unnava 1989). The predominant explanation for these findings is that self-referencing facilitates elaboration of incoming information because the self is a highly organized, complex memory structure (Greenwald and Banaji 1989; Klein, Loftus, and Schell 1994). Other research has found that self-referencing can also serve to distract attention away from and thus eliminate the differential effects of strong versus weak arguments

(e.g., Sujan, Bettman, and Baumgartner 1993; Escalas 2004). In these studies, persuasion is still enhanced as a result of self-referencing, but the effect is due to affect transfer. When participants recall autobiographical memories or simulate about the future, they generate positive affect, which is linked to the brand. From this research, it appears that an important aspect of self-referent processing is its affective nature.

This paper proposes that there are two distinct types of self-referent processing: analytical and narrative, that is, in the form of a story. Narrative processing has been shown to affect persuasion through a mechanism called transportation, which is defined as “immersion into a text” (Green and Brock 2000, p. 702; Gerrig 1994). Narrative transportation leads to persuasion through reduced negative cognitive responding, realism of experience, and strong affective responses (Green and Brock 2000), mechanisms that differ from the traditional elaboration-based explanations for self-referencing effects (e.g., ELM, Petty, Cacioppo, and Schumann 1983). Elaboration based models still apply to self-referent processing that is not in the form of a story, that is, analytical self-referencing. Here, cognitive elaboration is enhanced by relating incoming information to one’s self, resulting in a differential persuasive effect for strong versus weak arguments. These assertions are tested in three experiments.

Our first experiment examines the effects of narrative and analytical self-referencing on persuasion and examines whether transportation is at work in the case of narrative self-referencing. This experiment is designed to examine the differential effect of analytical versus narrative self-referencing across varying argument strength levels in a print advertising setting. Our results demonstrate that different types of self-referencing persuade via different mechanisms. We are able to manipulate self-referencing to encourage either narrative or analytical processing with our stimulus print ad for a fictitious running shoe. Under conditions of narrative processing, self-referencing serves as a distraction from message strength evaluation, resulting in enhanced ad attitudes and brand evaluations even when ad arguments are weak. Under conditions of analytical processing, self-referencing serves as to enhance elaboration such that only strong ad arguments are persuasive. The experiment finds support for the idea that narrative self-referencing persuades as a result of narrative transportation, with more compelling or “transporting” stories leading to lower consideration of weak arguments (and by extension, less consideration of other analytical factors, such as source credibility). In this case, we find that persuasion is mediated by narrative transportation, which leads to fewer negative cognitive responses and more positive affective responses.

The second and third experiments identify a moderator of narrative transportation, skepticism towards advertising, and test whether people who have a tendency to respond to advertising with skepticism (experiment 2) or are instructed to behave as an ad critic (experiment 3) are less likely to be transported by an advertisement that encourages narrative self-referencing. These experiments test the premise that consumers who are distrustful of marketers’ intentions will be less likely to engage in narrative processing and more likely to process the ad analytically (Friestad and Wright 1994). In both studies, participants are exposed to a print ad for a fictitious shampoo product that has text encouraging narrative self-referencing via instructions to imagine using the shampoo. Results for experiment 2 show that individuals who are highly skeptical of advertising are less likely to be persuaded by weak arguments because they are not transported by the ad’s instructions to imagine themselves using the product. These skeptical individuals are not distracted from paying attention to and analytically evaluating the

ad’s arguments. Less skeptical individuals, on the other hand, follow the pattern of results found in experiment 1: under conditions of narrative processing, self-referencing serves as a distraction from message strength evaluation. Here, persuasion occurs as a result of narrative transportation, with more compelling or “transporting” stories leading to less elaboration on weak arguments; narrative transportation mediates the effect of type of processing (here, operationalized as more likely to be analytical for consumers who are highly skeptical of advertising) by argument strength interaction on ad attitudes and brand evaluations.

Experiment 3 is also designed to examine whether ad skepticism moderates the effect of narrative transportation, but in this case, we manipulate whether or not participants act as ad critics while viewing the same shampoo ad used in experiment 2. In this study, we are again able to replicate the finding from experiments 1 and 2: under conditions of narrative processing, self-referencing serves as a distraction from message strength evaluation, while under analytical processing (evoked by our critique manipulation), self-referencing serves to enhance elaboration. Here, our critique manipulation evokes ad skepticism, which leads to analytical self-referencing, even in response to ad text encourages narrative self-referencing for less skeptical respondents. We again find that when self-referencing does not evoke narrative processing, persuasion occurs when product arguments are strong, consistent with a high degree of analytical elaboration. Finally, persuasion effects under conditions of narrative processing are again mediated by narrative transportation. Immersion into one’s storied thoughts leads to persuasion through reduced negative cognitive responding, realism of experience, and strong affective responses (Green and Brock 2000).

“The Impact of Prior Thinking on the Enjoyment of Experiences”

Daniel Lieb, Duke University

Joel Huber, Duke University

Many consumption experiences take place after one has both planned for and then thought about an event. The purpose of our research is to determine contexts in which thinking in advance about an event increases its value and to develop a theory parallel to both transportation theory and mental simulation that accounts for this increase in preference. We demonstrate our findings with two laboratory experiments in which participants watched films of both short and feature length. We find significant increases in preference measures between participants who were encouraged to think and write about a film’s abstract prior to viewing the film and control conditions in which participants were not given such opportunities to expand on their thoughts about the upcoming film.

There are several mechanisms through which such prior thinking increases the pleasure attached to an event. We investigate these mechanisms by relating two theoretical frameworks. First, transportation theory (Green & Brock, 2000) has been typically applied to narratives and suggests that highly transported readers become more immersed into a story. Such immersion incorporates the self and often increases positive affect related to the story and its protagonists. In our experiments references to the self in the prior elaboration stage may have increased the degree to which those in the experimental conditions were transported by the films. Second, mental simulation (c.f. Taylor, et al., 1998) describes a mechanism in which people simulate (mentally rehearse) the process of experiencing an event. Mental simulation has been previously applied to goal setting and coping (Taylor, et al., 1998) as well as in reducing judgment errors associated with cognitive heuristics (Sanna, et al., 2004). Both of these mechanisms share the property that advance

thinking limits the cognitive interruptions that can interfere with acceptance and enjoyment of the narrative process. We extend these theories by examining how mental simulation and allowing oneself to be transported through preparation can lead to greater pleasure of experiences.

We report two studies demonstrating the effect of future thinking on preferences and enjoyment for experiences. In one study, participants viewed ten-minute instructional films from the 1950's. After reading an abstract, participants in treatment conditions spend either five minutes discussing what they think they will like about the story and how the film might be self relevant. In control conditions, participants read the abstract and then were given a five minute distraction task where they were asked to discuss their most recent movie going experience. We find that participants in the treatment conditions enjoyed the film more as exhibited by both ratings and choice measures. In addition, participants who thought ahead about a film performed better on a memory task in which they had to recall the order of scenes from the movie. These memory results are highly suggestive that participants who mentally simulated watching the film became highly transported during while watching the film.

In study second study, we formed a movie-club where participants watched four feature length documentary films over the course of one month. In two different treatment conditions, participants were emailed the movie's abstract ahead of time and were asked to write about aspects of the movie they would enjoy. In a control condition, participants were only able to read the movie's abstract upon entering the auditorium just prior to viewing the film. We find that participants who were emailed the movie's abstract ahead of time enjoyed the movie more so than participants who only read the abstract just prior to watching the movie. We also analyzed all participants' open-ended responses to measures following the movie and found that participants who read and thought about the abstract ahead of time were less likely to use negative affective words and critical thoughts. We also administered follow-up surveys several days after each movie night had taken place and found both of these results to be stable over time.

The results from both studies suggest a process parallel to transportation theory and mental simulation may account for the increase in pleasure and preference ratings. This process is also akin to a fluidity account whereby viewers who are highly transported are less likely to suffer from a cognitive interruption from watching the film.

Interpersonal Behaviors during Service Encounter and Their Impact on Service Outcome: An Application of the Interpersonal Circumplex Model

Zhenfeng Ma, McGill University
Laurette Dubé, McGill University

EXTENDED ABSTRACT

Introduction

Consumers and marketing researchers have recently paid an increased attention to the interface between clients and service firms. However, despite its critical importance, the interpersonal aspect of service encounters and its impact on service outcome remain relatively unexplored.

Research into the interpersonal aspect of service encounters typically rely on static measurement tools such as retrospective self-reports to assess the impact of personal exchanges on service outcome. Past studies suggest that a process approach could facilitate the exploration of personal interaction and provide additional insights into its impact on service outcome. Previous research also suffers from limitations in scope of inquiry. First, past research typically focuses on the impact of the providers' behaviours on service outcome (i.e., the *exposure* effect from the client's perspective), whereas few studies explored the impact of clients' own behaviours (the *expression* effect) and the interrelationship between provider and client behaviours. Second, past research typically focus on behaviours along the power/control dimension to the exclusion of behaviours on other major dimensions such as affiliation.

The primary objective of the present research is to contribute to our theoretical understanding of interpersonal exchanges that naturally unfold during service encounters and of their impact on service outcomes. We build upon the interpersonal circumplex model (ICM) to examine client-provider interactions in a healthcare context.

Theoretical Framework and Hypotheses

The ICM holds that interpersonal behaviours can be characterized as a set of traits organized in a circle defined by two major dimensions, agency and communion. The agency dimension reflects an individual's strivings for mastery and power that enhance and protect the differentiation of the individual. This dimension is anchored by assured-dominant and unassured-submissive traits. The communal dimension, which is anchored by warm-agreeable traits and cold-quarrelsome traits, reflects strivings for union, intimacy and the participation in the collective.

Evidence suggests that during dyadic interaction, expression of, as well as exposure to certain type of interpersonal behaviours has significant impact on interactants' subjective well-being and satisfaction. Regarding expression effects, studies show that expression of agreeableness and dominance typically lead to better psychological wellbeing and adjustment outcome than expression of quarrelsomeness and submissiveness. Regarding exposure effects, studies show that exposure to agreeableness and submissiveness is generally associated with better positive interaction outcomes than exposure to quarrelsomeness and dominance. We therefore propose that during service encounters, clients' expression of agreeableness and dominance will have more positive impact on service outcome than client's expression of quarrelsomeness and submissiveness, whereas clients' exposure to provider agreeableness and submissiveness will have more positive impact than exposure to provider quarrelsomeness and dominance.

An important prediction from the ICM is the principle of complementarity, which refers to the extent to which behaviours of interacting partners fit with each other in prescribed ways. Complementarity is specified by similarity on the communal dimension (i.e., agreeableness invites agreeableness and quarrelsomeness begets quarrelsomeness) and reciprocity on the agentic dimension (dominance elicits submissiveness and submissiveness elicits dominance). Past research suggests that complementarity is central to maintaining relationship harmony and that complementary vs. a complementary behaviours typically lead to better interaction outcomes. We therefore propose that during service encounters client-provider interpersonal behaviours will generally show a complementary pattern, and that complementary interactions will have more positive impact on service outcome than a complementary interactions.

Method

Research design We adopted a longitudinal, naturalistic design and a process approach, collecting data on a series of service encounters in a natural setting, the dining room of a mid-term geriatric health care facility in Eastern Canada. On-line observation was made of clients' and providers' interpersonal behaviours and client's consumption behaviours over repeated meal episodes.

Participants 32 elderly clients (78.8 ± 12.7 years, 20 females, 10 males; all Caucasians) were recruited as participants. Clients who have insufficient cognitive ability (measured with Mini-Mental Status Examination) and who were in a state of clinical depression were excluded from the study.

Coding of interpersonal behaviours Provider-client interpersonal behaviours were coded using a validated inventory of behavioral descriptors (Moskowitz, 1994) designed to sample the four behavioral characteristics on the ICM. During each meal, coders simply endorsed the behaviours in a given coding list if that behaviour had been observed. Coders had been trained for 30 hours, using videotaped interpersonal exchanges. Inter-coder reliability was maintained at 80% or more over the course of the study.

Consumption behavior The major dependent variable is the amount of food consumed during a meal, which is also the primary service outcome from the perspective of the service providers. Consumption was derived from the estimation of plate leftovers using the Comstock scale. The estimated intake portions were translated into energy and protein intake using a standardized nutrient analysis program.

Results

As expected, correlation analysis of client-provider behaviors yielded a complementary pattern on both dimensions, and the pattern is stronger on the communal dimension than on the agentic dimension. The impact of interpersonal behaviors on service outcome was examined using random coefficient models. Quarrelsomeness was excluded from the model due to its extremely low frequency. Type of meals (breakfast, lunch or supper) and pre-meal hunger (assessed via subjective rating) were treated as covariates. Consistent with expectation, the results show that clients' expression of dominance and agreeableness made significant contribution to food consumption, whereas the expression of submissiveness had

no effect. Also consistent with hypothesis, clients' exposure to provider agreeableness had a significant and positive impact on consumption behavior. Contrary to expectation, exposure to provider dominance did not predict service outcomes. The hypothesized effect of complementarity on the communal dimension was also supported, with complementary behaviors resulting in more positive impact on consumption than complementary behaviors. However, complementarity on the agentic dimension failed to predict consumption. Further, mediation analysis shows that the expression effect of dominance and agreeableness and the effect of complementarity on service outcome were partially mediated through meal duration.

Discussion

This study shows that clients' own interpersonal behaviors, as well as provider behaviors, could significantly impact service outcomes. This study also complements existing literature on service marketing by demonstrating significant impact on service outcome of interpersonal behaviors on both agentic and communal dimensions, suggesting that focusing on one dimension to the exclusion of another could result in incomplete understanding of the interpersonal dynamics and their impact on service outcomes. Finally, this study recommends the ICM as a useful theoretic framework for examining the interpersonal exchanges in service encounters.

The Waiting Game: The Role of Predicted Value, Wait Disconfirmation, and Providers' Actions in Consumers' Service Evaluations

Ruoh-Nan Yan, Colorado State University
Sherry Lotz, The University of Arizona

ABSTRACT

Management of consumer waiting experiences is critical for practitioners in that unpleasant waiting experiences may result in negative service evaluations. This paper develops a conceptual framework in which predicted value of service, wait expectation (conceptualized as "consumer zone of wait tolerance" derived from the service literatures), wait disconfirmation (consumers' comparisons between wait expectations and perceptions), and affective response to waiting are proposed to directly or indirectly affect service experience evaluation. In addition, this paper proposes that actions of the service provider moderate the relationship between affective response to waiting and service experience evaluation. Conclusions and contributions are discussed.

INTRODUCTION AND JUSTIFICATION

From a practitioner's perspective, waiting lines can be damaging to businesses and have become an important marketing issue. Even though a growing number of companies have attempted to manage consumer waiting experiences through various strategies (e.g., increase of front-line employees, video displays with news updates as waiting time filler, or providing waiting time guarantees to their customers) (Kumar, Kalwani, and Dada 1997), consumer waits remain an unresolved issue. Consequently, more efforts need to be made to understand the waiting process and to reduce the potential negative impact of waits on consumers' evaluations (Kostecki 1996).

From an academician's viewpoint, various theories have been utilized to explain waiting phenomena and how waiting affects consumers' evaluations and satisfaction, including social justice (e.g., Larson 1987), attribution (Chebat, Filiatrault, Gelinias-Chebat, and Vaninsky 1995; Taylor 1994), field theory (Dube-Rioux, Schmitt, and Leclerc 1989; Hui, Thakor, and Gill 1998; Houston, Bettencourt, and Wenger 1998), and social comparison theories (e.g., Zhou and Soman 2003). Among these studies, consumers' affective responses to waiting and service evaluations have been frequently examined (e.g., Dube-Rioux et al. 1989; Houston et al. 1998; Hui and Tse 1996; Taylor 1994; Katz, Larson, and Larson 1991; Pruyn and Smidts 1998). However, the role of personal wait expectations has not been well documented and needs more exploration (Durrande-Moreau 1999) as well as other gaps.

First, the "expectation" concept in waiting has been linked with the concept of wait tolerance (Durrande-Moreau 1999) without a solid theoretical explanation. It has been portrayed as "probable duration," "reasonable duration," "acceptance of waiting time," "acceptability of the wait," and "acceptable waiting time" (Antonides, Verhoef, and van Aalst 2002; Chebat and Filiatrault 1993; Chebat and Gelinias-Chebat 1995; Houston et al. 1998; Hui and Tse 1996; Pruyn and Smidts 1998). The terms, definitions, and operationalizations appear to be somewhat inconsistent. Service expectations literature, which views expectations as a range of two levels of service expectations (i.e., the zone of tolerance), may help to further understand and refine this construct.

Second, existing wait research fails to explain the phenomenon as to why consumers sometimes stay and wait in long lines (e.g., Disney Land) and how their tolerances for waiting may differ. The value concept that emphasizes what is received (i.e., service)

and what is given (i.e., monetary and non-monetary costs) (Zeithaml 1988) may provide an explanation. Nonetheless, little research addresses how different types of values may influence consumers' tolerance for waiting.

Third, past research suggests that consumers' service evaluations are positively influenced by their affective responses to waiting (Hui and Tse 1996; Pruyn and Smidts 1998; Taylor 1994). However, preliminary evidence indicates this relationship may not hold in all instances. Service providers' recovery strategies may help alleviate the negative effect of waits (e.g., Sarel and Marmorstein 1998).

CONCEPTUAL FRAMEWORK

The purpose of this paper is to conceptualize a framework for waiting by incorporating predicted value, wait disconfirmation, affective response to waiting, and service evaluation. More specifically, there are three objectives. First, this research attempts to clarify the roles of consumers' wait expectations and wait disconfirmation in waiting. Second, it attempts to achieve a better understanding of the relationship between various types of predicted value and consumers' tolerance for waiting. Third, this paper expands the affect-service evaluation relationship and proposes that actions of the service provider play a moderating in that relationship.

Through an integration of three sets of waiting models examined by Taylor (1994), Hui and Tse (1996), and Pruyn and Smidts (1998), this paper provides a conceptual framework (see Figure 1) that centers on the wait expectation-affect-service evaluation relationship. In addition, one antecedent of wait expectation (i.e., predicted value of service) and one moderator (i.e., actions of the service provider) of the relationship between affect and service evaluation are incorporated into the proposed framework.

The following sections are dedicated to discussing the literatures for the constructs in the conceptual framework, including predicted value of service, zone of wait tolerance, wait disconfirmation, perceived wait duration, affective response to waiting, actions of the service provider, and service experience evaluation.

LITERATURE REVIEW

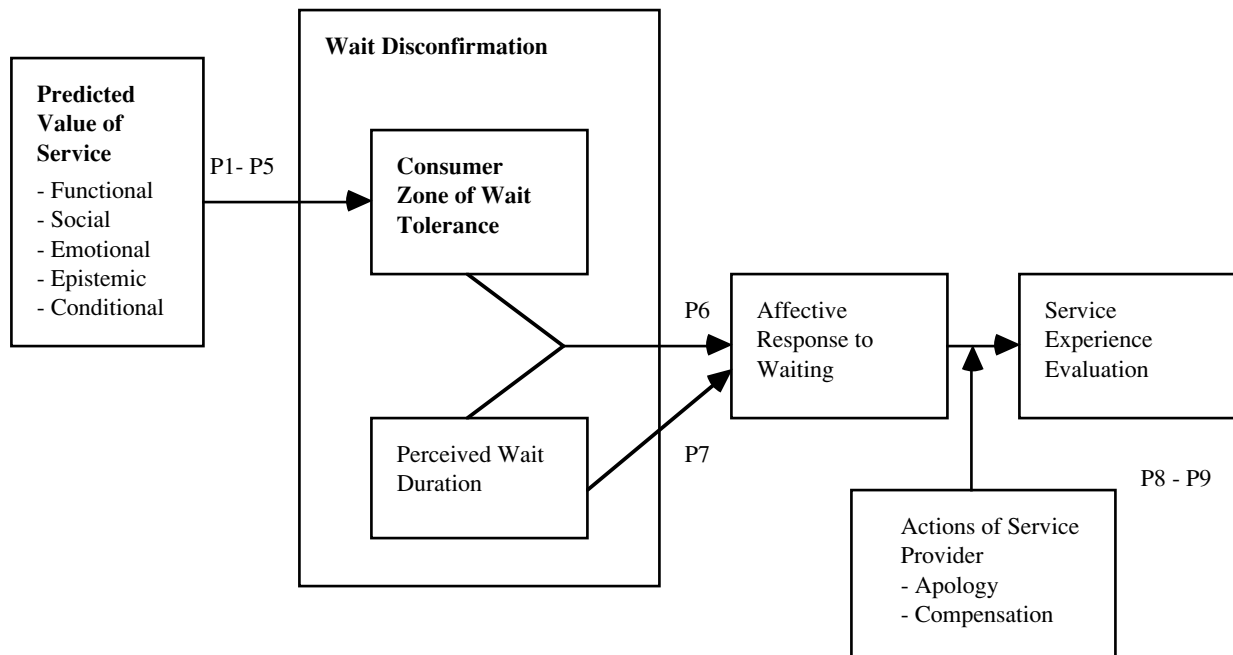

According to Taylor (1994), waiting for service is "the time from which a customer is ready to receive the service until the time the service commences" (p. 56). Waiting time is often regarded as a waste of time (Leclerc, Schmitt, and Dube 1995) and has been described by researchers as boring, frustrating, and irritating (Hui and Tse 1996; Katz et al. 1991). Nonetheless, research has suggested that overall value of service may help alleviate the negative emotions of waiting (Katz et al. 1991; Maister 1985).

Predicted Value of Service

The concept of perceived value has drawn considerable attention from consumer behavior researchers (e.g., Babin, Darden, and Griffin 1994; Bolton and Drew 1991; Sheth, Newman, and Gross 1991a, 1991b; Sweeney and Soutar 2001; Woodruff 1997; Zeithaml 1988). Zeithaml (1988) defined perceived value as "the consumer's overall assessment of the utility of a product based on perceptions

FIGURE 1

A Model of Waiting Experience Focusing on Value-Wait Disconfirmation-Service Evaluation Relationship

of what is received and what is given" (p. 14). This subjective value perception may exist not only after the consumption experience but also prior to it (Day and Crask 2000; Huber and Herrmann 2000; Sweeney and Soutar 2001; Woodruff 1997). It is possible that consumers may anticipate benefits from a product or service before consumption. This paper adopts this perspective of value concept and refers to it as "predicted value." When consumers are waiting to receive service, they are likely to anticipate certain types of value(s) they hope to obtain prior to consumption/usage regardless of their prior experience with the service. *Predicted value of service* refers to consumers' anticipated utility acquired from consumption of a service. For this paper, the framework of consumption values proposed by Sheth, et al. (1991a, 1991b) is adopted for its wide applications to further understand how various types of value may impact consumer zone of wait tolerance.

Zone of Wait Tolerance, Perceived Wait Duration, and Wait Disconfirmation

In the services literature, expectations are defined as "beliefs about service delivery that function as standards or reference points against which performance is judged" (Zeithaml and Bitner 2003, p. 60). According to Zeithaml, Berry, and Parasuraman (1993), customer expectations are not static and tend to vary due to the heterogeneous nature of service performance. Therefore, customers may evaluate service performance based on two expectation standards: what they desire and what they view acceptable (Zeithaml et al. 1993). The range between these two standards is known as the "zone of tolerance." According to Zeithaml et al. (1993), the zone of tolerance is defined as the extent to which customers recognize and are willing to accept service performance variation. Researchers support the idea that both desired and adequate service levels should be considered to better understand consumer expectations

(e.g., Parasuraman, Zeithaml, and Berry 1994; Walker and Baker 2000).

The concept of *consumer zone of wait tolerance* is developed in this paper representing consumer wait expectation. It refers to the extent to which customers recognize and are willing to accept the waiting time to receive the service. Consumer zone of wait tolerance, similar to zone of tolerance, consists of a range of two boundaries, i.e., desired wait and adequate wait expectations. *Desired wait expectation*, not previously discussed in wait research, refers to the most favorable waiting time in which the consumer hopes to receive a service and *adequate wait expectation* refers to the least favorable waiting time the consumer is willing to accept to receive a service. The former reflects what the consumer believes the wait "can be" and "will be" (Parasuraman, Berry, and Zeithaml 1991). It is proposed that the zone of wait tolerance may contract and expand. The greater the difference between desired wait expectation and adequate wait expectation, the wider will be the zone of wait tolerance for the consumer.

Based on discrepancy theory (Michalos 1985), the expectancy disconfirmation paradigm suggests that a consumer will compare his/her experience with a set of expectations. Research suggests that consumers are likely to establish pre-consumption expectancies, make observations about performance, compare performance with expectations, and then form disconfirmation perceptions. According to Oliver (1997), negative disconfirmation refers to "the negative discrepancy that occurs when performance is below standard" and positive disconfirmation refers to "the positive discrepancy that occurs when performance is above standard" (p. 104). A confirmation of expectations, or zero disconfirmation, exists if performance is equal to the standard. This paradigm is mainly cognitive in nature due to the comparison process that requires deliberate processing of information (Oliver 1980). *Wait*

disconfirmation, in this paper, refers to the comparison made by the consumer between his/her wait expectation (i.e., consumer zone of wait tolerance) and perception of wait duration. *Perceived wait duration* refers to the subjective estimate of the time over which the consumer is engaged in waiting. Wait literature has suggested that consumers' perceptions of waiting time may influence their affective responses to waiting (e.g., Taylor 1994).

Affective Response to Waiting

Emotions are valenced reactions to events or objects. Clusters of emotions with the same polarity are usually referred to as either positive or negative affect (Oliver 1997). Affective responses in wait research have been referred to as emotional types of constructs and have been measured in various forms, such as anger (e.g., Taylor 1994) and pleasure (revised from Mehrabian and Russell 1974) (e.g., Chebat and Gelinias-Chebat 1995; Houston et al. 1998; Hui and Tse 1996). *Affective response to waiting* is defined as a series of consumers' feelings and emotions that are provoked by waiting for a service. Numerous studies in waiting identify affective responses as adjacent determinants of consumer service evaluations (Chebat and Gelinias-Chebat 1995; Hui and Tse 1996; Taylor 1994).

Service Evaluations and Waiting

Consumers' service evaluations are usually regarded in waiting research as either (1) evaluations of service quality (Chebat et al. 1995; Taylor 1994) or (2) evaluations of customer satisfaction (Katz et al. 1991; Pruyn and Smidts 1998). Transaction-specific satisfaction is adopted because it helps to capture consumers' psychological responses to a product's or service provider's performance on a given occasion (Oliver 1997; Olsen and Johnson 2003). *Service experience evaluation*, in this paper, refers to the transaction-specific evaluation of satisfaction with a service experience (Cronin, Brady, and Hult 2000). While the relationship between affective response to waiting and service evaluation has been examined in past research, little attention has been drawn to the potential influence of actions of the service provider in that relationship.

Actions of the Service Provider, Fairness Perception, and Waiting

Service providers' actions, from a social justice perspective, have been investigated in the service literature (Brashear, Brooks, and Boles 2004; Goodwin and Ross 1992; McColl-Kennedy and Sparks 2003; Smith, Bolton, and Wagner 1999; Smith and Bolton 2002; Tax, Brown, and Chandrashekar 1998). However, social justice has been discussed in waiting mainly in the queue management context (Rafaeli, Barron, and Haber 2002). While queue systems may alter consumers' fairness perceptions, other actions of the service provider may play roles in fairness perceptions as well (Taylor and Fullerton 2000). The role of these actions in waiting experience has received limited attention. In this paper, *actions of the service provider* refer to visible strategies implemented through service personnel in response to waiting customers. Both interactional and distributive justice variables, e.g., apology and compensation, respectively, are discussed in this paper.

According to social exchange theory (e.g., Deutsch 1975; Goodwin and Ross 1992; Tax et al. 1998), interactional justice represents the manner in which information is exchanged and outcomes are communicated and distributive justice concerns resource or reward allocation and the perceived outcome of exchange. For instance, an apology from the service provider has implications for quality of interpersonal treatment (e.g., courtesy, concern, empathy) which may help to enhance consumers' evalu-

ations of the encounter. In terms of service recovery, compensation (e.g., free merchandise, refunds) can be regarded as a strategy to restore distributive justice perceptions (Blodgett, Hill, and Tax 1997; Goodwin and Ross 1992; Tax et al. 1998).

CONCEPTUAL FRAMEWORK DEVELOPMENT

Types of Predicted Value and Consumer Zone of Wait Tolerance

Predicted functional value is defined as the anticipated utility acquired through utilitarian or physical performance of alternatives. Sheth et al. (1991a, 1991b) stated that functional values may be attained from product/service attributes, such as price, performance, durability, and reliability. Sweeney and Soutar (2001) further suggest that value for money and quality are aspects of functional value. Raman and Leckenby (1998) concluded that consumers tend to spend more time at advertising web sites when they perceive the ads to have high utilitarian value. When the ad web sites are considered as important and useful, the time for consumers to spend on visiting the sites is likely to be longer. Therefore, there may be a positive relationship between perceived utilitarian benefits and consumers' willingness to wait for a service. Correspondingly, when consumers predict higher functional value from consuming a service, it may be more likely for them to wait patiently and to be more tolerant compared to when the service is predicted to be of low/no functional value.

P1: The greater the consumer's predicted functional value of service, the wider the zone of wait tolerance.

Predicted social value refers to the anticipated utility acquired through association with specific social groups on a basis of demographic, socioeconomic, and cultural-ethnic groups (Sheth et al. 1991a, 1991b). That is, services that allow consumers to share with each other or enhance their social image possess higher social value. Houston et al. (1998) examined the effect of waiting costs on consumers' acceptability of waits and found that wait acceptability is a function of the cost of waiting and the benefit of receiving the service. When waiting prevents the consumer from being punctual for an appointment/activity, which in turn, might harm the image of that person in front of his/her peers and colleagues, it is less likely for the consumer to accept the wait. When consumers perceive higher social value acquired by the service relative to costs, waiting may become more tolerable. Thus, there may be a positive relationship between predicted social value of service and consumer zone of wait tolerance.

P2: The greater the consumer's predicted social value of service, the wider the zone of wait tolerance.

Predicted emotional value concerns the anticipated utility acquired from a service provider's capacity to arouse feelings or emotional states (Sheth et al. 1991a). Services which are able to provoke consumers' emotional responses usually possess emotional value. In the context of shopping, Hornik (1984) found that consumers who enjoy shopping perceive a shorter wait at the checkout line than those who do not enjoy shopping. The enjoyment provided via shopping activities may be considered as hedonic shopping value (Babin et al. 1994). That is, enjoyment, as part of consumer emotions, may help consumers reduce their attentions to how long they wait for a service, implying higher tolerance for the time spent waiting. Berry, Seiders, and Grewal (2002) further proposed that consumers would perceive the time and effort spent to experience the service as less important when the service has higher hedonic value. That is, consumers may not pay as much

attention to the time spent waiting when they perceive high emotional/hedonic value associated with the service. Therefore, when consumers anticipate higher emotional value, they may be more likely to approach the service and be more willing to wait for the service.

P3: The greater the consumer's predicted emotional value of service, the wider the zone of wait tolerance.

Predicted epistemic value refers to the anticipated utility obtained from a product's or service's "capacity to arouse curiosity, provide novelty, and/or satisfy a desire for knowledge" (Sheth et al. 1991a, p. 162). Usually, this type of utility is obtained from stimuli that are unfamiliar and ambiguous or complex (Sheth et al. 1991b). Purely new experiences with products, services, or shopping trips may offer epistemic value according to Sheth et al. (1991a, 1991b). The novelty aspect of epistemic value in services can also be associated with its uniqueness in the marketplace. In explaining factors that may affect the zone of tolerance, Zeithaml and Bitner (2003) posited that consumers may have wider zones of tolerance when they perceive no other similar alternative available for them. This implies that consumers may be more willing to wait, i.e., wider zones of wait tolerance, when they perceive the service as unique and novel and not commonly available elsewhere. Therefore, when consumers predict higher epistemic value of the service, which may arouse their curiosity and provide a novel experience, their zones of tolerance may be wider.

P4: The greater the consumer's predicted epistemic value of service, the wider the zone of wait tolerance.

Predicted conditional value is defined as consumers' anticipated capacity of an alternative to "provide temporary functional or social value in the context of a specific and transient set of circumstances or contingencies" (Sheth et al. 1991b, p. 69). When an alternative is chosen based on its conditional value, the utility perceived by the consumer may not be the same outside the specific situation (Sheth et al. 1991a, 1991b). For example, graduation gowns elicit conditional value due to the special occasions in which these products serve their functions and fulfill consumers' needs. Research has suggested that situational contingencies influence consumer purchase or choice behavior (Belk 1974, 1975) and time allocation, especially in discretionary activities (Hornik 1982). In services expectations, Zeithaml et al. (1993) proposed that situational factors are likely to temporarily lower consumers' adequate service levels and thus widen the zone of tolerance. Therefore, when consumers anticipate benefits that can be obtained in certain situations through the consumption of a service, they may be more willing to accept the wait.

P5: The greater the consumer's predicted conditional value of service, the wider the zone of wait tolerance.

Wait Disconfirmation and Affective Response to Waiting

Research has shown that disconfirmation influences emotional responses (Bolton and Drew 1991; Muller, Tse, and Venkatasubramaniam 1991). Literature has suggested that service performance that falls above the zone of tolerance results in a highly satisfying outcome (e.g., surprise and delight) (Cronin 2003; Johnston 1995); on the other hand, when service performance falls below the zone of tolerance, the customer will judge the overall service as unsatisfactory and he/she will feel frustrated (Zeithaml and Bitner 2003). Moreover, when service performance falls within the zone of tolerance, consumers may be indifferent to the service

performance and thus react in neither a positive nor negative manner (Cronin 2003; Oliver 1997; Zeithaml and Bitner 2003).

In the context of waiting in a polyclinic, Pryun and Smidts (1998) concluded that consumers' affective responses to waiting depend on the difference between perceived waiting time and acceptable waiting time. Consumers were found to experience negative feelings when their perceived waiting time was longer than their acceptable waiting time. Hui and Tse (1996) and Houston et al. (1998) reported similar findings. Research also suggests that consumers may not react in a very positive or negative way when service performance falls within the zone of tolerance (i.e., zero disconfirmation) (Cronin 2003; Oliver 1997, Zeithaml and Bitner 2003). Therefore, it is assumed that consumers experience positive wait disconfirmation when perceived wait duration is shorter than desired wait expectation. As wait disconfirmation becomes more positive, consumers are likely to react to waiting with more positive feelings. On the contrary, consumers experience negative wait disconfirmation when perceived wait duration is longer than adequate wait expectation. As wait disconfirmation becomes more negative, consumers are likely to undergo more negative feelings about waiting. Moreover, when consumers experience zero disconfirmation, i.e., perceived wait duration falls within the consumer zone of wait tolerance, their affective responses may be less pronounced as compared to those who experience positive and negative wait disconfirmation.

P6: When comparing consumer zone of wait tolerance and perceived wait duration, for consumers who experience positive wait disconfirmation, there is a positive relationship between wait disconfirmation and their affective responses to waiting. For consumers who experience negative wait disconfirmation, there is a negative relationship between wait disconfirmation and their affective responses to waiting. Moreover, for consumers who experience zero disconfirmation, there is a weaker relationship between wait disconfirmation and their affective responses to waiting compared with the aforementioned relationships.

Perceived Wait Duration and Affective Response to Waiting

Affective response to waiting has been identified as a variable that mediates the relationship between perceived wait time and service evaluation in a number of waiting studies (e.g., Chebat et al. 1995; Hui et al. 1998; Hui and Tse 1996; Taylor 1994). For example, Taylor (1994) concluded that consumers' overall service evaluations are directly influenced by their affective responses to waiting (i.e., anger and uncertainty). As anger increases, overall evaluation of service decreases. Therefore, the relationship between perceived wait duration and affective response to waiting is also proposed as follows:

P7: As perceived wait duration increases, consumers' affective responses to waiting tend to become more negative.

Moderating Role of Actions of the Service Provider

Although there is a direct relationship between consumer affect and service evaluation (e.g., Hui and Tse 1996; Taylor 1994), wait situations may be better managed by service providers with plausible actions, such as apologies and compensation (Taylor and Fullerton 2000). McColl-Kennedy and Sparks (2003) concluded that firms modify customer emotions through specific actions when service failures occur. Through modification of emotions, it is likely that customer satisfaction can be achieved even after service failures. When the service provider apologizes to the consumer, he/

she may feel better and more positive about the service, which in turn, may influence the overall evaluation of the service. Social exchange theory (e.g., Goodwin and Ross 1992; McColl-Kennedy and Sparks 2003; Smith et al. 1999; Tax et al. 1998) is utilized in this research to better understand the role of actions of the service provider (i.e., apology and compensation).

Apology

An apology is a means of re-establishing psychological equity and can be expected to make up for any inappropriate or rude behavior (Goodwin and Ross 1992). Research has found that giving an apology has a predictive positive effect on customer satisfaction (McColl-Kennedy, Daus, and Sparks 2003; Smith et al. 1999; Tax et al. 1998). In the context of waiting, Taylor (1994) concluded that service providers communicate recognition of the delay and their concern to customers through apologies. Additionally, Sarel and Marmorstein (1998) suggested that customers' anger responses tend to be lower when receiving a sincere apology from the front-line employees in the bank. Their studies did not further discuss how actions of the service provider (i.e., an apology) and consumers' reactions to waiting may interactively influence subsequent service evaluations.

Compensation

Compensation, or outcomes, can take various forms, such as additional free service and actual monetary compensation (Zeithaml and Bitner 2003). Research suggests that compensation helps restore distributive justice that, in turn, increases consumer satisfaction (Goodwin and Ross 1992; Smith et al. 1999). Bitner, Booms, and Tetreault (1990) first concluded that compensation given to a customer for his/her long wait in a restaurant may help reinstate customer satisfaction. Smith and Bolton (2002) further found that emotional responses tend to influence how customers react to compensation provided after service failure. Consumers with negative emotional responses valued compensation more than those with no emotional responses (Smith and Bolton 2002).

Therefore, consumers who are presented an apology or compensation when finally being served after long waits may perceive interactional or distributive justice, respectively, and will be expected to have more positive feelings about the service provider and thus enhanced customer satisfaction compared with those who are not provided any recovery attributes. The positive relationship between affective response and service experience evaluation may become stronger due to the fact that the service provider does not ignore but acknowledges and apologizes for the customer's long wait; on the contrary, the positive relationship may be weaker with the absence of apology and compensation.

P8: Affective response to waiting will have a stronger effect on service experience evaluation when an apology or compensation is present than when an apology or compensation is absent.

In addition to the individual effects, research has suggested that consumer satisfaction is enhanced by the combination of apology and preferred compensation (Goodwin and Ross 1992; Mattila 2001; McCollough, Berry, and Yadav 2000). Making customers feel better about a failure through a mere provision of interactional justice (e.g., apology) may not always be effective unless distributive justice (e.g., compensation) is also addressed. Thus, the following three-way interaction is proposed:

P9: Service experience evaluation is dependent on a three-way interaction involving affective response to waiting, the presence of apology, and the presence of compensation.

CONCLUSION

The proposed conceptual framework of consumer waiting experience is differentiated from previous models in four ways and may advance academic understanding of the consumers' waiting experiences. First, in response to the suggestion that models outlining direct and indirect relationships among various wait-related variables are limited and there is a need to establish more comprehensive models and refine related constructs (Taylor and Fullerton 2000), this framework expands the expectation-affect-service evaluation relationship with two additional variables (i.e., predicted value of service and actions of the service provider) which have not been well discussed in wait research. Second, the concepts of consumer zone of wait tolerance and wait disconfirmation are developed with a more solid theoretical foundation based on service expectation literature and expectancy disconfirmation paradigm wherein they consider two types of wait expectations (i.e., desired and adequate wait expectations) and perceived wait duration. Third, the relationship between various types of predicted value of service and consumer zone of wait tolerance is proposed. To our knowledge, this is the first framework that considers the pre-consumption value perception (i.e., predicted value) rather than post-consumption value perception, via the five types of value dimensions (Sheth et al. 1991a, 1991b) to understand consumer wait experience. Fourth, this paper discusses the moderating role of actions of the service provider (i.e., apology and compensation) in the relationship between consumer affective response to waiting and service experience evaluation. This is important as past studies in waiting have merely focused on the direct relationship between affect and service evaluation (Chebat et al. 1995; Hui and Tse 1996; Taylor 1994; Taylor and Fullerton 2000).

This paper develops a conceptual framework to better understand consumers' waiting behavior by incorporating services literature, value literature, expectancy disconfirmation paradigm, and social exchange theory. In terms of the concept of consumer zone of wait tolerance, this paper explores how zone of wait tolerance might expand or contract due to different types of predicted value without focusing on how each of the two boundaries (i.e., desired and adequate wait expectation) may be affected. Further discussion may examine consumer zone of wait tolerance from this latter perspective.

In summary, it is critical to empirically test the proposed relationships and to determine the effects of specific types of predicted value, wait disconfirmation, and providers' actions on service evaluations in service settings (e.g., restaurant). Due to the fact that value may vary across individuals and situations (Woodruff 1997), it may be necessary to develop items in accordance with the consumption value framework to measure predicted values that tailor to a specific context chosen for empirical investigation. Given support from the literature, wait disconfirmation (i.e., difference between consumers' zone of wait tolerance and perceived wait duration) should be measured via three measures, consumers' desired and adequate wait expectations and their perceptions of waiting.

Customer Participation Strategies and Associated Goals: A Qualitative Investigation

Melissa Markley, University of Alabama

Lenita Davis, University of Alabama

EXTENDED ABSTRACT

The interaction between service providers and customers in a service setting is a complicated topic in consumer studies. Strategies used by customers to influence satisfaction in encounters have been identified; however the corresponding goals that customers are trying to achieve have been predominantly overlooked. Expanding on previous consumer behavior literature, this research begins to create a typology of customer goals in relation to customer participation strategies through the use of two qualitative studies.

The first study composed of in-depth interviews, was effective at identifying specific action plans and goals used by customers in service situations. Study two, a critical incident survey, was then used to strengthen, support, or disprove the results from study one. Therefore the two sets of findings are discussed together. The six strategies uncovered by this study are relationship building/social dynamics, service definition, reputation building (fame), managing, negative feedback (complaining), and interaction avoidance. Relationship building is the creation of a common ground between employee and customer. An active strategy for a consumer to use, this includes smiling or flirting, showing real or feigned interest in the other person, the sharing of life stories or investigation into shared backgrounds or interests that will help bond you to the other person. Although *information seeking* to previous authors meant preparation before the service situation, the second strategy type found in these interviews focused more on defining the service provider standards by using detailed questioning throughout the service encounter. Reputation building (or creating personal fame) is a new type of strategy not previously mentioned by other researchers. Consumers reported attempting to increase their overall personal reputation at the service setting by being overly friendly, overly appreciative, or by exemplifying their ability to purchase goods. A fourth identified strategy is that of a customer behaving like management. Management behavior is seen as acting as a superior or boss to the provider through the dictation of orders or directions and is typically used in conjunction with high-profile service situations such as job meetings or other times when impression management is key. Negative feedback or complaining behaviors typically occur after service failures as a way for customers to get benefits once the scenario is completed. Although previous literature describes participation strategies in a way that makes the reader believe there has to always be participation of some kind, during the interviews conducted here it became clear that there are some times when consumers simply don't want to use a strategy—thus making the behavior of avoiding interactions a strategy in and of itself.

The second set of findings explored information regarding the goals expected or targeted through customer participation strategies. Although these could be called a number of different things—rewards, outcomes, etc.—the term goal was chosen based on its basic definition—something that a customer wants to achieve (Encarta World Dictionary). The results from the first study led us to identify seven preliminary goal areas: receipt of benefits (increased value), social comfort (rapport), anxiety reduction, future treatment, satisfaction, recompense, and server happiness. Satisfaction, although not a specified goal area in and of itself, must be included due to previous literature and the basic understanding that everyone is attempting to find satisfaction in service encounters. Receipt of benefits is a simple concept which could include anything from the

receipt of free or discounted items to additional perks. Social comfort as a goal, such as ease with the provider, rapport building and friendship, were the most frequently mentioned. Anxiety reduction addresses easing the amount of anxiety often felt in different types of service situations. Many people discussed the idea of reputation, of behaving in certain ways in the hopes of receiving positive treatment at future encounters with the same service provider. Although in this study satisfaction was not the primary goal that people identified, it was still worthy of a mention and a category of its own. Much of the previous research in customer participation has focused on satisfaction as the primary goal and found it to be a key component driving what people do in service settings. However, satisfaction was not mentioned as a primary concept in our study. Recompense for service failures is also a key goal named during both studies. After a service failure occurs many consumers appear to use a strategy as some type of intervention specifically to get something back from the provider. Finally a new and interesting goal was found, that of server happiness. Instead of trying to achieve a personal goal of better service or higher satisfaction, a large proportion of CIT responses referred to “*cheering the waitress up*” or ensuring the providers happiness with the process.

Additional findings included the fact that over half of the CIT surveys showed a personal belief that there was some type of influence being used by consumers over the service situation. Over one-third of respondents reported influencing service situations with their behavior in excess of 80% of the time. 20% believed that they had the power to influence goal attainment 90-100% of the time, while fewer than 15% of the critical incident participants felt they had little or no control at all. It is possible, therefore, that perceived ability to control the service situation is a moderator of the relationship between goal setting and strategy used—this should be tested quantitatively in future research as well.

The findings suggest that although consumers cannot always openly identify for the researcher what they are actually doing, they do believe that their interactions and behaviors have some impact on the service experience. The results here work to extend prior research through the discussion of new customer participation strategies and more importantly, the identification of previously undefined goals and rewards being targeted. The use of customer participation strategies for goal fulfillment is new, and the exploration of the phenomenon opens up the scope of future participation studies.

SPECIAL SESSION SUMMARY
A Sociocultural Investigation of Consumer Credit and Consumer Debt

Jeff Wang, City University of Hong Kong

SPECIAL SESSION ABSTRACTS

“Consumers and Credit Cards: Building ‘The Good Life’ with Plastic Tools”

David Crockett, University of South Carolina
Randall L. Rose, University of South Carolina

In the consumption-centered quest to attain the good life it would be difficult to overstate the role played by credit cards. Yet historically, research involving credit cards has focused primarily on pathology and policy issues related to consumer pathologies such as compulsive consumption (Faber and O’Guinn 1988; O’Guinn and Faber 1989), impulsive consumption (Rook 1987), addiction (Hirschman 1992), and consumer self control (Hoch and Loewenstein 1991). This research has largely treated consumer credit either as a domain in which some other presumably more fundamental issue has been explored or as an arena for policy intervention rather than theoretical development. More recently however, there is growing interest among consumer researchers in exploring the role that credit cards play in facilitating the construction of consumer lifestyles. Credit cards facilitate the acquisition of consumption lifestyle markers much more easily than any other form of money. They make immediately obtainable consumption markers whose acquisition would have been less available to the majority of the working and middle classes of previous generations. In this sense credit cards facilitate a level of participation in contemporary consumer culture that is qualitatively different from what would be possible in their absence. Consequently, the entire range of practices consumers employ to manage their lifestyles with credit cards should be of particular interest to consumer researchers (Bernthal, Crockett, and Rose 2005). Bernthal et al. (2005) opine that the theoretical import of credit cards lies in their lifestyle-facilitating capacity, not simply in their ability to boost short-term purchasing power or to stimulate pathological consumption. They present a framework of credit card practice showing how consumers use them to both build lifestyles and to signal their efforts in this regard to aspirational referents.

The framework consists of two broad, categorical lifestyle spaces, achieving lifestyles and coping lifestyles, whose boundaries are defined in part by credit card practices that facilitate or impede movement between them (de Certeau 1984). They characterize achieving lifestyles by an ability to attain various consumption-defined lifestyle objectives. However, coping lifestyles, illustrated by use of the debtors’ prison metaphor, are characterized by restricted ability to attain them. The fluid and sometimes overlapping boundaries between achieving lifestyles and the debtors’ prison are paradoxical in the sense that consumers experience them distinctively yet simultaneously through credit card practices. The framework advanced by Bernthal et al. (2005), though insightful, focuses solely on card practices that display or enhance cultural capital. This focus likely understates the centrality of consumer credit in constructing lifestyle because it ignores the critical interplay between various forms of capital, traded off against each other in some instances but mutually reinforcing in others. Often credit card practice can determine the situated nature of this relationship by playing the lead role in translating social and cultural capital from one context into universally recognizable economic capital and ultimately into the markers that delineate lifestyle. Consequently this research further explores the relationship between credit card practice and consumer lifestyles from a social reproduc-

tion theory perspective, broadening the focus to account for the role of consumer credit in cultural, economic, and social capital formation.

To that end, in this project we investigate the role of credit cards in consumer lifestyle projects, focusing on lifestyle projects of those at the earliest stages of the traditional family life cycle (i.e., Bachelor/Bachelorette, Newly Married Couple, and Full Nest I). That is, we conduct in-depth interviews with consumers regarding credit cards and their role in facilitating the acquisition of lifestyle markers, particularly as they mark transition into and out of family life cycle stages often delineated by consumption acts (e.g., wedding, first home, first pregnancy, etc.). We include only those individuals living outside the proverbial debtors’ prison despite the fact that most consumers will experience their highest debt levels in the precise family life cycle stages highlighted in this research. Nonetheless, to generate the clearest understanding of the role of consumer credit in lifestyle construction we delimit our exploration to include only relatively stable lifestyle projects.

“It’s Not Who You Owe That Counts: Social Relationships and Consumer Debt”

Jeff Wang, City University of Hong Kong
Melanie Wallendorf, University of Arizona

The current study aims to integrate consumers’ various life domains to better understand debt’s manifest and latent functions in their life projects. As some research has suggested (e.g., Manning 2000; Ritzer 1995; Sullivan, Warren, and Westbrook 1989), consumer financial behavior is socially embedded and involves many aspects of social life. Debtors interpret and negotiate meanings of debt in line with their socially constructed environment and relationships in their networks. An uncharted area of consumer debt literature is how people employ debts in their life projects. Some aspects of life domains, such as consumption, personal relationships, and career development may be closely related to one’s debt situations.

Revolving debt is both a consequence of the past and an antecedent to the future. Therefore, debt needs to be studied dynamically, including an examination of how previous and future consumption behaviors are related to debt. Similar to consumer brand relationships (cf. Fournier 1998), debt represents the dynamic life projects of consumers and their meanings may evolve over time. Peoples’ life goals grow at different stages and debt may represent peoples’ foci at certain points in time. This study aims to integrate various aspects of one’s social life to better understand the meanings of consumer debt.

We also intend to understand how personal relationships and social networks play their roles for debtors. Consumer debt is simply an individual’s independent decision or behavior but it does involve his/her ties with many other actors in the network. A study on consumer saving found that non-savers hide their financial situations from their relatives and friends (Lunt and Livingstone 1991), which indicates that social support varies upon people’s financial situations. Debt is not only related to people’s personalities and values, but is often influenced by significant others. For example, people may accumulate more debt in order to reduce obligations with someone who provides financial support. On the other hand, debt may change one’s perception of his/her position(s) in the network and propel him/her to function differently in the network. The strength of ties and breadth of the network may thus

transform over time along with one's debt circumstances. We assume that one's strong ties are especially relevant to his/her debt situations.

How consumers use debts to accomplish their life projects and tasks in daily life has been unanswered. Before and after debts incur to consumers, we need to understand how consumers choose, interpret, and negotiate various types of debts. Debts may facilitate and hamper interpersonal relationships, expand or shrink personal networks, change family and friendship relations, and generate both obligations and freedom. It thus requires an in-depth analysis of debtors in order to delve into their personal stories that influence and are influenced by their attitudes toward coping with debt.

Our approach to studying consumer debt is to explore this phenomenon by painting a holistic picture of debtors' life domains. We make connections between consumer debts and the different aspects of a consumer's social life. We believe that consumer debt is not an isolated and purely individual decision or behavior; rather, it is embedded in consumers' social networks. In order to achieve this, the most appropriate method is to employ qualitative techniques to obtain information regarding consumers' backgrounds, goals, relationships, and consumptions, and then link them with debts. In-depth interview is an appropriate method to achieve this goal and we interviewed young debtors in college for this study.

By using in-depth interviews, we dig deep into college students' lifestyle, career goals, social relationships, as well as their financial behavior to provide a comprehensive picture. We then link consumer debt with college students' desires of independence and discuss how family support influences their debt accrual. Our findings reveal how college students employ debt as a leveraging tool to balance both obligations and freedoms in their social relationships. In addition, these young adults use debt as a mechanism to define and negotiate the meanings and boundaries of their responsibilities within their networks. Our study has demonstrated that consumer debt is a phenomenon which is inseparable from constraints in social relationships.

“Credit Card Advertising and Revolving Debt Management: A Poststructuralist View”

Nina Diamond, DePaul University

Suzanne O'Curry, DePaul University

Consumer credit may be viewed as an ideological system that manifests itself in the commodity texts of credit card advertising, and in the narratives and practices of credit card debt revolvers. We use the term, 'revolver' to refer to those who carry a credit card balance from month to month, and whose use of credit cards may therefore be inferred to reflect more than a desire for convenience. By bringing the notion of ideology to bear on the subject of credit, we suggest that ideas relating to credit are interdependent and emanate from a center or source to exert widespread cultural influence (Elliott and Ritson 1998)

Our investigation falls under the research program within Consumer Culture Theory (Arnould and Thompson 2005) called “Mass-Mediated Marketplace Ideologies and Consumers' Interpretive Strategies”. Within this realm of inquiry, consumers are viewed as meaning-creators whose interpretations of cultural signs and symbols reflect positions on a continuum between tacit acceptance of identity and lifestyle ideals promulgated by the dominant culture via advertising and the mass media, and conscious opposition to these ideological mandates.

We adopt a poststructuralist perspective, assuming that credit-related meanings are relationally constructed by a community of interpreters and are significantly constituted by practice-actions taken within a particular social context (Holt 1997). The poststructuralist frame within which we view credit-related phe-

nomena valorizes both the symbolic and the material, and locates 'actors' within a setting of power, conflict, and resistance (Elliott and Ritson 1998).

We employ discourse analysis to investigate the promotion of credit in popular culture, and the degree to which—and ways in which—constructs prevalent in credit card advertising are reflected in the household financial management narratives of consumers who revolve credit card debt. We examine the semiotic codes driving CitiGroup's “Live Richly” and Mastercard's “Priceless” campaigns (both of whose tag lines have entered the popular vernacular)—along with management commentary on these two campaigns from the business press—to explore the meanings implicit in these ads. The implied meanings are then mapped onto consumer narratives obtained from interviews with revolvers.

Fourteen semi-structured face-to-face interviews of 90-120 minutes each and fourteen 30-minute telephone interviews were conducted with Chicago area revolvers, many of whom described their financial situations in positive terms. All informants were “Household Financial Officers” responsible for day-to-day financial decision making and bill-paying; most were women. Interview topics included thoughts and feelings about financial history and current financial situation, budgeting, spending and saving, credit card debt management practices, associations to the terms “credit” and “credit card”, and credit card advertising recall.

We find that these campaigns both mirror and structure consumers' understanding of credit and revolving debt—and their day-to-day enactment of that understanding. Paradoxically, the fact that these ads incorporate implied criticism of advertising and—with a knowing wink demean the behavior they are intended to propagate—actually enhances their consumer appeal. Allusions to sentiments pervasive within the Zeitgeist (e.g., “You have to live a little”, “Time with your family is precious”, “There are things money can't buy”) add to the credibility and impact of the ads.

From their narratives we infer that a few consumers resist the appropriation of these sentiments by credit card marketers, sensing that the representations of credit being promulgated by these companies are false or duplicitous. Such consumers react by refusing to attend to credit card advertising, and may go so far as to cease to use—or even destroy—their cards. However, we find that the majority are re-appropriating meanings from the campaigns, and using them to make sense of their own revolving debt management practices. For example, time spent with young daughters on a new boat—purchased with a credit card—is described by the purchaser of the boat as “priceless”.

We consider the implications of these findings for both consumer behavior theory and public policy. We see this work as particularly relevant and timely, in light of the planned overhaul of the country's bankruptcy laws and rhetoric relating to the passage of this legislation by the U.S. Senate and the House of Representatives.

SPECIAL SESSION SUMMARY

Goal Distance and Consumer Choice

Ran Kivetz, Columbia University
Oleg Urminsky, Columbia University

SESSION OVERVIEW

A large body of literature has underscored the notion that goals play a central role in consumers' decision processes and ultimate behavior. Dynamic models of motivation (e.g., Atkinson 1957; Lewin 1951; Miller 1944) propose that people possess a strong achievement drive, which is heavily influenced by goals. The degree to which goals then affect behavior is determined by multiple factors. In addition to the valence and magnitude of goal outcomes, the degree of distance or remoteness from a goal or outcome has been recognized as an important determinant of how goals impact behavior. For example, the goal-gradient hypothesis, originally proposed by the behaviorist Clark Hull in 1932, states that the tendency to approach a goal increases with proximity to that goal.

More broadly, the notion that different forms of distance from a goal can affect consumer motivation is supported by a variety of theories of social-cognition and human decision-making. Researchers have investigated the impact on decision-making and behavior of individuals' *psychological distance* from their outcomes and goals (Kivetz and Kivetz 2004; Lewin 1951; Trope and Liberman 2003). Gollwitzer and Bayer (1999) identified two sequential stages of goal pursuit (and their associated mindsets) that exhibit increasing degrees of goal activation. Carver and Scheier's (1990) cybernetic control model further suggests that comparisons of the rate of progress toward the goal with a relevant criterion induces negative or positive affect and can therefore impact choices and behavior.

Building on the existing literature, the proposed session will contribute to a better understanding of the impact of goal proximity on consumer decision-making and behavior. The research papers in this session investigate the notion of distance from a goal or outcome based on multiple, yet related, theoretical perspectives and different conceptualizations of psychological goal-distance, including temporal, conceptual, and perceptual distance. The papers employ a variety of methods and data (lab and field experiments, paper-and-pencil problems, and secondary consumer data), and the session will offer a broad perspective on the ways in which the degree of goal proximity plays a role in the behavior of consumers.

In the first paper, Trope investigates the differential impact of central goals on choices concerning temporally near or distant outcomes. Building on Construal Level Theory he proposes that central goals, attitudes, and values, because of their relatively abstract and decontextualized nature, more readily guide choice for psychologically distant outcomes. In a series of studies, he demonstrates that temporal distance moderates the effect of central goals on consumers' choices, such that their central goals have greater influence on choices for the distant future, whereas their more peripheral goals and values have greater influence on choices for the near future.

Kivetz, Urminsky and Zheng build on the classic goal-gradient hypothesis to investigate the impact of progress towards a goal on consumer behavior. Using real reward programs, they demonstrate that participants purchase more frequently the closer they are to the reward goal and demonstrate higher frequency, effort and persistence as they approach that goal. They find that a stronger tendency to accelerate toward the reward, indicative of a higher degree of goal motivation, predicts greater retention and faster

reengagement. They further demonstrate that the mere illusion of progress toward the goal likewise induces effort acceleration. Their conceptualization and findings are captured in a parsimonious goal-distance model, in which effort investment is a function of the proportion of original (psychological) distance remaining to the goal.

Pocheptsova and Dhar investigate the interplay of mindset (deliberative or implemental) and goal focus (whether goals are activated) on subsequent preferences. They argue that for focal goals, whether an option is seen as facilitative or interfering with that goal determines preference for the option. In a series of studies, they demonstrate the effect and processes by which different mindsets influence preferences in a subsequent task. The paper shows that distinct mindsets have different levels of goal commitment, which affects how options are evaluated relative to the focal goal pursuit.

"Temporal Construal and Self-Consistent Choice"

Yaacov Trope, New York University

According to Construal Level Theory, people rely on more abstract representations, or high-level construals, of future situations when making decisions for the distant future than the near future. High-level construals consist of general, decontextualized features that convey the essence of information about future events, whereas low-level construals include more specific, contextual, and incidental details. Therefore, decisions regarding more distant future situations are more likely to be based on one's central, superordinate self-guides than on one's secondary, subordinate self-guides.

Initial evidence for this proposal came from studies on temporal changes in the effects of goals on choice. Depending on people's goals, some aspects of future options are primary and essential whereas others are secondary and incidental. Consider an activity consisting of two parts: A main task, which is the goal of the activity, and an unrelated filler task to be performed during a break in the main task. Because the main task is the primary goal of the activity, it is part of a high-level construal of the activity, and because the filler task is a secondary aspect of the activity, it is part of a low-level construal of the activity. CLT therefore predicts that temporal distance will increase the weight of the valence of the main task relative to the weight of the valence of the filler task in determining the overall attractiveness of the activity. Trope and Liberman (2000) presented participants with a choice between activities consisting of an interesting main task and a boring filler and activities consisting of a boring main task and an interesting filler. The activities were said to take place either on the same day or a few weeks later. The results showed that temporal distance increased interest of the activity with an interesting main task and boring filler, but decreased the interest in the activity with a boring main task and interesting filler. These studies show that people's primary goals are more influential in guiding distant future decision, whereas their secondary goals are more influential in guiding near future decisions.

Subsequent research examined temporal changes in forming value-consistent intentions. All of these studies used Schwartz's (1992) value questionnaire to assess the importance participants assign to a wide range of values (e.g., power, benevolence, hedo-

nism). The first study asked participants to imagine 30 behaviors (e.g., rest as much as I can) and to indicate the likelihood of performing each behavior either in the near future or in the distant future. We correlated the rated importance of each value and the mean likelihood for performing the behaviors corresponding to that value. As predicted, these correlations were higher when the behaviors were planned for the distant future than when they were planned for the near future.

In another study, participants read vignettes of hypothetical situations taking place in either the near future or the distant future. They were then asked to think about the importance and meaning of the event (high-level construal), about the concrete details of the event (low-level construal), or received no specific instructions (the control group). Participants indicated their intention to engage in the behavior described in each vignette. As expected, regression analyses showed that both greater temporal distance and higher level construal led to higher value-intention correspondence. Moreover, the effect of temporal distance on value-intention correspondence was mediated by changes in level of construal of the events.

Values differ in their centrality, with some values being central to an individual, and others being more peripheral and secondary. When a situation is related to different values, the individual's central values are more likely to guide choice from a psychologically distant than proximal perspective, whereas the individual's secondary values are more likely to guide their choice from the psychologically proximal than distant perspective. To test this prediction, Eyal, Liberman, Sagristano and Trope (2004) manipulated the centrality of values and examined how they predict behavioral intentions. In the first of these studies, participants were presented with both hypothetical and realistic situations in which two values were relevant to a particular behavioral intention. The framing of the scenario was varied to render one value primary and the other secondary. For example, one scenario involved carrying trash down a mountain, and this behavior was described either in terms of self-discipline or in terms of preserving the environment. Participants estimated their likelihood of undertaking the described behavior. The results showed that intentions regarding the more distant behaviors were better predicted by the primary values but not the secondary ones.

The second study used priming to manipulate centrality of values. Based on a procedure applied by Bargh et al., (2001), scrambled sentences were used to prime either cooperation or competition, after which participants had to decide between cooperation and competition in a resource-management fishing game, in which they had to decide on the number of fish they keep for themselves vs. the number of fish they return to the pool for common good. Results indicated that participants intended to keep more fish (i.e., exhibited more selfish behavior) when primed with competition in the distant future but not in the near future. That is, the value that was made primary or high level by priming affected distant future intentions more than near future intentions. Together these studies suggest that central values are more likely to be revealed in choices for the distant future, whereas peripheral values are more likely to be revealed in choices for the more immediate future.

“The Goal-Gradient Hypothesis Resurrected: Purchase Acceleration, Illusory Goal Progress, and Customer Retention”

Ran Kivetz, Columbia University
Oleg Urminsky, Columbia University
Yuhuang Zheng, Columbia University

The goal-gradient hypothesis, originally proposed by the behaviorist Clark Hull in 1932, states that the tendency to approach

a goal increases with proximity to the goal. In a classic experiment testing this hypothesis, Hull (1934) found that rats in an alley ran progressively faster as they proceeded from the starting box to the food. While the goal-gradient hypothesis has been investigated extensively with animals (for a review, see Heilizer 1977), its implications for human behavior and decision-making are understudied. In this article, we build on the behaviorist goal-gradient hypothesis and generate new propositions in the context of two real reward programs. We investigate these propositions using a variety of methods, data, and modeling approaches (e.g., field and laboratory experiments, secondary data).

The notion that goal progress affects consumer motivation is supported by theories of social-cognition and human decision-making. Dynamic models of motivation (e.g., Atkinson 1957; Lewin 1951) propose that people possess a strong achievement drive, which is heavily influenced by goals. Carver and Scheier's (1990) cybernetic control model suggests that comparisons of the rate of progress toward the goal with a relevant criterion generate affect. Researchers have also highlighted the impact of individuals' psychological distance from their outcomes and goals (Trope and Liberman 2003). Thus, prior theorizing regarding human motivation, affect, and cognition supports the relevance of the goal-gradient hypothesis for the human psychology of rewards. More specifically, as originally proposed by Kivetz (2000), the idea that achievement motivation increases with smaller goal-distance suggests that customers will accelerate and persist in their efforts as they near a reward program's incentive threshold.

To account for the hypothesized effort acceleration, we build on research in psychophysics and decision-making that has highlighted the sensitivity to relative rather than to absolute dimensions (e.g. Kahneman and Tversky 1979; Stevens 1957). We argue that consumers will spontaneously consider their distance to a goal incorporating the total distance as a reference point, leading to an evaluation of relative goal-distance. Accordingly, we propose a parsimonious goal-distance model, in which effort investment is a function of psychological goal-distance, defined as the proportion of the total (original) distance remaining to the goal. Algebraically, we denote this psychological distance as $d_t = (r - n_t)/r$, where r is the perceived total effort requirement of the reward (i.e., the starting distance to the goal), and n_t is the amount of the requirements already fulfilled by the individual at time t . The goal-gradient hypothesis implies that the latent motivation at time t to achieve the goal is a decreasing function of d_t . Because the underlying achievement motivation is unobserved, we model consumers' observed effort behavior.

In a large-scale field study, we recorded inter-purchase times for nearly 10,000 coffee purchases of members of a real café reward program (“buy ten coffees, get one free”). We found that as members approached the reward goal, the average length of time before their next coffee purchase decreased. On average, inter-purchase times decrease by 20%, or 0.7 days throughout the program. Using a hazard rate model, we found a significant linear effect of perceived goal-distance d_t , demonstrating purchase acceleration as a function of goal proximity.

In a series of tests, we demonstrate that the observed purchase acceleration cannot be explained by habituation, expiration concerns, other time-trend effects, or heterogeneity bias. For example, goal-motivated acceleration is observed after accounting for weekly sales and other time-varying covariates, and a majority of significant accelerators are found after accounting for unobserved heterogeneity in base purchase rates and the tendency to accelerate. Furthermore, using a sub-sample of members who completed at least two cards, we find that inter-purchase times reset (to a lower level) after the first reward is earned, and then re-accelerate toward

the second reward goal. Such “post-reward resetting” is consistent with our conceptualization but is inconsistent with the habituation rival account. In addition, we find deceleration among two groups of café customers who have low goal motivation: (1) “defectors,” who do not complete their card and (2) holders of “transparent” cards, who are paid a flat-fee to record their purchases irrespective of their purchase frequency.

Consistent with the notion that a steeper goal-gradient is generated by an increased drive to attain the reward (Hull 1934), we argue that members who exhibit stronger acceleration toward their first reward have greater goal motivation. Indeed, we find that members who accelerated more strongly toward their first reward exhibited greater retention and faster reengagement in the program. Importantly, these results were obtained after controlling for the duration and completion date of the first card, and for customers’ base purchase rate (a proxy for their coffee preference).

Next, we support the proposition that the psychological, rather than absolute, goal-distance drives motivation. We note that “illusory progress” toward the goal can be induced by increasing the total original distance to the reward while simultaneously increasing the perception of the requirements already completed (by giving bogus “head start” credits). Such a manipulation reduces the psychological (proportional) distance to the reward, d_p , while holding constant the real, absolute remaining distance. In a field experiment, we find that the mere illusion of progress toward the goal induces purchase acceleration. Specifically, customers who (through random assignment) received a “12-stamp” coffee card with two pre-existing “bonus” stamps completed the 10 required purchases significantly faster than customers who received a “regular” 10-stamp card. Separate process experiments show that the illusory goal progress effect cannot be explained by rival accounts like idiosyncratic fit and sunk cost.

In the last study, we analyze secondary data obtained from another real incentive program, akin to a freelance employment contract, in which participants earned a reward after rating 51 songs over the Internet. First, we replicated the finding of goal-motivated acceleration in inter-visit times (in the context of website rather than café visits). Second, we extended the goal-gradient effect to the domain of quantity decisions, demonstrating that the quantity of ratings per visit increases as a function of goal proximity. Third, we generalized the goal-gradient effect to the domain of effort persistence, showing that the probability of effort termination and program defection decreases with lower goal-distance. Finally, we again observed the phenomenon of post-reward resetting. In the general discussion, we explore the theoretical and practical implications of the findings.

“Mindset over Matter: The Interplay between Goals and Preferences”

Anastasiya Pocheptsova, Yale University
Ravi Dhar, Yale University

A major focus of choice research is on studying how consumers make tradeoff comparisons among the options provided. A major finding is that the manner in which people make tradeoffs is not consistent but changes with task and context (cf. Simonson et al. 2001). In much of this research, the manner in which consumer goals might influence preferences is relatively ignored as people are told to assume a goal (e.g., “Imagine you want to buy a VCR”). In contrast, a major finding in goals research suggests that most consumer behavior is goal driven and options that are consistent with active goals are relatively more valued. For example, Brendl et al. (2003) show a higher willingness to pay for a raffle ticket for a waiver on the university bill for students that were approached in

the bursar’s office (with a high bill paying goal) compared to students in the cafeteria.

Our paper looks at the interplay of mindset and goal focus on subsequent preferences. Past goals research has identified two distinct stages of goal pursuit, each of which is associated with different mindsets (Gollwitzer and Bayer 1999). The deliberation stage, for instance, consists of choosing between competing desires to form a goal. In contrast, the implementation stage is focused on when, how and where to act in order to achieve a chosen goal. These two stages give rise to different cognitive orientations or mindsets (i.e., deliberative and implemental mindsets) that extend to subsequent unrelated tasks. The purpose of this paper is to show that the mindset that participants bring to a choice task influences their preferences. Our key proposition is that an implemental mindset generates stronger commitment to the background goal than a deliberative mindset, and therefore one is less likely to purchase an item that might interfere with the background goal. Conversely, if the item in a subsequent task help pursue the background goal pursuit (for example, excelling in classes and purchasing a daily planner), implemental mindset participants are more likely to purchase this item.

Three studies are conducted to demonstrate the effect and processes by which the two mindsets influences preferences in a subsequent task. In each study, deliberative or implemental mindset was induced by asking respondents to either list pros and cons of a personal decision or plan an execution of an intended goal. The first study was designed to test the proposition that participants in an implemental mindset exhibit goal shielding (Shah et al. 2002) and are less likely to purchase items that are likely to interfere with the pursuit of their focal goal. In this study, after completing mindset manipulation, the participants were presented with a cell phone with hedonic features (e.g., a digital camera). Participants in the implemental mindset were less likely to purchase the hedonic item than participants in the deliberative mindset. Further, a content analysis of goals revealed that the goals generated by the respondents were of serious nature (for example, doing well in classes) supporting the proposition that a purchase of a hedonic item would interfere with the pursuit of a background goal.

The next study examines differences between mindsets when a subsequent item is facilitative to current focal goal and therefore we predict that implemental mindset would lead to increased purchase preference. At the same time, if an item is unrelated to the focal goal (meaning it is neither facilitative nor interfering) the two mindsets should lead to similar preference for this item. In Study 2a and the participants were asked to focus on either serious academic or fun travel-related goal. Following the mindset manipulation, participants were asked to rate their preference for either an alarm clock and a water filter (Study 2a) or travel guide and a water filter (Study 2b). Pretests have shown that an alarm clock was seen as highly facilitative product for academic goal pursuit, whereas a travel guide was highly facilitative item for fun travel-related goal. At the same time a water filter was judged as unrelated to both goals.

Consistent with our predictions, we found a complete reversal of the choice pattern obtained in Study 1. Participants in the implemental mindset were more likely to purchase an item, which was seen as facilitative to their current goal pursuit compared to the participants in the deliberative mindset. At the same time, when an item is not related to the current goal pursuit, no differences were observed between the two mindsets.

As a further test of our theory, in Study 3 we show that the participants in the implemental mindset exhibit significantly higher commitment and determination to pursue the focal goal than those in the deliberative mindset. This difference in their commitment to

the goal that people bring to the next task, we stipulate, moderates goal shielding by implemental mindset participants. In particular implemental participants, due to higher goal commitment, inhibit preferences for items that are inconsistent with their background goal. At the same time, deliberative participants, whose commitment to the focal goal is weaker, do not engage in such goal shielding.

Research on goals demonstrates that people evaluate options based on active goals whereas choice research ignores the goals that people bring to the study. An option can be seen as facilitative or interfering to the active goal and this determines the preference for an option. Two distinct mindsets (created by successive stages of goal pursuit) have different levels of goal commitment, which affects a degree to which an option is evaluated relative to the focal goal pursuit. Our paper examines the extended effect of mindsets on preferences for goal-consistent and inconsistent alternatives.

Triple Acculturation: The Role of African Americans in the Consumer Acculturation of Kenyan Immigrants

L. Wakiuru Wamwara-Mbugua, Wright State University
T. Bettina Cornwell, University of Queensland
Gregory Boller, University of Memphis

EXTENDED ABSTRACT

The U.S. is a nation of immigrants and the study of immigrant adaptation process has been undertaken in different fields. These research efforts have concentrated on examining the movement of the immigrant towards the dominant group. Studies of this genre include among many others, Gordon (1964) who examined assimilation of life in America. Berry (1980) developed a typology that examined the degree to which immigrants desired to have a positive relationship with the dominant culture. In this research Berry develops four acculturation strategies that an immigrant can adopt. These strategies are: assimilation, separation, marginalization and integration. Cross cultural psychologists have shown that immigrants who adopt an integration strategy have the best mental health. The examination of immigrant acculturation to dominant culture was adequate when the majority of immigrants to the United States were white. Changing demographics in the United States are resulting in research efforts that examine the differences between the acculturation of white immigrants and those from other ethnic groups.

In order to survive in the new environment, new immigrants must quickly "learn" new consumption habits, where to shop, what brands to consider, and/or how to evaluate different products and services (Tse and Lee 1994). Marketers have sought to understand immigrant consumer behavior by investigating different aspects of ethnic consumer behavior. For example, Hirschman (1981) looked at Jewish-American innovativeness. One of the classic studies on consumer acculturation was conducted by Penaloza (1994) who examined Mexican consumer acculturation in the United States. Oswald (1999) examined the experiences of Haitian immigrants in the U.S. All of the aforementioned studies examine consumer acculturation of immigrants to the dominant group. Researchers (see Hirschman 2001) have questioned the adequacy of existing acculturation models in examining the experiences of non-white immigrants. This research is offered in this genre. As stated elsewhere acculturation models do not examine the role of a subcultural group such as African Americans in the consumer acculturation of immigrants. It is our contention that the experience of black immigrants in the United States is different from that of other non-white groups because of the existence of a large African American population and the complexities of race relations. Historically, the legacy of slavery and racial discrimination has shaped the experiences of African Americans in the United States. This research introduces subcultural group acculturation by extending Berry (1980) and Penaloza (1994).

Thirty interviews were conducted with Kenyan immigrants in a metropolitan city in the Southern United States. Interviews were conducted one on one and respondents were provided with anonymity and confidentiality. All of the interviews were conducted in English and respondents were recruited using the snowball method. In our interviews we examined progressive learning (Tse and Lee 1994) of the immigrants but we also utilized a modified critical incident technique (Flanagan 1954) to understand their experiences in the consumption environment.

Reported here is one critical incident and two progressive learning patterns. The critical incident of interest across respondents was that of accessing hair-care services. The two progressive learning patterns discussed are with regard to choice of music and

dressings style. Our findings suggest that one of the ways that Kenyans learn about the importance of African Americans in their consumer acculturation is when they first look for a hair dresser or barber. They find out that there are dual delivery systems of services in the United States. In sum, recognition of the need for triple acculturation may come with a first critical incident that alerts the immigrant to subcultural requirements.

The musical tastes of the immigrants have changed. In a sense their consumption of music has been redefined. The immigrants expressed the fact that they no longer listen to country music because it was not considered appropriate to enjoy this music as a black person in the United States. There was a clear movement towards appreciation of African American music. Some of the immigrants have begun to appreciate their tribal music as a result of being away from home, expressing some nostalgic attachment to this music. They have progressively learned what music is appropriate in what sphere of interaction. An interesting finding of this research is that the immigrants' sense of style has been changed. There was a definite movement towards the subcultural group, i.e. the respondents described their sense of style to be in alignment with African American notions of style. Our data clearly shows prevalent subcultural acculturation with regards to clothing.

Our findings highlight the role of critical incidents in shaping the immigrant's understanding of potential subcultural acculturation requirements. From the critical incident, the immigrants progressively learn of the necessity to acculturate to the subcultural group. The findings of this research have implications for marketers and public policy makers.

Consumer Acculturation as a Dialogical Process: Case Studies from Rural-to-Urban Migrants in Turkey

Ozlem Sandikci, Bilkent University

Ahmet Ekici, Bilkent University

Berna Tari, Bilkent University

Consumer acculturation has received considerable research attention (e.g. Gentry et al 1995; Metha and Belk 1991; Oswald 1999; Penaloza 1989, 1994). Drawing mainly from literatures on acculturation, socialization and learning, these studies develop models that explain how consumers acquire and use consumption skills and practices while interacting with a new culture. Most of these studies concentrate on immigrants coming from less developed countries to the developed countries such as the United States, Canada and the United Kingdom, and investigate their adaptation to Western consumer cultural environment. Prominent in this literature is the model of acculturation strategies proposed by Berry (1980), which perceives acculturation as a linear process with four possible outcomes of assimilation, integration, separation, and marginalization. However, a few studies challenge the assimilationist view of acculturation and demonstrate that consumers can move between different social worlds without necessarily conforming to one culture (Askegaard, Arnould, and Kjølgaard 2005; Ger and Ostegaard 1998; Oswald 1999; Penaloza 1994). This perspective, which Askegaard et al (2005) refer to as 'postassimilationist acculturation research', regards consumer acculturation as a dynamic and multidimensional process that includes ongoing cultural negotiation or "culture swapping."

We aim to contribute to the existing literature by studying acculturation as a "dialogical process that involves a constant moving back and forth between incompatible cultural positions" (Bhatia 2002); we focus on rural-to-urban migrants' experiences in a less developed country, Turkey. We seek to understand how these migrants negotiate and articulate their cultural identities through consumption practices related to the body and physical appearance. Two premises underlie our research. First, we need to acknowledge that people from developing countries not only immigrate to the "West" in pursuit of a better life; many leave their villages and immigrate to the economically more promising cities in their own countries. Newly modernized cities in developing countries act as magnets that draw migrants from all over the country, promising them a relatively secure and recognizable glimpse of global modernity. These spaces, where Western consumption imaginations and experiences mingle in novel ways with traditional values and practices, make the acculturation process multidimensional and hybrid (Ma 2001).

Second, we direct our attention to consumption practices related to physical appearance and the body because they are significant components of self-identity (Schouten 1991). Previous studies demonstrate that acculturation incorporates cultural identity, language usage, religion, and social activities. Our premise is that one's cultural identity is linked to one's self, which is always embodied. Body and physical appearance can be altered through consumption so that individuals can achieve the desired set of meanings in new contexts. The few studies that discuss consumption of clothing and beauty products in relation to acculturation do not offer a detailed analysis of how people's understanding of their body and physical appearance are transformed as a result of migration and how people use consumption practices related to appearance to negotiate their cultural identities (Lindridge et al 2004; Oswald 1999; Penaloza 1994). We hope that our research both provides new insights into the concept of consumer acculturation and also generates new research questions as well.

RETHINKING CONSUMER ACCULTURATION

Acculturation is mainly concerned with "phenomena which result when groups of individuals having different cultures come into continuous first hand contact, with subsequent changes in the original culture patterns of either or both groups" (Redfield, Linton, and Herskovitz 1936, cited in Berry 1980, p.9). The term "consumer acculturation," a subset of acculturation process, is used to refer to "the general process of movement and adaptation to the consumer cultural environment in one country by persons from another country" (Penaloza 1994, p.33). Consumer acculturation involves both buying and consuming goods and services, and learning the meanings attached to them; therefore, it is an "eclectic process of learning and selectively displaying culturally defined consumption skills, knowledge, and behaviors" (Penaloza 1989, p.110).

Consumer behavior scholars use the concept of acculturation to study the consumption experiences and practices of immigrants and ethnic minorities (e.g., D'Astous and Daghfous 1991; Gentry, Jun, and Tansuhaj 1995; Herche and Blasubramaian 1994; Khairullah 1996; Lee and Tse 1994; Metha and Belk 1994; Penaloza 1994). Drawing from Berry's (1980) framework, which conceptualizes acculturation as a process with four possible outcomes—assimilation, integration, marginality and separation—most of these studies seek to categorize the immigrants in terms of their acculturation levels and map out factors that have an impact on acculturation. Many studies also make a distinction between attitudinal and behavioral components of consumer acculturation. Their findings indicate that one can own mainstream consumer objects without relinquishing one's cultural identity (e.g. Gentry, Jun, and Tansuhaj 1995); on the other hand, consumer acculturation can also result in more and deeper ties with the homeland (e.g. Metha and Belk 1994; Lee and Tse 1994).

Some exceptions notwithstanding, the consumer acculturation research tradition makes certain assumptions that need rethinking. First, there is a tendency to regard acculturation as a linear and stable process in which one goes from one mode to the other. However, Penaloza's (1994) findings suggest that there are times when immigrants' consumption patterns might suggest assimilation; yet at other times, the way products are used suggest ties with the original culture. Similarly, the concept of "culture swapping" introduced by Oswald implies that rather than conforming to one ethnic category, people constantly negotiate cultural identities and choose "when and where to wear their ethnicity" (1999, p.315). Although these studies indicate that people can and do assume multiple and even contradictory subject positions, they do not offer much insight into why people use a combination of adaptation strategies. Second, many studies assume a homogenous host culture to which the immigrant aspires. As Penaloza (1994) argues, underlying the assimilation framework is a modernist view of the nation, which assumes a socially integrated and culturally homogenous entity. However, this is neither an accurate nor sustainable argument, especially in the contemporary world where difference and fragmentation are even more pronounced.

Recognizing the limitations of the traditional approaches to acculturation, researchers, both within marketing and outside, made calls for alternative ways of thinking about the relationship between immigration, identity, and acculturation (e.g. Hermans and Kempen 1994; Ger and Ostegaard 1998; Bhatia 2002; Askegaard

et al 2005). Hermens and Kempen (1994), for example, argue that in a period of increasing globalization, with its rapid creation of multinational citizens, massive flows of transmigration and border crossing, acculturation becomes increasingly complicated. Rather than thinking of immigrants as moving linearly from one culture to another, they suggest that we should think of acculturation and identity issues and “mixing and moving” (Hermens and Kempen 1994, p.1117). Ger and Ostegaard (1998) also suggest that identities can be formed through a moving junction of multiple and diverse cultural and subcultural forces. Similarly, Bhatia suggests that acculturation should be conceptualized as a “dialogical process that involves a constant moving back and forth between incompatible cultural positions” and entails “feeling simultaneously assimilated, separated and marginalized” (2002, p.57). Drawing from a dialogical model of acculturation, this study focuses on rural-to-urban migrant women in Turkey, and investigates how these women negotiate their cultural identities through the consumption of products related to the body and physical appearance. We limit our study only to women as the relation between the self and the body is historically more pronounced and problematic in the case of female identity (Bordo 1993). Next, we briefly discuss the relationship between the body and self-identity, and then rural-to-urban migration in Turkey.

BODY AND SELF-CONCEPT

The self is embodied; the perception and evaluation of one’s own body and physical appearance contribute significantly to one’s self-concept (Schouten 1991; Thompson and Hirschman 1995). The body communicates physically and culturally salient meanings about an individual. Emphasis on the body as the source of meaning suggests that the body should not be considered only as an object but also as the subject of culture. The symbolism of the body as the embodiment of culture implies that “a complex cultural ideology of body underlies consumers’ satisfaction with their appearance, their sense of ideal or more desirable body, and the consumption activities that these self-perceptions motivate” (Thompson and Hirschman 1995, p.151). Contemporary consumer culture plays an important role in the proliferation of stylized images of the body (Featherstone 1982). Advertising and popular media make individuals more conscious of their physical appearance and they constantly compare themselves to the idealized images of youth, fitness, and beauty. The fluidity and indeterminacy of body—the possibility of altering one’s body or body image through various consumption practices—cast the body as an on-going process, an unfinished entity that needs to be worked on in order to achieve the desired set of meanings. Emphasizing the unfinishedness of the body, Schilling observes that “in the affluent West, there is a tendency for the body to be seen as an entity which is in the process of becoming; a *project* which should be worked at and accomplished as part of an *individual’s* self identity” (1993, p.5)

The notion of the body as project is of central importance in Giddens’s theorization of the relationship between agency and social structure. Giddens (1991) perceives the body as intrinsic to the reflexive project of self-identity. He suggests that, in conditions of high modernity, the body “becomes a site of interaction, appropriation and reappropriation,” that is, it becomes a project increasingly subject to intervention and constant revision (1991, p.218). In late-modern societies, the body becomes a central component of constructing, negotiating, and altering self-identities. Within the logic of consumer culture, the body turns into a site of endless choice and possibility. Furthermore, the growing preoccupation with the body and physical appearance in present Western cultures disseminates to the rest of the world through global flows of

consumer products, advertising images, and popular media. However, if the relation between identity and the body is one in which both are increasingly open to choice, then it becomes important to ask what choice really means in relation to one’s body in contexts where freedom is restricted by differential access to material resources, asymmetrical power relations, and the disciplinary power of traditions and localized modernities.

RURAL-TO-URBAN MIGRATION IN TURKEY

The newly modernized cities of the developing world offer a hybridized and domesticated version of Western modernity. These cities, which Ma (2001) refers to as sites of “satellite modernities” draw, like a magnet, rows of migrants seeking better living conditions, from rural and less-developed regions of the country. Several factors underlie rural-to-urban migration in developing countries like Turkey (Hemmasi and Prorok 2002). Limited availability of agricultural land and non-agricultural work, increasing mechanization of farming, political turmoil, natural disasters such as earthquakes and floods push rural people to the cities. On the other hand, shifting expectations due to social modernization and exposure to globalization as well as easier access to health, education and cultural amenities make city living attractive for rural people. Given the insufficiency of public housing and high levels of unemployment, rural migrants typically settle in squatter houses located at the periphery of the city and find employment in the informal sector of the economy. Eventually some move into the formal sector and generate enough financial resources to purchase or build a squatter house of their own. However, as Hemmasi and Prorok observe “new migrants to urban squatter settlements often experience significant levels of deprivation and adversity” (2002, p.400).

A recent survey (Uzuncarsili and Ersun 2004) reports that squatter houses comprise 35% of all dwellings in Turkey, and around 60% of those in Ankara, the country’s capital where the present study was conducted. Squatter settlements in Turkey date back to the late 1940s; at that time they were perceived as a temporary solution to the housing shortage experienced in big cities due to rapid urbanization. By the end of the 1960s, squatter settlements had not only expanded but become permanent features of all the major cities. Beginning in the mid 1980s, Turkey embarked of a massive economic and cultural liberalization and globalization program. As a result, big cities quickly turned into showcases of the global consumer culture, catering to a small segment of wealthy entrepreneurs and professionals who were eager consumers of imported products and services. However, the 1990s also witnessed the increasing income gap between the haves and have nots. Economic polarization fostered cultural polarization. The squatter settlements were stigmatized as ghettos and the residents came to be perceived as the ‘threatening Other,’ attacking the city’s values, its social order and the very core of its secular ideology of consensus and unity (Erman 2001).

The first migrants to cities were young men seeking jobs; later, the most migrants started moving to the city as family groups (Ozbay 1985), predominantly nuclear families (Kandiyoti 1982). The proportion of migrant women who are formally employed is low, although many work informally as cleaning ladies in the homes of the better-off urbanites (Kandiyoti 1982). This can partly be explained by patriarchy, which is much stronger in rural areas than urban contexts where more egalitarian gender roles are present (Moghadam 1993). Despite popular stereotypes, migrant women are very diverse in their backgrounds and levels of adaptation to the urban life (Erman 1998; Kadioglu 1994). While some do not experience much change in their lifestyle and role within the family,

others try very hard to break out of the traditional, patriarchal mold by demanding greater freedom in their lives (Erman 1998).

METHODOLOGY

As we noted earlier, our study aims to question a number of assumptions in consumer acculturation research, and thus, provide useful insights into the development of a more comprehensive theory of consumer acculturation. Given this motivation, we adopted a case study method. The scientific benefit of the case study method lies in its ability to open the way for discoveries (Shaughnessy and Zechmeister 1990). Like other qualitative research methods, an important virtue of case study research is that it lends itself to theoretical generation and generalization. Theoretical generalization involves suggesting new interpretations and concepts or reexamining earlier concepts and interpretations in major and innovative ways (Yin 1984). Since the case study seeks to capture people as they experience their natural, everyday circumstances, it can provide empirical and theoretical gains in understanding larger social complexes of actors, actions, and motives that affect acculturation. In other words, it permits us to examine not only the complex of life in which immigrants to urban Turkey are implicated but also the impact of the complex web of social interaction on beliefs and decisions.

The research design used in this study is an adoptive and emergent one. The design unfolds as fieldwork unfolds, and the emergent nature of the design affects decisions regarding sampling, data collection and analysis. An initial, exploratory analysis of earlier interviews with several immigrants, and an intense engagement with the chosen squatter area through participant observation for one year was followed by more focused and directional in-depth interviews with cases selected on the basis of differences in notions of physical appearance and differences in consumption practices.

Our data collection took place in a squatter area called Atapark in Ankara, the capital city of Turkey. The area is located in the northern part of the city and is approximately thirty minutes drive from the city center. The dwellings are one-storey, freestanding houses with electricity and running water. The primary data collection method for the case study was in-depth interviews. Focus groups were used to solicit the informants for the case study, and observations and pictures were utilized for methodological triangulation (Wallendorf and Belk 1989; Feagin, Orum, and Sjoberg 1991). Initial interviews were conducted during April and May 2004, and focused interviews were conducted during February 2005. Prior research noted intergenerational differences in immigrants' cultural adaptations (e.g. Penaloza 1994). In order to see if such variations exist, we sampled both first and second-generation immigrants.

Data analysis was a process of gradual induction. Analysis of textual data proceeded through two distinct stages of iteration: intra-text and inter-text (Arnold and Fischer 1994; Thompson 1997). The aim of the intra-text analysis was to identify the codes and categories of the findings. Once codes and categories were identified, we used inter-textual analysis to look for patterns of relationships (e.g. similarities and differences) across three cases (Thompson 1997). Due to page limitations, below we present only an abbreviated version of our case study data.

CONSUMER CASES

Ayse

Ayse is a 52 year old widow with one child. She is a first-generation migrant, who moved to Ankara 27 years ago. She lives together with her son, daughter-in-law, and two grandchildren. Her

family used to live in a village in Corum, a city 150 miles northeast of Ankara. Her father was a carpenter and her mother was a housewife; both of her parents were illiterate. Ayse attended to school only for three years, and then quit, which is the usual practice in her village where girls are not typically permitted to further their education. Her husband was a blue-collar worker in a bread factory. Ayse is originally from a very religious and conservative village where all women are covered. She states that men in her village do not even interact with women who are not covered, believing that such women are sinful. She is also covered, and believes that one's physical appearance is granted by God and no one should change his/her appearance, as this would mean rejecting God's will. She admits that city culture is very different from the culture she experienced in her village. She does not approve of urban women who wear revealing clothes and show their bodies, and thinks that there is too much emphasis on the physical appearance. Although she is aware that she is overweight, she is not concerned with how her body looks and not interested in changing her body shape. Ayse never wears make-up and does not use any skin or hair care products. However, she believes that it is necessary to wear a clean and more appealing dress during special days like religious holidays and weddings. She states that the only change in her physical appearance since her migration concerns the way she covers herself. While in the village, she used to wear a traditional headscarf with wide shirts and loose trousers; she now covers her head with a wide turban and wears a long, loose overcoat when she goes out.

Suna

Suna is a 24 year old housewife, married with one child. She is a second-generation immigrant and has a high school degree. Her parents are from a village in Bolu, a city 120 miles northwest of Ankara, where she visits from time to time. Her father is a cook and her mother is a housewife. Her husband works as a driver for a private bank. Although both her mother and mother-in-law are covered, she is not; however, she strongly believes in Islamic rules. She thinks that women should not cover themselves but should not appear very "inviting" either. For example, they should wear make-up, but use pastel colors. She believes that physical appearance is much more important in the city and feels the urge to adapt her appearance to fit the urban culture. According to Suna, while beauty is associated with cleanliness in the village, it is associated with bodily adornments, such as make-up, clothes, and hair in the city. Suna is highly involved in cosmetics and other beauty products, and uses advertisements and the sales personnel of cosmetics stores that she visits occasionally as information sources. She puts on make-up whenever the situation demands, such as dinners and family get-togethers. She mentions that some of the beauty products, such as powder and mascara, are indispensable, and she would not be able to live without them. Suna is not very happy with how her body looks. She thinks that after giving birth to her son her hips have become larger and she tries to reshape her body. While she dreams of having a treadmill, she cannot afford one due to financial constraints. Instead, she tries to exercise by walking with her husband around the squatter area or playing volleyball with children. Suna is also interested in fragrances and like to use them. However, as with her consumption of cosmetic products, she cannot afford the originals. Instead, she purchases fake versions of well-known Western perfume brands.

Cennet

Cennet is a 24 year old, single, second-generation migrant from a village in Cankiri, a city 80 miles north of Ankara. She is a high school graduate and is currently looking for employment. Her

father is also a high school graduate and works as a fireman. Her mother finished primary school and has never worked outside the home. Her family is religious and her mother is covered. While she is with her family, Cennet covers herself, does not wear any make up and tries not to look attractive, as her parents do not approve of women who draw attention to their physical appearance. When she is socializing in the neighborhood, she is generally covered; but when she visits the city she does not cover herself. When she meets her boyfriend, who is not a squatter neighborhood resident, she pays extra attention to her appearance. She does not cover herself, wears more fashionable clothes, and puts on make-up. She believes that, unlike the rural environment, city life demands that one change her physical appearance to fit into different contexts. For example, when she goes to a movie theater or a café, she cannot wear the clothes that she wears in the neighborhood; she needs to do her hair and apply make-up. Cennet mentions that she and her friends try hard to look like the city girls. However, such attempts may lead to highly dramatic results sometimes, especially when the girl does not have enough financial and cultural resources and skills. Examples include applying hydrogen peroxide on hair to highlight it, but ending up with terribly burned hair; or using watercolor paint as make up. Cennet is highly concerned about her physical appearance and constantly compares herself with others. She finds herself fat and unattractive, and believes that she needs to work hard to reach the ideal. She says she always observes how women look when she goes to the city center and pays attention to women featured on television. She tries to find out what is fashionable and how she can look beautiful without paying too much. Overall, she is highly alert to social cues indicating how she should dress and quite skillful in modifying her appearance to achieve what is expected from her.

ANALYSIS

Across our three immigrant cases, we note the existence of different notions and practices of beauty, physical appearance, and body exist. For Ayse, physical appearance is a God-given attribute that should not be questioned. Guided by this strong religious position, there was only a limited transformation in how she relates to her body following the move from the village to the city. Suna's family is also religious and she is herself a strong believer. However, unlike Ayse, she is highly involved with her physical appearance. She makes a distinction between looking attractive but not being too revealing. While beauty means cleanliness in her village, it connotes adorned, made-up, and well-dressed bodies in the city. Similar to the other two, Cennet comes from a religious family. Yet, she is the one who is most concerned and dissatisfied with her appearance. She believes that, unlike village life, urban culture demands that one pay attention to her body and adjust her physical appearance to fit different contexts. Similar to Penaloza's (1994) observation about Mexican immigrants in the United States, our findings suggest that immigrants are not necessarily homogeneous groups who draw from a uniform set of cultural meanings and practices. On the contrary, three cases indicate that the meanings the informants attach to their bodies and physical appearances are highly diverse and even conflicting, as in the case of Ayse and Suna.

We observe that, although it was not evident in the earlier research, religion is an important determinant of the acculturation process and resulting identities. More specifically, we see both a liberating and restrictive role of religion in the cultural adaptation of immigrants. Religious beliefs and practices may restrict an immigrant's adaptation to urban life as in the case of Cennet who feels obliged to cover her head when she is with her parents. At the same time, religion may have a liberating effect on the cultural adaptation of the immigrant. Among the three cases studied, Ayse is the most religious-looking respondent. From the traditional

acculturation standpoint, which assumes a fixed host culture, Ayse can be classified as a "separated" immigrant because she basically rejects the seemingly dominant urban secular notion of body and physical appearance, which favors the uncovered, Western-style dress code. However, from a dialogical acculturation point of view, which abolishes the distinction between dominant and dominated cultures, Ayse has successfully adapted one of the dress codes of the city-culture. In Turkey, there is a difference between rural and urban covering styles. While women in the villages cover themselves using the "traditional" headscarf, women in the cities use the "turban" (Sandikci and Ger 2001). Thus, it is possible to argue that Ayse has been assimilated into the city culture in terms of her physical appearance. While she used to wear a headscarf in the village, now she embraces city life by wearing a turban.

Patriarchy is another factor that affects the cultural adaptation of our immigrant respondents. Cennet is an interesting case showing that, even though patriarchic pressures are very difficult to overcome, there are strategies that one can creatively employ to negotiate the cultural borders. When she is with her family, she is always covered and never applies make-up. While she is socializing with other people in the squatter neighborhood, she still feels the patriarchic pressure and continues to cover herself. However, when she goes to the city center, or meets her boyfriend, she is open, wears more fashionable cloths, and applies make up. From the traditional acculturation stand point, it would be challenging to categorize Cennet in terms of her cultural adaptation. She would paradoxically demonstrate the characteristics of both assimilation and separation. However, from a dialogical acculturation point of view, the cultural adaptation of Cennet does not represent a paradox. The multiple and incompatible subject positions she assumes indicate the constant negotiations she undertakes while she tries to break out of the patriarchal mold and construct herself as a free individual.

DISCUSSION

In this study, we aimed to contribute to the existing literature by studying consumer acculturation as a dialogical process. We sought to understand rural to urban migrants' negotiation and articulation of their cultural identities through consumption practices related to body and the physical appearance. As Giddens (1991) suggests, in late-modern societies, body and physical appearance become a central component of constructing, negotiating, and altering self-identities.

Bhatia (2002) argues that the term *culture* used by the traditional acculturation theorists both implicitly and explicitly assume a single India, or China, or Japan, and so on 'out there' in a fixed geographical space. This assumption misleadingly suggests that all immigrants, irrespective of the differences in their backgrounds and subjectivities will adopt an integration strategy to successfully fit into the 'mainstream' society. Our findings, however, indicate that not only are the informants' notions of beauty, physical appearance, and body different, but their self-concepts and cultural adaptation strategies also vary. A closer look at our informant's stories suggests the complexities of the consumer acculturation process and the multifaceted nature of cultural adaptation. Each of our respondents assumes multiple subject positions in terms of their relationship to the urban culture. Our data highlight that conflicting voices and cultural positions can and do exist simultaneously, and this does not necessarily mean being caught in a cultural conflict (Ballard and Ballard 1991). As Oswald's study illustrates "in order to negotiate the day-to-day border crossings between home and host culture, immigrants switch cultural codes constantly, adapting to the expectations of both home culture and host culture as the situation demands" (1999, p. 307). Although previous studies noted that cultural adaptation of first and second-generation immigrants

differ, we did not observe such an intergenerational effect. Instead, our findings indicate that a number of factors, such as religion and patriarchy account for this moving back and forth between different cultural identities.

Our study also suggests that rural-to-urban immigrants could negotiate their identities through the use of a combination of adaptation strategies not only because there is no one immigrant culture (home culture) out there, but also because there is no one fixed host culture to which one tries to adapt. As Appadurai argues, global consumer culture is a “complex, overlapping, disjunctive order” that deconstructs the dominant-dominated dialectic (1990, p.226). It is the fragmented and polysemic characteristics of modern consumer cultures that facilitate the dialogical process of consumer acculturation. Consumption cultures of non-Western countries like Turkey present an interesting context to observe the intricacies of acculturation. In such places, characterized by different modes of modernities, traditions and Western imaginations mingle in novel ways (Giddens 1990), rendering conventional categories of consumer acculturation problematic. Contemporary urban culture in Turkey demonstrates a hybrid and fragmented characteristic where secular and religious consumption orientations and practices co-exist (Sandikci and Ger 2001). For example, although secular (Western) and religious dress codes appear conflicting, they have become equally acceptable modern urban forms. This makes Ayse emerge as an immigrant who has integrated into one fragment of the city culture and simultaneously separated from the other. However, while hybridity and fragmentation foster a dialogical acculturation process, this does not necessarily mean that individuals are free from all the structural constraints and power dynamics, and experience “culture swapping” without any cost. As much as our informants struggle to adapt to the city culture, they are still stigmatized as the “threatening Other” by the urban elite.

Our study contributes to the acculturation literature both by extending the notion to within-country immigration and by looking at how cultural identities are negotiated through body-related consumption meanings and practices. However, given its exploratory nature, it suffers from some limitations. First, future studies should draw from a broader set of informants and engage in more ethnographically oriented investigations of rural-to-urban immigrant culture. Second, similar studies could be conducted in other developing countries to find out if similar experiences are observed in different contexts.

Poverty Consumption: Consumer Behavior of Refugees in Industrialized Countries

Elisabeth Kriechbaum-Vitellozzi, Salzburg University of Applied Sciences

Robert Kreuzbauer, University of Illinois UC

ABSTRACT

To date, consumer research has devoted no attention to the consumer behavior of the unprivileged group of refugees in industrialized nations. This article summarizes research investigating the experiences of young refugees in a western country and the coping strategies they develop in consumer behavior in order to deal with the new situation of living in an affluent society. Moreover, the study focuses on "sacred" possessions and on the question of whether they have a significant meaning for the refugees and for what reasons. The research was conducted in an Austrian shelter for adolescent refugees and was based chiefly on ethnographic fieldwork, collage techniques and long interviews, especially making use of male informants from Africa and Asia.

INTRODUCTION

In industrialized countries, consumption plays an important part in everyday life. The affluent members of society can satisfy their needs and desires from a variety of goods and services. On the other hand, there are people living in poverty with little or no consumer choice-and to this group belong the refugees. Hill (2001, p. 2) stated in his study about the poor that "the material lives of such individuals are markedly different from those of the affluent population" as they suffer from constraints and restrictions.

This article should draw the attention on the particular situation of refugees and show the restrictions and difficulties they endure in a consumer society by portraying their living situation here. Thus, the awareness of politicians and the society should increase by highlighting the fact that this subpopulation constitutes a relevant group in western societies and that especially with regard to their integration, a profound knowledge about these individuals living in a consumer world is required. Consequently, the study should contribute to a better understanding of refugees asking for asylum and "help rid society of the common stereotypes", as Hill (2001, p. 7) stated relating to the poor. It is important that the citizens in industrialized countries get a more complex picture of the refugees' lives to avoid evaluations often based on little knowledge which only takes into consideration the own point of view.

In this context, also the differences between average consumers of industrialized countries and refugees who have to deal with poverty, uncertain future prospects and sometimes with psychological traumata due to their flight and/or their former living conditions are emphasized.

Two aspects are stressed in this work:

The primary part of this paper presents an analysis of adolescent refugees' experiences in and perceptions of an affluent society and the resultant coping strategies they develop in order to deal with these circumstances. Thereby, the characteristics of this group of people who are nearly adults when they first encounter the western world where they face legal and financial restrictions are highlighted.

Furthermore, "sacred" possessions also have been investigated as they may have a significant meaning for the refugees. Sacred entities which may embrace people, things and places involve some mystery or myth and they are exclusive, powerful, and unique, as stated by Wallendorf, Belk and Heisley (1988).

Further, they are worshiped and treated with inordinate respect unlike ordinary consumer commodities.

To date, consumer research has devoted no attention to the consumer behavior of refugees in industrialized countries. While earlier research investigated the consumer behavior of immigrants and of various subpopulations among the poor in western countries (Hill and Stamey 1990; Hill 1991, 1992; Penaloza 1994; Gilly 1995; Hill and Somin 1996; Hill 2001), this paper focuses on refugees, highlighting three particular aspects of this group of the population.

Firstly, while immigrants leave their countries voluntarily in search of a better life, the refugees are forced to flee their homes due to (the threat of) persecution, with no possibility of returning given the risks (whether real or perceived) to their health and safety. Moreover, most of them do not bring anything with them, mainly because of their short term decision to flee, as well as due to political concerns not risking to alert the authorities (Hill, Somin 1996, p. 207).

Secondly, those refugees who come from very poor countries in general were not part of a consumer society before and therefore have to face a different situation here than those who have grown up in industrialized cities of threshold countries. Nevertheless, both groups suffer from their status of being refugees. As stated by one of the informants: "You are born into this world like a baby with the big difference that you are shaped already by a completely different culture. You are in the situation of being a refugee and thus reduced to a Mr or Mrs 'Nothing' who have to orientate themselves in the new world."

Finally, despite the fact that many of the refugees are not accustomed to a consumer society, this topic is interesting particularly with regard to the fact that certain consumer products such as for example cuddly toys or mobile phones gain special values for all refugees in the course of time. Some of them are even considered as "sacred" possessions and serve as coping strategy for the young people helping them to deal with the difficulties they encounter in a foreign country.

Unlike immigrants, the refugees have to deal with a significant uncertainty concerning their future prospects as they do not know whether their application for asylum will be supported. At least during the initial period of their stay, they do not have the right to work in the host country, which may have a very negative impact on their lives, not only with regard to their financial situation but also to their psychological health. These restrictions affect their self-esteem since they feel useless and not integrated in society, as stated by some of the informants.

The refugees consequently depend on welfare which provides the basic commodities. They have to renounce many things a typical middle-class consumer takes for granted due to the small subsidy. On the other hand, they dispose of a lot of time, not knowing how to pass it since they often do not have the financial means to undertake specific activities. One informant has huge problems with his actual situation, saying: "If you consume, you have to pay back. Only consumption is not good!" He suffers from the fact that for the next months he will not have any possibility to earn his own money, neither being able to do professional sports nor

any other kind of work. The fact that he gets a weekly pocket-money, that allows him to a certain extent that he can go shopping or go out without doing nothing does not make any sense to him.

This may also explain the danger that individuals who have lost any hope for a better future and thus are deeply despaired may drift easily into criminality. Moreover, the young people during the rite of passage from adolescents to adults associated with the forming of their own identity may become open for ideological ideas and may even get deeply influenced by extremist body of thought.

According to recent statistics of UNHCR (2005), 368.000 refugees applied for asylum in 38 industry nations in 2004. But the total number of refugees is significantly higher: about 17 Mio. people are 'of concern' to UNHCR, such as refugees or asylum seekers who crossed the borders of their countries, while other 25 Mio. people are considered as refugees in the inland because of civil wars or other internal conflicts. Thus, the issue of refugees is still a pressing one, also in western societies. These individuals constitute an important group of the population worth to investigate since politics as well as societies of industrialized countries are concerned with this specific phenomenon.

The refugees' situation in an affluent society is maybe best pointed out by Hill and Somin (1996, p.208), although they referred to immigrants in the U.S.: "Unfortunately, when they arrived they often experienced profound disappointment at the lack of opportunity and overt or covert racism. National debate, of course, will continue to concentrate on the ethnocentric issue of how many, but a humane society also must consider the quality of life of these individuals once they exist with our borders."

LITERATURE REVIEW

In the available literature about various subpopulations among the poor, there are, firstly, studies about poor U.S. citizens such as homeless people, people who move from one shelter to another, welfare mothers and their children, etc. Another interesting group are the immigrants in the U.S. Finally, former research of "sacred" possessions is relevant in this context as it depicts their meaning for the various subpopulations, also including the immigrants.

Poverty consumption

An example of the former type of study is that of Hill (2001, p. 162) who undertook ethnographic fieldwork to investigate the lives and survival strategies of various subpopulations among the poor in the U.S. such as homeless people, welfare mothers and their children or those of children who are in prison because they committed property crimes with the purpose to gain access to the material world presented to them by the media. Hill finds that these groups are excluded from the affluent society and have to face considerable constraints in order to satisfy their basic consumption needs. Thus, unlike the average consumers, they spend a lot of time in search of basic commodities.

This is best depicted in Hill's stories about the poor (2001, p. 53). One of his stories for example is about a welfare mother and her child who is in continuous search for the fulfilment of her basic needs which has a substantial impact on her life as her decisions are strongly influenced by this fact (even regarding the choice of her man). Only after the basic commodities are satisfied, she detaches from material possessions considering them as merely functional objects not worth focusing too much on them. In other stories, Hill (2001, p. 3) reveals the homeless' manner of acquisition and consumption of basic commodities by describing on the one hand the lives of homeless mothers and their children who depend on shelters for their lodging, food, and clothing. On the other hand, he

describes the living conditions of other homeless people who try to live on their own by constructing their own homes of materials scavenged from construction sites and who earn their living by scavenging recyclable objects. Hill states that the homeless often use items such as for example clothes or shoes until they are consumed at their maximum and thus cannot be worn any longer. Moreover, they rarely waste food, even if it is spoiled. Consequently, they are considered as secondhand consumers because they consume what others have thrown or given away.

Immigrant consumers

Focusing on immigrants, Hill and Somin (1996) conduct long interviews with recently arrived immigrants and find that their informants, when confronted by reality, have "lowered their expectations" substantially regarding material fantasies. The few items brought from their home countries, "as well as customs such as food preparation, play an important role in the maintenance of the pre-immigration self". As one of the "atypical" possessions is mentioned the acquisition of English language skills seen as indispensable for a successful integration into the foreign society.

In an overview regarding the acculturation of immigrants, migrants and expatriates, Mary C. Gilly (1995) cites two aspects of the cross-cultural living experience: on the one hand, the ways in which consumers adapt to and adopt their new culture's products and behaviors and, on the other hand, the meaning of possessions. She describes emigration as a special challenge since it implies "daily cross-cultural consumer experiences" due to the differences in consumption concerning the "products available and the way of conducting transactions."

Immigrant consumers face difficulties in the evaluation of goods due to little knowledge of the country as well as language barriers (see Penalzoza 1989). McCracken (1986) demonstrates in his work the particularities of a "consumer society" and the cultural meaning of consumer goods drawn from a "culturally constituted world and transferred to an individual consumer".

The ethnographic investigation of the consumer acculturation of Mexican immigrants by Penalzoza (1994) describes their consumption experiences in the U.S. Her study leads to outcomes of assimilation, maintenance, resistance, and segregation.

Sacred possessions

When one decides to go and live abroad, this is always linked with the leaving behind of possessions as well as familiar products. Thus these may gain in importance "for the emigrant" (Belk, 1992). Certain possessions have a "deep meaning" for the lives of the informants because they are considered beyond the status of "merely utilitarian things" (Wallendorf, Belk, Heisley, 1988). They further note that some of these possessions even gain a sacred status as they are treated like sacred religious icons, and are therefore considered as priceless things and not as mere consumer products (see also Hill 1991).

Hill investigates in this context the meaning of possession and finds consistent with former studies that possessions representing a better life in the past or future hold symbolic value for the individuals (Wallendorf and Arnould 1988; Hill 1992). One respondent, for example, considers those items most valueable which reminds her of better times such as a small gift from her father and photographs of her family (Hill 2001, p.53). But also objects which symbolize ethnic or religious identities are meaningful (Mehta and Belk 1991; see also Belk 1988).

As a result of the actual political and social situation of refugees, it has to be emphasized that the investigation of this subgroup is important as they are part of our consumer society. This

work thus should contribute to a better understanding of these individuals and enhance the peaceful living together based on mutual respect and tolerance.

METHODS

The present study is based on ethnographic fieldwork, projective data involving collage techniques and long interviews with the informants. The fieldwork was performed in an Austrian shelter for adolescent refugees where one author acted as a volunteer for two months for data collection.

By choosing the various methods, the prudent attitude of the informants waiting for the official permission to remain here had been taken into consideration. Thus, the ethnographic method should help to gain a deep insight into the informants' lives, citing Hammersley and Atkinson (2002): "The ethnographer participates, overtly or covertly, in people's daily lives for an extended period of time, watching what happens, listening to what is said, asking questions; in fact collecting whatever data are available to throw light on the issues with which he or she is concerned." In this context, it was important to establish a trustworthy relationship with the informants. In order to fulfil these conditions, one author volunteered at the shelter between twice and three times a week for three to five hours and performed some work in the kitchen where the author got easily in touch with a group of individuals at the same time. The author usually arrived in the morning and remained until noon as this period of time was the most active part in the shelter (see also Hill 1992, p. 276). Sometimes, the author took lunch together with the people there and participated also at various events organized by the shelter such as a Samba workshop or a so-called "literature café" where several refugees recited their own-written poems. Such occasions provided an excellent opportunity for observation as well as talks.

In order to elicit detailed information and to learn more about the informants' psycho-social characteristics (Levy 1985, p. 69) and thus, about their thoughts and feelings often unconscious or difficult to express for them, the refugees were invited to construct a collage, (also others used this method as for example Belk et al. (2003)).

This technique had been chosen in view of the specific living conditions of the informants, following Levy (1985, p. 80) who states that projective techniques often enable people to overcome constraints and express themselves in a more fully and subtly manner. In this case, such techniques achieve greater validity than traditional research because qualitative as well as quantitative methods may be limited (Belk et al., 1997, p. 24).

Therefore, the author met the informants twice for a couple of hours in the shelter. The first time, the informants were given various magazines and asked to choose pictures which would best express their perception of a material world as well as their consumption desires and to stick them on a big piece of paper. The next day, when they had finished their collages, they were invited to interpret them by means of short interviews.

As far as this technique is concerned, it has to be pointed out that the informants had been beforehand prepared for the issue of consumption, for during their German lessons they had been dealing with the various expressions regarding this subject. As they had never lived in a consumer society before, they had little or no knowledge about the meaning of the relevant terms.

Finally, to complete the study, long interviews were conducted according to the interviewer's guide (see Table) with four voluntary male refugees at the shelter. The females, who constitute only a marginal percentage of the refugees, were not disposed to provide any information about themselves apart from the collage

technique where they participated assiduously. The informants were between 17 and 18 years old and came from different cultures and social backgrounds.

Further, one interview was conducted with an African university teacher who came to this country about 20 years ago on a scholarship. Despite the different circumstances, he had made similar experiences and developed coping strategies similar to those of the refugees. Moreover, he was the director of a shelter for refugees for some years. Therefore, the information obtained from him represents an important part of this study.

The interviews were conducted in English or German depending on the informants' language skills.

All the data gathered by the different methods was analyzed and the findings presented by means of four short stories including the collages to provide a "vivid portrait of the lived experience" of each informant (Hill 2001, p. 3). In this regard, the author used "thick description" as suggested by Geertz (1973).

According to former studies with an interpretative approach, subcategories of this research direction were identified on an "iterative basis" as discovered by the data during fieldwork (Fetterman 1989; Ozanne and Hudson 1989). The various points were discussed in the Findings of this work and emergent themes were identified to clarify the meanings inherent in these experiences for the refugees (Denzin and Lincoln 1994).

Consistent with Belk, Sherry, and Wallendorf (1988), Sherry (1990) and Hill (2001), real names were changed and their countries of origin not mentioned in order to avoid any identification of the informants.

Recapitulating, it can be stated that the decision for the variety of methods employed in this study was crucial for data collection. First, the ethnographic fieldwork established the necessary trustworthy relationship between the author and the informants. But only the collage technique enabled the authors to obtain relevant data because this method facilitated their access to the informants' thoughts and feelings. Finally, both methods served for conducting successfully the final interviews which took place only at the end of the fieldwork.

FINDINGS

The findings are divided into the following parts: 1) insights into the refugees' former lives and the reasons for their flight, 2) their experiences in an industrialized country with reference to the completely different way of living, focusing on the role of consumption, 3) their coping strategies in consumer behavior taking into consideration the significance of "sacred" possessions, and finally, 4) their future dreams and desires as presented in their own collages (see Fig. 1 and 2).

Having the results, it is important to point out that the informants are unaccompanied adolescent refugees and that most of them have been living here for less than a year.

Insights into the refugees' former lives and the reasons for their flight

In order to provide an understanding of the refugees' coping strategies in consumer behavior and with regard to their appropriate interpretation, it is important to portray their former living conditions. Starting with the question about the informants' former lives two aspects become apparent: firstly, the reasons for their flight such as violence, oppression, persecution were still occupying their minds. An Asian stated: "People fear to express themselves in public. I didn't even have the right to learn my mother tongue at school." An African explained: "I did not run away in order to have enjoyment but to save my life. I fled the war!" This condition was

TABLE
Interviewer's Guide-Refugees

1. Tell me a bit about yourself. (Probe for age, [note sex and race], education, country of origin, mother tongue). Does anyone from your family or former friends live abroad?
2. How long have you been staying here? Did you live elsewhere in this country before coming to the shelter?
3. What was your image of this country before your arrival? (Probe for the political and economic system—same or similar products as in industrialized countries). How did you come to adopt this image? (Media, school, specific individuals).
4. What is your impression now? How do you experience the affluent society? (positive and negative sides—probe for material things like shopping-centres, clothes, food, etc.; opportunities; restrictions, racism, etc.).
5. Tell me a bit about your day? (Probe for living in a shelter, structure of a normal day). How do you pass your spare time? (Hobbies, friends).
6. What did you bring from your home country that is especially important for you or what would you have brought with you if you had had the opportunity? (Probe for special possessions, especially “sacred” ones like photographs, gift, etc.). What do you miss from your home country and how do you compensate for it? Are there certain traditions or rituals of your home country which you still practise here? (Probe for cultural meaning in relation to the self).
7. How much money do you have at your disposal and how do you spend it? (Probe for coping strategy in consumer behavior). What did you buy first after your arrival and why? Do you buy some products of your home country here and why?
8. What are your expectations of this country? (Probe for future desires, plan for living).

perhaps best depicted in an African's collage (Fig. 1) that highlighted a skeleton reminding him of violence and death caused by a civil war. Also the following poem written by one of the refugees deals with violent death since it is about the loss of some family members in his homeland:

<p>Sag mir, wo steht ihr auf dem Himmel? Wie eine Wolke so schön. Sind in Frieden gegangen. Nehmen Lieben mit. Nehmen Lieben mit. (Asian refugee, 18 years old)</p>	<p>Tell me, where are you in the sky? Beautiful like a cloud. Gone in piece. Take the loved with</p>
---	--

The second aspect concerned the material situation in their home countries. The informants did not live in a consumer society and had therefore no access to the material world a middle-class family in an industrialized country takes for granted. One group of informants did not know anything about the country they fled to; the others only knew that it was a democratic nation and that people there had a good life. Thus, they had to face a completely new situation, learning to deal with the material world.

Experiences in an industrialized country

One of the first challenges confronting the refugees was the climate since most of them were used to considerably warmer temperatures; in addition, the refugees had to come to terms with the food and the German language. Only later did they have to face up to the issue of consumption and making consumer choices.

When asked about their perception of the consumer society, the refugees' answers depended on the length of their stay here to date. Those informants who had only recently come to this country

were overwhelmed by feelings of being lost, disorientation, homesickness and nostalgia for their families whereas those already living longer here were well accustomed to consumer society, appreciating especially the cleanliness, high technical standard, functionality and the high quality of life. One African stated: “Walking around is still like cinema to me! I can't believe my eyes seeing all these beautiful things” (referring to the houses, cars, shopping-centres, goods, etc.). Another informant was particularly impressed by the shopping centres: “If you enter (the shopping centre), there is all in one. There is a big door, then lifts, light everywhere. You can either take the steps or the elevator. Ah, it's beautiful! They are selling a lot of things there. It's expensive, I know. But the beauty in the hall and the shops there, they are super, they are cool!” One Asian noted that he liked going into town and admiring the nice products shown in the numerous shops although he knew very well that he could not afford them and was thus restricted to window shopping. However, just the fact that he has the opportunity to enter a shop where so many of the goods promoted by the media can even be tried out for free, fascinates and provides a certain satisfaction to him. Most of the informants know the shopping centres of the city very well and are able to distinguish precisely the various kinds of supermarkets. Consequently, they know where to buy nice items cheap.

Nonetheless, the authors noticed that some of the refugees had serious problems dealing with the way of consumption here as well as the vast choice of products most of which they were not at all acquainted with as they have never been members of an affluent society before in their lives. They seemed being lost in a material world in which they were dropped inexperienced like babies without a real sense of how things were going on. As a result, they measured the goods solely by the different price levels. Only expensive items seemed desirable to them as a high price was

Meanwhile, they found some parallels between certain well-known products from home and those offered here, as explained by one informant.

By the time, they agree to a compromise in consumption patterns (Mehta and Belk 1991), as for example to food, they appreciate the meals offered at the shelter but when they have the possibility to cook for themselves, most of them often prepare some traditional dishes of their home countries.

Unlike immigrants, refugees usually arrive in the country they flee to with nothing else than the clothes on their back. Consequently, they do not dispose of any item of their home countries that might serve as transitional object providing to some extent security (Halpern 1968; Kahne 1967; Nemy 1986; Mehta and Belk 1991) and comfort like the so-called "security blankets" for children separated from their mothers (see Hong 1978; Passman and Halonen 1979). As compensation for the missing items, the informants focus on a few products they had acquired in the host country and that gained "deep meaning" in their lives (Wallendorf et al. 1988), amongst others also cuddly toys. The authors noted that surprisingly almost every refugee in the shelter owned one, even the male. This was also depicted in the various collages (see also in Fig. 1 and 2) of the informants. By means of observation and further discussions, it turned out that they had one in order to deal with the difficulties they encountered by living abroad, alone from their families, facing racism. Thus they clung to something providing a bit of personal security, in this case even to a consumer good.

Also mobile phones played an important role for the informants. Apart from the fact that everybody possesses one, they are also well informed about the latest models. In order to be able to purchase at least one phone offering more than the standard functionality, they accept the need to renounce many other items so as to keep up with the youths of industrialized countries, as noted by the remarks of the informants. Besides, it serves as an important means of communication as expressed by the informants saying that they would need it to arrange appointments with their friends, but mainly to be reachable for their families.

It was also striking that all informants wear an earring. When asked about the motivation for it, one informant answered, "because all of my friends wear one" and he wanted to be part of them.

Further, all informants mentioned clothing. Despite the financial restrictions, they, like the youths of industrialized countries, set high value on wearing smart, fashionable clothes preferable of a certain brand to impress people as one informant remarked: "People would say—oh, sexy, cool!" It procures him a sense of social affiliation to a group of people who define themselves by consumer goods. One of the refugees used to wear a red cap of a certain brand when he left the house, similar to this one in the collage (see Fig. 1). For him, this special garment had the same significance as to put on shoes, namely to complete his outfit and to look smart. As to shoes, he started to wear them only after he had been living here already for a certain period of time. Like most of the young people at the shelter, in the beginning, he generally wore slippers the whole day, even when he went out.

Apart from certain products, there are also some activities that have a very special, almost "sacred" meaning for them, namely sports, like football, and music. Since playing football was an important part of their former lives, practising it here reminds them of home and help them to accommodate to their new environment. On the other hand, practising a kind of sport or playing an instrument like drums (as offered by the shelter) are some of the few possibilities to pass their time, since they do not have the right to work. These activities provide some stability in their lives as refugees. Some of the informants even dream of a football-career, however, being aware that it would be very hard to succeed. But

they make efforts in their daily training in order to be accepted by a club.

As to music, the informants are used to listening to English or American Pop music as well as to interpreters of their home countries, but their favourites are Rap music or HipHop. An African explained: "When I listen to HipHop, I forget my family. I miss them so much! (...) HipHop gives me a sense of delight." Besides, he believes that the texts of those songs correspond to the reality like those of Bob Marley, "no matter you come from, no matter who you are, if you are white, if you are black, we are all one." It helps him to cope with the problems he has to face as a black in a western country.

Moreover, according to the study of Mehta and Belk (1991), it could be observed that the informants treasure photographs of their families (are part of these items the informants miss most), food and music of their home countries as well as certain activities like sports or rituals like praying they used to do at home because they offer a "symbolic source of security and cultural identity" as well as a connection to their former lives and "some familiar continuity in behavior" (Mehta and Belk 1991).

Finally, the German language as an "atypical possession" is considered as a condition precedent to a successful acculturation and to economic success by the informants (Hill, Somin 1996, p. 207).

Besides all these issues, the most important "possession", however, is the positive official notification giving them the right to remain in a democratic and industrialized country which is crucial for their further lives.

Dreams and desires

Future dreams and desires are best expressed in the collages (see Fig. 1 and 2) being similar to those of a typical middle-class family as they wished to own a house and a car. But they differ with regard to their significance for the refugees because possessing such objects would go beyond the meaning of merely status symbols but imply a considerable turn towards quality and stability and thus towards a "better life" for the informants.

An African explained that his favourite house would dispose of many windows and glass-doors giving a bright, modern impression not comparable to the mud cottages in his country. Another informant said he would like to have a bright, modern apartment equipped with a stylish furniture, including a big refrigerator which provides enough space for a lot of food. Disposing of enough food has an essential meaning for all refugees, especially for those who suffered from starvation. In the shelter, it could be observed that these individuals took their plates full to the brim and gorged their meal as if they would not get anything to eat for the next week. One informant explained: "At home, I often ate some rotten bananas for dinner." As to cars, all informants would like to have one as they consider them as prestige objects and they have a weakness for certain brands like also the youths here. At present, however, they do not aspire for one of a certain brand because just the fact that one possesses a car at all means something special to them, as they could not have afforded one in their home countries.

Also electric and electronic facilities are desired as they serve to make life more comfortable such as a washing machine, a television set or a stereo set. For some of them, a computer constitutes one of the most important items stating: "It seems that everywhere you go, people talk about computers!" Some of them aspire to a job in this field and would like to acquire the necessary skills for it.

In general, the collages are dominated by various prototypical consumer goods (see also Fig. 1 and 2), the informants daily encounter and it is noticeable that they are highly familiar with

FIGURE 2
Collage of African refugee

brands, in spite of the fact that only a few number of items are available for them. Most of them declare that if they had the choice, they would prefer products of a certain brand rather than no names, especially with respect to clothing or electronic items as brands stand for high quality in their eyes.

Apart from these material wants, the informants wished to have a family of their own, one day. They prefer attractive, erotic and feminine-looking women wearing elegant or fashionable clothes with adequate accessories and jewellery as expressed in some of the collages (see Fig. 2). An African found that in his country, there were very beautiful women dressed worse than the Europeans but in his opinion the latter were very pale. One informant desired to be accepted inspite of being black, stating "Liebe kennt keine Farbe." (Love does not look at the color.)

Further, it could be observed that due to the difficulties the refugees have to face abroad including the hardships they experienced at home, they became more sensible for values and attitudes and are concerned with issues rather unusual for people at their age. This may also explain the following statement of one informant: "Children are like angels! They cannot do any harm", or the opinion of another: "The main task of a mother is to protect her child", expressing his fear of violence and his longing for protection. Being

alive and being healthy plays thus an important role for them since the respect of their lives and appropriate health care was not provided in their home countries. As a result, the informants put much value on cleanliness and a cosy atmosphere that should contribute to their health and pleasure. In one of the collages (see Fig. 1), there is the picture of an ice-bear having a "soft silky fur" representing strength and health. Also the perfumes refer to this tendency citing one of the informants: "If you put perfume on your skin, you make it smell nice. Having a pleasant smell means you are healthy."

But the majority of the informants showed serious concern about their future situation: they neither know whether they will obtain the permission to stay in this country nor how they were to improve their financial situation from the day they had to leave the shelter. As a result, it could be observed that all of the young people were torn between feelings of hope and fear.

In a consumer society desiring is life-affirming. Since the poor members of the population cannot hope to fulfil their desires, they have to find other means such as avoiding to desire or imagine the consumption in their fantasies (Belk et al., 2003, p. 347; see also Hill 1991). However, not everybody succeeds in doing so. Some of the adolescents found that the best way to take their minds off their

difficult situation was to sleep long hours. Others smoked a lot of cigarettes to get some relaxation. Depending on their religious identity, they hope to find confidence and sustain in the continuity of their religious practises. It was striking that some informants often mentioned "God" in conjunction with their future desires: "God helps me, maybe, to stay on my own," or "Let's pray that I'll make it." Others put their confidence in the help of the angels and some young men determine their lives by the rules of the Koran.

DISCUSSIONS AND CONCLUSION

The experiences the informants had made here can be summarized by the following aspects: on the one hand, they consider the industrialized countries as a consumer paradise for those who fulfil the premises to take part in it. On the other hand, they often feel discriminated by certain rules established by a part of the society, excluding special individuals from the consumer world even having enough money. The African informants for example said: "We mustn't enter the disco because the door steward said 'No Blacks admitted!'" Other refugees remarked that they did not feel treated as individuals but stereotyped as asylum-seekers or criminals.

Besides, they believe that a high developed infrastructure including numerous shops full of goods attest to a well-functioning business system where new jobs are created and thereby a high living-standard is provided. They think that the citizens of the western world in general dispose of enough money to acquire the desired goods and services.

It was striking that although most of the informants have not lived in a consumer society before, they were well acquainted with a high number of brands which they considered as symbols of a modern way of life. Thus, they were longing for brands which seemed desirable to them expressing the lifestyle of the affluent members of western societies. This fact shows also their wish to be part of those individuals who define themselves by consumption.

The informants unlike the typical middle-class youth of western countries suffer from restrictions and must renounce a lot of things. They often feel like unwelcome guests waiting in front of the door for the permission to enter and to participate, instead they only can have a glance on a world in affluence and their wish to fit in seems unrealizable.

One substantial difference between members of affluent societies and those who are not part of them is that the latter have limited access to the numerous goods and services on offer. Thus, their consumer behavior is markedly different from the average consumer of western countries since their primary goal is to come along with their financial means in order to satisfy their basic needs.

Furthermore, due to their status as refugees in the host country and accordingly the feelings, experiences, and difficulties involved, consumption can take on a very special meaning for them as it may serve as coping strategy helping them to come to terms with the problems they encounter abroad.

The authors found that there are certain possessions getting a special meaning for the informants such as cuddly toys helping them to cope with loneliness or homesickness on the one hand and special pieces of clothing of a certain brand or even mobile phones giving them the feeling of being similar to the youths of the western countries on the other hand.

As the informants do not have the same security as the members of affluent societies that their basic commodities are met, they often imagine their future in fantasy how life should be like, serving as coping method.

Despite all the difficulties the informants have to face, they wish nothing more than to obtain the permission for staying in a democratic country where they are in safety and where their basic

needs are satisfied. They cannot imagine to go back to their home countries citing one informant: "I only want to have security and the permission to live here because I am accustomed to so many things (referring to all the facilities and commodities) here." Although the adolescents enjoy living in an affluent society and therefore aspire to become a member of it, they are highly aware that the respect of their life is more important than consumption.

In their desperate strive for remaining here, they would be disposed to accept also such opportunities which might seem strange to members of the affluent societies and not find their moral approval.

Hill (2001, p. 167) stated in his work about the poor, "when we remove our middle class lenses of affluence and opportunity and replace them with lenses of poverty and restriction, our understanding of how and why people become or remain impoverished is forever changed." In the case of the refugees, it would also mean to take into consideration the reasons for their flight and the problems they have to deal with in the host countries.

Since there exist conditions in countries which will threaten people's life, there will be always refugees fleeing to get in safety. In order to provide a climate facilitating the untroubled living together of different races among a society, the politics as well as the media are claimed to get over stereotypes and prejudices, so that a revise of people's opinion can take place. For a successful integration of refugees who are a significant group in western countries, it is therefore important to develop strategies which take into consideration their particular consumption habits and avoid that they remain a disadvantaged group in a consumer society.

LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

The first limitation of this research is that the author cannot be absolutely sure that the informants are political refugees rather than economic ones. But the various methods employed such as shelter fieldwork and collage technique depicting torture scenes or other signs of violence provided a deep insight into the informants' lives. Having observed how they behaved and what they said, it can be supposed that the refugees' flight was politically rather than economically motivated.

Other limitations of this study stem from the particularities of informants and of the field sites examined. As a result, it was very difficult to get access to potential informants. Due to the psychological and emotional state of some refugees as well as the fact that the procedure for granting asylum to the informants was pending, only four persons were willing to give an interview. In this context, it has to be pointed out that their approval to an interview depended on the trustworthy relationship established during the previous two months of fieldwork and that the interviews were conducted only in the end of this period and after having employed the collage technique. Only by means of this projective method, the authors obtained relevant data. Moreover, it facilitated a lot the interview situation as the informants already concentrated on this very subject.

As stated already in the beginning, the investigation of young refugees is interesting because they are in the rite of passage from adolescents to adults involving the process of forming their own identity. Although they are already shaped by the culture of their homelands and the experiences they made there, they, unlike adults, are more flexible concerning the adaptation and integration process in the foreign country as well as the development of useful coping strategies. The situation of adolescent refugees living in a shelter is a very specific one and as typical to the interpretation of consumer research not generalizable. A comparison between adolescents and

adults would have been interesting but it was not possible to obtain access to adult refugees in time as in general, it is very difficult to gain informants for such delicate issues as this of refugees.

While this work has provided an insight into the consumer behavior of adolescent refugees in industrialized countries, it remains a tentative glimpse into its subject matter. Many questions remain. Thus it is necessary that further research follows informants over time.

In order to obtain a more complex idea of the situation of refugees, there are a number of promising research directions such as the study of other refugee groups in other nations. One question worth investigating is the gender aspect, for it would be interesting to see to what extent the experiences of male and female refugees in a consumer society as well as their behavioral and emotional coping strategies differ from one another.

It would also be interesting to focus more closely on the cultural, social and educational background of the refugees and to examine whether or not these aspects play a significant role in their acculturation process.

Moreover, all informants who were interviewed in this study come from very poor countries. Further research is, therefore, called for that investigates refugees being from highly industrialized cities of threshold countries. This would be particularly interesting with regard to the fact that these individuals have already lived in a consumer society before.

Another question that could be addressed is the situation of children compared to that of adults. Do there exist some parallels as far as the challenges both groups have to face are concerned and to what extent do they develop similar coping strategies?

As to families, it would be interesting to examine whether they, as a closely-knit group, find it less hard to deal with the new situation than refugees who arrive on their own in the foreign country. Is it easier for families to cope with the difficulties arising from their legal and financial situation in the western world?

In this context, the meaning of sacred possessions in the phase of acculturation could be investigated and compared to the present findings.

The present study focused on refugees living in a shelter. It would be interesting to know how refugees who are accommodated in other forms of housing perceive their present situation of living in a material world and whether this has an impact on their consumer behavior.

Further, also the question about the future prospects of refugees could be examined to see whether they have a real chance of becoming a member of the affluent society or instead will remain poor and, as a result, at the low end of consumption. Therefore, it would be necessary to interview those to whom asylum was granted some time ago.

Consumer Market Orientation: Measurement and Prediction in a Developed and a Transitioning Economy

Simona Stan, University of Oregon
David Boush, University of Oregon
Carmen Barb, Sibiu University
Helder Sebastiao, University of Oregon

EXTENDED ABSTRACT

Problem

The marketplace in countries transitioning from former socialist regimes to free market economies is characterized by continuous change, uncertainty, and much consumer and seller frustration (Lasclu et al. 1993). Consumers need to find ways to cope with increasing complexities and inconsistencies in the market. Despite these difficulties, a market economy has the potential to improve consumer welfare in a variety of ways. As an economy becomes more market oriented, we would expect consumers to see greater product assortment, more price competition, greater use of mass media advertising, and more competitive service.

However, a key assumption for an economy to move toward a market orientation is that consumers can identify and will reward such an orientation. This may be difficult in transitioning economies either because consumers lack the necessary attitudes and skills, or because the institutional framework does not support such actions. Consumers need to be able to recognize and buy products of higher quality or with better value propositions. They need to be able to evaluate the credibility of advertising claims and to patronize retailers offering better service. Therefore, we introduce and investigate a new concept: "consumer market orientation" i.e., behavior oriented toward improving and rewarding marketers' market orientation. We believe that both consumers and firms must possess market orientations to achieve a successful, sustainable transition to a market economy.

Romania is a good example of an economy still in transition. Romania's restructuring lagged the rest of Eastern Europe and it remains one of the poorest countries in the region. To better understand consumer responses to the marketplace in Romania seven in-depth interviews were conducted with ten Romanians. Generally the interviews suggested that consumers in transition economies face resource constraints and lack certain consumer skills, such as the ability to accurately evaluate price/quality relationships. These erode the ability to reward marketers for communicating and providing superior value.

Conceptualization

Based on the interviews and an examination of the literature we propose a model using consumer values, resources, and expectancies to predict market-oriented consumer behaviors. The consumer values included in the model are social interdependence (Triandis, McCusker and Hui 1990) and materialism (Moschis 1981). Social interdependence refers to the presence and importance of close personal relationships. Materialism is the extent to which a person values physical possessions. Resources are time and money, while expectancies relate to marketplace risk, action-outcome expectancies, and perceived marketplace self-efficacy (Bandura 1997) and are described below.

Marketplace Risk. Consumer actions in the marketplace only matter if different outcomes are possible: getting a better product, getting a better deal, avoiding a scam. The range of possible outcomes represents marketplace risk.

Action-Outcome Expectancies. Consistent expectations about what happens when you act a certain way are at the heart of making sense of the world. Action-outcome expectancies involve results that flow from personal action and are sometimes called "response efficacy" (Block and Keller 1997). These expectancies involve beliefs about the relationship between customer actions and marketplace rewards. They are categorized in our model as collective expectancies (e.g., if people complained more, then service would improve) and individual expectancies for themselves (e.g., if I complain I might get my money back).

Perceived Marketplace Self-Efficacy. Even if you believe that a particular action leads to a particular outcome, you may not believe you can execute the action yourself. Self efficacy refers to people's beliefs in their own capabilities to perform actions that affect desired outcomes. In the marketplace this might involve skills in evaluating information, such as advertising, comparing alternatives, or accurately judging the relationship between price and quality.

Market-oriented behaviors such as demonstrating good customer service or high product quality can be rewarded by loyalty to the firm and generating positive word of mouth. Conversely, consumers can punish a firm for behavior such as deceptive advertising, price-gouging, or shoddy products. Switching and complaining are the main punishments. In addition to behavior that rewards or punishes specific firm behavior, consumers can engage in behavior that is either helpful or harmful to the market (i.e., that either aids or hinders the ability of marketers to offer better customer value). Helpful behaviors include things like offering ideas for new products or taking the time to participate in market research. Harmful behaviors include things like switching price tags or returning damaged merchandise when the consumer caused the damage.

Method

Scale items measuring the constructs described above were both adapted from previous and or created specifically for this study. A survey containing these measures was administered to participants in the US and Romania. US participants were 209 students enrolled in business classes at the University of Oregon. Romanian participants were 232 students enrolled in business classes at Sibiu University. Principal components and reliability analyses were used to assess dimensionality and reduce the number of items in each scale. Coefficient alphas across both samples indicated acceptable scale reliability.

Results

The most important factor for Romanian consumers is perceived self-efficacy in the marketplace. Overall, Romanians are more likely to engage in reward (positive WOM and loyalty) and punishment behaviors (switching and complaining) versus specific marketers if they have higher levels of self-efficacy. In addition, self-efficacy has three moderating effects which suggest that Romanians who have low levels of self-efficacy and perceive high levels of marketplace risk are more likely to reward good marketing

and behaviors and punish bad ones. For US consumers, self-efficacy is a less important factor in exhibiting a consumer market orientation. Both Romanian and US respondents are most likely to engage in helpful behaviors (e.g., participating in marketing research) if they believe that consumers collectively have the power to improve the marketplace. Finally, a consumer's sense of social interdependence has a pervasive positive effect on all types of market-oriented behaviors. Both Romanian and US consumers expressing high levels of social interdependence are more likely to engage in market-helpful behaviors and are less likely to engage in market-harmful behaviors.

SPECIAL SESSION SUMMARY

It Matters Who You Are: New Perspectives on the Role of the Individual Differences in Brand Evaluations

Rohini Ahluwalia, University of Minnesota

INTRODUCTION AND OBJECTIVES:

Past research in the area of branding has uncovered several important findings relating to how information about brands is perceived (Aaker 1997), how it may be updated (Ahluwalia and Gurhan-Canli 2000; Loken and John 1993) and the extent to which consumers form relationships with brands (Aaker, Fournier and Brasel 2004; Fournier 1998). This research, however, has typically overlooked the role of consumer individual differences in understanding branding-related phenomena.

The session attempts to bridge this gap. It included three papers, one from each of the major areas of branding research (brand personality, brand extensions, consumer-brand relationships), which examine this issue. Taken together, these papers provide a (a) deeper understanding of the role of consumer characteristics/individual differences in understanding branding phenomenon, (b) the opportunity to generalize and generate higher level models to understand the role of individual difference variables in branding, (c) an array individual difference variables to examine in this regard, and (d) identify new and important boundary conditions for previously well-researched findings in the branding area.

OVERVIEW

Gita Johar presented her research, coauthored with Jaideep Sengupta and Jennifer Aaker which builds on past research in the area of brand personality (e.g., Aaker 1997). Their research focuses on the role of *consumer's personality* in influencing the mechanism adopted for updating brand personality inferences. It delineates two mechanisms that guide the updating of personality trait inferences about brands. The results of three experiments show that chronics (those for whom the trait is accessible) update their initial inferences based on the trait implications of new information. Interestingly, nonchronics (those for whom the trait is not accessible) also update their initial inferences, but do so based on the evaluative implications of new information. The framework adds to the inference making literature by uncovering two distinct paths of inference-updating and highlighting the moderating role of trait accessibility.

Rohini Ahluwalia presented her research in the area of brand extensions which examines the effect of culture (as operationalized by salient self-construal— independent versus interdependent) on consumer evaluation of brand extensions. Data collected from two countries (United States, and India), utilizing different assessments of interdependence (at the nation-level, as individual difference variable, as well as via priming), was used to test two alternative perspectives on this issue. The results reveal that interdependent and independent consumers differ in their evaluations of the moderate fit extensions, but not the close and far extensions. The findings obtained with consumers whose interdependent self was either chronically or temporally accessible, were remarkably different from those obtained in past research in this area, where the independent self was more accessible (e.g., Ahluwalia and Gurhan-Canli 2000; Loken and John 1993).

Susan Fournier presented her research co-authored with Marcel Paulssen which builds on past research in the area of consumer-brand relationships (e.g., Fournier 1998). Their research provides a new perspective, rooted in individual differences, for understand-

ing the strength of the consumer-brand relationship (e.g., brand loyalty, commitment). They argue that people have different attachment styles, and the likelihood that a company may be able to convert them into loyal consumers is to a great extent a factor of consumer attachment styles. As such, some individuals are more likely to become loyal consumers as compared to others. The research attempts to identify who such individuals might be.

LISREL results demonstrate that secure and anxious personal attachment styles predispose individuals toward different satisfaction, trust, and loyalty responses, revealing patterns parallel to those found for interpersonal relationships. Results reinforce the legitimacy of inquiries that extend relationship and personality theories in consumer research.

Individually, each paper offered an interesting viewpoint, based on an individual difference perspective, on a previously well researched branding phenomenon (e.g., brand personality, brand extensions or brand relationships) and thereby, outlines some new boundary conditions.

Deborah Roedder John (University of Minnesota) served as the discussion leader. She pointed out that the extant research in the area of branding has tended to focus heavily on identifying and understanding the role of features and characteristics of brand stimuli (e.g., fit, name, brand characteristics). However, the future research in the branding area would benefit from a better understanding of the role of individual moderators as well as examining the influence of situational factors. She provided a typology for categorizing the relevant individual-difference moderators for this area: (i) processing style variables (e.g., interdependence, self-referencing); (ii) interpersonal style variables (e.g., attachment style of consumers); (iii) processing states of consumers (e.g., trait accessibility).

Wanting a Bit(e) of Everything. The Role of Appetitive Desire in Variety Seeking

Caroline Goukens, K.U.Leuven
Siegfried Dewitte, K.U.Leuven
Mario Pandelaere, K.U.Leuven
Luk Warlop, K.U.Leuven

EXTENDED ABSTRACT

Conceptualization

Most people prefer some variety in their activities, snacks, music, clothes, restaurants... In this article, we examined the effect of appetitive desires like hunger, thirst, and the desire for holidays on the tendency of individuals to seek diversity in the desired product classes like food, drinks, or holidays. Drawing on cognitive emotion theory (Lerner and Keltner 2000), we expected appetitive desire to facilitate variety seeking. By the reasoning that desire is an affective state that triggers changes in the attractiveness of the object of desire, we expected that desire makes it easier to divert from one's favorites.

Experiments

In a first study, we examined how hunger influences variety seeking. We asked hungry versus satiated participants to choose five sandwiches from a set of eight for the coming week. Variety seeking was operationalized as the number of different sandwiches participants ordered. We found that hungry participants chose significantly more variety than satiated participants. Moreover, our results indicated that this effect was mediated by increased food attractiveness. In particular, consumers rated food items more positively when hungry, and, because more food items satisfied their needs, they opted for a more varied choice set. Further analyses revealed that in comparison with satiated participants, hungry participants chose more in proportion to their food ratings and less for their favorite.

A follow-up study confirmed the crucial role of food attractiveness. In the second study, we also manipulated sandwich attractiveness by placing a plate of sandwiches in the laboratory. Previous research has shown that seeing a food stimulus has a positive effect on consumers' food attractiveness (Lambert and Neal 1992). Here, however, instead of using fresh sandwiches, we displayed sandwiches that were about two days old. In a pilot study (n=63), we found that a plate of stale sandwiches as a food cue increased the sandwich attractiveness for low disgust sensitive people, and decreased it for high disgust sensitive people. The results corroborated the findings of study 1 regarding the facilitating effect of hunger on variety seeking. We also found that the presence of the stale sandwiches was able to block the hunger effect in high disgust sensitive people. So, hunger does not increase variety seeking when the presence of stale food blocks the increase in food attractiveness that typically follows a hunger state. We can conclude that an increase in food attractiveness is a necessary condition for hunger to influence variety seeking.

In a third study we tried to generalize the above-found effects to other types of "hunger", namely thirst and desire to go on holiday. We found that consumers who are thirsty (at the exit of a fitness centre) or desirous to go on holidays (at a travel agency) prefer more variety in their drinks, respectively in their holiday activities, compared to consumers who are not particularly thirsty (at a travel agency) or not particularly desirous to go on holidays (at a fitness

centre). Thus, desire appears to increase variety seeking, at least when the objects to choose from are relevant for the specific desire.

Major findings

In sum, the three studies reported in this article provide strong evidence that appetitive desire leads to more variety seeking in the desired object class, caused by an increase in the attractiveness of the object of desire. We propose that, because of this increase in the attractiveness, more items in the desired object class are considered as satisfying, which makes it less threatening to divert from the absolute favorites.

Our results strongly support the view that when consumers are in a non-neutral visceral state, in this case desirous, they fail to correctly predict their future tastes (Loewenstein 1996). Several articles report that the current hedonic response provides a powerful anchor in predicting future tastes in the relative short term (Kahneman and Snell 1992; Read and van Leeuwen 1998). So, in predicting, consumers do not take sufficiently into account how much their tastes change over time (Kahneman and Snell 1992). Instead, they persist in weighing their current tastes heavily when predicting what they will want, even though these are poor or useless guides to future tastes (Loewenstein 1996).

All in all, our findings point to the power of appetitive desires. Although our findings suggest that desire has an unmistakable role in consumption decision making, previous studies have devoted little attention to the role of desire (but see Belk et al. 2003). Our studies provide evidence that, when trying to increase the attractiveness of a product, marketers do not only have to focus on the product features. One should be aware that marketers can often increase a product's attractiveness via the desire of the consumer. Gibbs and Forehand (2003) recently found in their experiment that desire can be primed. Our results indicate that also 'natural desire' states, like hunger, thirst and desire to go on holiday, can offer a possible means to influence variety seeking tendencies.

The Unhealthy=Tasty Intuition and Its Effects on Taste Inferences, Enjoyment, and Choice of Food Products

Rajagopal Raghunathan, The University of Texas at Austin

Rebecca E. Walker, The University of Texas at Austin

Wayne D. Hoyer, The University of Texas at Austin

EXTENDED ABSTRACT

In December of 2001, the American Surgeon General announced that approximately 300,000 deaths were associated that year with a preventable health problem: obesity (Parloff 2003). The same year, the Center for Disease Control and Prevention (CDC) classified 39.2 million Americans (or roughly 30% of the population) as obese, a 74% jump from 1991 (Vence 2004). This trend is of grave concern not only because a variety of ailments including hypertension, heart problems, diabetes, liver malfunction, arthritis, and respiratory problems are directly linked to obesity (Allison et al. 1999; Parloff 2003; Spake 2004), but also because of the economic cost of treating ailments associated with obesity, which was estimated at \$117 billion in 2000 (American Obesity Association 2002).

To many consumers and consumer activists, fast food restaurants and organizations interested in promoting “unhealthy” eating habits (e.g., lobbyists for grocery manufacturers) are to blame for the obesity epidemic (e.g., Brownell and Horgen 2003). However, in this research, we examine whether a more subtle (and as yet unrecognized) factor may also contribute to the over consumption of food perceived as being unhealthy. What if people consume food that is considered unhealthy not despite of its perceived unhealthiness but *because* of it? That is, what if part of the attractiveness of food lay in its perceived unhealthiness? This can happen if consumers intuitively believe that unhealthy food is inherently tastier. The operation of such a belief would increase the chances that people will over consume food portrayed as less (vs. more) healthy since such food will be expected to taste better. Consistent with this idea, we propose that the perceived unhealthiness of food has the ironic effect of enhancing its attractiveness.

In this paper, we derive predictions of how the intuition affects three variables of theoretical and substantive interest: (1) taste inferences of food products when information pertaining to their healthiness is provided, (2) differences in enjoyment of the same food product when it is presented as being more versus less healthy, and (3) choice between a more versus less healthy entrée from a restaurant as a function of differences in the propensity to pursue a hedonic goal.

Based on the idea that people assume an inverse relationship between tastiness and healthiness—an assumption that we term the Unhealthy=Tasty intuition—we hypothesize that when information pertaining to assessing the healthiness of food items is provided, foods perceived to be less healthy will be: (1) inferred to taste better, (2) enjoyed more during actual consumption, and (3) preferred in a choice task when a hedonic goal is more (vs. less) salient. Results from three controlled experiments confirmed our expectations. Participants in Experiment 1 inferred that the less healthy an item, the better its taste. Participants in Experiment 2 derived greater actual enjoyment from consuming food that was portrayed as less healthy. Finally, participants in Experiment 3 chose an entrée portrayed as more unhealthy when they were prone to seeking hedonic (enjoyment) goals due to greater hunger. Interestingly, these results were obtained both among those who agreed and those who disagreed that healthiness is inversely related to tastiness.

Our research also speaks to the important issue of why consumers continue to believe in the Unhealthy=Tasty intuition despite

a lack of rigorous evidence for its validity (reflected in the general difficulty in determining if a specific ingredient is healthy or unhealthy). A conjunction of two mechanisms appears to underlie this phenomenon. The first is the generation of the hypothesis that unhealthy food is tastier. We posit both internal and external sources for the generation of the hypothesis. The fact that the Unhealthy=Tasty relationship is a specific manifestation of a more general principle—of an assumed inverse relationship between the wholesomeness and hedonic potential of stimuli—is a potential internal source for the hypothesis. Externally, an inverse relationship between healthiness and tastiness is at least implicitly, if not explicitly propagated across a variety of media sources. Once the hypothesis that healthy food is less tasty is generated, the second mechanism of the hypothesis confirmation bias (Hoch and Ha 1986) helps sustain belief in the intuition. Results from Experiment 2, in particular, demonstrate how, once the hypothesis that unhealthy food is tastier is generated, it tends to be confirmed—even when there is a lack of objective evidence for it.

This research makes two other significant theoretical contributions. First, it attests to the robustness and generality of the influence of the Unhealthy=Tasty intuition on judgments and decisions concerning food. It is well known that consumers’ decisions are influenced by their lay theories and intuitions (e.g., Mukhopadhyay and Johar 2005), even when the lay theories are invalid (e.g., Broniarczyk and Alba 1994). What is noteworthy in the present research is that our predictions were confirmed across three different types of food products, three types of judgment tasks, and two conceptually different types of unhealthiness manipulations. The generality of our findings across these experimental differences hints at the prevalence and strength with which people believe in the Unhealthy=Tasty intuition, suggesting that overcoming the influence of the intuition may be difficult.

The final theoretical contribution, which also points to the robustness of the influence of the Unhealthy=Tasty intuition, stems from our finding that the intuition can influence the judgments and decisions of even those who explicitly disagree with the idea that unhealthy food is tastier. This finding indicates that the influence of the intuition may lie outside of the awareness of consumers making judgments about what to consume. At a conceptual level, this finding shares similarities with the work on implicit learning by Lewicki and his colleagues (e.g., Lewicki, Hill, and Czyzewska 1997). At a more substantive level, this finding raises the disturbing possibility that consumers may be unaware of *why* they seek and over-consume food that is perceived or portrayed as unhealthy. Without such awareness, controlling one’s consumption patterns becomes much more difficult.

Taste Discrimination: The Influence of Visual and Verbal Cues

JoAndrea Hoegg, University of Florida
Joseph W. Alba, University of Florida

EXTENDED ABSTRACT

Perceptual discrimination is a precursor to choice in many categories, yet previous research has largely ignored consumers' discrimination skills. The present research focuses on the extent to which consumers accurately perceive the degree of difference between identical and nonidentical gustatory stimuli when presented in the context of visual and verbal marketing cues. The visual cue of interest is color. We consider the conflict between color and taste—an interaction that is not without precedent in marketing research but one that has been investigated primarily from the perspective of affective response rather than sensory discrimination (e.g., Garber, Hyatt, and Starr 2000). We test the effect of color by focusing on two measures: (a) the perceived difference between stimuli that are identical in taste but different in color and (b) the perceived difference between stimuli that differ in taste but not in color. Both discriminations are tested against a same-color control to determine whether color dominates taste such that there is greater perceived similarity between two stimuli that share the same color but differ in taste than between two stimuli that share the same taste but differ in color. The verbal cues consisted of well-established market-based cues that previously have been shown to alter consumer perceptions (e.g., Allison and Uhl 1964; Hoyer and Brown 1990).

Experiment 1. Experiment 1 involved an orange juice taste test that compared the influence of subtle color differences (i.e., similar hues of orange) against two benchmarks. The first was a same-color control condition. The second was a verbal-label condition that should prompt expectations of difference. Specifically, the labels referred to the juice samples as having been produced in California versus Florida. The orange juice was manipulated to create three levels of sweetness: low, medium and high. Participants were presented with four cups of juice: one low sweet, two medium sweet, and one high sweet. In the color condition, the low sweet and one of the medium sweet items were both a lighter color whereas the other medium sweet and the high sweet items were both a darker color (counterbalanced). In the Label condition, the low and one of the medium sweet items were labeled "Florida" whereas the other medium sweet and the high sweet items were labeled "California" (counterbalanced). In the Control condition, the samples were labeled 1, 2, 3, and 4. Participants tasted the juices in random order and then expressed their perceptions of taste difference between (1) the two identical (medium sweet) items with different colors or labels and (2) the distinct items (low-medium or medium-high) with the same color or label. Results indicated that, relative to the control, participants in the Color condition exaggerated the difference between identical tasting stimuli and minimized differences between distinct stimuli. In fact, participants in this condition perceived a greater difference between identical tasting stimuli that differed in color than between different tasting stimuli of the same color. Thus, color dominated taste. Participants in the Label condition exaggerated the difference between identical stimuli with different region labels but did not minimize differences between distinct stimuli with the same label. Thus, the region label influenced but did not dominate taste.

Experiment 2. Experiment 2 was conducted to (a) confirm the color dominance observed in Experiment 1, and (b) strengthen the label manipulation by replacing the region labels with cues that have previously been shown to influence preferences, namely,

brand and price labels. Participants in the Brands condition were told that the stimuli were either Tropicana Pure Premium Orange Juice (a premium brand) or Winn-Dixie Orange Juice from Concentrate (a generic EDLP brand). Participants in the Prices condition were told that the stimuli were either \$3.29 or \$1.89 for two liters. To maximize the believability of the labels, the sweetened juices used in experiment 1 were replaced with actual Winn-Dixie and Tropicana juices. In all other respects the procedure was identical to Experiment 1. The results of the Color and Control conditions replicated the findings from Experiment 1. Surprisingly, and in contrast to prior work on the influence of brands on taste perception and preference, the Brands condition mirrored the control. The Prices condition was statistically indistinguishable from the control group, showing no exaggeration of between-group differences. Thus, the visual cue again dominated taste, but the verbal cues did not overwhelm taste perception. One possible explanation for these results involves consumers' expectations of differences. Participants might have assumed two samples of different hue could not both be pure orange juice—which would lead to stronger expectations of taste variance relative to the verbal labels. However, a follow up study assessing expectations of difference across the three cues rendered such an explanation unlikely.

Experiment 3. Experiment 2 suggested that taste discrimination may operate differently from preference. Experiment 3 provided a more direct test of this possibility, comparing preference to discrimination for brand labels and color differences. Using identical-tasting stimuli only, participants either rated the perceived difference or rated the extent to which they preferred one over the other. Results showed that color creates greater perceived difference in taste than do brands, but, consistent with prior research on brand effects, brand labels result in stronger preferences.

Together the studies offer a starting point for much needed research on perceptual discrimination. The results suggest that discrimination does not map directly onto preference. Visual cues can dominate taste perception, whereas verbal cues, which are known to have dramatic effects on preference, exert less influence on discrimination ability.

Sensory Metaphor and Meanings: Development of a Cross-Sensory Heterogeneity Index

Robin A. Coulter, University of Connecticut
Tilottama G. Chowdhury, Quinnipiac University

EXTENDED ABSTRACT

“All human knowledge comes from the senses” (Marks, 1978, p. 2).

In the early 1980s, Holbrook and Hirschman (1982, p. 132) noted that little research had focused on the nonverbal multi-sensory properties of consumption situations, despite the fact that many products project important nonverbal cues that must be seen, heard, tasted, felt or smelled to be appreciated properly. During the past two decades, consumer researchers have considered the importance of our physical senses and sensory imaging, yielding important insights about effects of senses in memory, processing, attitudes, and purchase intentions. The vast majority of this research, however, has focused on an individual sense, that is, taste, touch, sound, smell, or sight; at most, studies have concurrently considered two of the five senses (see for example, Macklin 1994, Wirtz and Mattila 2001). Recently, Joy and Sherry (2003) have argued that it is important to sell an experience, not a product, and that the experience should be a combination of all senses; marketing practitioners concur (Gobé 2001, Lindstrom 2005; Schmidt 1999).

A number of observations are critical to our research. First, we assume that different senses can provide information on an object of interest—the rough texture of sand paper is evident via sight and touch; we can smell and taste a homemade apple pie. Second, each sensory modality provides information, and in some instances, the information is identical across two or more senses; for example, the peacefulness associated with financial security can be articulated in terms of sound of the ocean and the blue sky; this cross-modal correspondence is referred to as auditory-sight synesthesia. Third, individuals convey their sensory experiences with words that reflect intersensory analogies or cross-modality matching in terms of sensory metaphors—smooth (touch) music or bright (visual) sneeze. Thus, “language acts as an internal medium of communication among different [sensory] modalities” (Marks 1978, p. 24).

An important component of language, generally and with regard to the senses, is the metaphor, the representation of one thing in terms of another (Lakoff and Johnson 1980). Literatures as diverse as cognitive psychology, cognitive neuroscience, linguistics, and anthropology indicate that metaphors are central to thought, and are important means of expression (Lakoff and Johnson 1999; Ortony 1993). Recently, metaphor has received considerable attention in the consumer and marketing research (Burroughs and Mick 2004; Coulter, Zaltman, Coulter 2001; Joy and Sherry 2003; Zaltman and Coulter 1995; Zaltman 2003). Zaltman (2003, p. 38) observed that metaphors reveal “‘embodied cognition’—the referencing of our sensory and motor systems to express our thinking” (see also Danesi 1990; Lakoff and Johnson 1999). Sensory metaphors are articulated in our everyday conversations through metaphorical expressions—the words, phrases, or sentences that are the surface realization of the cross-domain mappings (Baron-Cohen and Harrison 1997; Cytowic 2002; Howes 1991; Marks 1978). Sensory metaphors provide a window into deeper meanings consumers associate with products and experiences; “metaphor is a means to disclose new analogies and equivalences” (Marks 1978, p. 252).

The objective of our research was to bring attention to sensory imaging and metaphor in consumer research and to develop a

measurement tool to assess consumers’ multi-sensory imaging; that is, the extent to which consumers report thematic meanings consistently across senses. We employed the sensory imaging step from the Zaltman Metaphor Elicitation Technique (ZMET) (Zaltman 2003; Zaltman and Coulter 1995) to examine sensory metaphors as a means for eliciting thematic meanings that consumers associate with a given topic across the senses. Specifically, in two different data collections, we asked participants to “imagine that you are explaining the meaning of financial security to some friends using sensory images.” For each sense, participants were asked to identify one sensory metaphor, and provide the meaning(s) that they associated with the sensory metaphor.

The first data collection (72 undergraduate students) served as a basis for identifying sensory metaphors (e.g., touch of velvet; sound of classical music) and developing of a coding scheme for the thematic meanings (e.g., freedom; no worries) associated with financial security. The procedure for the analysis was systematic and grounded in qualitative data analytic procedures (Spiggle 1994).

Based on the coding scheme developed, the second data set (139 undergraduate students) was analyzed. Perhaps not surprisingly, we found money (including cash/money, money to buy expensive items, and simply money to buy things) as relatively consistent themes across these senses. The frequency with which other meanings were articulated varied across the senses and we identified uniquely important meanings for each sense: touch—strong and comfort; taste—rich/elegant/sophistication; smell—fresh/refreshing; and sound—money to buy things.

Finally, we developed the *Cross-Sensory Heterogeneity Index* to calibrate the diversity present in the set of thematic meanings reflected across senses by each individual. *CSHI* involves three measures, N , U , and H , where N is the total number of meanings mentioned by an individual across all the senses, U is the total number of unique meanings mentioned by an individual across all senses, and H is the number of homogeneous pair-wise connections for an individual. N and H are used to construct a pairwise connection homogeneity ratio (F), i.e., $[H/((N*(N-1))/2)]$, and *CSHI* is calculated as: $[((U-1)*(1-F))/N]$, and ranges between 0 and 1. A higher *CSHI* indicates more the individual identified a greater number of meanings, as well as more heterogeneous meanings across the senses.

SPECIAL SESSION SUMMARY

When Increasing Control Decreases Consumers' Well-Being: The Negative Psychological Consequences of Choosing

Simona Botti, Cornell University
Tom Meyvis, New York University

SESSION OVERVIEW

Classic research in both psychology and economics has shown that people want to have choices because choosing leads to beneficial consequences such as greater intrinsic motivation, more positive affect, and superior cognitive performances. Consistent with this view, modern marketing practices as well as public policy reforms increasingly rely on the provision and exercise of choice as a means to increase individuals' satisfaction. For example, stores offer increasingly large assortments and entice shoppers to customize product offers, and the current US administration has proposed reforms in the field of healthcare, social security, and education that switch choice from the government to the citizens. The papers presented in this session challenge the assumption that choice is always beneficial by investigating situations in which the provision of choice in different degrees (from no-choice to too many choices) have negative psychological consequences, thereby worsening, rather than improving, consumers' well-being. In addition, these papers indicate that in specific circumstances consumers may be willing to restrict their choice. This result is particularly important because it contradicts prior findings showing that, even when dissatisfied with the decision outcome, people still prefer autonomy and choice. These studies contribute to a nascent body of literature that posits that decision makers' evaluation of decision outcomes depends less on their ability to match personal preferences and available alternatives than on the psychological processes experienced during the decision task. Marketers as well as policy makers should therefore reconsider policies aiming at providing or increasing choice in light of the potential negative psychological effects of choosing.

"Avoiding Pain: Choice Preferences and Emotional Responses in Medical Decision Contexts"

Simona Botti, Cornell University

Sheena S. Iyengar, Columbia University

Kristina Orfali, Columbia University, ISERP

Prior research has found that people prefer situations in which they can make their own choices to those in which these choices are externally dictated (Brehm 1966). This preference for self-choice is supported by findings showing that the provision of choice improves emotional states while the removal of choice negatively affects psychological and physiological well-being (Langer 1975; Taylor and Brown 1988). Even in the field of bioethics there is a general consensus about the benefits of choice. Indeed, the autonomy model, according to which patients know what is the best treatment for them and should decide for themselves, prevails over the paternalistic model, which considers patients cognitively and emotionally unable to decide so that physicians should make the decision on their behalf.

More recent evidence has however challenged the assumption that choice is always beneficial. Research has shown that the emotional conflict often involved in decision making heightens when the importance of the choice increases (Luce 1998). In addition, choosing among all undesirable options has been found to generate psychological distress, thereby reducing outcome satisfaction (Botti and Iyengar 2004). Some evidence in medical deci-

sion research also suggests that, contrary to the principles of the autonomy model, patients are sometimes reluctant to decide and that their actual desire for autonomy is overestimated by both the physicians and the general public (Schneider 1998). The present research examines whether the psychological pain of choosing raises so much in highly consequential, aversive choices to weaken people's preferences for personal choosing. This question is important because it contributes to the current literature on the detrimental effects of choice (e.g., Iyengar and Lepper 2000) by directly assessing choosers and non-choosers' affective reactions to real-life decisions about medical treatments.

Study 1 is an ethnographic study about infants' healthcare. We analyzed the protocols from 32 in-depth interviews with parents of critically ill newborns under life-sustaining treatments in two similar Neonatal Intensive Care Units (NICUs), one located in the United States, where the autonomy model is adopted, and the other in France, where instead the paternalistic model is used. These parents were facing the decision of whether or not to interrupt the treatment: The usual outcome of treatment interruption is the death of the baby, whereas the decision to prolong the treatment generally involves a higher probability of severe neurological impairment versus a lower probability of death. The sample included only cases in which the treatment was terminated causing the death of the babies, with the difference that the decision was taken by the parents in the American unit and by the doctors in the French unit. Results suggest that American parents reported more intense negative emotions such as anger, depression, guilt, or regret as compared to French parents following the death of the babies. In addition, both French and American parents expressed an ambivalent attitude towards being the decision makers, on one side resisting the idea of making a choice that will hunt them for the rest of their lives, and on the other side associating the decision to forgo the choice with being irresponsible caregivers.

Two follow-up laboratory studies were conducted to control for factors other than decision autonomy that could potentially influence the parents' affective reactions observed in the ethnographic study. For example, cultural variables could explain the different emotions felt by French and American parents. More importantly, French parents were not always aware of the uncertainty involved in the doctors' decisions because these decisions were often framed as the "only" solution in the baby's best interest. In the first laboratory study participants read a scenario describing the situation of a premature baby undergoing a life-sustaining treatment. In the choice condition, participants were asked to choose between continuing the treatment, with 40% probabilities of death and 60% probability of severe neurological impairment, and withdrawing the treatment, which would determine the death of the baby. In the risky-no choice condition participants were given the same information as in the choice condition but were also told that the doctors had made the decision to withdraw the treatment and let the baby die. Finally, in the sure-no choice condition participants were told that the doctors had decided to withdraw the treatment and let the baby die without being informed about the alternate course of action. Results were consistent with those of the ethnographic study. Participants in the risky-no choice condition experienced the

most positive and least negative emotional responses, while no significant affective difference was found between participants in the choice and sure-no choice conditions, ruling out the framing of the decision in terms of medical certainty as an alternative explanation. Also consistent with the ethnographic study, participants were ambivalent towards their preference for choosing: choosers liked their experimental condition less than both non-choosers. Nevertheless, the willingness of choosers to have the doctors make the decision for them was lower than that of risky and sure non-choosers to decide autonomously.

The second laboratory study controlled for yet another alternative explanation. It might in fact be argued that the lower positive affect experienced by choosers as compared to equally informed non-choosers is a consequence of choosers' inability to engage in preference matching, as the preferences of those who will be directly affected by the decision are not known to those who actually decide. In this study we used the same hypothetical decision of the previous study, with the only difference that the consequences of the choice were to be experienced by oneself rather than another. Results showed that even when the choice consequences were endured by the decision maker, self-made choices led to less positive emotional responses than doctor-made choices, and decisional autonomy was not fully endorsed.

Overall, these studies indicate that highly consequential, average choices may negatively affect emotional reactions and that people's desire for autonomy in these choice contexts is more ambiguous than that observed in prior research. This research is relevant for public policy makers in that it suggests that the autonomy model may not ensure individuals' welfare in healthcare decisions.

"When Consumers Choose to Restrict Their Options: Regret and Choice Set Size Preference"

Cenk Bülbul, New York University

Tom Meyvis, New York University

Past research studies have found that the provision of choice increases intrinsic motivation and enhances performance on a variety of tasks (Deci, 1975, 1981; Deci and Ryan, 1985; Taylor and Brown, 1988). Yet, Iyengar and Lepper (2000) find that—while having a choice is a good thing—having an abundance of choice

alternatives is not. Choosing from larger assortments decreases purchase instances and makes people less satisfied and more regretful about the choice they make. Interestingly, Iyengar and Lepper (2000) also find that people would like to choose from larger assortments, even though it tends to make them regretful and demotivated.

We conducted three studies to examine whether people always prefer more choice however de-motivated, frustrated and regretful they feel in the end. More specifically, we investigate how the anticipation of regret determines how much choice people allow for themselves. We argue that anticipated regret play a critical role in determining consumers' ideal choice set size. Furthermore, we propose that to understand the impact of anticipated regret, it is important to distinguish between the different sources of regret (and the corresponding consumer focus). In each of the following studies, regret was manipulated in an unrelated first study, after which participants were asked to specify how many desk lamps they would like to choose from.

We argue that consumers' normative strategy is to "keep their options open" and maximize the number of alternatives they can choose from. Given that this is the default strategy, the anticipation of regret should increase consumers' preference for large choice sets (Kahneman and Miller, 1986). However, we propose that the activation of regret may also have an opposite effect depending on the type of regret that is being anticipated. In particular, when the choice process itself is made more salient, we expect that the anticipation of regret will increase the preference for *smaller* assortments in order to minimize the pain of choosing. One factor that may increase the salience of the trade-off difficulties in the choice process is the presence of a concrete exemplar from the choice sets. In study 1, we manipulated anticipated regret (none versus primed) and exemplar priming (none versus primed) between subjects. Regret was primed in a seemingly unrelated task that was adapted from Simonson (1992). The exemplar priming consisted of a picture of a typical desk lamp. As predicted, regret priming increased the preference for the large assortment when subjects were not primed with the exemplar, but decreased preference for the large assortment when they were primed with the exemplar.

In the second study, we examined how exemplar priming may moderate the effect of regret anticipation. Exemplar priming could create a *process focus* by making people anticipate the trade-off difficulties during choice process or it could create an *outcome focus* by making people think about the product they will end up with. We propose that, while a process focus would explain the observed increased preference for smaller choice sets when primed with regret, an outcome focus would instead activate the keep-your-options-open norm and increase their preference for the larger sets when primed with regret. In study 2 we tested these predictions by directly instructing participants to either focus on the actual choice process or the outcome of their choice. As predicted, we found that when people focused on the choice process, the anticipation of regret shifted their preference away from the larger assortments. However, when people focused on the outcome of their choice, the anticipation of regret shifted their preference towards the larger assortments.

In study 3, we found converging evidence for our choice process theorizing using a 2 (Regret: Anticipated versus None) X 2 (Timing of actual choice: Now versus Later) between-subjects design. Based on Construal Level Theory (Trope and Liberman, 2003), we hypothesized that a short-term perspective would induce a process focus, which is more contextual and includes more incidental details, while a longer-term perspective would induce an

outcome focus, which is more de-contextualized and general. In the “choose-now” condition, participants were told that they would make their actual choices immediately after indicating their preferences for the choice set size, whereas in the “choose later” condition, participants were told that they would make their actual choices in the next experimental session three weeks later. As predicted, anticipation of regret in the “choose later” condition increased the preferred size of the choice set, while anticipating regret in the “choose now” condition decreased the preferred size of the choice set.

These results suggest that the impact of anticipated regret on choice set size preference depends on the focus of this regret. We propose that in our exemplar priming, process focus, and ‘choose now’ conditions, that focal regret is the anticipated regret during the actual choice process (i.e., the negative feelings people experience when making trade-offs between alternatives). In order to minimize this regret, participants preferred smaller assortments. However, anticipation of regret can also work in the opposite direction and boost people’s preference for more choice. We propose that in our baseline (no priming), outcome focus and ‘choose later’ conditions, the focal regret was the regret of having passed up better outcomes than the one obtained. To minimize this particular regret, participants wanted to keep their options open and hence boosted their natural preference for larger assortments.

“Choosing Inside The Box: When More Choice Narrows Our Thinking”

On Amir, University of California at San Diego

Sheena S. Iyengar, Columbia University

Consumers face decisions which vary on the amount of choice. One can choose between two music CDs, or from amongst five or six CDs. We propose that larger choice sets, that is, choice-sets that include more products from the same category, generate narrower and more mundane thinking in the decision process. In particular, we predict *less creative* thinking, or greater thinking within “the box”, as the choice categories are invoked more strongly, hindering associations to non-category schemas. For the abovementioned CD example, this would mean that consumers will be less likely to think of alternatives that are not other CDs when choosing from the larger choice set as compared to the smaller one.

In Experiment 1, we demonstrate that as within category choice increases, consumers are less likely to consider outside alternatives. Specifically, we offered participants the option to buy a discounted CD in three conditions that varied on the number of possible alternatives (1, 2, or 3 CDs). We then asked participants to write all the alternatives that came to mind when making their decision. While the overall number of alternatives written by participants did not significantly vary across conditions, participants were reliably more likely to refer to other CDs as alternatives the greater the choice set. In contrast, the smaller the choice set, the greater the likelihood of participants considering alternatives that were not related to the choice category, such as meals, DVDs, etc. We hypothesized the stronger invocation of the category and its subsequent heightened accessibility as the driver of this effect. If indeed this effect is driven by hyper accessibility of the focal category, we should find the same effect on creativity. We tested this in Experiment 2.

Experiment 2 tested whether this enhanced accessibility would influence thinking “outside the box”. Participants were asked to aid the process of the development of a new product. To better explain the process, they were given a choice from either a set of two MP3 players or five MP3 players, as examples of products with innovative features. Participants were then asked to write ideas for product innovations. Specifically, we asked participants to try and predict “the next ‘coolest’ and most innovative product”. We counted the number of ideas and measured the likelihood of those ideas to relate to MP3 players. In addition, the data was given to two independent judges that were asked to rate their creativity. As predicted, participants choosing from a larger set were reliably more likely to be confined to that category (i.e., MP3 player) when thinking of new product ideas. In contrast, participants choosing from the smaller set were much more likely to write ideas judged to be more creative and diverse. In this experiment participants in the smaller choice set were even more likely to suggest more ideas than their large choice set counterparts.

We conclude that a choosing from amongst a larger set of same-category products seems to focus thoughts on that category and obstruct considerations of external alternatives. An example of this might be that the more types of cakes one can choose from as desert, the less likely is one to think of fruit salad or of not having desert as viable alternatives. Greater choice has been shown to have negative consequences for consumers (Iyengar and Lepper 2000). Our findings suggest another mechanism by which having more choice interferes with increasing our well being, as it decreases our flexible use of resources (money, time, etc...)

SPECIAL SESSION SUMMARY
The Production of Consumer Representations
Julien Cayla, Australian Graduate School of Management
Lisa Peñaloza, University of Colorado

SESSION SUMMARY

This special session investigates one of the key practices of consumer research: representation. Academics, consumers and marketers are all at one point or another engaged in the practice of representing. First, academics make choices about what type of consumer experiences they want to represent and how (Stern 1998). From this perspective, the word “consumers” is not an ontological given but a socially constituted and institutionally-produced category. Second, consumers are often engaged in representing themselves when asked to participate in consumer research (Applbaum 1998; 2000) or when using products and services to enact identities (Firat 1998). Finally, marketers also spend much of their time imagining and constructing consumers. With the increasing institutionalization of markets, producers and consumers rarely meet each other and managers rely on mediated images of consumers to design their strategies. Representations may be seen in the images appearing in television and print ads, in the intermediary stages of market research and theorizing about consumers, in talk and other social practices that give meaning to consumer research, and in symbols that stand in for the experiences of consumers. This session looks specifically at the way marketing practitioners represent consumers.

By focusing on the cultural work of casting consumers in different roles and turning them into actionable targets for action, the present papers converge on the question of how marketers represent. Cayla and Peñaloza look at the lack of representation of Muslims in advertising and other forms of popular media in India. They show advertisers and marketers discussing what it means to be Indian, ignoring certain consumer differences and emphasizing others in the process of developing ads and marketing strategies. The paper then turns to a sample of Muslim consumers and their reaction to the hegemony of Hindu representations. Rather than showing Muslims resisting these representations of Indians as Hindus, the data speaks to a Muslim desire of not being represented. Overall, the paper discusses the politics of consumer representations, in the form of their construction by marketers, their reception by consumers, and the dialectic implication of both processes. Sandikci and Ger also look at the representation of Muslims, but in a very different cultural context: Turkey. Starting from the observation that marketplace activities and religious practices influence each other, they investigate how fashion marketers construct and represent Islamist women in advertising and other commercial imagery, and how these representations transform over time as a result of competition, consumption ideology, and global capitalism. They argue that Islamist style clothing companies have adapted contemporary fashion marketing tools, and the stereotypical image of the veiled Muslim women as the oppressed and the non-fashionable has given way to the images of a modern consumer. Overall, the paper demonstrates how changes in advertising representations relate to the underlying social, economic and political forces.

Finally, investigating representation in electronic consumption spaces, Zwick and Nyman examine the cultural work of database marketers. Drawing from interviews with customer data workers, the authors examine the logic of the database as it abstracts consumer bodies from their territorial settings, recodes them into a series of data flows, and then reassembles them into distinct data

subjects, which can be analyzed and targeted for intervention. The authors argue that database marketing should be regarded as a response to the twin condition of marketing modernity, the increasingly mobile consumer and the disappearing consumer body. Systematic surveillance of consumers’ movement and transactions, an inherently ambiguous process that should not be considered in a merely negative light (Lyon, 2001), produces a new regime of signification, which entails a number of managerial and theoretical implications. Of particular interest is the authors’ claim that equipped with digital facsimiles of consumers, marketers now regard all consumer actions and movements, indeed even *life itself*, as having value (Arvidsson, 2004). Moreover, the digital format allows for techniques of customer assemblage that the authors call *laboratory marketing*.

Overall we make three important contributions to consumer research. First, this session explores managerial practices of representation, which has largely been ignored by consumer researchers (exceptions include Kover 1995). Anthropologists have been at the forefront of analyzing marketing practice as discourse for “framing” consumers (e.g. Applbaum 1998). Their studies show how television producers and advertising professionals imagine their audiences and how the shows and commercials they produce are shaped by this act of imagining. Consumer researchers, on the other hand, study representations with regard to their effect on consumer behavior (O’Guinn and Shrum 1997) or as objects of interest in and of themselves (Belk and Pollay 1985), but not as social practice. In addition, while past studies locate representations within their historical, cultural, and social context, consumer researchers rarely analyze how these representations are constructed. Of special importance is what type of consumer differences marketers choose to emphasize and why. Not all differences receive the same treatment. The market is selective in gleaning those parts that lend themselves to representation and incorporation. This session will map how marketers select these differences and why.

Second, illuminating how consumers exist in marketers’ minds and materialize through their practices, we hope to better understand the chasm we see between marketing practitioners, consumer researchers, and consumers. Put differently, all can benefit by examining and potentially overcoming the boundaries that exist between marketers, consumers, and academics’ representational paradigms. Malefyt (2003) shows how advertisers and marketers together represent consumers and eventually come to reinforce the boundary between consumers and themselves. As they work together to define the contours of consumer profile, they come to think of “us versus them.” Our discussion will revisit these practices as well as basic models of consumer behavior that are predicated on separate notions of marketers, consumers, and researchers. A key question here is how these practices and models would change if consumers and marketers were more or less integrated.

Third, we highlight the relationship between the politics of representation and consumer identities. Denzin (2001) remarks that the interpretive rituals and practices surrounding consumption are anchored in a larger system, called the “circuit of culture” (du Gay et al. 1997, p. 3) where meanings are defined by the mass media, including advertising, cinema, and television. These processes mutually influence one another, continually shaping consumers.

By looking at marketers' practices of representation, we hope to provide a complementary perspective on the circuit of culture and identities that goes beyond representations as texts to integrate structures that constrain their production.

ABSTRACTS

“Domesticating the Indian Imagination”

Julien Cayla, Australian Graduate School of Management

Over the last two decades, advertising and other popular media have increasingly addressed and represented Indians as global consumers. With the liberalization of the Indian economy, the ideology of a self-sufficient socialist nation has receded from the Indian landscape. The ideologies of globalization and capitalism have risen to the fore. Previously, advertising had helped construct the prototype of the patriotic consumer who rejected British and other foreign goods in support of local industries (Doctor and Alikhan 1997). The “new India” is now a postcolonial nation embracing globalization and advertising representations of hybridity abound as modern and traditional, Indian and Western ideas, objects and practices come into articulation.

In constructing representations of modern Indians, marketers and advertisers have to deal with the complexity of the subcontinent: the extreme variety of languages, communities, religions and social classes (Venkatesh and Swamy 1994). Because of this heterogeneity, advertisers heavily borrow from a Hindu religio-ritualistic imagery that most Indians can relate to (Rajagopal 1998, 2001). Hindu gods and goddesses, housewife characters wearing *bindis* and *mangalsutras* all endow contemporary domestic commodities with the aura of a Hindu-Indian heritage that cuts across regions and social classes. While advertisements cater to the desire of upper-middle class Indians to join the global elite, many of them combine images of successful Indians with explicitly Hindu and “traditional” signs of Indian identity.

This paper problematizes the construction and reception of these Indian mainstream representations by Indian Muslims. How successful are advertisers in domesticating the Indian imagination? Since Indian advertising predominantly portrays Hindu men and women, many questions emerge about the way religious minorities respond to these messages. There are more than a hundred and forty million Muslims in India. But apart from a few billboards, films and television series representing Muslim families, this huge community remains largely absent from television screens and ads (Mishra 2002). A focus of this research is to examine how Muslim consumers negotiate their sense of identity, citizenship and ‘Indian-ness’ in a cultural world dominated by Hindus.

This paper relies on eleven months of ethnographic work in Mumbai and Hyderabad. I spent the first nine months of fieldwork engaging in participant observation and interviewing advertising executives about the development of advertising campaigns. During the remaining time, I interviewed fourteen informants from the Indian middle and lower middle social classes, focusing on the ways they negotiate their position of consumers. Field notes, interim transcripts, in-depth interviews, archives of agency correspondence and artefacts (i.e. local newspaper articles; print and television ads) comprise the data.

Preliminary analysis indicates that while upper-middle class Muslim Indians easily play the role of global consumers, Muslims from the lower social classes tend to resist this position. This is nuanced, however, by their desire to connect, through the consumption of TV programs and products from the Middle-East, to another sphere of globality which is less influenced by Western consumerism. Another key finding is Indian Muslims’ desire to blend in as

well as their reticence to being represented as a marketing group standing out to be targeted. Finally, Muslim consumers seem to be especially responsive to the depiction of family life in advertising, despite the prevalence of Hindu symbols in such depictions. These representations seem to transcend the Hindu/Muslim divide and continue to symbolize what it means to be Indian.

“Representing the Islamist Consumer: Transformation of the Market”

Ozlem Sandikci, Bilkent University

Guliz Ger, Bilkent University

One of the fundamental ways that the consumerist ethos circulates and continuously reproduces itself is through commercial imagery. Advertising, marketing and fashion discourses construct and disseminate aestheticized and stereotyped images of the modern consumer. Who is represented how in the marketing discourse reveals forms of identity that are legitimized and privileged over other identity formations. As Schroeder and Zwick argue “advertising representations influence cultural and individual conceptions of identity, and must be understood as the result of changing social and cultural practices” (2004, p.24). While there is a wealth of literature dealing with the nature and politics of stereotypical representations in advertising, there is little on how stereotypes are created and transformed as a result of social, cultural, political and economic factors. This study looks at how marketers in Turkey construct and represent the Islamist women in advertising and other commercial imagery, and how these representations are influenced and transformed by the local and global forces of consumerism and capitalism.

The issues of who is represented and how become critical in the case of Islam and fashion where the conventional images of the veiled Muslim woman almost always take the form of the oppressed, non-modern and non-fashionable. In contrast to these stereotypical images, contemporary advertising and other commercial representations of the Islamist women in Turkey portray a modern consumer who draws from multiple cultural references and resources. In this paper, we map out various representations of Islamist female as a modern consumer and the marketing agents authoring these representations. Specifically, we investigate the following questions: How Islamist women are constructed and represented in advertisements, catalogues and other commercial media? What assumptions are embodied in these representations? How do marketing and advertising representations create, reinforce, subvert or mock the existing assumptions about the Islamist female identity?

Previous studies outline the emergence of a prolific Islamic consumptionscape in Turkey in last decade, and indicate that consumption orientation has become particularly visible in the domain of fashion (Kilicbay and Binark 2002; Sandikci and Ger 2001, 2002, forthcoming; Navaro-Yashin 2002). While these studies trace the changes of the meanings and practices of the headscarf, they remain mostly silent on the relation between marketing activities and religious practices. Religion affects marketplace activities (Mittelstaedt 2002; Mittelstaedt, Klein and Mittelstaedt 1998). Religious traditions and institutions can influence the rules of trade, prohibit or obligate the trade of certain products, and affect the time and place of markets. Spiritual practices and beliefs translate into demand for certain goods and services and markets develop to meet that demand. Market forces, however, also affect religious practices and traditions. Mittelstaedt (2002) argues that through political, institutional, moral and competitive mechanisms, markets can affect the parameters of religion and can force the organizations to make choices between being faithful and competitive, and the

believers to reevaluate what it means to be faithful. We focus on Islamist market agents, namely companies that sell clothing and related products to Islamist women in Turkey, and explore how their discursive practices influence religious identities and activities as well as how they themselves are affected and transformed as a result of local and global forces of market and consumption cultures.

We draw from data collected through ethnographic work conducted over a period of three years in Turkey. These include in-depth interviews with owners and personnel of Islamist style clothing stores in Ankara and Istanbul, observations at Islamist fashion shows, shopping centers and hotels, and a visual archive that consists of pictures taken by us as well as pictures circulating in the media, advertisements and company catalogues. We find that Islamist advertisements and catalogues represent covered women as attractive and well-groomed females with shapely bodies, much like the representation of uncovered women. The global ideals of beauty of both the face and the body are evident in these images. These representations counter the existing assumption that covering is a practice of faith and the secularist supposition that the sight of a covered woman is ugly and outdated. We also observe that the market agents have evolved overtime, adapting fashion marketing tools and practices in order to compete with their secular counterparts. They now employ more globally fashionable looks as well as looks that they consider would be more acceptable to the secularists. The shift from “religious attire” to “fashionable outfit” indicates a change in the understanding of the identity—from a ‘pious woman’ to a “modern consumer.” We argue that this shift is a co-production of the political milieu, the global and local market forces, and the demands of the urban Islamist women.

“Consumer Representation: The Age of Database Marketing”

Detlev Zwick, *York University*
Jacline Nyman, *York University*

At the beginning of the 21st century, data-driven marketing is ubiquitous and shaping business practice in a growing number of industrial and consumer markets. Consumers are under permanent and systematic surveillance by marketers, whose panoptic techniques are capable of capturing the physical, social, and cultural mobility of consumers that has been described as the hallmark of postmodern life (Arvidsson 2004). With the rise of database technologies and electronically mediated communications, new forms of marketing power have emerged that are typically realized as improved market segmentation and targeting capabilities and often captured in concepts such as customization, customerization, personalization, one-on-one relationships, and interactivity. In this sense, customer databases constitute massive computer-assisted classification systems that operate, according to Haggerty and Ericson (2000, p. 606), “by abstracting human bodies from their territorial settings and separating them into a series of discrete flows. These flows are then reassembled into distinct ‘data doubles’ which can be scrutinized and targeted for intervention.”

Marketing and consumer researchers have ignored the “cultural innovations brought about by the integration of database technology into existing political, economic, and social institutions” (Poster 1995, p. 78). In particular the role of databases as language constructing markets and consumers has not been given due attention by marketing and consumer theorists (cf. O’Shaughnessy and Holbrook 1988). A poststructuralist perspective upholds that new systems of representation—be it writing, statistics, or digits—articulate newly ordered spaces of knowledge in which the object of representation (e.g. the consumer) becomes observable, measurable, quantifiable, in short, known (Foucault

1972; Poster 1995; Holt 1997; Thompson and Hirschman 1995). The systematic surveillance of consumers’ movement and activities, an ambiguous process that should not be considered in a merely negative light (Lyon 2001), produces such a new regime of representation that results in the constitution of consumers as *data subjects*. Hence, database marketing enables what Michel Foucault called biopower: making people up by classifying them according to categories.

Whether consumers accept the digital representation of themselves or not and under what circumstances is an empirical question. However, contrary to the logic of traditional types of marketer-produced consumer representations such as advertisements, for database representations to “work” consumer acceptance of the category is not essential. In other words, as soon as consumers are abstracted from the “real” and subsequently reassembled as data flows they always already constitute actionable representations. Paul du Gay’s observation that market research, while aiming at capturing the ‘Real’, in fact produces ‘Reality’ (du Gay 1996, p. 60) seems instructive for understanding the theoretical effect of the representational power of the database.

For this paper, we draw from interviews with database marketers in a wide range of industries to illustrate a number of managerial and theoretical implications of the recoding of consumers into digital representations.

First we elaborate on our claim that database marketing should be regarded as a response to the twin condition of marketing modernity: the increasingly mobile (spatially, economically, culturally) consumer and the disappearing consumer body (Dholakia and Zwick 2004; Lyon 2003). Then we argue that the ability of the customer database to appropriate what Arvidsson (2004, p. 467) calls “the communicative action of life in all its walks” effectively turns increasingly complex and mutable consumer practices into value. In other words, ubiquitous information gathering transforms what has previously been seen as a problem in need to be contained and reduced—the mobile and disappearing consumer and her changing activities and diverse practices—into a productive force. Finally, we theorize the effects of database-driven customer intelligence on marketing practice by proposing the metaphor of *laboratory marketing*. This term refers to a process that conceptualizes the database as an *experimental structure* akin to the scientific laboratory where marketers, in an attempt to continuously valorize consumer life, generate an ongoing cycle of testing, revelation, discovery, and evaluation of the representations they create. Herein lies in fact one of the most fascinating contradictions of database marketing. The possibility of generating an unlimited amount of digital customer representation via creative yet undertheorized data mining activities at the same time facilitates and always already undermines the process of materially defining the consumer object for targeted intervention.

EXTENDED ABSTRACT

Marketing activities are shifting increasingly from a focus on market segments and targeting to a focus on individual consumers and customization. While providing products or services to satisfy the wants and needs of customers has always been at the core of the marketing concept, the degree to which companies seek to match their offerings to customers' *individual* tastes has changed dramatically over the past few years (e.g. Simonson 2005).

While both customers and companies may benefit from customization (e.g., Alba et al. 1997; Häubl and Trifts 2000; Lynch and Ariely 2000), the success of tailoring product offers to individual preferences is based on assumptions that may not always hold. Specifically, customization assumes that consumers rely on their individual preferences when making choices and will reward those companies that provide them with products that match their preferences most closely. However, prior research in cross-cultural psychology has shown that, in many cases, consumers' individual preferences may be less important (and hence less predictive of choice) than the average preferences of relevant in-groups.

One of the most widely researched cultural difference variables in marketing and psychology relates to Hofstede's (1980) dimension of individualism-collectivism (e.g., Han and Shavitt 1994). Referring to the relationship between an individual and the larger collective, individualism-collectivism describes how individuals weigh their personal goals against those of a relevant group, such as their family, friends, or co-workers. Furthermore, in relating to how valued the individual is relative to the group, the individualism-collectivism dimension affects how individuals construe the self, others, and the interdependence between the two (Markus and Kitayama 1991).

Differences in how individuals define themselves in relation to others have stable and predictable consequences for cognition, emotion, and motivation (Markus and Kitayama 1991), including for the relative importance of individual preferences compared to social norms or collective preferences. For example, Singelis (1994) shows that members of collectivistic (vs. individualistic) cultures are less likely to perceive it to be their right or duty to make choices that reflect their personal inner attributes, and are much less concerned with being distinct from others. This is, collectivists (vs. individualists) tend to rely more on external factors, such as their role in a group or their relationship with other group members, than on their internal attributes (Hofstede 1980; Markus and Kitayama 1991; Morris and Peng 1994). Collectivistic (vs. individualistic) consumers tend to act in accordance with the expectations of others to express their interdependence and connectedness, rather than in accordance with their individual preferences. Furthermore, Iyengar and Lepper (1999) find that Asian American children are more motivated and perform best in situations in which choices were made for them by relevant in-group members, but for Anglo American children motivation and performance are best when they make their own choices.

This suggests that the success of customizing marketers who uniquely tailor product offers to individual preferences may be limited by the cultural orientation of their customers. In particular, consumers who exhibit interdependent or collectivistic tendencies may be less receptive to product offers that are based on their

individual preferences, and more likely to patronize marketers that provide them with offers that are based on the preferences of other consumers like them.

It is therefore important to consider the conditions under which consumers are receptive to customized offers. In particular, we investigate differences in receptivity to customized offers due to cultural orientation, operationalized as interdependent versus independent self-views in our first study, and show that as expected, individuals with an interdependent self-construal respond less favorably to a customized offer than individuals with an independent self-construal. Furthermore, Study 2 replicates this effect by operationalizing cultural orientation as collectivism versus individualism. Specifically, we show that collectivistic individuals are less receptive to a customized offer than individualistic individuals. However, Study 2 also finds a boundary condition of the effect, showing that collectivists only respond more favorably to those offers that are not based on their own preferences when these are consumed in public. The difference in receptivity to the customized offer due to cultural orientation is eliminated for products that are consumed in private. Additionally, we show that the effect of cultural orientation on receptivity to customized versus segmented product offers is independent of consumers' need for uniqueness and is not due to differential levels of a need for control.

The results of this research have important implications for marketers, showing that there is a distinct segment of consumers that evaluates customized offers less favorably than offers provided to them based on a segmentation approach. These consumers may be lost if they are forced to customize or personalize a product to their own specifications.

Revisiting the Cultural Identity Model: Sojourners' Negotiations of Identity and Consumption Experiences

Siok Kuan Tambyah, National University of Singapore
Raymond Chng, National University of Singapore

EXTENDED ABSTRACT

This research explores the relationship between cultural identity and the readjustment process by revisiting the cultural identity model and its applications in the context of returning sojourners (Sussman 2000, 2002). The cultural adjustment to the foreign host culture and the phenomenon of "culture shock" has been well-researched (Adler 1975; Oberg 1960), but there has been relatively less literature on repatriation, readjustment to the home culture and the phenomenon of "reverse culture shock" (Adler 1981). While some studies have examined the identity projects of cosmopolitans (e.g., Thompson and Tambyah 1999), consumer researchers have focused on the longer-term acculturative processes for immigrant groups (e.g., Mehta and Belk 1991; Oswald 1999; Penaloza 1994; Stayman and Deshpande 1989; Wallendorf and Reilly 1983).

Cultural identity is defined as the psychological counterpoint to national identity. Where national identity is defined as one's place of birth or country of origin, cultural identity is more aligned with who an individual perceives him/herself to be and the more specific cultural influences in his/her life (Costa and Bamossy 1995; Hall 1992). Based on the cultural identity model, there are four types of identity shifts: affirmative, subtractive, additive, and global, each with a different repatriation outcome. Sojourners with an affirmative identity shift possess positive feelings towards their home country identity, and evaluate themselves as having a strong common bond with their compatriots. The cultural identity model predicts that sojourners with an affirmative identity shift would have low adaptation to the host country and low repatriation distress as they are the "grateful repatriates" who view the return home as positive. Subtractive identifiers would experience high adaptation to the host country and high repatriation distress upon return to the home culture. The high repatriation distress is due to identity loss with feelings of alienation from the home culture. They feel less positive about their home country and feel less in common with their compatriots. Similarly, additive identifiers would also experience high adaptation to the host country and high repatriation distress upon return to the home culture. However, high repatriation distress is due to embracing too many aspects of the host culture such as their values, customs, beliefs and social rituals. This additive shift is an identity gain whereby cultural identities have been sufficiently changed such that repatriation becomes a negative experience. Global identifiers experience high adaptation to the host country and moderate or low repatriation distress. They are often sojourners who have had multiple international experiences, and movements in and out of cultures only heighten the sense of belonging to a global community. On the whole, repatriation becomes a positive experience for them.

Data was collected via in-depth phenomenological interviews with fourteen Singaporean returning sojourners, ranging in age from 24 to 38 years who have spent at least two years overseas. Informants were asked about their sojourning experiences, cultural adjustment to their host countries, repatriation experiences, consumption experiences throughout their sojourn and repatriation, the meanings of home and what it means to be Singaporean. Verbatim transcripts were analyzed using the hermeneutic tradition. Generally, all of the informants expected some form of difficulty in returning home. Those whose actual experiences of coming home were more difficult than originally anticipated experienced a higher

degree of repatriation distress. A positive motivation to come home overrides the initial discomfort and enables the sojourner to readily readjust back to life at home. Social support from the home culture can play an important role in helping these sojourners overcome reverse culture shock as well as provide the emotional attachment to Singapore.

The findings provided evidence for the four types of identity shifts as suggested by Sussman (2000, 2002). Sojourners with affirmative identity shifts exhibited a greater appreciation of their local culture (e.g., Singaporean cuisine, Asian values), while those with subtractive identity shifts expressed dissatisfaction with their quality of life after returning home. Sojourners with additive identity shifts shared examples of how they have appropriated various elements of their host cultures in terms of media consumption, adoption of new lifestyles, changes in value systems, etc. Others with a global identity shift attempted to re-create their own unique consumption experiences (e.g., American Thanksgiving with a Singaporean twist).

In addition to Sussman's model, we propose two more identity shifts. A resistive identity shift was identified when the sojourners displayed resistance to changes in the cultural environment. A marginal identity shift emerged when sojourners demonstrated no affinity to either the host or home cultures. Sojourners with a weak sense of cultural identity may experience more negative identity shifts upon repatriation. The resistive and marginal identity shifts are differentiated from the subtractive identity shift by their more negative and subversive undertones. The resistive identity shift may be less problematic because over time, the sojourner may better manage his/her initial adaptation difficulties and ease back into life in the home culture. Like the additive and subtractive identifiers, someone who has experienced a marginal identity shift was a very adaptable person in the host country but who experienced a high level of repatriation distress. However, unlike those who have managed to find a mooring in identifying more with the host or home culture, a marginal sojourner has no affinity to either culture. This rootlessness may take a longer time to be resolved.

This research highlights the dynamic construction of cultural identity as sojourners negotiate both host and home cultures, underscoring the transformative effect that comes with a sojourn to a foreign culture. Although this research proposed two more identity shifts (i.e., the resistive and the marginal identity shifts), there could be other identity shifts as cultural identities become more malleable. Some informants may also display traits of different cultural identities. As the readjustment process varies for different individuals, a longitudinal study can be carried out to better trace the readjustment process and movements in cultural identity. It would be interesting to explore if sojourners may experience multiple cultural identity shifts over time as they readjust to their home cultures.

The Effects of Cultural Individualism on Consumer Self-Confidence for Marketplace Interfaces

Piotr Chelminski, Providence College
Robin Coulter, University of Connecticut

EXTENDED ABSTRACT

Businesses that encourage voicing by dissatisfied consumers have an opportunity to learn of problems arising during consumption and, in turn, to take corrective action. Past research suggests firms that provide consumers with an opportunity to voice have higher customer retention rates, help diminish negative word-of-mouth, and improve bottom line performance (e.g. Fornell and Wernerfelt 1987, Bolting 1989, McCollough and Bharadwaj 1992, Kelley, Hoffman, and Davis 1993, Reicheld 1996). Moreover, proper handling of voicing can improve customers' perceptions of service quality and enhance customer relationship with and commitment to the firm (Tax, Brown, and Chandrashekar 1998).

This paper examines the effects of cultural individualism on the consumer self-confidence for marketplace interfaces (CSC-MI). This facet of consumer self-confidence focuses on consumers' ability to stand up for their rights and to express their opinions when dealing with marketing personnel (Bearden, Hardesty, and Rose 2001). Thus, CSC-MI is a construct indicative of consumer's propensity to engage in a consumer voicing behavior.

An important contribution of the present study is an attempt to relate an individual-level cultural characteristic to other individual-level psychological variables. Most studies in the cross-cultural domain thus far have failed to measure the cultural variable and drew conclusions about differences in dependent measures based on the assumption that cultural differences exist. In this research, we offer a unique approach to cross-cultural analysis. Rather than simply comparing means, which is not warranted in most cross-cultural studies due to lack of scalar measurement invariance, we link an individual difference cultural variable to two other individual difference psychological variables to show that such direct relationships are indeed present in differing cultural systems (Leung 1989).

Past research suggests that cultural individualism can influence the propensity to engage in voicing. In individualistic societies, where people's social circles are large and constantly changing, people favor methods of adjudication to facilitate an all-or-nothing outcome (Leung 1987). Further, respondents in an individualistic culture (U.S.) preferred dispute resolution using adversary procedures rather than non-adversary conflict resolution which were favored by collectivists respondents from Hong Kong (Leung and Lind 1986). In contrast, collectivistic respondents from Taiwan were found to prefer obliging and avoiding styles in conflict resolution more than their American counterparts (Trubinsky, Ting-Toomey, and Lin 1991). These findings suggest that less individualistic consumers avoid direct voicing behaviors because of the concern of violating relational harmony by confronting the person or company responsible for failure. Research by Huang (1994) also supports this perspective by showing that Americans are more likely than Taiwanese subjects (presumed to be less individualistic than Americans) to complain directly to the seller or take legal action in response to a dissatisfying purchase.

Based on these perspectives, we hypothesize that greater cultural individualism is associated with a greater the propensity to engage in voicing (measured by CSC-MI). We also hypothesize that the relationship between individualism and consumer propensity to voice will be mediated by general self-confidence, that is, the more individualistic consumers, the more self-confident they are,

and, in turn, the more likely they are to engage in voicing.

Our data set includes demographically matched convenience, non-student samples of 280 adults from the United States and 513 from South Korea. The data were collected using a mail survey methodology. We conduct the analyses using a multi-group structural equation model to assess whether the hypothesized relationships are present in the two differing cultural systems (i.e., United States and South Korea). First, we assess the measurement model and the measurement equivalence of constructs between the two samples. We find that the measures exhibit appropriate reliabilities and the constructs are characterized by configural and, at least, partial metric invariance between the two different cultural groups under study. Second, we use a multi-group, hybrid structural equation model to test the hypothesized relationships. This model exhibits an appropriate level of fit. In support of hypothesis 1, the results of the structural path model show that individualism, as an individual difference cultural characteristic, has a positive affect on CSC-MI in each of the cultural groups. This relationship is assessed using the analysis of total, direct, and indirect effects (Brown 1997). Additionally, our results support hypothesis 2, indicating that general self-confidence fully mediates the relationship between individualism and CSC-MI (Baron and Kenny 1986, Brown 1997). To determine whether the structural paths are invariant between the two samples, Chi² difference tests between the unconstrained default model and series of constrained models in which each path is constrained to be equal between the two samples are performed. Our multi-group analyses indicate that all structural paths are statistically invariant between the two cultural samples.

Our study makes a number of important contributions to the cross-cultural research domain in the context of understanding cultural influence on consumer behavior. First, we find that cultural individualism, measured as an individual difference variable (rather than pan country) has a direct and positive impact on consumers' propensity to voice. Additionally, our results indicate that general consumer self-confidence fully mediates the relationship between individualism and consumer propensity to voice.

Second, we contribute to the growing literature related to the measurement challenges in the cross-cultural research context. Consistent with previous studies incorporating the measurement invariance analyses (e.g., Mullen 1995, Singh 1995, Steenkamp and Baumgartner 1998), we find that scalar invariance is very difficult to establish in a cross-cultural research context, and thus testing for mean differences is not appropriate. However, we are able to establish configural and metric invariances for our measures.

Third, our study provides insights for companies doing business with consumers from multiple cultures. Specifically, companies operating in cultures or cultural groups characterized by low individualism might consider implementation of communication strategies to encourage consumers to voice their dissatisfaction. In view of our findings, communication strategies focusing on boosting general self-confidence could prove particularly useful because there is clear positive link between the level of individualism and general self-confidence. The results of this study may also have implications for governmental consumer protection policy. Realizing that certain cultural groups exhibit lower levels of general self-confidence, and thus, are less prone to voice problems they encoun-

ter in the marketplace, governmental organizations might consider a public policy to encourage consumers to share their negative experiences, including facilitating complaints.

Netnographic Study of a Community of Beauty Product Enthusiasts in China: Consumer Reflexivity and Social Concerns

Stella Yiyan Li, University of Hong Kong
Kineta H. Hung, University of Hong Kong

EXTENDED ABSTRACT

A virtual community is a cyberspace built by groups of people who utilize networked computers to form and sustain a community through ongoing communication (Bagozzi and Dholakia 2002). Its development paralleled technological advancements that rendered networked computers an inexpensive medium accessible to many people around the world. Since there are more and more people communicating via virtual communities, this approach to meet, communicate and relate to people is emerging as a major social phenomenon. It has attracted research attention from disciplines ranging from social psychology (Turkle 1995) to sociology (Wellman 1997) and marketing (Kozinets 1997, 1998, 1999, 2002b).

A virtual community cuts across geographic boundaries and unites people with a common interest. Specifically, virtual communities that are structured around consumption interests provide both opportunities and challenges to marketers and consumer researchers because of their potential effects on branding, advertising, pricing and customer loyalty program (Hagel and Armstrong 1997). On the one hand, a virtual community facilitates the communication between companies and consumers, allowing marketers to leverage consumers' ideas in designing and customizing products. On the other hand, a virtual community encourages consumer-to-consumer communication independent of companies and marketers (Catterall and Maclaran 2002). This form of communication can effectively influence fellow consumers and reject particular marketing activities through the members' collective stance (Catterall and Maclaran 2002).

A number of studies have examined the factors influencing consumer's navigation behaviors (Bagozzi and Dholakia 2002; Novak, Hoffman and Yung 2000; Joines, Scherer and Scheufele 2003). These studies tend to examine the issue from a psychological or social psychological perspective. Less attention has been extended to examining the context of the community, the voluntary sharing of consumption-related information among members as well as the implication of consumers' changing attitudes towards consumption and their relationships with the markets.

The purpose of our study is to examine how consumers make use of a virtual community to become proactive in the marketplace. Hagel and Armstrong (1997) suggested that the rise in computer-mediated communication significantly changes the relationship between marketers and consumers and it shifts some of the power from producers/marketers to customers by reducing the information advantage vendors enjoy. Our study would examine how Chinese consumers are becoming more reflexive upon their own consumption behaviors as well as becoming more critical about practices in the marketplace. We drew upon theories on social institutions and consumption reflexivity to understand the underlying rationale. Details of the institutions in China are discussed to support the framework. Findings of our study would reveal how consumers in China at this developmental stage are learning to be an active consumer.

We conducted netnographical research on a virtual community—a beauty forum affiliated with ONLYLADY (www.onlylady.com) that is popular among women in China. Netnography, as a naturalistic enquiry technique developed especially for the cyberspace environment, was considered an appropri-

ate methodology for this study. Our analysis focuses on two major themes identified in the postings that are related to consumption activities: (1) reflexivity on consumption behaviors (susceptibility to marketing influences, forum members as experts, and reflection upon consumption criteria) and (2) strategic response to unwanted actions and agents (stop excessive buying, stop pirated goods).

Results showed that similar to other consumption communities, the beauty forum offered an important source of information to community members, provided them with communal interaction and social benefits, enhanced their level of reflexivity, and empowered them to protect fellow consumers. These results confirmed, as we have postulated earlier, that consumers in China are becoming reflexive on their consumption behaviors and are somewhat critical of the marketing process. Results of our study also show that the function of a virtual community is complex. As an agent independent of commercial forces, a virtual community is regarded by consumers as an alternative (and potentially additional) source of information boosting the consumers' consumption aspiration. But at the same time, it has the potential to improve the bargaining power of consumers and guard against unwanted behavior in the marketplace.

Our findings also point to two directions in which the current research can be extended to. First, consumers exchange tailored-made information and adjust their purchase decision making based on other members' comments and suggestions. Understanding the underlying group information processing will provide important implications for research about eWOM in the cyberspaces and benefit practitioners' IMC planning. Besides, our study shows that Chinese consumers' attitudes toward consumption are evolving as they become more involved and connected to other consumers through cyberspace. Members' diversified backgrounds result in discussion on various consumption patterns and lifestyles that are desired and emulated throughout the community. Meanwhile, the consumer's value set such as her consumption aspirations and materialistic orientations also appear to be interactively enacted. These are important issues to understanding the motivations behind consumption decisions. Future research could illustrate these processes using either case studies or a more structured research design.

ROUNDTABLE

Beyond Individualism/Collectivism: New Theoretical Perspectives in Culture-Based Research

Sharon Shavitt, University of Illinois at Urbana-Champaign
Ana Valenzuela, Baruch College

This roundtable focused on the discussion of new frameworks that are transforming culture-based research beyond the emphasis on individualism/collectivism. Issues addressed included relevant instruments, tacit measures, and cognitive mechanisms that can enrich the study of culture. The session provided an opportunity to discuss these issues with cross-cultural researchers differing in their disciplinary backgrounds, areas of expertise, and methodological approaches. Our panel included marketing scholars as well as social psychologists whose work is shaping current thought about cross-cultural consumer psychology. Some of these scholars had approached culture through the lens of social cognition and applied similar paradigms to the study of culture. Others had approached cultural influences on consumers' judgments and choice through the lens of behavioral decision-making. Some had examined situational factors that affect salient self-construal, whereas others had focused more on dispositional aspects and/or chronic and stable cultural differences. The substantive focal areas represented by these participants also varied broadly, including causal reasoning, country of origin perceptions, persuasion, categorization, self-concept, regulatory focus, choice, affect, etc.

Among the issues and questions discussed at the session:

Can culture best be understood as a set of values and goals, as cognitive structure(s), or as a system of behaviors? What are the implications of these distinctions for theory and measurement?

A salient issue in current research on cross-cultural consumer psychology concerns methods of measurement or assessment of cultural orientation and values. Should the results of cultural orientation measures be expected to be isomorphic with national and group-level cultural designations? If not, how can observations across these levels of analyses be integrated?

What are the drawbacks and proper uses of direct self-rating measures of orientation in consumer psychology? What tacit measures show promise for capturing differences in culturally patterned behavior?

At the roundtable, Carolyn Yoon (University of Michigan) presented two databases of norms for cross-culturally tested stimuli developed through comprehensive study. For those with an interest in using these stimuli, the links are provided below.

SPECIAL SESSION SUMMARY

Children's Obesity: Is Consumer Research Relevant?

Elizabeth S. Moore, University of Notre Dame

William L. Wilkie, University of Notre Dame

SESSION OVERVIEW

Children's obesity has become an increasingly serious health problem in the U.S.A. According to the Institute of Medicine, obesity among preschool children (ages 2-5 years) has more than doubled since the 1970s, and has more than tripled among children ages 6-11 (Institute of Medicine 2005). This public health issue has attracted attention from public policymakers, consumer interest groups, nutritionists, academics, and food marketers. Inputs are being sought from the consumer research community, with an opportunity to help direct the future of this debate. The goal for this session was to highlight critical research issues, report new empirical evidence, and suggest future research directions.

The Moore and Wilkie paper opened the session with a brief analysis of how consumer research was used in previous FTC efforts to regulate advertising to children. They then discussed emerging research issues, especially re: the changing landscape for marketing to children. To illustrate, the authors presented findings from a content analysis of children's "advergaming" websites. These findings point to a pressing need to further understand children's response capacities and defenses at different ages in new media. Needs for research on children's food consumption choices and behaviors over time were also discussed, and recommendations made as to how this might proceed.

The Desrochers and Holt paper shifted focus to the nature of consumer research evidence needed for public policy decisions. Here major policy proposals to restrict food advertising to children are analyzed. Highlighted were research projects underway and needed to investigate any link between television advertising and obesity. Coverage was then broadened to research needs on the consequences of (and possible alternatives to) an advertising ban, as well as alternative solutions to obesity such as guidelines regarding portion size, and/or comparisons across product classes and nutritional content.

In the third paper, Seiders, Miller, Kenny and Walsh reported findings from an empirical test of a model of children's preventive health behaviors, set within a health education intervention being implemented in nine urban, racially and ethnically diverse elementary schools. Outcome measures linked to children's food choices, decisions about nutrition, and physical activity were reported. Both individual level characteristics and environmental factors were assessed. These environmental factors have not previously been studied, and are a key issue given the extensive market distribution of certain foods. The authors' findings provide new insights into the determinants of children's health decisions, the impact of environmental influences, and the drivers of childhood obesity.

Jerome Williams, University of Texas, served as the discussion leader for the session. He is a member of the Institute of Medicine (IOM) committee charged by Congress to investigate the effects of food marketing on children's diets. In discussion he provided attendees with useful insights into dimensions of the policymaking process in this area.

"Consumer Research Inputs to Public Policy: The Case of Children's Obesity"

Elizabeth S. Moore, University of Notre Dame

William L. Wilkie, University of Notre Dame

The disturbing trend of a steady and alarming increase in obesity among the nation's youth has captured the attention of a broad set of citizens and institutions, with calls for action becoming increasingly powerful. Public policymakers are considering various alternatives. Marketing and advertising are being questioned, and inputs are sought from the consumer research community. This paper provides an analysis of key issues for those interested in contributing to this research. It first offers an historical analysis of previous public policy efforts to regulate advertising to children, followed by current assessment of consumer research needs, challenges, and opportunities.

Lessons Learned from FTC's Earlier Effort to Ban Advertising to Children

Concern with children as a vulnerable group has been longstanding, with many societal protections afforded by law. A number of issues involving marketing to children are as yet unresolved, however. The most notable previous undertaking occurred in the late 1970's when the Federal Trade Commission (FTC), in response to petitions from citizen groups, undertook Trade Regulation Rulemaking to investigate possible new rules for advertising to children. Emphasis was on sugared products, dental caries, and nutrition (not substantially distinct from today's concern with obesity). A range of rules were considered, ranging from required ad disclosures to an outright ban of all television advertising to younger children.

Given the legal setting, FTC and industry had considerable interest in receiving evidence and insights from consumer researchers. In this section of the paper some of the key children's research contributions are summarized, as are key research questions that emerged in retrospect (e.g., "Does children's exposure to TV commercials assist or suppress their use of a healthy/unhealthy dimension in food choices?" or "'What possible roles and approaches are there for effective consumer education for children?"). These are likely to prove useful in informing today's debates as well.

Finally, the public policy outcome (FTC terminated the proceeding) and reasons for it are briefly described. It is pointed out that this outcome left the debated issues in this area unresolved for the ensuing thirty years: many of these same issues are arising today on childhood obesity.

Current Research Needs, Challenges, and Opportunities

The second, longer section of the paper turns to the current concern with children's obesity. In a major public policy initiative, the U.S. Congress recently issued a mandate to the Institute of Medicine of the National Academies of Science—to thoroughly investigate this problem and provide a set of recommendations for action. The first author of this paper served as an invited expert from marketing academia to present consumer research-based insights at the Institute's special workshop. This section extends that work in offering key considerations for consumer researchers.

A primary target for public policy today is, as earlier, television advertising to children. However, today's nature and scope of marketing to children is much broader than this. Consider, for example, other areas likely to be related to obesity, including easy product availability (distribution, display, and convenience), product innovation, and appeals to taste, price, and quantity. Also, integrated marketing communications programs now need to be incorporated into our analysis of advertising itself. Finally, children today are exposed to a fast-changing, interactive media and promotion landscape. For example, new technologies have brought "advergaming" to the fore. Sixty-four percent of children on the Internet play games there (U.S. Department of Education 2003), with many of these featuring brands in fun, involving manners (readers should consult, for example, *Candystand.com*, *Nabiscoworld.com*, *Postopia.com*). Further, 98% of children's websites now permit advertising (Neuborne 2001).

The paper then reports findings from an extensive content analysis of these websites, conducted in cooperation with the Kaiser Family Foundation. Consider how different these exposures are, and how extended they can be (the average Internet visitor spends 26 minutes on a site (Fattah and Paul 2002)). It is clear that our repository of children's research based on 30-second advertising exposures clearly needs to be extended, and that our age conceptualizations of children's response capacities and defenses also needs to be investigated within these new venues. Public policy needs insights here to assist in moving beyond the current preoccupation with television advertising, and consumer researchers can clearly contribute to such broadened understanding.

The paper then points to a need for more research on children's actual food consumption decisions. Here timing is a factor to be investigated, as obesity is obviously the result of numerous behaviors with possibly repetitive patterns (note that much experimental research studies single decision occasions). Consuming in a continuous fashion is important here, as is learning more about how prior product usage impacts subsequent behaviors. Finally, the roles of social factors relating to food consumption, exercise, and nutrition also offer promise. Given that obesity runs in families (as well as subcultures), intergenerational influence research holds considerable potential to contribute new insights and possible directions for ameliorating this growing problem (e.g., Moore, Wilkie, and Lutz 2002).

In summary, the alarming increase in childhood obesity is a powerful societal trend portending dire health consequences for millions of Americans in the years ahead. Consumer research is being called upon. This paper is intended to help to alert our field to the challenge, and to offer positive directions for future research undertakings.

"Researching the Link between Food Advertising & Childhood Obesity"

*Debra M. Desrochers, University of Notre Dame
Debra Holt, Federal Trade Commission¹*

The increasing prevalence of childhood obesity throughout the United States now ranks as a critical health threat (Institute of Medicine 2005). In an effort to combat this threat, several constituencies are calling for restrictions on food marketing, particularly television ads for less nutritious foods that are directed to children. This segment of the special session focused on the past, current, and needed research pertaining to the relationship between the advertising of fast food and childhood obesity.

The first section of the presentation briefly covered the public policy history of television advertising to children, and highlights some recent evidence and concerns that have revitalized the issue. The topic of television advertising to children emerged as an important public policy issue early in the 1970s (Kunkel and Gantz 1992). In response, the Federal Trade Commission (FTC) conducted the Children's Advertising Rulemaking proceeding in 1978 to consider the possibility of restricting television advertising of highly sugared food to children. Several studies prepared at that time provide a baseline for future analysis. The first study was prepared by Howard Beales (1978) (who later became Director of the FTC's Bureau of Consumer Protection) based on local, or spot, advertising, the second by John Abel (1978) based on national advertising, and a third by Richard Adler (1978) based on all programming, supported by a National Science Foundation grant. The conclusions of the rulemaking session were presented (Beales 2004).

Since 1978 there have been significant changes in television viewing. For example, there are now several kid-specific networks competing around the clock (Brown 2004). Meanwhile, more than \$1 billion is spent on media advertising of food and beverages to children that reaches them primarily through television (Institute of Medicine 2005). Consequently, various groups, such as the Center for Science in the Public Interest (CSPI) and the Kaiser Family Foundation, are arguing for a re-examination of this issue by public policymakers.

In response, a recent article reviewed and assessed several research projects and hypotheses on the causes of obesity, children's exposure to food advertising, and the effects of food advertising on consumer choice (Zywicki, Holt, and Ohlhausen 2004). This article determined that, based on publicly available data, it did not appear that children's exposure to food advertising had increased since children's obesity rates began to rise around 1980. However, since there had been no rigorous studies on food advertising exposure since the late 1970s, the question of whether food ad exposure has increased since then remained an open question. Therefore, the FTC began an analysis of comprehensive current data on television advertising. Some of the preliminary findings of this study were presented and compared to findings of the 1977 studies. To complement the FTC study, ideas for future work addressing the link between food marketing and childhood obesity were proposed. Even if a causal link between television advertising and obesity is not established, some groups may argue that restricting food advertising on children's programs would do no harm and might help to protect children. Therefore, it is important to consider another policy related question: what would be the overall impact of marketing restrictions? Several areas of needed research were presented on this topic.

In closing the presentation, several areas of research were listed that would further inform the issue of food marketing and obesity. For example, regarding the issue of television advertising itself, some of these are: (1) the continued investigation of a potential causal link, (2) the impact and effectiveness of integrated marketing communications including television advertising, and (3) how we can use advertising to promote weight loss / healthy diets & lifestyles. In the area of advertising bans, we need more research on the benefits and harms of a ban, and on assessing whether the benefits more than offset the harms. Finally, research is needed to identify other solutions to the obesity problem, such as: (1) increasing the focus on the reduced activity component of obesity, (2) changes to labeling and portion size standards, and (3) healthy lifestyle initiatives.

¹The opinions expressed herein are the authors' alone and do not necessarily represent the views of the FTC or its Commissioners.

**“A Model of Children’s Preventive Health Behavior:
Understanding the Role of Individual, Contextual, and
Attitudinal Determinants”**

Kathleen Seiders, Boston College

Elizabeth G. Miller, Boston College

Maureen E. Kenny, Boston College

Mary E. Walsh, Boston College

In the last three decades, the obesity rate among children 6-11 years of age has tripled; obesity rates are particularly high for subpopulations of minority and economically disadvantaged children (AAP Policy Statement 2004). Obesity in the pediatric age group is associated with significant health problems, including Type 2 diabetes, and is a major risk factor for adult morbidity and mortality (Ogden et al. 2002).

A number of biological, psychological, cultural, and economic factors have been associated with increased childhood obesity. Although it is difficult to show a conclusive link between specific risk factors and population-wide obesity increases, many experts agree that the epidemic is based on availability of energy-dense foods and decreased physical activity (e.g., Andersen et al. 1998). Intervention efforts that aim to reduce childhood obesity typically focus on correcting the energy intake and expenditure imbalance. School-based nutrition and activity interventions are widely advocated because of the high percentage of time children spend in school (Institute of Medicine 2005; Ruiz et al. 2004). However, the effectiveness of school-based programs is debated: most school-based trials designed to promote more healthful lifestyles have produced disappointing results and have not effectively reduced pediatric overweight (Ebbeling, Pawlak, and Ludwig 2002).

A greater understanding of factors that influence children’s health-related decisions could advance the design and delivery of effective nutrition and activity interventions. Although researchers have proposed and tested a variety of models of behavior change related to preventive health measures, these models have rarely been applied to children. Further, knowledge concerning the individual and contextual determinants of childhood obesity, including those related to food marketing impacts, is very limited.

We address these gaps in the literature by examining determinants of children’s decisions about diet, nutrition, and exercise. Drawing on the expanded health belief and other prevention-specific models (Bush and Iannotti 1990; Moorman and Matulich 1993; Rosenstock 1990), we develop and test a model of individual, contextual, and attitudinal influences on children’s preventive health behavior. We examine the model in the context of a health education intervention where objectives include behavioral change with regard to healthful nutrition and beneficial physical activity.

Model Description and Research Approach

The multi-faceted, evidence-based health education curriculum was implemented across nine urban elementary schools. All of the schools are racially and ethnically diverse; the curriculum was delivered to all 4th and 5th grade students (approximately 435) in the nine schools.

Individual level characteristics include basic demographics (sex and age), body mass index (BMI), economic resources, and ethnicity. Environmental factors are geographically-based, related to the neighborhood and community in which the child lives. Relative to neighborhoods, factors include the density of fast food restaurants, the density of full-service supermarkets, and prevalence of parks and other recreational facilities. Early prevention models have not incorporated environmental predictors and individual-environmental interactions, and empirical studies examining the impact of environmental influences are limited (Drewnowski

and Specter 2004). This is an important issue for marketers to address; for example, some researchers believe that nutrition knowledge is less important than the pronounced availability of certain foods (e.g., fast food items and soft drinks) in the environment (Schwartz and Puhl 2003).

The core constructs of our model reflect earlier proposed prevention models, most notably the health belief model. Specifically, we measure locus of control, self-efficacy, health motivation, response efficacy, and perceived health status. Outcome variables include nutrition knowledge, food choices, and physical activity. Food choices include decreased fast food and increased fruits and vegetables consumption. Physical activity measures include increased physical education participation and reduced sedentary activity (e.g., television viewing). The outcome data is self-reported. Some of the multi-item measures have been adapted from studies with adults, but most have been validated in studies with children.

Conclusion

This study contributes to the literature on two major dimensions. First, it tests a model of children’s preventive health behaviors, taking much-needed steps to investigate the complex relationships that affect children’s health-related decisions. Second, it increases our ability to gauge health education’s potential to influence obesity-related preventive behaviors. From a policy perspective, this is important. If educational campaigns consistently show weak results, policy makers are likely to accept more restrictive remedies (e.g., restrictions on advertisements targeted to children; mandatory restaurant labeling; taxes on low-nutritional value foods) in their attempts to blunt the impact of obesity. From a consumer behavior perspective, the increasing purchase autonomy of children underscores the need to better understand their nutrition and activity decisions and choices.

SPECIAL SESSION SUMMARY

Thinking about the Future: Positive and Negative Effects on Consumer Judgment and Well-Being

Cecile Cho, Columbia University
Gergana Yordanova, University of Pittsburgh

SESSION OVERVIEW

Many consumer behavior models have implicitly assumed that consumers are forward-looking and anticipate future outcomes, events, behaviors or feelings before making a decision. The ability to think about future events had been examined extensively in psychology, but has been somewhat disregarded in consumer research. With the exception of literature on reference price and time discounting, consumer researchers are only beginning to recognize the role of forward-looking thoughts and behaviors, such as affective forecasting and construal level theory. This session attempts to bring together psychological and consumer research on future oriented thinking and will help to stimulate greater consumer research on different ways to think about the future and their effects on cognition and behavior.

Not all kinds of thinking about the future are equally beneficial when it comes to motivating people, helping them regulate their behavior or attain satisfaction with their outcomes. The objective of the session is to provide a closer look at different modes of thinking about the future and their impact on subsequent judgment and behavior. We present three papers that examine different forms of thinking about the future—fantasies about future events, anticipation of potential future outcomes, and motivated expectation setting. The first paper in the session will compare the differential effects of fantasies and expectations on effective self-regulation, the second paper will examine the positive effects of pre-decision consideration of potential future outcomes on self-regulation and decision making, and the last paper will talk about the negative effects of motivated expectation setting on satisfaction with an outcome. The three papers together will allow for a lively discussion on the issue of whether future-oriented thinking is always beneficial for judgments and behavior.

The topic of future-oriented thinking and its effects on self-regulation, goal pursuit, and satisfaction holds enormous relevance and significance for the issue of consumer happiness and well-being, and thus is particularly relevant to the conference theme of Transformative Consumer Research. Having two of the leading experts on this topic in the session provides an invaluable opportunity for an interesting and meaningful discussion.

Research on thinking about the future has made an important distinction between imagining different possibilities (e.g., fantasies, prefactual thinking, outcome simulations) and expecting them to occur (e.g., outcome expectancies, elaboration on potential outcomes). Some research on thinking about the future has recognized that different modes of future-oriented thinking differ in terms of their motivating function and the extent of persistence towards a goal, such as weight loss and smoking cessation (Oettingen and Wadden 1991; Oettingen 1996; and Oettingen and Mayer 2002). The first paper in the session, by Oettingen herself, provides the latest research on the differential impact of positive expectation (judging a desired future as likely) and positive fantasies (vicarious ruminations of desired future outcomes). Across domains of health, interpersonal, and achievement domains, she demonstrates that, while both are positively-valenced considerations of the future, they differ widely in their predictive ability of effort and performance. Positive expectations aid in self-regulation, but positive fantasies actually interfere with it.

The second paper by Yordanova, Inman, and Hulland examines the extent to which consumers are forward-looking when making decisions—more specifically the extent to which they think about the consequences of their behaviors. They develop a scale to measure individual's tendencies to elaborate on potential future outcomes and relate the construct to a variety of traits and behaviors. In a series of studies they show that elaboration on potential outcomes is beneficial for consumers' exercising of self-control, overcoming procrastination, compulsive buying, credit card debt, obesity, and promoting a healthy lifestyle. They also relate the trait to information processing and decision making by showing that it predicts the type of pre-decision elaboration consumers engage in and the decisions they make.

The third paper by Cho and Johar focuses on a particular form of forward-looking, strategic thinking in a consumption situation—motivated setting of expectations. Specifically, they focus on the phenomenon of lowering one's expectation so as to ensure satisfaction and to avoid disconfirmation. Under purchase or decision situations involving uncertain outcomes, consumers have been known to lower their expectations so as to avoid negative disconfirmation of their expectation. The satisfaction literature's empirical demonstration that people maintain multiple expectation levels such as "should" and "will" expectations is strongly suggestive of the idea that people lower their expectations in order to assure themselves some degree of satisfaction with the impending outcome. In three studies involving an unfamiliar product domain, the authors find that, contrary to what one intends and anticipates, setting expectation levels low has the unintended consequence of lowering—rather than increasing—one's satisfaction and happiness with the outcome. They further provide evidence that counterfactual thoughts are the process mechanism by which this occurs.

"Motivational Impact of Thinking about the Future: Expectations versus Fantasies"

Gabriele Oettingen, New York University/University of Hamburg

Psychological research in the past decades has conceived of thinking about the future as judgments on how likely it is that certain events or behaviors will occur or not occur in the future. Such expectancy judgments are held to reflect a person's performance history. As past behavior has always been a powerful predictor of future behavior, it comes as no surprise that to this date expectancy judgments have been one of the most important cognitive variables to predict motivation and behavior.

My talk had two parts. First, based on William James's distinction between beliefs and images, I differentiated two forms of thinking about the future, expectancy judgments versus fantasies, and presented a series of studies showing that these two forms of thinking about the future differentially predict motivation and performance (Oettingen & Mayer, 2002).

In these studies, we hypothesized that because high expectations of success are based on successful performances, they signal that future efforts will not be futile. To the contrary, positive fantasies tempt the person to mentally enjoy the desired futures in the present moment, concealing the necessity to still realize them in actuality. Moreover, fantasies about a trouble-free path to success

should hinder planning to prevent potential obstacles and to overcome hindrances. Feeling no necessity to realize the desired events and the lack of preparatory action should compromise motivation and successful performance. In sum, whereas positive expectations should predict high motivation and success, positive fantasies should predict low motivation and success.

A series of studies tested these ideas (Oettingen & Mayer, 2002). We measured expectations and fantasies long before we measured respective effort and success. While positive expectations were precursors of successful recovery, positive fantasies were a hindrance. This pattern of results held for different paradigms, cultures, and life domains, with participants of different ages, and for effort and success measured by subjective and objective criteria. All the studies attest to the problematic consequences of positive fantasies about the future.

However, positive fantasies develop motivationally fruitful consequences when they are turned into binding goals that lead to subsequent goal striving and goal attainment. To turn positive fantasies about the future into binding goals one needs to contrast them with negative reflections on impeding reality (Oettingen, 2000). This conjoint mental elaboration of future and reality makes both cognitively accessible in the sense that the reality stands in the way of the desired future. Thus a necessity to act emerges that activates expectations of success which now guide the forming of goal commitments. To the contrary, when people only indulge in the positive future or only dwell on the negative reality, no necessity to act will emerge and expectations will not guide the formation of goal commitment. It is solely sponsored by the pull effects (indulging) and the push effects (dwelling) of the imagined positive and negative events (summary by Oettingen & Hagenah, 2005).

A series of experimental studies supported these ideas (Oettingen, 2000; Oettingen, Pak, & Schnetter, 2001; Oettingen, Mayer, Thorpe, Janetzke, & Lorenz, in press; summary by Oettingen & Thorpe, in press). We measured expectations of successfully solving an important concern and then had participants mentally contrast their fantasies about solving the concern, indulge in positive fantasies, or dwell on the negative reality. The predicted effects on goal commitment emerged no matter whether we used cognitive, affective, and behavioral indicators, whether goal commitment was measured long-term or short-term, by self-report or objective indicators, whether the studies were conducted in the US or Germany, in the lab or in the field, and whether they pertained to the achievement, interpersonal, or health domains.

In the third part of my talk, I discussed applied implications of the findings. I showed intervention studies showing that mental contrasting make people discriminate in their investments between promising and unpromising projects. In addition, in an intervention that combines the goal setting strategy of mental contrasting and the goal realization strategy of "if-then" planning, 30-50 year old participants improved their health behavior (exercise and healthy diet) over a period of four months (Stadler, Oettingen, & Gollwitzer, 2005). Finally, I presented data showing that individual differences in mental contrasting mediate the classic relationship between responsive parenting style and high academic achievement (Grant, Oettingen, Gollwitzer, & Schneider, 2005).

“Expectations About the Future: Examination of Consumers’ Tendency to Elaborate on Potential Future Outcomes”

Gergana Yordanova, University of Pittsburgh

J. Jefferey Inman, University of Pittsburgh

John Hulland, University of Pittsburgh

It is widely accepted that the extent to which people consider the future consequences of their behaviors can have significant implications for their choices and for their future outcomes. Many psychological theories of motivation have advanced the idea that peoples’ actions are greatly affected by their beliefs about the probable outcomes of those actions. According to these theories, people motivate themselves and guide their actions anticipatorily by the outcomes they expect to result from given courses of behavior (e.g., Bandura 1997). This assumption of forward-looking individuals who evaluate the potential end results of their actions has not been assessed adequately in the literature. In our research we address the issue by examining the extent to which consumers are forward-looking when making decisions, and more specifically the extent to which they think about the consequences of their behaviors.

In the past peoples’ consideration of potential consequences has been studied by clinical psychologists, developmental psychologists, and criminologists. Interestingly, no studies on this topic exist in consumer research. This is surprising given the construct’s potential relationship with a variety of consumer behaviors.

In this research we look at individuals’ tendencies to elaborate on potential future outcomes and relate this tendency to a variety of consumer traits and behaviors. We conceptualize the process of consequences consideration as a construct that encompasses three related dimensions: (1) generation/evaluation dimension-the extent to which people generate potential outcomes and evaluate their importance and likelihood, (2) positive focus dimension-the extent to which they focus on the positive potential outcomes, and (3) negative focus dimension-the extent to which they focus on the negative potential outcomes. In a series of studies (total n=887) we

develop the Elaboration on Potential Outcomes (EPO) scale that assesses all three dimensions of the construct. After establishing the scale's reliability and validity, we conduct several studies that investigate its relationships with various consumer behaviors such as procrastination, compulsive buying, credit card debt, healthy eating, drinking, as well as the type of information processing consumers engage in when making an important consumer decision, and their likelihood to undertake a risky endeavor.

Since EPO is a new construct, we first examine its relationship to various existing traits such as impulsiveness, risk aversion, need for cognition, tendency to focus on long-term versus short-term consequences, optimism, chronic regulatory focus, and defensive pessimism. We conclude that EPO is related to these existing constructs in the expected direction, and is yet clearly discriminated from them.

We next compare the EPO tendencies of different naturally existing groups. We find that defensive pessimists tend to focus more on the negative outcomes and less on the positive outcomes than optimists do; that compulsive buyers consider potential positive and negative consequences to a lesser extent than non-compulsive buyers; and that obese people consider potential positive and negative consequences to a smaller extent than non-obese people.

In a subsequent study we examine the effects of people's tendency to elaborate on the outcomes of their decisions on their information processing and decision making. We find that people who have different tendencies to consider potential outcomes have different information processing patterns and make different decisions. Results revealed that: 1) consistent with their tendency to generate a greater number of consequences, people who score high on the generation/evaluation dimension of the EPO scale consider a greater number of potential outcomes before they make a decision than people who score low on this dimension, and people who score high on the positive (negative) focus dimension, think about more positive (negative) outcomes than people who score low on this dimension; and 2) the more people focus on the positive (negative) outcomes, the more (less) likely they are to engage in consumer behaviors that might result in significant risks and/or benefits.

Next we examine the effect of EPO on consumer self-regulation behaviors. Since self-regulation involves seeing the immediate situation in terms of future concerns, values and goals (Baumeister and Heatherton 1996; Carver and Scheier 1981), effective self-regulation often requires the individual to be able to transcend the immediate situation by considering future consequences and implications. When transcendence is weak and attention is bound to the here and now, the chances of self-regulation failure are increased. Therefore, one proximal cause of self-regulation failure is the failure of transcendence. Baumeister and his colleagues suggest that factors directing attention to future goals and implications will tend to improve the capacity for self-regulation (Baumeister and Heatherton 1996). These may include both situational and dispositional factors. We propose that one dispositional characteristic that is an important determinant of self-regulation is one's tendency to elaborate on potential outcomes.

To examine this issue we administered the EPO scale to 302 adults ranging in age from 20 to 67 years. Furthermore, following Baumeister et al.'s review (1994) of different spheres of self-regulation failure, we included a number of behavioral contexts that reflect behaviors which can result from lack of self-regulation: procrastination, credit card overuse, excessive drinking, unhealthy eating, and avoidance of exercise.

Results from a series of regressions reveal that consumers' tendencies to elaborate on a variety of potential outcomes, as measured by the generation/evaluation dimension of the EPO scale, are negatively and significantly related to the extent to which their

self-regulation fails and they procrastinate, engage in excessive drinking, incur excessive amounts of credit card debt, and fail to consume healthy food and exercise. Furthermore, EPO has predictive ability above and beyond other existing constructs such as trait self-control, impulsiveness, tendency to focus on the immediate versus the long-term consequences, and risk aversion.

"Motivated Expectation Setting and Its Unintended Consequence on Satisfaction"

Cecile Cho, Columbia University
Gita V. Johar, Columbia University

This research posits that consumers actively seek to manage their expectations and examines the consequences of such motivated expectation setting on satisfaction. Faced with uncertain outcomes (e.g., product performance), consumers are motivated to protect themselves from potential disconfirmation of their expectations and the negative affect that accompanies such a disconfirmation. The basic premise of this research is that people try to strategically manage their future affective states through strategic expectation management but that they are not very good at such management. We predict that this is because counter to the initial intention, setting one's expectation low generates counterfactual thoughts of alternative outcomes or courses of action, such that, even upon confirmation of this expectation, one is dissatisfied. This prediction is inconsistent with the premise and the robust empirical findings of the expectancy-disconfirmation paradigm which posits that confirmation of one's expectation (positively-valenced) should at least lead to a moderate amount of satisfaction (Oliver 1997).

Recent research has suggested that faced with an uncertain outcome, consumers deliberately lower their expectation so as to ensure future satisfaction with the outcome. Specifically, Kopalle and Lehmann (2001) find suggestive evidence that people lower their expectations strategically, in anticipation of potential product failure and the accompanying discomfort of having their expectancies disconfirmed. This is consistent with the notion that people maintain multiple expectation levels of a *should* (i.e., desired or deserved) and a *will* (i.e., predicted) expectation (Boulding, Kalra, Staelin and Zeithaml 1993). Kopalle and Lehmann's findings demonstrate that people who are disconfirmation-sensitive are motivated to set their expectations low, in anticipation of the potential for negative disconfirmation.

Given the intuitive appeal of motivated expectation setting, however, little research has looked at whether such forward-looking behavior does indeed lead to satisfaction as one intends and anticipates. Would having one's (lowered) expectation confirmed lead to satisfaction as anticipated? On a more theoretical level, would confirmation of deliberately low level of expectation lead to satisfaction, as predicted by the well-established paradigm of expectancy-disconfirmation theory? Three rounds of studies suggest the opposite—and unintended—consequence of lower satisfaction. This research proposes that lowering one's expectation

triggers counterfactual thoughts of how the outcome “could have been better,” or how one “could have chosen better,” hence creating a subjective gap between the outcome and an imagined alternative outcome. Counterfactual research provides that such counterfactual thoughts of comparing the outcome to a better imagined outcome lead to negative affect and decrease in satisfaction (Roese and Olson 1993, Roese 1997).

In study one, level of expectation and awareness were manipulated to examine the level of satisfaction upon confirmation of one’s expectation. The purchase scenario involved battery rechargers and it was used to manipulate expectation level (your goal is “at least 1,000” vs. “700” charges); respondents were told that battery rechargers in general could handle “up to 1200” recharges. High awareness level was induced by having the participants respond to a 9-point questionnaire regarding their expectation BEFORE the dependent measure, thus strengthening the awareness level, whereas the control group (low awareness group) responded to the expectation questionnaire AFTER the dependent measure. The outcome of product performance was held constant for all conditions (1000 recharges). Dependent measures were 9-point ratings of satisfaction and regret with the purchase decision and purchase process. Results show a cross-over Expectation x Awareness interaction for repurchase intent and likelihood of recommending to others. For those with high expectations, satisfaction was higher when one was highly aware of having set a high expectation, whereas for those with low expectation, satisfaction was significantly lower when one was made aware of having set a low expectation.

Study two provided stronger support for the idea that setting expectation low leads to lower satisfaction. Expectation (high vs. low) and search (high vs. low) were manipulated using a similar purchase scenario involving battery rechargers. Results indicate a main effect of expectation on satisfaction, namely, one’s likelihood of repurchasing the brand. There was also a main effect of search, where those with high search had a significantly lower happiness with the outcome for both high and low expectations, suggesting that people may be satisfied with the process of buying the brand as long as they feel they did not search too much for this.

In study three, expectation and search were manipulated in a similar manner, but using three levels of expectation (high vs. medium vs. low). The main effect of expectation was replicated for outcome satisfaction, repurchase intention and process satisfaction. Furthermore, the high expectation group had a significantly higher emotional satisfaction than medium and low expectation groups. A significant interaction between search process and the level of expectation suggests that the decision process is an additional factor in people’s judgments of satisfaction. Analysis of thought protocols indicate that respondents in the low expectation groups generated significantly greater number of counterfactuals about their initial expectation and the extent of search they undertook.

In summary, the three studies examined the role of expectations, and whether expectancy confirmation does indeed lead to satisfaction. Results show consistently that people’s levels of satisfaction were negatively impacted when they set low expectations. This result would not be consistent with the expectancy-disconfirmation paradigm, which would predict that having one’s expectation confirmed would lead to some basic evaluative state of satisfaction. Furthermore, it is noted that assigning the participants to different expectation levels, rather than inducing them to set the expectation levels, is a more conservative test of the notion that counterfactual thoughts about how one “could have done better” is the underlying mechanism behind the negative impact of motivated expectation setting. Taken together, the three experiments offer encouraging support to the counterintuitive notion that setting one’s expectation low is likely to lead to dissatisfaction, even when

the outcome meets the expectation. This finding suggests that the effects of motivated expectations are not always positive, and contributes to the broader topic on consumer well being.

Consumer Activism on the Internet: The Role of Anti-brand Communities

Candice R. Hollenbeck, University of Georgia

George M. Zinkhan, University of Georgia

ABSTRACT

As a backlash against capitalism, there is a growing resistance to transnational brands and corporate globalization. To cite a few trends, consumers are opposing global brands and expressing concerns about corporate practices related to environmental issues and human rights. The purpose of this study is to investigate the current anti-brand social movement by examining consumer activist groups on the Internet. We identified three anti-brand websites for in-depth analysis: anti-Wal-Mart, anti-McDonald's, and anti-Starbucks. Based on 36 interviews and a two-year examination of anti-brand communities, we provide an understanding of why online anti-brand communities form, we explore the behavioral manifestations of such movements, and we discuss technological influences. The concluding section discusses our findings in terms of implications for theory.

INTRODUCTION AND PURPOSE

Brand names identify, label or symbolize abstract values such as quality, status, or reputation and are a means for differentiating one product, service, manufacture or retailer from another. According to Dobni and Zinkhan (1990) "people buy products or brands for something other than their physical attributes and functions" (p. 110). Fournier (1998b) indicates that people buy brands because they have established loyal, long-term, committed, affect-laden relationships with particular brands. Consumers not only form relationships with their brands, they form relationships with other consumers that have similar brand preferences. This network of consumer relationships is called a brand community or consumption community.

Brand communities are networks of consumer relationships that situate around a commonly used brand. These communities create a sense of belonging among consumers and the brand becomes the central purpose and meaning for group interaction. As "brands attach meaning to a good" (Muniz 1997, p. 308), brands also have potential to symbolize negative perceptions associated with corporations. The antithesis of a brand community is an anti-brand community. In the same way that brand communities are forming around commonly used brands, anti-brand communities are forming around common aversions toward brands.

Similar to descriptions of brand communities (McAlexander et al. 2002; Muniz and O'Guinn 2001), anti-brand communities typically focus on one dominant brand or corporation and are non-geographically bound communities based on a structured set of social relationships. Anti-brand communities could oppose specific brands (e.g., Jeep, Marlboro cigarettes), but could also oppose corporate brands (e.g., Wal-Mart, Procter & Gamble). In this paper, our focus is on the latter.

In anti-brand communities, consumers take on social activists roles by voicing their opposition to corporate domination. Anti-branding demonstrations are emerging as a new form of consumer activism and these activist strategies have received more recognition in recent years as consumer rebellion is viewed as a world-wide social movement (Bourdieu 1998; Dobscha 1998; Fournier 1998a; Holt 2002; Zavestoski 2002). The term social movement refers to "the coming together of relatively large numbers of people around a commonly held set of values or notion of rights (human and/or social) in order to bring about social change" (Dykstra and Law 1994, p. 122). Cohen defines social movements as "normatively

oriented interactions between adversaries with conflicting interpretations and opposed societal models of a shared cultural field" (Cohen 1985, p. 695).

In the twentieth and twenty-first centuries, consumer movements and marketplace rebellions are sometimes labeled as "consumerism." Ralph Nader (1968) defines consumerism as "a term given vogue recently by business spokesmen to describe what they believe is a concerted, disruptive ideology concocted by self-appointed bleeding hearts and politicians who find that it pays off to attack the corporations" (p. 27). More conventionally, consumerism emphasizes a consumer's right for protection against adulterated, deficient, or unsafe products and services. For Buskirk and Rothe (1970) "consumerism is attempting to tell industry something their research has not found, or that management has rejected or ignored" (p. 64). Kotler (1972) defines consumerism as "a social movement seeking to augment the rights and powers of buyers in relation to sellers" (p. 49). According to Kotler, consumerism is enduring and ultimately beneficial for both consumers and businesses. Consumerism mobilizes the energies of consumers, businessmen and government leaders to seek solutions and advance society, and ensures short-term and long-term values for consumers (1972).

Kotler (1972) identified three distinct waves of U.S. consumerism movements in the early 1900s, the mid-1930s, and the mid-1960s. According to Herrmann (1970), these three eras have important common characteristics. First, each movement occurred during economic and social unrest where rising consumer prices accompanied declining incomes. With limited financial power, consumers were forced to protest by joining efforts to voice their rights. Second, consumers began to fight for their own interests since they were hard-pressed by their declining purchasing power.

This paper explores a new, emerging social movement referred to by Holt (2002) as the "anti-brand movement." The anti-brand movement is similar to former social movements but it also has some unique aspects. First, the anti-brand movement represents a confluence of ideas. For example, the issues prominent in the anti-brand movement range from workplace equality and corporate domination to environmentalism and marketing propaganda. Historically, social movements emphasized one prevailing cause (e.g., women's rights, worker's rights, environmentalism) (Boggs 1986, Eyerman and Jamison 1991, Holst 2002). Second, the Internet has changed the way people participate in social action. The Internet has enabled anti-brand communities to proliferate online in unprecedented numbers. With World Wide Web capabilities, action strategies and coalition building are not restricted by space or time (Shepard and Hayduk 2002). These two unique characteristics represent a new kind of movement utilizing different resources and taking on broader goals.

The purpose of this study is to understand the nature of online, anti-brand communities as an emergent social movement. The investigation is guided by three research questions. First, why do online anti-brand communities form? Second, what behavioral manifestations are associated with anti-brand community involvement? Third, in what ways are emerging technologies influencing and interacting with consumer activist strategies? To begin, we offer a brief discussion of the anti-brand movement. Then, we present our findings based on 36 in-depth interviews and a two-year examination of anti-brand websites. In conclusion, we relate our

findings to the current consumer behavior literature and discuss implications for theory.

THE ANTI-BRAND MOVEMENT

Historically social movements have emerged in a geographical pattern, revolving around physical gathering spaces. Today social movements are transpiring in virtual space, which sets the stage for new forms of protest, organization, cooperation, and coalition-building. The Internet plays a major role in the anti-brand movement because it provides communication methods for people around the globe irrespective of geographical space and/or time zones.

In most cases, anti-brand communities originate and communicate solely in cyberspace. This virtual community is built around common social and political interests. Communities form online because people are able to come together, regardless of geographical proximity, and identify with a common need, goal, or identity. The community is situated around common detestations of corporate brand names. Various consumer groups form to support each other in their efforts to resist marketplace practices and globalized consumption patterns.

Traditionally, the interactions between marketer and consumer are viewed as an exchange-based relationship ascribing mutual benefits to one another (Kotler 1986). The brand serves as a conduit for marketers to provide consumers with identities that satisfy their needs, wants, and desires (Zinkhan and Martin 1987). The consumer purchases the branded good and is fulfilled. The collective actions of both consumers and marketers are thought to bring about balance in the marketplace by producing a dynamic dialectical relationship (Holt 2002). Although marketers may strive for a balanced relationship, there is a movement of consumers who engage in social action and argue against the imbalances of power in a profit-driven marketplace consisting of large, global corporations (Ozanne and Murray 1995). In the twenty-first century, many consumers view corporations as dominating and oppressive by means of imbalanced distribution systems or deceitful marketing tactics (Dobscha 1998). In an era marked by rapid globalization, corporations are perceived by some as using sophisticated promotional techniques to attach world-wide meanings to their brands. Consumers who internalize these meanings implicitly grant corporations the cultural authority to dictate their values, tastes, and preferences (Firat and Venkatesh 1995; Ozanne and Murray 1995). Anti-brand communities consist of consumer groups resisting imposed meanings or values that are prescribed by a brand. In this way, the brand name serves as a negative symbolization by representing corporation domination.

METHOD

This study resulted in a two-year examination of consumer activists who participate in online anti-brand communities and self-identify as social activists. An initial investigation identified 104 anti-brand web communities. Web community characteristics were compiled indicating the number of active anti-brand members, the shared values within the community, common goals, and action strategies. From this list, three community cases were chosen for in-depth analysis using three selection criteria. First, the researchers selected communities that oppose popular, transnational brand names. Second, we identified online communities that had been in existence for more than ten years. Lastly, active communities with the highest number of regular participating members (e.g., daily interactions) were studied which ensured information-rich cases. Using this criterion, three online anti-brand communities were identified for further analysis: anti-Starbucks, anti-Wal-Mart, and anti-McDonald's.

Data were collected through 36 in-depth interviews with an equal number of participants from each community. In addition, online documents (e.g., chat logs, web pages, email transcripts) from the three web communities were analyzed for the following: (1) the content of conversation, (2) the promoted and dissuaded products/services, (3) the number of people discussing topics synchronously and asynchronously, (4) activities/events being arranged or protested, (5) formal and informal patterns of communication, (6) website graphics and pictures, and (7) symbolic or connotative meanings of words posted on the site and/or used in conversations. Using a constant comparative method of data analysis, individual case and cross-case analyses were conducted. Descriptions of interactions among consumer activists as well as quotes, documents, and artifacts were examined to provide a holistic description of each case. This descriptive data was used to establish common traits or themes across the three cases.

FINDINGS

Data analysis revealed four distinct reasons why anti-brand communities form: 1) to provide a social community comprised of members with common moral obligations, 2) to provide a support network to achieve common goals, 3) to provide a way of coping with workplace difficulties, and 4) to provide a resource hub for taking action. Behavioral manifestations include: 1) publicizing marketplace inequalities (e.g., unethical marketing tactics, unethical corporate actions), 2) informing fellow members about the rewards associated with a restrictive lifestyle (e.g., voluntary simplicity), and 3) constructing a new collective identity (e.g., in opposition to prefabricated marketplace identities). Technological advances provided by the Internet such as speed, convenience, anonymity, and virtual formation are enhancing consumer activist strategies.

Why Anti-brand Communities Form

Common Moral Obligations. The most salient reason why anti-brand communities form is to provide a social community comprised of members with common moral obligations. Moral responsibility is a sense of obligation to the betterment of society (Muniz and O'Guinn 2001). Community members collectively articulate matters of right and wrong with regard to corporate actions. Within each of the three anti-brand groups studied, a common entity (i.e., Starbucks, Wal-Mart, McDonald's) challenged community members' worldview of how a corporation should function. In response, moral systems are challenged and community members feel a common call to action. During interviews with anti-brand community members, words such as "oppressive," "exploiting," "destructive," "unethical" and "monopolizing" were used to describe the corporations they were fighting against. All 36 participants in this study talked about a personal commitment to fight against a corporation.

I cannot ignore what this corporation is doing to our environment, our children, and our future. I have to be an activist because I would feel guilty otherwise. (Betsy, anti-McDonald's)

It is up to us as citizens to join together to fight these bullies. (Mel, anti-Wal-Mart)

It is up to me to make a change. I know that my efforts are not in vain because every single thing I do will matter in the end. That is why we have to join together to become stronger. (John, anti-Starbucks)

I made the decision to give my time to this cause because I felt like it was important to me and my future. Joining with other people only makes it better. (Judy, anti-Wal-Mart)

At some point in time, our participants made a conscious decision to play an active role in their anti-brand campaign. Each participant decided that it was his or her responsibility to make a change. This moral consciousness compels them to bond with other community members in an effort to improve society.

Support Networks. Another prominent reason anti-brand communities form is to provide a support group to achieve common goals. It was evident, from the onset of this investigation, that a social support network existed within all three communities. Through nurturing social interactions via the Internet, each community resembled a support group, which also served to legitimize their fight for a common cause. These support networks have three common characteristics. They are based on a reciprocal exchange, they mimic a family structure, and they are purposive.

Anti-brand members are involved in a reciprocal exchange partnership with other community members because relationships are based on an exchange of ideas, advice, and support. Discussion boards, chat rooms, and blogs serve as a dynamic form of relationship building where the exchange of ideas mutually fulfills the social needs of community members. Relationships within the community are interdependent, meaning community members depend on each other to accomplish tasks for their common cause.

I connect with other anti-Starbucks people online. We rely on each other for support because as you know, most people I talk to on the street are infatuated with Starbucks. (Greg, anti-Starbucks)

We give advice and support to each other and that is the how we stay committed to our cause. (Freda, anti-McDonald's)

We rely on each other to get our message across. It is not just one person making a change, it is all of us working together to change our environment. (Betsy, anti-McDonald's)

I would not know what to do if it were not for this website. It helps me to know that I am not the only one fighting for my rights. (Casey, anti-McDonald's)

When asked to describe their anti-brand community, participants used similar terms such as "family," "friends," and "support" when telling stories about their website communities. Anti-brand communities provide the supportive, family-like environment necessary to achieve common goals. Community members teach, guide, and support one another in their common endeavors, developing relationships that resemble close friendships rather than mere acquaintances.

The relationships cultivated among community members are purposive in that they stimulate confidence through camaraderie. The confidence it provides individual members serves to be useful in accomplishing common goals; however, this camaraderie is not a result of planning. Camaraderie results from the group's coming together and uniting through their common needs, goals, and priorities.

This website gives me confidence to stand up for my beliefs. I know that I am supported by my online friends and that gives me the motivation I need to take a stand. (Michelle, anti-Starbucks)

I would not have the confidence to take on this multi-billion dollar company without the support from this website. They have become like part of my family. (Tom, anti-Wal-Mart).

Through continuous interactions, community members begin to develop a supportive and purposive social network that provides a framework for better understanding the world in which they live.

Workplace Challenges. Coping with difficulties at work is a major motivation for one-third of the participants in our study, who are current or previous employees of the company they oppose. Through pep-talks, sympathy, and personal counsel, community members strategize together about how to overcome challenging workplace issues such as demanding schedules, unfair pay, unsympathetic managers, or rude customers. In addition, the web community provides a social structure that is not provided at work, offering individual self-assurance and support. When corporations lack a supportive environment, findings suggest that employees search for and find solace from website communities.

Sometimes we need someone that is going to tell us the truth and someone that I can trust and that is what I find online. (Freda, anti-McDonald's)

Whenever I need something I just go to the website and ask somebody that has already been there and done that...there's always somebody that can give you advice for almost any situation that comes up. (Amy, anti-Starbucks)

Community members collectively create an environment where participants can be open and honest with one another. Employees search for answers in how to alleviate the stress of workplace challenges. Likewise, employees receive ad hoc solutions to problems at work. When employees do not receive support or guidance in the workplace, direction is sought from online community members. These negative workplace stories inherently influence other community members, adding reason to their cause.

Resource Hub. Sharing resources is an important means for creating and maintaining a community. For instance, the anti-Starbucks website was created to publicize Starbucks' unethical practices. Six months later, the website transformed into a central location for information sharing. With respect to Wal-Mart, the Internet served as a more efficient and effective means for reaching people and providing them with information (e.g., to resist expansion of new stores). Over time, the website became a locus for accumulating knowledge and building coalitions. The anti-McDonald's website was created to educate people about the McLibel court case (a trial that took place in Britain in response to a defamatory leaflet). By utilizing the Internet, the fight against McDonald's transformed from a localized campaign (e.g., one country) to a global campaign (e.g., 150 countries). In all three cases, the website was created to inform others by providing resources for getting involved or taking action.

Behavioral Manifestations

Publicizing Marketplace Inequities. Community members critique corporate actions and try to correct imbalances in the marketplace. Some community members believe that twenty-first century corporations adversely affect society, and they strive to create a new paradigm. For example, members of the anti-Wal-Mart community contend that mega stores use a type of "sprawl-math" to persuade small towns to entrust development to Wal-Mart. Community members remind one another that small towns do not prosper when large corporations dominate local communities, and they emphasize job losses and environmental degradation.

Companies like Wal-Mart and Home Depot utilize a form of “sprawl-math”, which only looks at gross impacts on a community—never of the net effect of their stores. Sprawl-Math is not taught in local school systems. It’s a form of developer’s calculator that had no minus pad to subtract out jobs lost, or revenues diverted. The real truth about Wal-Mart and Home Depot, and the rest of the sprawl-mathematicians, is that they represent a form of economic displacement, not economic development. (Al, anti-Wal-Mart)

Anti-brand communities create a virtual reality that fosters utopian thinking. These communities are visionary, creating ideal social and political schemes. The interactions among community members are based upon visionary ideals of urban planning, activist projects, and controlled consumption lifestyles.

We offer a place where people can come together and be valued for who they are and not what they own. I feel like our online community is a place of equality and true democracy. (Dave, anti-McDonald’s)

When we meet online, it almost feels like we are escaping our surrounding environment. So many people that I talk with think that Wal-Mart is great and I can’t understand why. They all want the lowest prices they can find. Yet they complain about outsourcing! I want to scream at them, ‘don’t you know that you are the cause of outsourcing!’ (Tom, anti-Wal-Mart)

We focus on developing ideal communities that are not cluttered with urban sprawl. (Marie, anti-Wal-Mart)

I hate my job and I am just sticking with it to finish school. Finding this online group helps me to tolerate my job and my nagging boss. I go online sometimes during my break and it helps me forget about the fact that I have to work four more hours. (Greg, anti-Starbucks)

The following is a quote from the anti-McDonald’s website illustrating one member’s critique of capitalism. The community member suggests that consumers are drawn into an endless and meaningless cycle of consumption. People are assigned roles and stereotypes that diminish independence.

From the day we’re born, until the day we die, we are expected to believe that money makes the world go round. We are meant to trust the authorities and experts who tell us that they have everything under control. Our lives are determined and exploited by the perceived need for money and status; dominated by the power and influence of companies, bureaucracies and laws to keep us in our place; marginalized by a traffic system based on cars and concrete; swamped by the mass media; and controlled and affected by all manner of remote institutions and decisions. In fact, people barely get a look in—they are just expected to go along with their set roles as obedient workers, dependant consumers and occasional passive voters. Such is the reality of capitalism and centralized government. At least we have each other. We provide our own escape from this subjugated world. (James, anti-McDonald’s)

Members believe that contemporary consumption practices distort reality, and consumers unconsciously participate in a consumer culture that automatically assigns roles and images that are subservient to corporations. In an effort to overcome cultural influences,

community members publicize that consumerism cannot always provide what it promises. In doing this, members create a utopian community.

Instructing Members in the Rewards of Voluntary Simplicity. Voluntary simplicity encourages freedom and expression based on individual choice. By choice, consumers design their own lifestyles (in opposition to lifestyles driven by consumption trends). Anti-brand websites provide an informal setting where community members teach each other how to engage in voluntary simplicity. Voluntary simplicity is “the degree to which an individual selects a lifestyle intended to maximize his/her direct control over daily activities” (Leonard-Barton 1981, p.244).

In this study, online discussions typically focused on common desires to limit consumption. Members instructed one another to avoid societal pressures, indulgences in materialism and unhealthy practices. Following is an excerpt from the anti-McDonald’s community conveying one member’s desire for simplicity.

McDonald’s promote their food as “nutritious”, but the reality is that it is junk food—high in fat, sugar, and salt, and low in fiber and vitamins. A diet of this type is linked with a greater risk of heart disease, cancer, diabetes and other diseases. Their food also contains many chemical additives, some of which may cause ill-health, and hyperactivity in children. Don’t forget too that meat is the cause of the majority of food poisoning incidents. In 1991 McDonald’s was responsible for an outbreak of food poisoning in the UK, in which people suffered serious kidney failure. With modern intensive farming methods, other diseases—linked to chemical residues or unnatural practices—have become a danger for people too. We need to rid ourselves of these unhealthy substances. Life is simplified when we take the time to take care of ourselves. What ever happen to whole grains and vegetables? We need to go back to the simple things that will make our lives last longer. (Betsy, anti-McDonald’s)

The website acts as a gathering place for individuals to become and feel authentic. Through a process of advising and counseling one another, community members engage in a course of self-improvement and self-purification. In this next illustration, another anti-McDonald’s member joins the online discussion about eliminating unhealthy foods. She explains how she acquiesced to eating foods that were high in fat. She finally took control of her own life by decoding marketing messages.

I lost 20 pounds by giving up all fast food, soda and candy. It sounds so simple and it is! Do I regret it? Not one bit! The USA is the largest fat country in the world. Gee, I wonder why? McDonald’s food is not only fattening, but the burgers have no doubt been frozen in the back of the store for a long time, and the only thing they do to the fries is take them out of the freezer and oil them. Tempting right? Well, I believe if we had healthier options maybe America would be thinner. I mean I was just following the crowd and doing whatever the media told me to do. Every time I turned on the television or radio I was bombarded with another fast food commercial. When I got hungry, the first thing I would think about eating is some fast food burger that I saw on a commercial. I was in this never ending cycle of consuming food that was giving me heart disease, high cholesterol, and obesity. I was being controlled by the mass media and told what I should and should not eat. Finally, I decided that I was not going to be controlled anymore. We’re told everyday that fast food tastes better than

healthier foods, and in reality healthy foods taste better and make us feel better. If you are thinking about giving up unhealthy foods—just do it. It is a simple way to improve your life and the rewards will pay off! (Margy, anti-McDonald's)

Anti-brand communities provide a supportive, family-like environment where voluntary simplicity is encouraged. Community members teach, guide, and support one another in their common endeavors, developing relationships that resemble close friendships. The common quest for a purified or simplified lifestyle bonds community members together and provides the motivation for achieving personal goals.

Constructing a New Collective Identity. Community members join in a collective process of identification. Along with evaluating society as a whole and seeking for ways to improve it, participants unite in a renewal of the self. This self-improvement venture is a group-driven process where the community becomes a catalyst for individual transformation.

I used to view myself as a McDonald's junkie, but then I realized how bad it was for my health. I was overweight and depressed and I finally decided that I was not going to do this anymore. The people I have met on the website have helped me with my new perspective. I feel better and I am losing weight...and I usually turn off the TV or turn the radio when I hear fast-food commercials. (James, anti-McDonald's)

Since I met other people who believe in the same things I do, I feel more confident. I know that I am not the only one out there who cares about society and wants to make a difference. (Judy, anti-Wal-Mart)

Anti-brand communities provide new identities and provide resources for constructing a desired self-image. For instance, community members strive to increase individual autonomy and enhance confidence in marketplace decision-making. Community members believe that individual purchases provide a means for exercising power by supporting or condemning corporate actions.

I have gained a lot of confidence in my shopping decisions since I started participating online. I feel like I am in control of what I buy. Instead of just shopping for bargains, I shop to support certain companies and that makes me feel good. (Judy, anti-Wal-Mart)

I felt like crap when my manager would talk down to me. I always felt like such a loser. But this group has helped me to see that I am not defined by where I work. Just because I work somewhere doesn't mean that I agree with their work ethics. I can't wait to get a new job. For now I'm just gonna keep believing in myself because I know that I have higher values than the company I work for. (John, anti-Starbucks)

Collective identity plays a central role in consumer activism and the group's vision of consumer justice. Shared meanings are constructed by the group, and the effort to overcome corporate influences is a group process.

Role of the Internet

The Internet serves as an innovative means for building coalition. Communities that situate in virtual contexts are more flexible and durable than physically situated communities because there is an ongoing availability of resources and a continuous

process of multileveled communication. The virtual space allows for fusion of various conversations, the linking of conversations across Web sites, and the archiving of discussions and other types of information for future reference (Shumar and Renninger 2002). Online anti-brand communities are built upon virtual social interaction and even though they are not geographically united, these groups still manifest common characteristics of community such as reliance upon one another (Selznick 1992), joint decision making (Wellman 1979), social identification (Tonnie 1887), standardized procedures for socializing and communication (Boissevain 1974), and commitments to each other and the group (Bender 1978). Just as in other human endeavors, the Internet provides a means to enhance speed, convenience, anonymity, and formation of anti-brand communities.

Speed. The Internet is radically shaping action strategies by expediting consumer activism endeavors. Speed significantly advances the abilities of consumer activist groups in terms of efficiency and effectiveness. For example, the anti-Wal-Mart community once relied on communication via a community newsletter which was sent out monthly. Now, the Internet provides a more efficient and effective means for information sharing. When events occur, community members can be updated instantly. Community members no longer need to rely on traditional forms of media (i.e., newsletters, newspaper, television) to communicate to large numbers of people. Instead, members are able to log on to the community website any time of day to get the most current updates. The online medium maximizes the potential for consumer activism because it is conducive to the world in which people live.

Convenience. The Internet enhances consumer activist strategies by making participation, information-sharing, and identification of social groups more convenient. Anti-brand members in this study participated in community activities on the job, on vacation, at home, or on the road. One member in the anti-McDonald's community participated in online discussions while commuting back and forth to work on the train. This was the only free-time available to participate in community discussions. The activities of everyday life in the twenty-first century are inherently dependent upon technology and accordingly, consumer activism is becoming more virtual. For most participants in this study, communication between members took place solely online. In other words, there is rarely an exchange of phone numbers or street addresses. Online social action communities are outgrowths of a society intertwined with technology. These new forms of social action are capable of influencing large numbers of people, developing skills to bring about social change, and making changes fast.

Community Formation. The Internet enhances the diversity of consumer activist groups. Historically, social movements formed around visible commonalities (e.g., age, race, nationality, sexual orientation); however, the anti-brand movement emphasizes inconspicuous commonalities. Members are evaluated on the basis of their contribution to the community.

I don't really care who participates in our group discussions. The only thing that I care about is their contribution. I believe it is important to value differences because we usually all have valid points. (Betsy, anti-McDonald's)

I have more culturally diverse friends online than I do in person. I feel like the Internet breaks down the barriers to building friendships because you value people for who they really are and not for how much money they have, what they look like, or where they come from. (Mel, anti-Wal-Mart)

Common interests and values are the bonding criteria for virtual activist groups. Diversity is an advantage to modern social movements because it stimulates “thinking outside the box,” and diverse viewpoints facilitate creative and unique action strategies.

Anonymity. The Web offers many ways for masking identities. For several of the participants in this study, anonymous involvement influenced their decision to become “active members.” For some social activists, the extent of anonymity determines the extent of participation. One result may be that individuals are more willing to participate in immoral or unethical actions.

Because no one really knows who I am, I feel like I can be a little more risky in my actions. Virtual social action is great because I can do things I normally wouldn't do in-person. (Tom, anti-Wal-Mart)

I could not participate in protests in-person because I'm an employee. But, I can participate as much as I want online because no one will ever know. I've donated over 100 dollars this year to the campaign. (Lucy, anti-Starbucks)

I like the fact that no one knows who I am. I feel like I can say whatever I want. I don't hold anything back. (Dave, anti-McDonald's)

Through masking identities, consumers are able to oppose major corporations with minimal threat of peer disapproval, employee termination, or legal ramifications. Technology is fundamentally enhancing social action strategies and coalition efforts.

DISCUSSION

This study underscores both negative and positive aspects of anti-brand communities in relation to the opposed firm. From a negative viewpoint, participation in anti-brand communities does not require much time or energy. As a result, these communities serve as a powerful consumer agency and information resource. Consumers have instant access to an empathizing audience and to historical accounts of accusations against the firm. These communities also provide social benefits as the Internet enables one consumer to connect with a group of other likeminded consumers. Their common negative stance against the firm unifies members, and as a community, the group has more marketplace power. The Internet enhances marketplace power by providing members with a speedy, convenient, and anonymous means of communication. With easy access and widespread communication, anti-brand communities have the ability to damage a firm's brand name.

Positive aspects of anti-brand communities for firms include the notion that these communities serve as a means for rejuvenating business functions. As has been argued in other anti-branding contexts (Holt 2002), this study makes a strong case for using these communities as “grist for the branding mill that is ever in search of new cultural materials” (p. 88). The Internet provides an open forum for discussion about branding activities and it also serves as a free marketing research tool. Communities of this nature can incite firms to recognize innovative branding opportunities and Wal-Mart is a company that is putting this idea into practice. For example, Wal-Mart counteracts resistance by demonstrating its dedication to local communities during store-opening ceremonies. As a creative means for building customer relationships, Wal-Mart invites the community to a grand opening that centers around personal testimonies from employees and retirees, greetings from local officials, and the giving away of prizes.

The opening festival is a preemptive defense against opposition. To name a few tactics, devotion to the country is represented

by the flag and by singing the national anthem. The county is represented by county commissioners. Religious interests are signified by an invocation at the opening of the ceremony. Schools are represented by members of the school board and grants are given to local community organizations during the ceremony. This community-building strategy is aimed at winning the trust of local consumers and reversing the claims of anti-Wal-Mart groups. Consumer activism has traditionally been viewed as a natural occurrence in society which provides opportunities to improve business functions (Buskirk and Rothe 1970; Herrmann 1970; Kotler 1972), and this is a prime example.

CONCLUSION

This study provides important insights about anti-brand communities and advances prior research in two primary ways: (1) it sheds light on the role of community when interpreting anti-brand motivations and behaviors; and (2) it focuses on anti-brand communities as a social movement with Internet capabilities. Web-communities provide a place for anti-brand consumers to gather and discuss marketplace practices and these groups inevitably influence consumption. The community reinforces negativity toward the brand and influences a member's attitude and/or decision to take action against a corporation. This research establishes the relevancy of the role online communities play in present social action endeavors and, with Internet capabilities, these communities are more powerful (e.g., number of participants) and progressive (e.g., technology-driven action strategies) than earlier social movements.

Brand Community Under Fire: The Role of Social Environments for the HUMMER Brand Community

Marius K. Luedicke, York University

ABSTRACT

This research was undertaken as part of a larger consumer behavior research project investigating brands and brand communities as social systems. The paper is concerned with the particular role of social environments for brand communities previously neglected in literature. Grounded in a social-constructivist interpretive framework, a multi-perspective study was conducted to explore how the HUMMER brand community and its social environments discursively construct, situate, and legitimate one another. Findings reveal brand communities as powerful, socially embedded phenomena that continuously negotiate a set of core distinctions with and against their social environments.

INTRODUCTION

Brand communities have become powerful socio-economic phenomena and are as such of great interest for the study of marketplace cultures in consumer culture theory (Arnould and Thompson 2005). A brand community is a “specialized, non-geographically bound community, [that is] based on a structured set of social relations among admirers of a brand” (Muñiz and O’Guinn 2001, p. 412). Prior studies portray these specialized communities and akin subcultures of consumption as true social phenomena that share values, cultivate communal rituals and traditions, and care for community members (Arnould and Price 1993; Caldwell and Henry 2004; Kozinets 1997; McAlexander, Schouten and Koenig 2002; Muñiz and O’Guinn 2001; Schouten and McAlexander 1995).

Yet even though numerous leading brands have become the focal point for passionate disputes among admirers and opponents (Buechler 1995; Giesler and Pohlmann 2003; Handelman 1999; Klein 1999; Kozinets and Handelman 2004), consumer culture theory has remained surprisingly silent about the impacts and potentials of committed social environments for brand communities. By conceptualizing, for instance, oppositional brand loyalty as the single internal process that explicitly involves an (economic) environment, Muñiz and O’Guinn (2001), among other authors, largely underestimate the importance of pro- and antagonistic societal counterparts for the successful perpetuation of brand communities. To better understand the empirical relevance of reactive social environments for the emergence, proliferation, and dissolution of brand communities, consumer researchers need to move beyond the theoretical constraints of single-sided brand community investigations.

Drawing from a multi-perspective interpretive study of the HUMMER brand community (HBC)¹ and its relevant social context, this paper explores how a brand community and its environments discursively construct, situate, and legitimate one another. The HBC offers an ideal context of study as the presence of the massive, military-style sport utility vehicles provokes extreme, even violent pro- and antagonistic responses.

The study begins with a review of existing brand community theory. Then, a conceptual framework is introduced that allows for observing brand communities as distinctive, dependent, and ephem-

eral social systems. Subsequently, attention is focused on the community’s particular means of distinction, reproduction, and reflection. The paper concludes with discussing the implications of the findings for brand community and consumer culture theory.

THEORY

This study builds upon two ongoing scholarly discourses: Market Cultures Theory on brand communities and European Social-Constructivist Systems Theory, the tenets of which shall be briefly reviewed.

Prior Research

A “brand community” as introduced by Muñiz and O’Guinn (2001) is understood as a “specialized, non-geographically bound community, [that is] based on a structured set of social relations among admirers of a brand” (p. 412). Consumer researchers have investigated the idiosyncrasies of these specialized communities and akin subcultures of consumption in the contexts of vehicles (McAlexander et al. 2002), motorcycles (Schouten and McAlexander 1995), computers (Muñiz and Schau 2005), celebrities (Caldwell and Henry 2004), sports teams (Holt 1995), television shows (Kozinets 1997), or temporal servicescapes (Arnould and Price 1993; Peñaloza 2001). Findings reveal that communities around products and services entail various advantages for individual identity projects (Belk 1988; Elliott and Wattanasuwan 1998; Holt 2002), such as social distinctiveness (Schouten and McAlexander 1995), room for social refuge (Kozinets 2001), meaning and spiritualism (Muñiz and Schau 2005; Schouten and McAlexander 1995), and opportunities for strengthening family ties (Arnould and Price 1993). Muñiz and O’Guinn (2001) offer three markers for structuring the analysis of these particular social relations. Consciousness of kind (Gusfield 1975) embraces intrinsic connections felt among members (Tönnies 1957; Weber 1922) and a “collective sense of difference from others not in the community” (Muñiz and O’Guinn 2001, p. 413). The notion comprises oppositional brand loyalty (Muñiz and O’Guinn 2001), which elicits the value of threatening economic competition for community coherence. Rituals and traditions “perpetuate the community’s shared history, culture, and consciousness” (p. 413) through celebrations of the brand’s history, sharing of stories, and symbolic behaviors (McCracken 1986). Both consciousness of kind and sense of belonging inspire among members the third marker, introduced as “sense of duty or obligation to the community as a whole, and to its individual members” (Muñiz and O’Guinn 2001, p. 413).

The importance for understanding internal brand community processes not-withstanding, the “core community communalities” (p. 413) provide a single-sided and thus incomplete picture of the brand community. Considering the efforts of certain brand communities to differentiate and the empirical presence against them, it is surprising that the particularities of these structural interdependencies between brand communities and their social environments have received so little attention.

Conceptual Framework

In line with the social-constructivist epistemological tradition in consumer research (cf. Belk 1988; Bonsu, Belk, Mick et al. 2003;

¹HUMMER, HUMMER H1, and HUMMER H2 are registered trademarks of the General Motors Corporation (GM).

Brown 1993; Firat and Venkatesh 1995; Giesler and Venkatesh 2005; Hellmann 2003), systems theoreticians accept that there is no way of creating knowledge other than drawing distinctions (cf. von Foerster 1979). Knowledge is consequently understood as a result of social construction rather than of positive discovery (Varela 1979). Within this epistemology, brands are conceived of as social systems that reproduce their underlying economic, aesthetic, political, and social distinctions through continuous communications (Giesler 2003). Framing not only brands but also brand communities as ongoing communications, or discourses in the sense of Foucault (1972), which establish and maintain the social distinctiveness of admirers of a brand, entails a departure from the core community communalities in three key aspects. First, the discovery of communalities is replaced by the identification of bivalent distinctions (Baecker 2001). The prism of distinctions encourages investigations from multiple perspectives and thus allows for comparing inside and outside constructions of meaning. Second, the existence of shared meaning and brand identification as imperatives for community proliferation falls prey to the necessity of ongoing discourses. Thus, quantity and quality of communicative contributions rather than institutional membership or attitudes determine membership and the survival of the community (cf. Luhmann 1995). Third, the initial assumption of community stability (Berger and Luckmann 1966; Kates 2004) is replaced by presumed instability (Holt 1997). Due to human obliviousness (Glaserfeld 2003), social communities are considered to be dependent upon ongoing communicative reproduction rather than being generally persistent. This conceptual framework provides a preliminary understanding of brand communities as distinctive, dynamic, socially embedded phenomena and thus extends the communalities framework towards the social environments.

METHOD

This paper provides a multi-perspective account of the HUMMER brand community and its relevant social environments by using an effective combination of phenomenological interviews (Thompson 1997), netnographic data (Kozinets 2002), and historical artifacts. The HUMMER vehicles inspire unprecedented amounts of both admiration and opposition among the North American public. As a true “brand community under fire” the HBC does not only attract public interest and sympathy, but also frequent accusations, aggressions, and affronts.²

To obtain an overview over central discourses around, and key contributors to the HBC, the Internet was searched for relevant netnographic data such as HUMMER fan- and hate-pages, weblogs, owner clubs, online discussion forums, mailing lists, news reports, and corporate commercials. Salient sources were identified, archived, and continuously monitored over the course of the study. The key pro- and antagonists of the HBC were invited for interview participation — among them, AM General and General Motors marketing staff, HUMMER club celebrity Arnold Schwarzenegger, members of The HUMMER Club Inc.,³ leading web forum contributors, and the initiators of the most popular HUMMER hate page.

Phenomenological interviews of 50 to 150 minutes in length were conducted with five key informants, all of which were daily HUMMER drivers. Four of them were strongly, one remotely affiliated with the HBC. The interviews provided insights into motivations to own the vehicles, into personal consumption experiences, and into the particular ways the community communicates and organizes (Thompson 1997). Outside views on the HBC were studied at the 2005 North American Auto Show in Detroit. 23 interviews of 15 to 25 minutes in length were conducted with 48 informants of Asian-American, African-American, and Caucasian

origin. The sample included 31 male, 12 female, and 5 adolescent informants. Respondents were asked about their opinions, feelings, particular relationships and communicative contributions in favor of or against the HBC. About 50% of the respondents tended to generally dislike the vehicle and their drivers. Every person contacted had either seen or driven a HUMMER. Via email, additional netnographic interviews were conducted with prominent antagonists of the HBC that provided rich insights into the key motives of non-members for extensively contributing to the HUMMER discourse. Following Thompson (1997), the transcribed and archived data was continuously analyzed in multiple iterations of hermeneutic interpretation (Denzin and Lincoln 2000). In addition, the contribution of comments and stories was encouraged with postings on the leading web forums. Throughout the project, a research homepage offered a project overview, participant legal information, web links, guestbook, and contact information. This virtual home of the project proved useful for inviting stories and informing interviewees. Table 1 provides an account of the data used for this study.

FINDINGS

“At HUMMER our customers can’t be labeled by color, gender or creed. HUMMER is a mindset. A mindset of daring, self-assured, entrepreneurial people who see HUMMER as being a reflection of themselves—unique.” (Randall Foutch, GM)⁴

“The [HUMMER] H2 is the ultimate poseur vehicle. It has the chassis of a Chevy Tahoe and a body that looks like the original Hummer; i.e. it’s a Chevy Tahoe in disguise. The H2 is a gas guzzler. Because it has a gross vehicle weight rating over 8500 lbs, the US government does not require it to meet federal fuel efficiency regulations. Hummer isn’t even required to publish its fuel economy (owners indicate that they get around 10 mpg for normal use). So while our brothers and sisters are off in the Middle East risking their lives to secure America’s fossil fuel future, H2 drivers are pissing away our “spoils of victory” during each trip to the grocery store.” (Jason, none, forum)⁵

These key statements of GM employee Randall Foutch and HUMMER opponent Jason amply illustrate that the HUMMER brand community evolves around an extraordinarily distinct and controversial consumer product. The adapted war vehicle “HUMMER H1” (in the following: H1) and the redesigned sport utility vehicle HUMMER H2 (H2) are appreciated for their safety, capability, and physical appearance, whereas opponents criticize those same properties as dangerous, ecologically irresponsible, and in-

²See Belk (2004) for an account of the deep emotional bonds male consumers develop with their cars.

³At least twelve larger clubs have evolved around HUMMER vehicles in North America. The HUMMER Club Inc. with about 2000 members is the largest registered community and currently the only one that is formally acknowledged and supported by GM and AM General.

⁴Except for official corporate statements and news reports, the names and identities of all informants of this study have been concealed, accepting the loss of information. The ownership status of the informant (H1, H2, H1/H2, none, n/a) and the data source (web, forum, interview, email) are indicated.

⁵All informant quotes in this paper are cited in original idiom, including spelling and grammar. Where necessary, clarifications have been added in rectangular brackets.

timidating. Some supporters of the brand communicate their admiration of the “King of off-road” (Tim, n/a, forum) in various personal and mediated forms, whereas some critics voice their dislike in online forums, public demonstrations, driver affronts or even vandalism. In this study, the notion “HUMMER brand community” includes all those contributors who communicate about and socialize around their consumption of HUMMER products, whereas the notion of “social environments” embraces all other contributors, reaching from owners who do not socialize, to the uninvolved public, to passionate HUMMER opponents.

This extreme constellation of a brand community under fire holds the opportunity for analyzing how a brand community differentiates, why it attracts opposition, and if and how especially extensive protest influences the community. Using micro-level data within the conceptual framework introduced earlier, this section first delves into the functional, aesthetic, political, and social distinctions that the community uses for differentiation. Then it portrays the community’s ways of reproducing itself within its social environments. Finally, key strategies of reflection are unveiled.

Distinction

HUMMERS are advertised as being “like nothing else” (GM) and thus as providing maximum distinctiveness. All informants of this study readily support this statement, yet for diametrically opposite reasons. This section examines the functional, aesthetic, political, and social distinctions the HBC uses to set itself off from its social environments.

Functional distinctions are concerned with the functional utility of HUMMER products. For the HBC and its environments, the distinctions between safety and threat as well as capability and subordination are predominant. HUMMER drivers are convinced they possess the safest consumer vehicle on North American roads. This belief is equally inspired by size and weight as well as by the presumed capabilities of the vehicles. Although most HUMMER owners have never got “off Highway 101 and (...) over Mount Tam” (sfgate.com, 12/29/2002), trust in these characteristics is nevertheless frequently articulated. HUMMERS are, for example, considered to be a “family insurance policy” (ibid.) or even a must for any responsible head of the family. Consider the statement of HUMMER role model Arnold Schwarzenegger, who owns several H1 and H2 vehicles:

“I want a big SUV because I have four children and to protect the family” (A. Schwarzenegger, cited at CNN.com, 09/22/03)

For non-owners, however, this feeling of safety turns into a feeling of threat, as road-safety is perceived as relative. H2-owner Ray and Stephen, who drove an H1 for the Army, provide reasons for these feelings:

“I’d rather be the one that survives the impact with the small car than the poor schmuck treehugger that i run over. I’d rather pay the money for the gas than have to worry about some dumbass in a rice rocket blowing through a light and hitting me in the side.” (Ray, H2, forum).

“If you are driving a big truck and got this little Honda civic ahead of you, your first thought is: I am just gonna run him over.” (Stephen, none, interview)

The other central functional distinction separates capability from subordination. At the national events of The HUMMER Club Inc., the off-road capability of both H1 and H2 vehicles is frequently contested and celebrated. Among the HBC there is little doubt about the superior capability of HUMMERS. In the urban realm, capability and dominance materialize quite differently. Owners like Brian contribute tales of heroic potency that are readily confirmed and criticized by outside contributors like Jason:

“This weekend will be taking the H2 out to the sticks [...] to get some peace and quiet away from the city and all those tiny, wimpy vehicles that are always getting stuck in my grill and between the little groves in my tires” (Brian, H2, web).

“The H2 is a death machine. You’d better hope that you don’t collide with an H2 in your economy car. You can kiss your ass goodbye thanks to the H2’s massive weight and raised bumpers. Too bad you couldn’t afford an urban assault vehicle of your own.” (Jason, none, forum)

Aesthetic distinctions are concerned with positive appeals to human senses (cf. Postrel 2003). The central aesthetic differences cover the range from fascination to intimidation. Surprisingly, the data unveiled that although some informants generally reject HUM-

MERS, they are nonetheless intrigued by the vehicles' aesthetics. Marc, who has driven a HUMMER once, argues against the vehicle but still cannot conceal his fascination with the H2 over the course of the interview:

"I've driven one, I don't like it. It's too big. It is very intimidating for people in front of you if you come up very high on behind, they scatter. [Feels like you are saying] get the hell out of the way." (Marc, none, interview)

HUMMER owners agree that the public feedback they receive on the looks of their vehicles is "99% positive" (Peter, H2, interview). Jonathan reports on this as a positive experience, whereas Nathalie expresses her negative feelings of intimidation and fear:

"We get waved to by children like we are driving a fire truck. People are constantly asking us to sit in, look in & even feel it." (Jonathan, H2, email)

"It's a very intimidating looking vehicle. It's just the size and shape of the vehicle." (Nathalie, none, interview)

Political distinctions mark HUMMER-related communications that revolve around the prevailing distinction of freedom versus responsibility. Occasionally, the HBC also gets involved in various political discourses. When it comes to justifying purchases, the HBC frequently refers to ideals of freedom and the dictum of economic choice.

"The good thing about marketing economy is that you can vote with your dollars and if I choose to purchase a vehicle that is less efficient ... that is my choice." (Rick, none, interview)

Opponents vehemently attack owners like Rick for ignoring external effects of their consumption choices. In web forum discussions, participants often draw on cultural resources such as patriotism, national pride, political and local affiliations, job and literacy hierarchies, gender differences, or the Iraq Wars to support their arguments. Characteristic claims are: "Driving a Gas Guzzler is not patriotic," bumper stickers like "I drive a... WEAPON OF MASS CONSUMPTION," or a demonstration billboard saying "Soldiers die in their HUMMERS, so you can play Soldier too!" (Authors unknown, n/a, web).

Social distinctions, as they are observed and enjoyed by most HUMMER drivers, are deeply embedded in various social discourses, and continuously fueled by numerous contributors. Outside informants Rick and Nathalie summarize the two primary social effects of HUMMERS as "consumption symbols" (Belk 1988, p. 152):

"Like it or hate it, it gets you noticed." (Rick, none, interview)

"If you see a HUMMER, you automatically don't think of a lower class individual." (Nathalie, none, interview)

In addition to the symbolic effects of perceived functional superiority, aesthetic extravagance, and political affiliation, HUMMER vehicles are associated with cultural stereotypes of masculinity, athleticism, fame, and economic success.⁶ These associations are largely fueled by the military heritage, the number and presence of athletes and movie stars driving HUMMERS (ca. 60 celebrities were known in 2004 for driving HUMMERS) and the above-average prices of the products.⁷ Arnold Schwarzenegger, the best-known member of the HBC, personifies for most informants these

social distinctions of the brand. As Nathalie summarizes: "[I can] picture him being the Terminator coming out of the HUMMER. Totally see those two together" (none, interview).

The HBC uses these social distinctions extensively. Tom (H2, web), for example, impresses potential real estate customers with his H2; the tall blonde H1 driver Susan irritates men ("women will drive by and give me a thumbs up, and guys will mumble and say grrrr, it's a women driving a HUMMER!" (Susan, H1, interview)); Peter (H2, interview) enjoys the attention ("Every time we drive out on the streets we turn heads."); and Ronny simply likes to show off ("I like taking the kids and wife places and park up front so everyone can see!! That's the best part is when other kids look and hit there moms and dads and say look!! My kids like it tooo!!" (Ronny, H2, web)).

While especially the adolescent informants of this study largely support and enjoy the feeling of social superiority, critics confront the owners with rationalized arguments.

"According to Bradsher, internal industry market research concluded that S.U.V.s tend to be bought by people who are insecure, vain, self-centered, and self-absorbed, who are frequently nervous about their marriages, and who lack confidence in their driving skills." (Malcom Gladwell, www.gladwell.com)

Within the HBC, differences exist about the importance of social distinctiveness. Among the urban H2-fractions of the HBC (approx. 70,000 owners), design and social attention are more likely to be predominant motives for purchase. H1-owners (approx. 10,000) seem to be more attracted by the vehicle's off-road capability. However, these particularities of the HBC's social distinctiveness presuppose social environments that pay attention and feed back to the community. In this empirical context, social attention appears to be a given for both sides.

Reproduction

The interpretive framework of this study conceptualizes the aesthetic, political, and social distinctions of the HBC as socially constructed through ongoing discourses. This section details the HBC's particular communicative means for producing and reproducing these distinctions. Attention is focused on communication and interaction between community protagonists as well as communication and interaction with the social environments.

Among its members, the HBC employs personal forms of communication, such as club events, and mediated ones, such as club magazines, web pages, mailing lists, and online forums. Members of The HUMMER Club Inc., for example, meet for the "Chile Challenge" or the "Death Valley HUMMER Happening" to pursue and share their off-road passion with other members. This is where Muñiz and O'Guinn's (2001) core community communalities can be observed most readily. As social relationships are the core constituent of the HBC, these events play an important role for reproducing and updating shared meaning, for retaining old members, attracting new ones, and deepening social ties among owners, spouses, friends, children, club board members, representatives of the manufacturers, and guests (cf. McAlexander et al. 2002; Muñiz and O'Guinn 2001; Schouten and McAlexander 1995). In the online realm, sharing knowledge about parts, repairs, tuning, events and off-road tips are predominant communications. Glorious road-

⁶For an account of the underlying American ideology of manhood see Holt and Thompson (2002).

⁷HUMMER H1 vehicles start at \$112,000. H2s begin at \$55,000.

side stories that are shared over the Internet contribute to the reproduction of the perceived capability and superiority of the HUMMER vehicles.

Communicating distinctiveness to the social environments is equally central for the HBC. Aside from corporate advertising for the vehicles, HUMMERS have attracted extensive media attention. As of early 2005, HUMMER vehicles have been featured in at least 60 movies, 13 music videos, 40 TV-shows, 12 video games, 6 books and 12 non-GM commercials. Community protagonists also personally engage in reproducing a positive image of the HBC. Two varieties of individual contribution are predominant, compensation and exploitation. Protagonists that are concerned with signaling the HBC's social responsibility frequently use the distinctiveness of and fascination with HUMMER vehicles to support their community. The Rocky Mountain News reports:

"Volunteers wearing Santa hats with "H2" stitched on them smiled as they drove through Medved's Wheat Ridge service center to load trunks with toys [that were later given out to needy children]." (Jennifer Miller, Rocky Mountain News, 12/20/2004)

Similarly, GM and The HUMMER Club Inc. use the vehicles' distinctive features to promote initiatives like "stars after school," the environmental organization "Tread Lightly!" and the "Sierra Club."

Consumers like Ronny, on the other hand, are instead exclusively interested in supporting their individual identity projects by means of conspicuous consumption. Like Arnold Schwarzenegger, who is quoted saying "I needed a vehicle that matched the expressiveness of my personality" (Padgett 2004, p. 91), many HUMMER owners show off their vehicles to impose style and meaning of their possessions on their own identities (Belk 1988; Holt 2002). The HBC can leverage these efforts, for example, by offering gatherings in public places. Consider this invitation of the H2 Club Chapter New York:

"East Coast Dinner at NYTIMES SQUARE ... 43rd & 44th @ ABC Studios Bldg. Time: 6:30 pm, Trucks from all over are welcome. With the approval of the NYPD, we're going meet at NY Times Square at 6:30 sharp to meet, compare, and take pictures. About an hour later, the crew will depart to "Tao Asian Bistro" for dinner and fun ... Make sure you bring your cameras!" (H2 Club, Chapter New York, web)

The social opposition to the HBC reproduces itself as well. Informants agree that opposition usually forms spontaneously on the road but there are also planned events by social activist organizations like "Code Pink" or networks like the "Earth Liberation Front." In public spaces, HUMMER owners are frequently insulted, yelled at or cut off. Peter, for example, reports that his vehicle was keyed once and spat on several times.

"I have people yell obscenities and when we come to a four way stop they ... well ... 'you and your god-damn HUMMER, get out of my way' ... you know. (...) We get flipped off about once every two weeks." (Peter, H2, interview)

Organized protests materialize in street demonstrations such as the "Code Pink" anti-HUMMER demonstrations on Earth Day 2003, where participants produced placards with slogans like "How many lives per gallon?" or "BIG HUMMER little brain" in front of HUMMER dealerships. Testing the extreme, the Earth Liberation Front burned several HUMMERS being displayed at a California

dealership and spray-painted slogans such as "Fat, Lazy Americans" (Associated Press, 08/22/03) on the walls.

On the netnographic site, various web pages and online forums invite and communicate H2 protest. A popular hate-page presents more than 1.600 individually submitted and commented photographs of people making obscene gestures at H2 vehicles. The owners of the page recently started selling t-shirts and baseball caps with the web address and a popular picture on them.

In sum, inside and outside of the HBC the two opposing sides reproduce using personal and mediated, spontaneous and organized, online and offline forms of communication. In doing so, each contribution refers to and reproduces the opposite side as well.

Reflexivity

Reflexivity conceptualizes the particular means that social systems employ for making sense of and reacting to inside and outside communications. So far, findings unveil that the fundamental distinctions of off-road capability versus environmental irresponsibility, positive attention versus selfish vanity and social superiority versus excessive overconsumption are used and reproduced by the HBC and its social environments. Data also supports the existence of immediate interaction between the HBC and its social environments. This section explores if and how this interaction affects the HBC.

In spite of high gas expenditures and social protest, the environmental effects of HUMMER consumption are not an issue for the HBC. On the contrary, the HBC considers itself environmentally responsible.

"We [The HUMMER Club Inc.] have a large percentage of the population with discretionary income. They do what is environmentally correct: join the Nature Conservancy, or the Sierra Club, or Land Trust. (...) 'I am giving money to these groups, therefore, it's ok.'" (Susan, H1, interview)

By displaying environmental consciousness and showing responsible behavior on off-road tracks, the community frames itself as ecologically conscious. In a similar vein, gas-guzzler accusations against urban drivers are ignored or circumvented with reference to freedom of choice.

"Peoples' concerns are that it burns too much gas and it's bad for the environment. There are a lot of reasons... It's just a matter of opinion." (Peter, H2, interview)

Arnold Schwarzenegger, being harshly criticized during his campaign for backing environmental policies as Governor of California and driving HUMMERS at the same time, reacted in the same fashion. Instead of accepting the argument and parting with his HUMMERS, he chose to support a GM initiative for developing sustainable engines. Followed by the media, he occasionally drives an hydrogen-fueled H2 through California (Padgett 2004).

Partial acceptance of the stigma of selfish vanity inspired HUMMER owners and clubs to engage in charitable activities. Susan (H1, interview), for example, entertains physically challenged children by offering them rides in her H1. Jason (H1/H2, interview) holds guest lectures at a business school to inform prospective leaders about the benefits of the public private partnership of The HUMMER Club Inc., and a Colorado HUMMER dealer cooperates with the Department of Human Services and the Colorado State Foster Parents Association to deliver Christmas gifts to foster children.

Allegations of overconsumption are based on the fact that the HUMMER is a vehicle, which exceeds most customers' needs. The

HBC reacts to these charges in various ways. The program “HUMMER Owners Prepared for Emergency (HOPE),” for example, is a HBC-initiated cooperation which has emerged between The HUMMER Club Inc., GM, and the American Red Cross. HOPE membership legitimates HUMMER owners to provide transportation for Red Cross workers and their supplies to reach emergency sites that “are not accessible with normal vehicles” (Morris 2004). The program has three key impacts on the perceived meanings within the HBC. First, it responds to intimidation allegations by depicting HOPE members as (national) security supporters rather than as a menace. Second, it signals to the social environments that the vehicles are a useful and necessary enrichment to society rather than an excessive luxury. Third, the program enhances the original distinction of functional superiority by adding altruism and moral superiority to the set of relevant distinctions. HOPE membership constitutes further pride, as owners become entitled to assist the drivers of less capable vehicles in the case of an emergency.

When it comes to reasoning against oppositional communication, the arguments of the HBC are manifold. Usually, the HBC simply frames protests categorically as envy, as there is no other acceptable way of rationalizing certain threats. Consider the following contribution by Jack to an explicitly anti-H2 forum:

“The shame of all of the “people” who have so much negativity to say about the H2 either are just totally jealous, or can’t make enough money to afford one, two or more! Maybe these “people” should not have “Partied” so much in College, if they ever went to college? ... And by the way—Fuck you ALL!! That are Jealous of a Vehicle—Period!!!!” (Jack, H2, forum)

Another reflexive strategy that was frequently observed in interviews is accusing opponents of insufficient knowledge about the true capability, utility, and gas mileage of HUMMERS. Owners go into passionate defenses of their vehicles.

“Hey Peter let me just be the first to say (edit) your H2. I don’t need it to dog it. I drive an H1 almost everyday. Its called Army. Your hummer is a sissy truck. It is for rich girls that want to feel like they are special and older guys that can’t afford the insurance on a Porsche. I flip off everyone I see on the road.” (Cliff, n/a, forum)⁸

Discussions that emerge from contributions like Cliff’s draw on a host of cultural resources, including the Army, slavery, Al Qaeda, or political affiliations. They provide insights into the depths of passion that both sides share about the HUMMER, yet on diametrically opposite sides.

The existing tensions often result in informants feeling only more rather than less strongly about their HUMMERS. Jonathan summarizes this strengthening effect as follows:

“People actually try and cut us off on the freeway. We have been cussed at, yelled at, given the thumbs down for “killing children” (not sure what that was about). Six times in the last three months people have tried to steal a parking spot from us when we were waiting first. (...) This only makes me want to drive a Hummer more. Why be like everyone else, when you can make a statement and cause much hooplah everyday!” (Jonathan, H2, email)

In summary, the above findings illustrate how the HBC inspires, uses, and reproduces social discourses (cf. McCracken 1986). The community generally reacts with benevolence to positive feedback and often also with demonstrative behavior such as

communal show-offs or excessive car tuning. Vis-à-vis its critics, the community reacts in three ways. Arguments that threaten the validity of the HUMMER distinctions are simply ignored. If possible, they are rationalized as to fit the accepted meaning within the community. Some allegations may entail reactions of the HBC, such as participation in social and environmental missions or creation of a program for emergency support. Yet, these reactions do not result in parting with the vehicles but rather in seeking compensation elsewhere. By using a form of mental accounting (Thaler 1985) the HBC clears external costs on one side (driving a HUMMER) with payments on the other (supporting a Hydrogen initiative).

DISCUSSION

This study explored the role of committed social environments for the HUMMER brand community (HBC). Grounded in a social-constructivist interpretive framework, a multi-perspective study was conducted to explore how the HUMMER brand community and its social environments discursively construct, situate, and legitimate one another.

Adding to existing consumer culture theory on brand communities, findings reveal that a group of shared ideological *distinctions*—such as off-road capability versus environmental irresponsibility, positive attention versus selfish vanity, and social superiority versus excessive overconsumption—combined with knowledge about which side to favor forms the social foundation of the brand community. These core distinctions provide pro- and antagonists with topics for discussion, reasons to socialize, and meanings to identify with. These distinctions rather than intrinsic communalities initially inspire brand community as well as protest community building. As distinctions are bivalent, critics emerge, refining and making use of the opposite side for organizing protest and taking aim at the community’s foundations. By addressing, for instance, the “ultimate off-road vehicle” (GM) as an “ultimate poseur vehicle” (Jason, none, forum), the opposition of the HBC involves the community in an ongoing dispute about the predominant meaning of brand and community.

In its continuous discursive *reproduction*, a brand community considerably depends on, alludes to, draws on, and interacts with its social environments. Theoretically, a community is free to form around any brand (Muñiz and O’Guinn 2001), to accept or reject any meaning individuals, marketers, and cultures have to offer (cf. Holt 2002), and to proliferate or dissolve if distinctiveness is lost. Yet by accepting the design, functions, and advertised meanings of a brand, as well as by alluding to the cultural stereotypes of masculinity, athleticism, fame, and economic success, brand communities become dependent on their social environments. Even though the core functional and aesthetic distinctions are inevitably corporate products, a brand community can develop further aesthetic (e.g. tuning), social (e.g. altruism), or political distinctions and thus emancipate itself from marketing influence.⁹ In order to maintain these distinctions, a brand community is bound to continuous communicative reproduction within and against its relevant social environments. Internally, the HBC communicates at national events, during local road-trips, on online web forums, or in member magazines. Vis-à-vis the outside, it consciously triggers both positive feedback and inevitable protest through conspicuous consumption. The study reveals that brand community and social environ-

⁸This submission was edited by the forum administrator.

⁹See Muñiz and Schau (2005) for a description of a community that proliferates even though the marketer has long discontinued the product.

ments construct and strengthen each other and their fundamental distinctions through their ongoing reproductions.

A brand community that builds on strong distinctions cannot escape social attention if the brand is publicly consumed. A brand community employs at least *six discursive strategies* of responding to outside stimuli. Positive feedback is silently consumed, eagerly responded to, or actively reinforced. Oppositional arguments are ignored, rationalized, or recontextualized.

For some parts of the HBC, the extensive positive attention is a core motivation for purchasing a HUMMER and socializing around the product. Some owners, who fear that the product's distinctiveness is fading due to its increasing popularity, for example, regain the public momentum by extensively tuning their vehicles or driving in large HUMMER convoys.

In reacting to outside threats, such as affronts, aggressions, and accusations, a brand community may predominantly react in three ways. Outside allegations that are either not of interest for the community or endanger its legitimacy are entirely ignored. The HUMMER-owning mother of young children, for instance, overlooks the allegation of overconsumption. If arguments can be rationalized within the interpretive framework of the core distinctions, the brand community self-referentially reframes opposing arguments to fit the accepted meaning of the community. For example, the HBC often simply frames protests categorically as envy. The most subtle interpretive strategy of a brand community is the recontextualization of accusations. The HBC-initiated cooperation HOPE, for instance, can be theorized as such a recontextualized response. By establishing a cooperation between HUMMER owners and the American Red Cross, the HBC responds to intimidation allegations by depicting HOPE members as (national) security supporters rather than as a menace. It also signals to the social environments that the vehicles are a useful and necessary enrichment to society rather than an excessive luxury, and enhances the original distinction of functional superiority by adding altruism and moral superiority. Recontextualization strategies are favored when the brand community has no other means of reacting to a relevant outside argument than through remote compensation. Protagonists of the HBC do not give up their vehicles and community affiliation because of opposition, but they can donate to environmental organizations to clear their mental account (Thaler 1985). With these discursive strategies of selective blindness, the brand community reduces social complexity by banning certain interpretations and encouraging others (cf. Glasersfeld 2003; von Foerster 1979).

As part of a larger research project investigating brand communities as social systems, this research has begun to explore the complex relationships between a brand community and its social environments. Yet, more research needs to be done to fully understand the particular influences of distinct product characteristics, marketing efforts, media reports, or social activist groups on brand community success and failure.

In summary, social environments comprise curses and blessings for a brand community under fire. Blessings, as outside sympathies and threats co-create the distinctiveness the community is built upon; and curses, as the social environments also constantly question the validity and social acceptance of the community's foundations.

When David Becomes Goliath

Ideological Discourse in New Online Consumer Movements

Andrea Hemetsberger, University of Innsbruck¹

ABSTRACT

This article seeks to contribute to the issue of consumer sovereignty by introducing the concept of adversary innovation. The functionality of ideological discourse for the sustainability of new consumer movements is discussed and investigated. Empirical investigation is based on a discourse analysis of online conversation of the free and open-source software movement. The findings reveal that the movement is constantly fueled with revolutionary energy by applying two dialectical categories of cultural codes in discourse—exclusion and integration. Processes of exclusion that become apparent in discourse comprise demonization, purifying, and remembering. Educationalism, pluralism and tolerance are processes, which seek integration.

INTRODUCTION

Since the advent of postmodernist thought in consumer behavior, there is a growing body of literature on tensions between consumers and markets (Murray & Ozanne, 1991; Firat & Venkatesh, 1995; Thompson, 1997; 2004; Kozinets, 2002b; 2004; Holt, 2002). As consumers live in this tension, they are constantly confronted with contradictory signals on the market. Glamorous brands are diluting when used, multinational corporations turn out to be 'Potemkin villages' instead of responsible social actors. Consumers start musing and publicly reflecting on the things they value most. Activist consumers engage in boycotting, and revolting.

Consumer behavior literature, so far, has discussed this issue mainly in terms of brand authenticity, consumer resistance, and adversary consumption (Grayson & Martinec, 2004; Penalzoa & Price, 1993; Rumbo, 2002; Moiso & Aaskegaard, 2002; Kozinets & Handelman, 2004), but also in more positive terms as emancipatory, liberatory and creative consumption (Firat & Venkatesh, 1995; Kozinets, 2002b; Holt, 2002; Toumajian, 2003; Thompson, 2004). Recently, consumer research also revealed the resisting power of gift-exchange in consumer communities (Bergquist & Ljungberg, 2001; Hemetsberger, 2002; Giesler, 2003a; 2003b; Zeitlyn, 2003). Peer-to-peer exchange is subversive in that it successfully circumvents prevailing modes of transaction in capitalist economy.

Recently, resisting online consumer communities, who collaboratively work on innovative software solutions, have attracted the attention of practitioners and researchers (Wayner, 2000; Bergquist & Ljungberg, 2001; Hemetsberger, 2002; Zeitlyn, 2003). Adversary innovation challenges well established industries in a radical manner in that it attacks one of their core competencies, namely to innovate. Practitioners and researchers alike are struck by the fact that those subgroups of consumers have developed software of top quality, and, in some areas, have reached a world market share of approximately 70 percent. I am talking about the free and open-source (F/OSS) movement, which has successfully established an authentic online culture of free collaboration on innovative software solutions. This software is free for download, and the source code is open, so that people can improve it, if they are capable of doing that. The open-source movement has brought forward a powerful consumer culture with an authentic claim for freedom. Here, freedom occupies an emancipatory notion of liberation. The movement has created a world of free exchange of software, knowledge, and friendship. It has been lively and pulsating ever since; it is stimulating, inspiring, and provocative.

In its early days and ever since, the resisting character of the movement has been fueling this liberating consumer effort with more and more contributors, affiliates, and advocates. Today, distributions² are successfully marketing their software products. Company engagement and sponsoring is increasing, and expert software developers are now employed by those benevolent industry partners. By now, open-source software has become commercialized and incorporated into the capitalist system to a considerable extent. This seemingly obvious opposite of the movement's ideological foundation longs for explanation. Commercialization of free or open-source software sounds like an oxymoron. Would not indoctrinated developers cease contributing when the ideological basis starts crumbling away? Are those consumer movements to lose their resisting, emancipative, and liberatory appeal? Hence, are they to lose their members, will they shrink, or die away?

This article aims to contribute to a deepened understanding of producerly forms of consumer resistance. Emphasis will be put on the functional character of ideological discourse for the sustainability of online movements. The empirical investigation is based on a netnographic observation (Kozinets, 2002a), and discourse analysis (Potter & Wetherell, 1987) of online conversation of the free software (<http://www.fsf.org/>) and open-source movement (<http://www.opensource.org/>). I will conclude with a discussion of the findings.

THEORY

Consumers that cause trouble

Literature that addresses the issue of consumer resistance and collective action is fairly recent. The topic of resistance evolved out of a changing, postmodern, and more humanist understanding of consumers, who are on their way back from consumer society (Baudrillard, 1998) to reflective, and creative emancipatory action. Penalzoa and Price (1993) provided a first classification with the aim of emphasizing the many forms of consumer resistance. They argued that consumer resistance already begins with the daily minutia of differentiated product use and signification. Brand community research made visible another form of resistance—oppositional brand loyalty (Muniz & O'Guinn, 2000; Muniz, Lawrence & Hamer, 2001). However, oppositional brand loyalty reflects resistance only to the extent that it is a radical expression of consumer support for another brand. Yet another, more radical form of consumer resistance is documented in recent studies of consumers, who act against prevailing consumption practices and forms, as for instance documented in Kozinets' Burning Man study (Kozinets,

¹Acknowledgements: The author would like to thank the millions of volunteer programmers for their wonderful creations, and their stimulating public discourse. May their spirit continue to light up their lives and those of others.

²A Linux distribution is a Unix-like operating system plus application software comprising the Linux kernel, the GNU operating system, and assorted free software. Companies such as Red Hat, SUSE and MandrakeSoft, as well as community projects such as Debian and Gentoo Linux, assemble and test the software and provide it as a complete system, more or less ready to install and use.

2002b). However, those studies have disclosed that consumer engagement in resisting behavior does not release them from the market's social logic. It has been argued that ordinary so-called 'counter-cultures' are regularly incorporated into consumer culture and pose little threat on the market (Holt, 2002). Instead, it creates opportunities for companies which understand the emerging new cultures of consumption. More overt forms of consumer activism, as described by Kozinets and Handelman (2004), suffer from the stereotyping construction of their anti-consumerist ideology, and the radical exclusion of dissenting consumers. However, now that the networked society became reality we seem to enter a new era of consumer resistance, which seems to be less radical in nature, but much more powerful in its consequences. Consumer innovation (innovation by and for consumers) has become a new possibility to fight multinationals, monopolies, and the powerlessness of consumers.

Adversary innovation substantially differs from boycotting and consumer resistance in its active, positive approach towards social change. Contrary to anti-consumerism or anti-capitalist movements (see: Kozinets & Handelman, 2004; Rumbo, 2002), the emphasis is not primarily on attacking or destroying products, ads, and established market structures, but to radically alter and introduce new elements to it. Whereas many other forms of resistance rely on propagation and revolutionary utterances, innovative consumer communities construct a culture of creativity and collaboration; they actively do something about the source of their grievances. Furthermore, the revolutionary consequences of online consumer movements might be far more effective due to the networking effect of the Internet. The Napster file-sharing community (Giesler & Pohlmann, 2003a; 2003b) and the open-source movement, for instance, owe much of their global expansion to Internet technology. However, Napster's decline leaves us wondering whether online movements will ever be able to uphold their resisting power. Will all of those movements be swallowed up by the capitalist system and cease revolting, or will there be still authentic, oppositional energy? Will they be able to leave a thumbprint on the world?

Leaving a Thumbprint on the World

Collective action is not simply a reaction to social and environmental constraints, or a strategy of appropriation in response to structures of domination, as suggested by Poster (1992). Innovative consumer movements are not only exhibiting rebellious acts against the prevailing capitalist practices and forms of consumption. There is an equally strong tendency to engage in active co-construction of alternative market structures. This said, it is not intended here to argue that consumer movements hold the destiny of the market in their hands. Online consumer movements may take too many unforeseeable routes, with many deviant consequences that might result from action. However, I promote the view that resisting cultures are intentionally constituted so as to reflect the antithesis of the social and/or economic situation they strive to alter.

Here, adversary innovation will be approached with a socio-cultural perspective of reflexive and creative resistance (see: Holt, 2002). This view reflects a clear emphasis on emancipatory discourse, on the one hand. On the other hand, it also encompasses the overt producerly form of adversary innovation. Hence, resistance manifests itself in reflective collective discourse, and overt action. Consumers emancipate themselves from the market firstly, by creating a distinct common space, which is protected from external control or oppression (Melucci, 1996). Secondly, within this 'Noo-sphere' (Raymond, 1999), market-imposed codes and rules are flip-flopped and juxtaposed with a culture of free exchange and gift-

giving. Recent consumer research provides clear evidence of how people are making use of emancipatory spaces for collective action, and how they establish counter-cultures that reflect these common goals (Kozinets, 2002b; Hemetsberger, 2002; Giesler & Pohlman, 2003a; 2003b).

Ideology is one of the cornerstones that fuel and strengthen collective action (Melucci, 1996; Moisiso & Askegaard, 2002; Touraine, 1985). In an attempt to escape the ideological influences that sustain a capitalist economy (Thompson, 2004), and in order to regain control over one's own consumption behavior, counter-ideologies are established with the aim of opposing dominant market forces. Because cultural challenges occur primarily through ideological discourses, the interlinked study of discourse and ideology is critical within this field (Kozinets & Handelman, 2004). The advantage of examining social phenomena through the lens of discourse analysis is the ability to capture the meanings of texts and their relation to ideological interests, along with ways in which such meanings are either reproduced or contradicted in the discursive actions of individuals (Toumajian, 2003). Melucci (1996) holds that movements establish their ideological foundation through the elaboration of cultural codes and language. In order to reproduce culture, these codes are regularly re-assured and re-vitalized in discourse. This article advances the perspective that consumer movements are using cultural codes in online discourse in order to promote, challenge, and re-create ideology. Hence, the aim of the study is to understand in what way discursive processes are functional for resistance and sustainability of a movement.

METHODOLOGY

This research revolves around the adversary discourse and innovative action of the free source and open-source movement. It is part of an extensive netnographic research (Kozinets, 2002a). I started out with an exploration of several free and open-source related Websites in order to apprehend the history, the culture, the structure, and the organizational entities of the F/OSS network. For the purpose of this article, community discourse was observed, retrieved from the archives, and analyzed. In order to overcome the drawbacks of self-report data, an agency-oriented approach to discourse analysis was chosen. This approach aims to uncover the hidden ideological symbolism and action behind social conversation, that what is intentionally said in discourse (Geertz, 1973 [2000]).

The research site

"The free and open-source movement is comprised of individuals, each one free to do whatever he wants with the software. No more shackles, no more corporate hegemony. It is the latest episode in the battle between the programmers and the corporate suits. The revolution is also about defining wealth in cyberspace. ... just discovering how much can be accomplished when information can be duplicated for next to nothing." (Wayner, 2000).

The seeds of the F/OSS movements have been planted long time ago. At that time, a group of MIT's most passionate programmers had developed a common ideology of free sharing. They started calling themselves hackers. Hackers are people who program enthusiastically and who believe that information-sharing is a powerful, positive good, and that it is the ethical duty of hackers to share their expertise by writing free software (Himanen, 2001). It took them almost 30 years to watch an online movement growing, which consists of computer-literate software consumers from all over the world, who share similar grievances and strivings.

The term movement is partly a self-description, and reflects the community's emphasis on its creative, resisting character to the outside world. Its resisting character rests on millions of programmers and advocates who are operating on a global basis, and collaborate on the Net. They are working on the improvement of free and open-source code in their spare time, and release their software including the source for free. It is not a violent, nor a radical revolution. But still, it is acting subversively and rebellious. The resisting actions are based on the liberal culture of the Internet, and a strong belief in the power of factuality. Meanwhile, its revolutionary consequences affected the software business in a sustainable manner. Free and open-source software, like Linux, KDE, Gnome, and the Apache Webserver, has achieved a considerable popularity and is distributed all over the Globe. It is such a great success that they found support from corporations, which are leaders from a cross-section of the computer industries.

Research method and analysis

The online data used for this study were gathered during a period from 1998 up to 2004. Observation of the F/OSS movement revealed the outstanding importance of news and discussion forums for ideological discourse. This has led to an informed choice of Web sites, which have been selected for discourse analysis. Massive ideological discourse primarily takes place on: <http://slashdot.org/>. The sites: <http://linuxtoday.com/> and <http://freshmeat.org> were used to reflect discourse which is more media-related, and technical in nature, respectively. Discourse on these news and discussion forums has been tracked and retrieved from the archives. A Perl³ script was written for automatic and pre-structured download of the archived topics. Five years of discourse from the beginning of 1998 to 2002 were tracked and downloaded. Discourse in the years 2003 and 2004 were used as 'probing' samples for evaluating whether the analysis is accurate and exhaustive. For analysis, only threads above a critical threshold of 600 to 1000 replies were used. The threshold depended on the overall intensity of discourse in the respective year. In total, 140 postings and their respective replies were analyzed. The threads have been read, and re-read several times until the cultural codes became apparent. A textual agency approach to discourse analysis was chosen (Potter & Wetherell, 1987; Cooren, 2004; Hardy, 2004). This approach adopts a performative view of language, that is, one that highlights that talk and writings are media for action. The findings were regularly discussed with community members and other researchers. Related literature was used to refine, rework, and narrow the results.

FINDINGS

Two fundamental categories of cultural codes, which are dialectical in nature, have been extracted from discourse. One is directed towards the conservation of a pure ideological core and constant re-direction towards the historical roots of the movement. Hence, it excludes. Its counterpart emphasizes integration, pragmatism, and progression. Due to their dialectical character, the ideological codes of the movement provide oppositional energy that is fueling a constant stream of discourse and action. In the following, it will be demonstrated how different cultural codes are used in language for various sustaining purposes.

David against Goliath—the excluding nature of traditional codes

Traditional codes are confronting and they draw a picture of the world as given. They presume that the revolution is necessary and the community members are not to blame for any hostilities, because they are fighting the good fight. Resistance seems natural,

as the history of the movement has shown that it is necessary. David has to fight Goliath. Hence, the message is distributed in a very ambitious and evangelizing manner with an orthodox undertone. Discourse is lively, provocative, and full of flamewars.

Fighting monopoly. It has been argued, that for the success of its distinction, a protest system depends on everything it excludes (Giesler, 2003). Hence, it is vital to emphasize the distinctions from "the evil empire" and to fight "the holy war". Similar to the Napster community, the F/OSS movement opposes commodification, corporations and copyright (Giesler and Pohlmann, 2003b). The community aims at breaking the old paradigms of corporate thinking, however, in a reflective way. The power of a monopoly serves as a symbol for the exploitation of consumers by multinational corporations.

"No, you're right. There's nothing illegal about being a monopoly. However, there IS something illegal about using that monopoly position to squash possible competition (say, by creating hidden API calls into your operating system that only your application programmers know about, thereby putting the competition's applications at a disadvantage, to name but one practice), or to use that market dominance to try to control the market in the future.

....

Don't worry, there's LOTS of ways to illegally use a monopoly. I suspect we'll find out that Microsoft used most of them."

(posted at: slashdot.org)

Monopolies, here, are accused not because of being a monopoly, but because of the initiatives they take. This discourse reflects a very subtle variant of fighting the adversary. They are not to blame for what they are, however it is impossible for them to be converted, because they are and will ever be fundamentally different in what they do. Drawing clear distinctions for now and for the future, for members and non-members of the community is the function of this traditional code. Better beware of the enemy, as he will never change.

Beware the Gates of Hell.

XXX: Beware the Microsoft shell game

May 2, 2001, 23 :30 UTC (79 Talkback[s]) (72336 reads)

"A few hours ago, a friendly journalist tipped me that Craig Mundie of Microsoft is going to make a major speech in New York tomorrow attacking open-source software—specifically, attacking the GNU General Public License. This speech is probably intended to define Microsoft's party line on open source, and to shift the terms of the debate over it to one that Microsoft thinks it can win.

I haven't seen the speech; the friendly journalist told me it was embargoed. But I'm expecting it to be a masterpiece of

³Perl is an open-source, interpreted programming language.

FUD [=fear, uncertainty, and doubt; the term refers to any kind of disinformation as a competitive weapon]. You watch; it's going to be a studied and ingenious attempt to create fear, uncertainty, and doubt in the minds of software users and the public—and to obscure Microsoft's underlying motives by cloaking them in affected concern for the public welfare.”

(posted at: linuxtoday.com)

In this verbatim account, the adversary is symbolically articulated by the use of accusations, presumptions, and exaggerations. The opponent is blamed for everything that negatively affects the software industry. He is blamed for exerting monopolist power and makes the perfect scapegoat for the movement to prove their morale superiority. Moreover, negative scenarios are built that are affecting not only the software industry, but mankind as a whole. Discourse about licensing issues, for instance, regularly exhibits such accusations. These unjustified attributions are the ingredients of demonization. Demonization is a cultural code, which is stronger than ingroup-outgroup thinking, but serves a similar function. Without it, group identity and ideology would be in danger. Hence, demonization is a constituent element of oppositional discourse.

Thou shalt not. The revolutionary character of the movement is determined by its oppositional character, as well as by the uncompromising pursuit of emancipatory action. Preserving freedom and everything related to it is the evangelists' highest value. Violations of that core value are regularly subjected to purification. A return to a situation of original purity allows collective action to combine its ancestral components into a new solidarity. Most religions provide a means whereby cleansing may take place. So does the F/OSS movement with the help of its evangelist proponents.

XXX on Qt, the GPL, KDE, and GNOME

(Sep 5th, 12:33:18)

By XXX

“....

The design of KDE was based on a fundamental mistake: use of the Qt library, which at the time was non-free software. Despite the good intentions of the KDE developers, and despite the fact that the code of KDE itself was free software, KDE could never be part of a completely free operating system as long as it needed a non-free program to function.

..... But the KDE developers were not concerned about this problem, and recruited helpers who shared their views.

.....Also, where code was copied from other GPL-covered programs, their copyright holders need to be asked for forgiveness. To lead the way, the FSF hereby grants this forgiveness for all code that is copyright FSF.....

.....GNOME and KDE will remain two rival desktops, unless some day they can be merged in some way. Until then, the GNU Project is going to support its own team vigorously. Go get 'em, gnomes!

(posted at : slashdot.org)

Telling people that they shall ask for forgiveness probably demonstrates best the religious undertones of that cultural code. According to this code, community members who are violating traditional rules and norms are to be subjected to a purification

ritual. Of course, such statements are discussed controversially, and also heavily flamed in online discourse. However, they are important and functional as they constantly recharge the ideological core and educate aspirant members.

Remembering. As Melucci (1996) stated, a movement always views its own action as a rebirth—as a regeneration of the present through the mythic reaffirmation of the past. Recharging the ideological core also means to constantly remind the members of the movement's original intention. As membership in a networked movement is fluctuating it necessitates regular 'updates' of its historical roots and claims.

“Yes, Yes, Yes and... Yes.

XXX is a hard liner, there is no doubt about it. What people seem to forget, however, is that it took a hard liner like XXX to get the ball rolling. XXX was necessary in the grand scheme of things, without XXX or another hard liner who stuck to his guns and just plain simply refused to give an inch we'd not have all the wonderful choices we have today, we'd all be running Windows 95 (because there'd be no reason for MS [Microsoft] to improve its OS [operating system], no competition), shelling out hundreds, thousands of dollars for unreliable proprietary software, and being locked into vendors.

People around here don't give XXX enough credit, and condemn him for doing the very thing that started this whole movement.”

(posted at: slashdot.org)

Codes of remembering often exhibit a struggle among 'religious zealots' and the progressive mass. Those internal fights between the generations of F/OSS programmers are nevertheless important for the continuity of the movement. They keep its members close to the path and help re-vitalize the myth of the movement's genesis. Remembering is not about memories of the good old days but rather emphasizes the ideological core and 'the grand scheme of things', as has been pointed out in the above quote. Hence, the movement ensures collective identity through the re-creation of shared history.

David is becoming Goliath-the integrating nature of universalistic codes

When societies develop universalistic codes, their strivings are primarily oriented towards a societal change through emancipation, progression, and reasoning. Social betterment is achieved through secularization and transcendence, but not by fighting the holy war. The relief of tensions by transforming the profane into the sacred constitutes the basic idea of universalistic coding (Giesen, 1999).

The idea of *salvation* from the evil empire by giving represents a very powerful cultural code in the community. By generously giving their products and its source code away for free, F/OSS developers create an abundance of economic, cultural, educational, and symbolic capital (Raymond, 1999), which liberates consumers from being indebted and constrained. By embracing all four kinds of capital, the F/OSS movement gained substance and power.

Hence, the free flow of those assets lies at the core of the community's liberation from the stranglehold of the market. By giving gifts the movement engages in a peaceful crusade in the name of progression and emancipation. Salvation from the 'evil empire' is the reward they are hoping for.

Educationalism. Universalistic codes foster a culture of integration. Non-members are regarded as potential members. However, they are yet to be converted and enlightened. Education is the way to enlightenment. Educationalist postings avoid accusations of the adversary. Instead, they emphasize the importance of doing the right thing—the good deed.

(posted at slashdot.org)

The above posting shows how members are trying to achieve their pedagogical aims. Famous personalities are cited in order to underscore the propagated issue. Similarly, including the opponent in the line of arguments is a way to highlight the importance of this issue. Pointing out that s/he would even fight with the opponent side by side if they would "stand up for what is Right" emphasizes that s/he is fighting the good fight. Contrary to codes of purification, educationalism seeks *not* to brand people with 'deviant' behavior as sinners. In contrast to purification rituals which clearly accuse and condemn, educationalist codes are rather seeking to integrate those who are doing good.

Let The Children Come To Me And Do Not Hinder Them. The importance of integration is regularly pointed out in articles and discourse, in order to convince community members that this is the way to successfully sustain communal goals:

"..... This kind of social organization, based on exclusion and secret social codes, is found in childish youth cultures and is the same "I'm part of the group; you're not part of the group" mentality that leads to race wars and genocide.
Still, isn't exclusion one of the main things the free software movement fights against? Isn't one of the strengths of our community that we accept people regardless of any considerations other than they want to be part of Linux? Eric Raymond has libertarian values, Richard Stallman has socialist values, and Linus just charms everyone. Look at the community at large: we don't even speak the same language, share the same religion, or view the world in the same way. Where else would you find cooperation among such diverse people?
Linux has embraced everyone, from the fanatical free-software enthusiasts to the greedy cats looking for some cheap way to make a buck, from the genius to the well-intentioned

beginner, from all fields of computing and with diverse interests, so why are we now becoming exclusive?"

The speech act of convincing is wrapped in soft, suggestive, and rhetoric questioning. By turning integration into a strength of the community, integrating becomes naturalized in discourse (Thompson, 1997). Social discourse surrounding the integration theme is not exclusively related to the F/OSS movement. Other, more subtle variants of integration discourse are brought up by posts which tap into more general political or societal issues, as for example the Hellmouth case in 1999. The massacre that took place in a school in Colorado had been discussed as an example for the devastating consequences of exclusion. Additionally, integration is fostered by regularly emphasizing the common goal of the movement. As everybody within the community is 'bitten by the same bug', differences are somehow evened out. However, tolerance is still demanded.

Pluralism and tolerance. Contrary to consumer activists as described by Kozinets and Handelman (2004), the open-source movement is also characterized by tolerance, at least according to their own words. Regularly, when extreme traditional codes are sent out and get flamed the discussions are entered by wise men, who balance out the oppositional stances. Those messages are sent out to the public as a propagation of tolerance and humanist principles to remind the members of the community of their strong ethic of free and self-determined human beings.

".....Followers of a severe person will develop a kind of fanaticism based on mimicry, without really understanding where their leader is coming from or giving much thought to the meaning of freedom themselves. If the goal is freedom, one can never achieve it by denying freedom to others.

I agree with a previous poster that those who really want their software to be free should place it in the public domain—they should not use GPL [*is an open-source licensing scheme*].

But they should also have the right to build on the work of others to create proprietary software, claiming ownership for a reasonable amount of time to what THEY have added to the common pool of knowledge. XXX is right that software patents are abhorrent, but so is a licensing scheme which denies freedom and respect for individual humans in the name of freedom. Extremists are unable to see the need for balance, because they are unable to see other people as individuals when fueled with fanaticism and intolerance. Laws and licensing schemes do not a great civilization make. The degree of human-ness of those who participate is more important."

Tolerance and pluralism are codes that are established to balance out fanaticism. Pluralism, of course, is at war with conformism. It encourages people to think and act differently. Yet, pluralistic thoughts are also regularly used for flaming religious zealots. Flames, however, draw distinctions and exclude others. Hence, the community needs regulatory elements in discourse, which relieve the insulting notion of flames, but also the oppositional discussions that regularly occur.

Playfulness and humor. Therefore, the free and open-source community fosters a humorous and playful culture. Dry humor, irony, puns, and a mildly flippant attitude are highly valued—but an underlying seriousness and intelligence are essential in discourse.

Humor, most of the time, is directed towards pointing at inconsistencies in the arguments and actions of the movement's opponents. Yet, it helps covering up harsh accusations or disillusioning facts. Furthermore, humor helps pinpoint scapegoats, enemies, and gets to the heart of the disputed points.

St. Petersburg (!AP)—St. Petersburg police have found the bodies of three young computer experts. The three were found in one of the their apartments, lying on the floor in front of their 486 running SuSE Linux.

“Our police experts stated that they were those who broke into Microsoft's servers and stole large amounts of code”, says a police agent via translator. “Experts were able to tell from lengthy headers, pointless libraries, and pointers to nowhere-in-particular that this must be actual code for Windows 2000' successor.”

After a preliminary exam, forensic pathologists state that their deaths were all caused by ruptured lungs.

“If I didn't know better, I would think that they would have died laughing”, said the pathologist.

One of the police experts who determined that the code was in fact Microsoft's also began laughing uncontrollably, and was rushed to a nearby hospital. He remains in serious condition and on heavy sedatives.

Humor in community discourse derives much of its power from provocative elements that juxtapose wrong and right, the good and the bad, and strengthen the authenticity of their claims.

DISCUSSION

This research has tried to advance a theory of new online consumer movements by introducing a more positive, and active form of adversary action into consumer behavior literature—the innovating consumer. The article sought to correct the tendency in literature to implicitly view resisting consumers as being entangled in contradictory forms of consumption, engaged in constant controversy with the market, with only temporary escapism. It re-introduces the idea of consumer sovereignty by consumers engaging in online collaboration and innovation. In search of empirical evidence, an online consumer movement was investigated that succeeded in establishing an alternative, emancipatory business model.

Baudrillard (1993) and Melucci (1996) argued that contemporary consumer movements' actions are geared towards offering, or gift-giving. The above findings underscore this argument in that they show how consumers liberate themselves from the economic cost-calculation rational, and offer a different model at a cultural and symbolic level. New online movements develop forms of action aimed at the autonomous production of cultures which are based on an abundance of symbolic and material wealth. As they give away their products for free, they extricate themselves from the asymmetric power and dominance in the market. However, as ‘David is becoming an experienced warrior himself’ the movement is prone to losing its revolutionary character.

The findings show that innovative consumer movements develop a differentiated language and oppositional cultural codes in order to guarantee a constant flux of revolutionary energy. This is in line with Melucci's (1996) theory of collective action. However, oppositional codes are not exclusively directed towards the outside

adversary. There is a considerable amount of oppositional discourse also among members of the movement. Whereas theories of collective action and new social movement theory discuss internal ambivalence and conflicts as a major challenge, the F/OSS case has shown how two quasi-opposing categories of cultural codes *within* the movement help foster rejuvenation and reconsolidation of the collective effort. The F/OSS movement is characterized by an idealist-pragmatist dualism. Its success is partly based on the dialectics, which constantly forces reflection and discourse. However, it is important to notice that the two ideological lines of thought within the movement are not equivalent to the processes of exclusion and integration. Although they tend to approximate, they should at least be thought separately.

Textual discourse has revealed diverse forms of resistance. Distinguishing the good and the bad is an important prerequisite for the resisting character of a movement. Hence, one form of functional discourse revolves around remembering, advocacy, and even religious zealotry of the movement's ideological core. Its function is to reproduce what is experienced as the natural order of things (Thompson & Haytko, 1997). Another one is to produce texts with subversive meaning, incorporating provocative elements, drawing attention to inconsistencies (Hardy, 2004), or problematizing interpretations of culturally prevailing meanings (Thompson & Haytko, 1997). Emotional struggles are drained off by being displaced onto symbolic enemies (Geertz, 1973 [2000]). These codes are important for depicting the scapegoat and upholding the adverse character of the opponent.

Discourse is also directed to foster collective reflection and to fuel revolutionary energy. Codes of exclusion fulfill the tasks of securing the ideological core, preserving the historical roots, depicting the adversary, drawing distinctions to market forces, and safeguarding the morale. Hence, codes of exclusion tend to be conservative and traditional with respect to a movement's core ideology. Successful movements, however, develop counterbalancing cultural codes, which enable them to grow. Hence, codes of integration are functional for sustainability. They foster pragmatic action, provide future perspectives, and invite the mass. Albeit the importance of both, exclusion and integration, for sustainability of the movement, they also produce discursive struggles and flames. Extremely controversial issues necessitate codes that relieve those tensions in order to avoid paralysis. The cultivation of humor and playfulness helps mitigating such insurmountable conflicts.

The findings presented above give reason to assume that the F/OSS movement succeeded in establishing an innovative consumer community and has achieved a sense of independence, self-determination, and liberation from *within* the market. It is not the market itself they are opposing, but the disrupting and destructive escalations of the capitalist market system. An anti-monopoly persuasion still exists, however anti-monopoly movements are to be distinguished from anti-capitalist movements. Monopolies are representing an egocentric, profit-oriented world economy, one in which consumers are caught in the straitjacket of impersonal corporations, and have no choice. This, of course, is against capitalist *and* Marxist principles; against liberal *and* communist political attitudes. Innovative activists provide hope. They invite us to engage in discourse, collective action, and free sharing. Moreover, they provide products of high quality. A new class of consumers draws our attention to their existence. Consumers who have fun *and* take responsibility—those caring Outlaws might become the new Heroes of the market. They seem to know how to play the market game however, they set different rules. We shall see whether the F/OSS movement will “undercut the high-tech titans” (Wayner, 2000), or the high-tech titans will succeed in “The Taming of the Shrew”.

Uncovering Rhetorical Methods of Word-of-Mouth Talk in an Online Community

Anat Toder Alon, Boston University
Frédéric F. Brunel, Boston University

EXTENDED ABSTRACT

Word-of-mouth (WOM)—the “person-to-person communication between a receiver and a communicator whom the receiver perceives as noncommercial, regarding a brand, a product or a service” (Arndt, 1967: 5)—is a diverse and complex phenomenon. WOM communications can have different number of participants, with different degrees of acquaintance between them, can be achieved through several communication modes, and can follow varying interaction patterns. Yet, the development of WOM theory has adhered to an “individualistic paradigm which isolates people from their social context” (Bristor, 1990: 52). While a few studies have incorporated relational properties (e.g., Gilly, Graham, Wolfinbarger & Yale, 1998; Brown & Reingen, 1987), none have studied WOM as part of group interactions. The traditional view asserts that WOM interactions are performed by individuals who occupy either the role of WOM seeker or WOM source. Past studies have considered WOM roles as constant throughout the interaction, and with a limited potential repertoire (e.g., WOM receiver requests information and/or evaluation, and WOM source provides information and/or evaluation). Further, since WOM information is exchanged in private conversations, direct observation of the WOM dialog has traditionally been limited (Godes & Mayzlin, 2002). Therefore, researchers have treated WOM rhetorics as a black box, relying instead on consumer recall or inferences from aggregated data.

Nowadays, online communities make it possible to unobtrusively observe consumers-to-consumers conversations (Godes & Mayzlin, 2002). Leveraging this opportunity, this research proposes a more comprehensive perspective of WOM behavior as it is manifested in daily life, suggests extensions of existing theories, and provides new insights that address previously ignored issues. Overall, this project seeks to fill two main lacunae in our understanding of WOM.

First, WOM communication is essentially a conversation. Thus, this research advocates that there are WOM-bound-activities that center around a problem talk, and include rhetorics that are designed and used in terms of the activities being negotiated (e.g., describing the problem, requesting advice, providing a recommendation, and so on). Accordingly, WOM rhetorical methods are defined as the forms of advice seeking and recommendation giving practices that are enacted habitually by members of a community. This argument stresses that WOM rhetorical methods are the building blocks that people use in constructing versions of advice seeking and giving and that members of a group may have a repertoire of WOM rhetorical methods that are used in appropriate contexts. Second, this research extends the study of WOM beyond the traditional dyadic approach, and recognizes that WOM commonly occurs in a group setting. Therefore, since “WOM is a social phenomenon, properties of social relations are likely to play a critical role in WOM behavior at micro as well as macro levels of inquiry” (Brown & Reingen, 1987: 351).

In this research, we analyzed text data from the discourse of bulletin boards hosted at BabyCenter.com. This is a website for new and expectant parents. Our unit of analysis was the verbatim thread transcript, which was operationalized as a post (seed) with all of the replies. The complete text of all messages of one bulletin board was captured for a nine month period. Over the nine months, 12,162

threads were captured and reviewed, and 1,076 threads were archived for further analysis. All of the archived threads were concerned with WOM talk (661 threads) or interpersonal relationships within the community (used for contextual grounding of the data). WOM episodes were defined broadly, and could include any positive or negative statement made by potential, actual or former customers, about a product, service, idea, or company (see Hennig-Thurau, Gwinner, Walsh & Gremler, 2004). The messages were read during the initial downloading to confirm that some WOM processes (e.g., providing a recommendation, asking for advice, etc.) were evident. Throughout the analysis, these messages were read and re-read several times, along with messages providing context for the WOM exchange.

The analysis followed an ethnomethodology program (Garfinkel, 1996). Analyses of WOM actions (i.e., WOM initiations, WOM responses) revealed a number of ways in which WOM seekers and WOM responders sensibly organize their messages via the use of categorization devices. In a nutshell, participants’ meaningful selection of categories determines the sense of WOM actions. Correspondingly, the invoked categories provide for different message readings due to the particular category selection and arrangement of items within the message. Tables 1 and 2 provide a summary of the major components and rhetorical methods of WOM initiations and responses.

A major contribution of this study is its ability to capture the richness and subtlety of everyday WOM interactions. Building on Miller’s work (1984), this research demonstrates that a rhetorically sound definition of WOM method must be centered not on the substance or the form of discourse per se, but on the action it serves to accomplish. Thus, although many of the WOM methods identified in conversation may seem mundane or even sometimes intuitive (e.g., self-referential advice versus other-referential advice; seeking pros and cons of a product versus seeking a phenomenological experiential narrative), it is precisely their commonplace role in the structure of everyday thought that may help us to capture the richness and subtlety of everyday conceptions of WOM behavior.

Enhancing Self-consciousness: Implications for the Effectiveness of Ad Appeals

Chingching Chang, National Chengchi University

ABSTRACT

This paper explored the influence of self-consciousness on responses to ad appeals. Study one established the positive relationship between self-monitoring and self-consciousness. Study two tested whether level of self-consciousness could influence ad responses. Findings showed that magazine articles written in the second-person, as opposed to the third-person, directed attention to the self and enhanced self-consciousness. Enhancing self-consciousness caused participants high in self-monitoring to generate more favorable ad responses, but it had no effect on those low in self-monitoring. In addition, enhancing self-consciousness significantly improved the effectiveness of image appeal ads, but had no effect on utilitarian appeal ads.

INTRODUCTION

Attention can be directed either internally to the self or externally to the environment (Duval & Wicklund, 1972). Directing attention to the self enhances self-consciousness, which in turn influences individuals' evaluations of the self (e.g., Duval & Wicklund, 1972), attributional styles (e.g., Fejfar & Hoyle, 1990; Wicklund, 1975), responses to emotion (e.g., Scheier & Carver, 1977) and product preferences (e.g., Bushman, 1993). Extending this line of research, I argue that enhancing self-consciousness also can affect responses to advertising messages.

Contextual priming in advertising literature refers to the effect the context in which an ad is presented can have on individuals' responses to the ad. For example, in a competitive ad viewing context, Yi (1990a) demonstrated that evaluation of the target product was influenced by the attributes a previous competing ad promoted. In addition, editorial contexts have also been shown to prime accessibility of different concepts and invite multiple product interpretations. In a similar vein, I propose that reading magazine articles that raise self-consciousness could influence readers' responses to the ad messages embedded in those articles.

The list of the top 25 magazines includes news magazines as well as general and special interest magazines (Adweek, 2004). The latter two magazine types feature articles on a variety of personal topics, including self-improvement, parenting, dating, cooking, fashion, and fishing. Whereas news magazine articles are written mostly in the third-person, articles in interest magazines sometimes try to enhance a sense of intimacy by using the second-person perspective. Articles written in the second-person may be more likely to enhance self-consciousness.

Researchers usually distinguish between two positively correlated sub-dimensions of self-consciousness: private and public (Fenigstein, Scheier, & Buss, 1975). Self-monitoring, a construct widely explored in consumer research, refers to the degree to which individuals monitor or regulate their own behaviors. Its relationship with private and public self-consciousness is examined in this paper. In addition, I hypothesize that those high in self-monitoring will favor magazine articles that direct attention to the self, and therefore will respond more positively to ads embedded in those articles. I also predict that the articles participants read will moderate the effectiveness of image and utilitarian appeal ads. The effectiveness of image appeal ads should improve when participants read a story directing attention to the self, but the effectiveness of utilitarian appeal ads should not vary as a function of story type. Two studies tested these proposed hypotheses.

CONTEXTUAL PRIMING

Cognitive psychologists have suggested that contextual priming can increase the mental accessibility of primed constructs and influence how stimuli are categorized and judged (Higgins & Chaires, 1980; Higgins & King, 1980; Wyer & Srull, 1980). The underlying assumption of this literature is that message perceivers do not search all available information to formulate a judgment but rather rely on the most accessible information. Therefore, recently activated constructs are more likely to be used as judgment inputs or processing frames than un-activated constructs. As a result, what is primed and thus more accessible in the context will exert influence on a message perceiver's judgments.

Past research has established that aspects of the self can be primed and made accessible by contextual cues (Aaker & Lee, 2001; Trafimow, Triandis, & Goto, 1991; Ybarra & Trafimow, 1998). Enhancing accessibility to certain characteristics of the self leads individuals to respond differently to information. For example, memory of information (Aaker & Lee, 2001), attributional styles (Hong et al., 2000), and risk taking behaviors (Mandel, 2003) are affected when specific aspects of the self are primed. Accessibility of self-concepts also can influence what information people take into account when formulating behavioral intentions (Ybarra & Trafimow, 1998).

Consumer research has shown that making aspects of the self more salient can affect individuals' responses to product information as well (Aaker, 1999; Aaker & Lee, 2001). Priming effects also have been explored in advertising research, but not with a focus on the accessibility of consumers' self-concepts. For example, Strahan, Spencer, and Zanna (2002) demonstrated that priming goal-related conditions increases the persuasiveness of advertising appeals that feature these goals. Schmitt (1994) showed that advertisements are more positively evaluated when primed with positive as opposed to negative terms. Similarly, in political advertising, priming certain aspects of existing attitudes can alter how citizens formulate voting decisions (Valentino, Hutchings, & White, 2002).

The advertising literature also has explored contextual priming. In a competitive ad viewing context, Yi (1990a) demonstrated that a computer with multiple functions could be interpreted either positively (the computer is versatile) or negatively (the computer is not user-friendly), and this interpretation depended on the attributes a preceding ad promoted. In addition to the typical ad-embedded context, editorial contexts have also been shown to prime the accessibility of different categories and invite multiple interpretations of a product. For example, Yi's (1990b, 1993) research revealed that reading an article about air travel safety increased participants' positive evaluations of an ambiguous product attribute (i.e., the large size of a car), whereas reading about an oil entrepreneur reduced positive evaluations of the same attribute. Yi reasoned that, in the former case, thoughts about car safety were more accessible leading to more positive product evaluations, whereas, in the latter case, the fuel economy of the car was more accessible causing more negative evaluations.

Yi's research on contextual priming illustrates that judgments and evaluations of a product can vary as a function of the context in which product information is presented. Unfortunately, Yi's investigation is limited to the priming of consumer product information and to the interpretation of ambiguous product attributes. Similar to Yi's work, the present study builds upon cognitive psychology and

suggests that editorial contexts can alter consumer responses to ad messages. However, the focus of this paper shifts from editorial articles that feature consumer information to general interest articles that can enhance self-consciousness.

SELF-CONSCIOUSNESS

Attention can be directed to the self or the external environment (Duval & Wicklund, 1972). Directing attention to the self enhances self-consciousness. According to Argyle (1969), self-consciousness is “the extent to which the self-system is readily activated, so that an interactor becomes concerned with the reactions of others to himself” (p. 378). Duval and Wicklund argued that consciousness can be focused on any aspect of the self and is not limited to a concern with others’ responses to oneself. Self-consciousness may direct an individual’s attention to “his conscious state, his personal history, his body, or any other personal aspects of himself” (Duval & Wicklund, p. 2).

Self-consciousness can refer to a state or trait. Fenigstein et al. (1975; see also Fenigstein, 1979) proposed that the trait of self-consciousness has two dimensions: private and public. The former concerns attention to one’s thoughts, motives, and emotions, whereas the latter pertains to awareness of others’ responses to oneself. Nasby (1989) argued that private and public self-consciousness are not polar anchors of a continuum. Indeed, past research has demonstrated that these two types of self-consciousness are positively correlated (e.g., Abe, Bagozzi, & Sadarangani, 1996).

Even though self-consciousness can be an inherited personal tendency (Fenigstein, 1979), it also can vary as a function of situational factors (Duval & Wicklund, 1972). For example, self-consciousness has been enhanced experimentally by having participants look into a small mirror (Carver & Scheier, 1978; Duval & Wicklund, 1973); listen to their own voices (Ickes, Wicklund & Ferris, 1978); write a story about themselves using first-person terms (Fenigstein & Levine, 1984); and focus their thoughts on themselves (Ellis & Holmes, 1982). This line of research does not specifically distinguish public from private self-consciousness. Given these dimensions positively correlate, Wicklund and Gollwitzer (1987) argued that distinguishing between them does not seem necessary when studying self-consciousness as a state. It is likely that directing attention toward the self will cause activation of both the private and public forms of self-consciousness.

Empirical evidence in social psychology has indicated that enhancing a self-consciousness state encourages self-examination and evaluation (e.g., Duval & Wicklund, 1972), self-attribution (e.g., Fejfar & Hoyle, 1990; Wicklund, 1975), and intense emotional experiences (Scheier & Carver, 1977). However, consumer research has been concerned mainly with the influence of the public self-consciousness trait on consumption behaviors. Studies have shown that individuals high in public self-consciousness wear more makeup (Miller & Cox, 1982), express more interests in clothing (Solomon, & Schopler, 1982), attribute more control to service managers for waiting in line (Marguis & Filiatrault, 2003), and prefer national brands to bargain brands (Bushman, 1993). This paper will extend consumer research by exploring the influence of the self-consciousness state on ad processing.

As mentioned earlier, instructing participants to think about themselves can enhance self-consciousness (Ellis & Holmes, 1982). I propose that certain magazine articles may be able to direct individuals’ attention to themselves. Past literature has shown that using the second-person perspective, as opposed to third-person, increases self-referencing and self-related thinking (Burnkrant & Unnava, 1989). Moreover, instructing participants to construct a story using first-person terms directs their attention to themselves

(Fenigstein & Levine, 1984). Davis and Brock (1975) also showed that participants placed in self-consciousness enhancing situations used more first-person pronouns when determining pronouns in articles written in ambiguous foreign languages. These findings suggest that first-person or second-person perspectives in writing can direct attention to the self. Therefore, I reason that magazine articles written in the second-person will direct readers’ attention to themselves, thereby enhancing self-consciousness.

Assuming a positive correlation between private and public self-consciousness, this paper will explore the effect of enhancing self-consciousness in general, not distinguishing between the two types. The focus of this investigation will be on comparing the effect of reading magazine articles that direct attention to the self, as opposed to articles that do not direct attention to the self, on participants’ responses to advertising messages.

SELF-MONITORING

How likely individuals are to tailor their self-presentation to accommodate situational needs can be measured by their “degree of self-monitoring” (e.g., Snyder, 1974, 1979). According to Snyder’s (1979) discussion,

[T]he prototypic high self-monitoring individual is one who, out of a concern for the situational and interpersonal appropriateness of his or her social behavior, is particularly sensitive to the expression and self-presentation of relevant others in social situations and uses these cues as guidelines for monitoring (that is, regulating and controlling) his or her own behaviors. (p. 89)

In contrast, “the prototypic low self-monitoring individual is not so vigilant to social information about situational appropriateness self-presentation” (p. 89). Snyder developed a self-monitoring scale to measure individual differences on this construct (e.g., Snyder, 1974, 1979). Different from public and private self-consciousness, which are positively correlated, high self-monitoring and low self-monitoring polar anchors of a continuum.

Since consumption to a certain extent is related to self-presentation, self-monitoring has been well explored in consumer literature. Past research has found that high self-monitoring individuals favor products advertised with an emphasis on user image (Snyder & DeBono, 1985). This seems to indicate that those high in self-monitoring direct more of their attention to the self, in general, and self-image, in particular, compared with those low in self-monitoring. Therefore, I hypothesize that individuals higher in self-monitoring will also be higher in self-consciousness, both private and public forms.

Hypothesis 1: Individuals’ self-monitoring is positively correlated with their public and private self-consciousness.

Aaker (1999) demonstrated that situationally primed self-concepts are more important to high self-monitoring decision makers than chronically accessible self-concepts, which are, conversely, more important to low self-monitoring decision makers. She concluded that high self-monitors are more susceptible to the influence of situational factors. Therefore, it is argued that people high in self-monitoring will be more affected by stories containing self-related cues. Specifically, they will be more favorable of magazine articles written in the second-person, which direct attention to the self. This preference will carry over to improve their responses to the ads and brands embedded within these articles. As a result, they will rate the ads as more diagnostic and likable, rate

the brands as more favorable, and express greater purchase intention. On the contrary, individuals low in self-monitoring will not respond differently to magazine articles that direct attention to the self versus others.

Hypothesis 2: When reading magazine articles that direct attention to the self versus others, those high in self-monitoring will rate ads as more diagnostic (2a) and likable (2b), evaluate brands as more favorable (2c), and report higher levels of purchase intention (2d). In contrast, those low in self-monitoring will not respond differently on these measures when reading articles that direct attention to the self versus others.

IMAGE VS. UTILITARIAN APPEALS

The two most widely used types of advertising appeals are image and utilitarian appeals (Johar & Sirgy, 1991; Snyder & DeBono, 1985). The image appeal, also known as the value-expressive or symbolic appeal, "holds a creative objective to create an image of the generalized user of the advertised product (or brand)" (Johar & Sirgy, 1991, p. 23). In contrast, the utilitarian appeal is "a creative strategy that highlights the functional features of the product (or brand)" (Johar & Sirgy, 1991, p. 23). Utilitarian appeal ads focus on product attributes or performance. This type of appeal is also referred to as the functional appeal (Johar & Sirgy, 1991) or the quality-oriented appeal (Snyder & DeBono, 1985).

Snyder and DeBono (1985) found that high self-monitoring individuals are influenced more by image advertising appeals, whereas low self-monitors are influenced more by utilitarian appeals. When image appeals are used, high self-monitoring individuals judge the advertised product to be of better quality (DeBono & Snyer, 1989), rate it as more personally relevant (DeBono & Packer, 1991), and are willing to pay more for the product (Snyder & DeBono, 1985). In contrast, low self-monitoring individuals judge the product to be of better quality (DeBono & Snyer, 1989), rate it as more personally relevant (DeBono & Packer, 1991), and show greater willingness to pay (Snyder & DeBono, 1985) when utilitarian appeals are employed.

As discussed earlier, people high in self-monitoring may evaluate image appeals more favorably because they pay more attention to themselves and their self-images. In line with this argument, I hypothesize that directing attention to the self will cause individuals to perceive the image of the product users as relevant to their judgments. Consequently, the effectiveness of image appeal ads will increase, resulting in more favorable attitudes toward the ad and the brand, which will further lead to greater purchase intentions. In contrast, directing attention to the self will not influence the effectiveness of utilitarian appeal ads.

Hypothesis 3: When reading magazine articles that direct attention to the self versus others, participants exposed to image appeal ads will rate ads as more diagnostic (3a) and likable (3b), evaluate brands as more favorable (3c), and report higher levels of purchase intention (3d). In contrast, participants exposed to utilitarian appeal ads will not respond differently on these measures when reading articles that direct attention to the self versus others.

Study one tests hypothesis 1, and study two tests hypotheses 2 and 3.

STUDY ONE

Methods

Participants (N=97) were recruited from a university in a metropolitan area. They were told a professor in the Psychology department was interested in understanding personality traits in college students. They completed a self-administered survey for which they rated themselves using a 7-point scale on a long list of personality trait measures, including a self-consciousness scale (Fenigstein et al., 1975) and a self-monitoring scale (Snyder, 1974).

Results

Means for public self-consciousness, private self-consciousness, and self-monitoring were 5.60 (SD=0.99), 5.43 (SD=0.85), and 4.34 (SD=0.61), respectively. The difference between participants' ratings of public and private self-consciousness was not significant, $t(96)=1.69$, $p=.09$, indicating that participants were paying attention to their internal selves as well as others' responses to their self-presentation. Also, consistent with past research, public and private self-consciousness were positively correlated (Pearson's $r(95)=.42$, $p<.01$). Most importantly, ratings of self-monitoring were positively correlated with ratings of private self-consciousness (Pearson's $r=.23$, $p<.01$) and public self-consciousness (Pearson's $r=.26$, $p<.01$). Thus, hypothesis 1 was supported.

STUDY TWO

Methods

Participants

Participants (N=131) were recruited from the campus of a metropolitan area university and were paid for their participation. Fifty-two percent were male.

Design

This experiment was a 2 x 2 x 2 between-subjects factorial design. The factors were: article type (self-directed vs. non-self-directed), ad appeal (image vs. utilitarian), and self-monitoring (high vs. low).

Materials

Magazines articles. Magazine articles served as the contextual priming material for directing attention and enhancing self-consciousness. The article directing attention to the self was written in the second-person perspective, whereas the article that did not direct attention to the self used the third-person. Participants were told that the magazine was going to be launched in the area and targeted at college students. The featured article was about college life.

Ad stimuli. Professional copy writers and designers at advertising agencies wrote the ad messages used in this experiment. The featured products were shoes. The utilitarian appeal ad featured product attribute information that was selected based on a pretest in which 20 participants listed the attributes they considered most important when purchasing shoes. The image appeal ad described product users but did not address specific product attributes.

Procedures

Participants were randomly assigned to one of the four manipulated conditions. To discourage participants from guessing the true aim of the study, at the beginning of the experiment the research coordinator falsely informed them that they would be participating in three independent studies. The first study was a survey of college students' values and traits. The second study was designed to understand how people respond to layout and formats in magazine articles. The third study examined the effects of different ad layouts

on reader responses. Participants first rated themselves on a number of scales including the self-monitoring scale (Snyder, 1974) and other filler scales. Next, participants read a magazine article and rated how comprehensible the article was and how much they liked the format. They then completed the private and public subscales of the self-consciousness scale (Fenigstein et al., 1975). Finally, they read the target ad, rated its diagnosticity, and reported their attitudes toward the ad and the featured product.

Independent Variables

Article type. Following presentation of the magazine articles, the private and public self-consciousness subscales (Fenigstein et al., 1975) were administered as a manipulation check. Responses to the subscale items were averaged together. As expected, articles written in the second-person perspective generated significantly higher self-consciousness ratings, $F(1, 129)=6.90, p<.01, M_{\text{self}}=5.81, SD=0.83, M_{\text{non-self}}=5.45, SD=0.72$.

Ad appeal. Responses to four statements measured on 7-point Likert-type scales were used for the manipulation check. The statements included: "The ad features product attributes," "The ad focuses on product functions," "The ad describes product users," and "The ad features a profile of consumers." The last two items were reverse scored, and then all items were averaged. The manipulation was successful, as ratings for utilitarian appeals were significantly higher than ratings for image appeals, $F(1, 129)=33.32, p<.01, M_{\text{utilitarian}}=4.50, SD=0.67, M_{\text{image}}=3.67, SD=0.95$.

Self-monitoring. Using a 7-point Likert scale, participants completed Snyder's (1974) self-monitoring scale (Cronbach's $\alpha=.69$). Participants were categorized as high or low self-monitoring based on a median split of their ratings. The two groups' average ratings differed significantly, $F(1, 129)=223.45, p<.01, M_{\text{high}}=4.72, SD=0.37, M_{\text{low}}=3.77, SD=0.34$.

Dependent Variables

Ad diagnosticity. A 3-item, 7-point Likert scale was adopted from Chang (2003) to measure ad diagnosticity. The items were: "The ad made me confident in making judgments of the product," "The ad made me able to evaluate the advertised product," and "The ad made me confident to make a purchase decision." Cronbach's α for the scale was .89, indicating good internal reliability.

Ad attitudes. Attitudes toward the ads were measured using a 5-item, 7-point Likert scale adopted from MacKenzie, Lutz, and Belch (1986) and Madden, Allen, and Twible (1988). The items were "interesting," "good," "likable," "favorable," and "pleasant." The scale had high internal reliability (Cronbach's $\alpha=.89$).

Brand attitudes. Brand attitudes were measured with a 5-item, 7-point Likert scale adopted from Mitchell and Olson (1981) and Holbrook and Batra (1987). The items were "good," "likable," "pleasant," "positive," and "high quality." Cronbach's α was .92, indicating good reliability.

Purchase intentions. A semantic differential scale was adopted from Zhang (1996) to measure purchase intentions. It contained three items: "improbable-probable," "unlikely-likely," and "impossible-possible." Reliability for this scale was high (Cronbach's $\alpha=.93$).

Results

Between-subjects analyses of variance followed by simple effects tests were conducted on the four dependent variables to test hypotheses 2 and 3. As expected, the interaction between self-monitoring and article type on ad diagnosticity was significant, $F(1, 123)=4.79, p=.03$. For participants high in self-monitoring, the influence of article type was marginally significant, $F(1, 69)=3.57, p=.06$, with means in the expected direction, $M_{\text{self}}=3.58, SD=1.26; M_{\text{non-self}}=3.07, SD=1.48$. However, as expected, for participants low in self-monitoring, the influence of article type was not signifi-

cant, $F(1, 54)=1.56, p=.22, M_{\text{self}}=3.10, SD=1.48; M_{\text{non-self}}=3.46, SD=1.24$. Therefore, hypothesis 2a was moderately supported.

There was also a significant interaction between self-monitoring and article type on ad attitudes, $F(1, 123)=5.05, p=.03$. For participants high in self-monitoring, reading self-directed magazine articles resulted in more favorable attitudes toward the ad, $F(1, 69)=7.61, p=.01, M_{\text{self}}=4.44, SD=1.14; M_{\text{non-self}}=3.71, SD=1.20$. As expected, the influence of article type was not significant for participants low in self-monitoring, $F(1, 54)=.28, p=.61, M_{\text{self}}=4.17, SD=1.17; M_{\text{non-self}}=4.27, SD=1.02$. Therefore, hypothesis 2b was fully supported.

The self-monitoring by article type interaction was also significant for brand attitudes, $F(1, 123)=5.74, p=.02$. For participants high in self-monitoring, reading self-directed magazines articles led to more favorable brand attitudes, $F(1, 69)=4.24, p=.04, M_{\text{self}}=4.30, SD=1.30; M_{\text{non-self}}=3.74, SD=1.28$. Consistent with expectations, for participants low in self-monitoring, the influence of article type was not significant, $F(1, 54)=1.91, p=.17, M_{\text{self}}=4.06, SD=1.19; M_{\text{non-self}}=4.41, SD=1.03$. Therefore, hypothesis 2c was fully supported.

For the analysis of purchase intentions, the interaction between self-monitoring and article type only approached significance, $F(1, 123)=3.38, p=.07$. The influence of article type was neither significant for participants high in self-monitoring, $F(1, 69)=2.33, p=.13, M_{\text{self}}=2.59, SD=1.36; M_{\text{non-self}}=2.12, SD=1.34$, nor for participants low in self-monitoring, $F(1, 54)=1.22, p=.27, M_{\text{self}}=2.37, SD=1.46; M_{\text{non-self}}=2.83, SD=1.07$. Hypothesis 2d, therefore, was not supported.

Results showed a significant interaction between ad appeal and article type on ad diagnosticity, $F(1, 123)=4.44, p=.04$. Self-directed articles led to higher diagnosticity ratings for image appeal ads, $F(1, 63)=4.78, p=.03, M_{\text{self}}=3.18, SD=1.26; M_{\text{non-self}}=2.54, SD=1.09$. Consistent with expectations, the influence of article type was not significant for utilitarian appeal ads, $F(1, 62)=1.44, p=.23, M_{\text{self}}=3.56, SD=1.47; M_{\text{non-self}}=3.96, SD=1.28$. Therefore, hypothesis 3a was fully supported.

The interaction between ad appeal and article type on ad attitudes was not significant, $F(1, 123)=1.56, p=.22$. Given that a hypothesis regarding lower level differences was established a priori, lower level comparisons were justified (Winer, Brown, & Michels, 1991). The results of simple effects tests were consistent with expectations. For image appeal ads, self-directed articles led to significantly more favorable attitude ratings, $F(1, 63)=5.18, p=.03, M_{\text{self}}=4.26, SD=1.18; M_{\text{non-self}}=3.61, SD=1.12$. For utilitarian appeal ads, the effect of article type was not significant, $F(1, 62)=.03, p=.87, M_{\text{self}}=4.39, SD=1.14; M_{\text{non-self}}=4.32, SD=1.08$. Hypothesis 3b, therefore, was supported only by the results of simple effects tests.

Contrary to expectations, the interaction between ad appeal and article type on brand attitudes was not significant, $F(1, 123)=.58, p=.45$. Simple effects tests showed no significant influence of article type for image appeal ads, $F(1, 63)=1.32, p=.25, M_{\text{self}}=4.03, SD=1.24; M_{\text{non-self}}=3.69, SD=1.14$, or for utilitarian appeal ads, $F(1, 62)=.04, p=.84, M_{\text{self}}=4.36, SD=1.26; M_{\text{non-self}}=4.40, SD=1.19$. Therefore, hypothesis 3c was not supported.

Finally, there was a significant interaction between ad appeal and article type on purchase intentions, $F(1, 123)=10.86, p=.01$. For image appeal ads, self-directed articles led to greater purchase intentions, $F(1, 69)=6.64, p=.01, M_{\text{self}}=2.77, SD=1.47; M_{\text{non-self}}=1.97, SD=.98$. Whereas, for utilitarian appeal ads, self-directed articles generated lower purchase intentions, $F(1, 54)=4.51, p=.04, M_{\text{self}}=2.23, SD=1.29; M_{\text{non-self}}=2.92, SD=1.35$. Therefore, the results for image appeal ads were consistent with hypothesis 3d.

Discussion

The relationship between self-monitoring and responses to ad appeals has been widely explored in the consumer literature (e.g., DeBono & Packer, 1991; DeBono & Snyder, 1989; Snyder & DeBono, 1985). However, the possible influence of self-consciousness on the effectiveness of different ad appeals has never drawn research attention. Findings reported in this paper suggest that self-consciousness moderates the effectiveness of image and utilitarian appeals, the two most common advertising appeals. Image appeal ads were more favorably perceived when self-consciousness was enhanced, paralleling the research on high self-monitoring. However, contrary to research findings on low self-monitoring, utilitarian appeal ads were not preferred more when self-consciousness was not enhanced. Past research found that less than six percent of the variance in each of the self-consciousness subscales is shared with variance in self-monitoring (Turner, Scheier, Carver, & Ickes, 1978), indicating that self-consciousness deserves its own research attention. Future research can explore how self-consciousness interacts with other advertising appeals.

As previously reviewed, more research attention in the consumer literature has focused on individual differences in self-consciousness as a stable personality trait. In this paper self-consciousness was explored as a state, which was manipulated by reading magazine articles. However, Aaker (1999) pointed out that individuals' traits can moderate the influence of situational primes. It seems likely that individuals who are more self-reflective may be more susceptible to a self-consciousness manipulation than less self-reflective individuals. Future studies can explore the interaction of situation-primed self-attention and existing difference in attention orientation on individuals' responses to advertising messages or product information.

Study two focused on a state of general self-consciousness, not specifically distinguishing between private and public self-consciousness. In this experiment self-consciousness was enhanced by reading a magazine article, which generally provides a personal context. However, public self-consciousness is more likely triggered by the context of the social environment (Buss, 1980). Therefore, public self-consciousness may have been less enhanced in this experiment. Given that private and public self-consciousness are positively correlated, however, it is likely that activating one type of self-consciousness may automatically increase activation of the other type. As the definition suggests, when public self-consciousness increases, an individual pays more attention to others' responses to the self. Attending to others' responses to the self may cause attention to be directed toward one's own view of the self as well, thereby enhancing private self-consciousness. Yet, the same spreading activation effect may not occur in the other direction. Future research can explore this possible difference. In addition, how variance in consumers' responses to advertising is explained by each type of self-consciousness and how important it is to distinguish these two constructs in advertising research should be further explored.

This study extended contextual priming literature by showing that magazine articles can direct attention to the self and enhance the effectiveness of image appeals. This finding has important implications for practitioners. For instance, fashion products marketed with a focus on boosting the consumer's image could purchase more space in magazines featuring articles that direct attention to the self. There are many ways to direct consumers' attention to themselves; featuring stories in second-person perspectives is simply one of them. A future direction for research in this area could be to establish the specific characteristics of magazines or articles that are capable of enhancing self-consciousness in consumers and thereby influencing their product judgments.

The Role of Self-Affirmation in Consumer Persuasion

Pablo Briñol, Universidad Autónoma de Madrid

Richard E. Petty, Ohio State University

Ismael Gallardo, Universidad Autónoma de Madrid

Kenneth G. DeMarree, Ohio State University

EXTENDED ABSTRACT

Consumers are often motivated to resist changing. Resistance to persuasion is influenced by many individual and situational factors related to both the ability and the motivation of consumers. For example, although much is known about characteristics of attitudes that make them resistant to change (e.g., Petty and Krosnick 1995), less is known about factors that influence individuals' motivation to resist persuasion (e.g., Briñol, Rucker, Tormala and Petty 2004; Wheeler, Briñol and Hermann 2004).

Contemporary research on self-affirmation processes has provided one perspective to understand how consumers' attitude-defensive repertoires can be undermined. In general, self-affirmation involves the reinforcement of the self on an important personal aspect, such as a person's values (e.g., honesty, Steele 1988). Because our attitudes are part of the self, a persuasive message can be a potential threat against the self. By expressing a personally important value, the threat may be diminished, reducing the need to resist the new information and, as a consequence, increasing attitude change by reducing resistance (e.g., Cohen, Aronson and Steele 2000).

Consistent with this logic, recent research has found evidence for self-affirmation inducing an "open minded" mind set in which people are less resistant to persuasion when they are self-affirmed (e.g., Sherman, Nelson and Steele, 2000; Cohen et al. 2000, Reed and Aspinwall 1998, Steele and Liu 1983). Although the dominant explanation for this phenomenon is that affirming oneself decreases the need to defend one's attitudes, leading to increased vulnerability to persuasion, alternative mechanisms are possible. For example, self-affirmation could increase persuasion by producing positive mood or by trivializing the importance of the attitude object as a source of personal identity (see, e.g., Correll, Spencer and Zanna 2004).

The present research suggests a new explanation based on the idea that self-affirmation lead to confidence, and this confidence can increase or decrease persuasion depending on the circumstances. Specifically, we predict that self-affirmation, and the confidence it induces, can reduce information-processing activity when people are affirmed prior to a message, but it can increase the perceived validity of cognitive responses to a message when people are affirmed after message-exposure.

Experiment 1

Sixty-eight university undergraduates participated in partial fulfillment of a course requirement. Participants were randomly assigned to the self-affirmation condition (in which they had to write about previous episodes in which they behaved consistent with an important personal value, Zuwerink and O'Brien 2004) or to a control group. Following this induction, participants received a strong or weak version of an advertisement promoting a new cell phone. Argument quality was varied to examine the extent of information processing (see Petty and Cacioppo, 1986). After reading the ad, participants listed their thoughts and reported their attitudes toward the product.

We predicted and found a significant interaction between self-affirmation and argument strength revealing that self-affirmation

influenced advertising effectiveness by affecting the amount of thought devoted to the ad. Specifically, self-affirmation reduced message processing. As a result, self-affirmation increased consumer attitude change only when the arguments contained in the ad were weak. In contrast, self-affirmation reduced persuasion for compelling arguments. Thus, self-affirmation induced prior to the ad can increase or decrease persuasion depending on the quality of the arguments contained in the ad.

Experiment 2 addresses what happens when self-affirmation is induced after a message has already been processed. In this case, self-affirmation could not affect how much processing was done, but we expected it to influence confidence in the thoughts produced. If this occurs, self-affirmation should produce the opposite interaction with argument quality as was found in Study 1.

Experiment 2

Seventy-one undergraduate students were first exposed to a persuasive message in favor of a new program of magnetic cards containing either strong or weak arguments. Argument quality was varied in this study to manipulate the dominant thought in which participants would have high or low confidence (see Petty, Briñol and Tormala 2002). After participants read the message and wrote their thoughts about the proposal, they were asked to write about a personally important value (self-affirmation condition) or not (control group). Following the self-affirmation manipulation, all participants reported their attitudes toward the message proposal.

We expected and found self-affirmation to interact with argument strength in predicting participant's attitudes. Specifically, when the arguments elicited mostly favorable thoughts toward the proposal (strong message condition), self-affirmed participants reported more positive attitudes than control individuals. In contrast, when participants generated mostly negative thoughts (weak message condition), there was more resistance in the self-affirmation than in the control group. Thus, when self-affirmation follows rather than precedes the message, it influences consumer persuasion by affecting the confidence that people have in the validity of their thoughts.

Discussion

The present research provided initial evidence in support of a new explanation for the persuasive effect of self-affirmation based on the idea that self-affirmation leads to confidence. Confidence can play different roles in consumer persuasion, affecting attitude change by different psychological mechanisms. In study 1, when people were self-affirmed before receiving an ad, self-affirmation influenced advertising effectiveness by affecting the amount of information processing consistent with prior work inducing confidence prior to a message (e.g., Tiedens and Linton 2001). Alternatively, in study 2, when people were self-affirmed after processing the message, self-affirmation affected persuasion by influencing thought-confidence, consistent with prior work inducing confidence after a message (e.g., Briñol, Petty and Tormala 2004; Petty et al. 2002; see also, Briñol, Petty and Falces 2002).

While this research offers compelling initial support for our predictions, there are a number of conceptual issues that need to be

addressed with future research. First, the timing of the self-affirmation manipulation should be manipulated within the same experiment and using the same arguments. Furthermore, future research should collect more process data demonstrating the link between self-affirmation and confidence. Third, it would be desirable to replicate the obtained findings with different manipulations of self-affirmation and other more comparable, control groups. Finally, since the present research has used relatively personally irrelevant messages, it would be interesting to explore the postulated mechanisms for more threatening, personally relevant messages (Correll et al. 2004; Sherman et al. 2000).

Mothers, Food, Love and Career—The Four Major Guilt Groups? The Differential Effects of Guilt Appeals

Monica C. LaBarge, University of Oregon
John Godek, University of Oregon

EXTENDED ABSTRACT

Marketers have become increasingly interested in the use of emotions in advertising appeals, particularly negative emotions. Several of the negative emotions that are of interest include fear, guilt, embarrassment, regret, remorse, annoyance, and irritation (Burke and Edell 1983). From a marketing perspective, it is important to understand how the use of these different negative emotions affects consumers' reactions to persuasion attempts. Guilt is a complex emotion, with correspondingly complex effects on persuasion. For example, in response to guilt appeals, Englis (1990) found that consumers experienced high levels of anger, disdain, disgust and embarrassment. Coulter and Pinto (1995) found that while guilt appeals may be successful at inducing behavioral compliance, they also produce unintended reactions such as anger that can ultimately negatively impact perceptions of the advertiser. In this paper we examine several aspects of guilt and determine the effects of different types of guilt appeals on attitudes and behavior.

Guilt: Definition and Characteristics

Guilt can be seen as a combination of negative emotions such as regret, remorse and self-blame that are usually experienced upon either contemplating or actually committing a transgression (Lascu 1991). Generally that takes the form of some sort of comparison between one's actual and one's optimal behavior according to a socially-defined standard, rule or moral imperative (Lewis 1993, Ortony et al. 1988, Giner-Sorolla 2001). Guilt can be broken down into three distinct types: existential, anticipatory, and reactive. Each of these types is currently employed by advertisers (Huhmann and Brotherton 1997, Cotte et al. in press, Coulter et al. 1999). *Existential* guilt is most often found in social marketing advertisements which compare one's own well-being to the well-being of others (Izard 1977) and encourage action to bring the two closer together. *Anticipatory* guilt is stimulated when an individual contemplates the *potential future* violation of some internalized standard of acceptable behavior, whereas *reactive guilt* occurs in response to a *past, overt* act of having violated those standards (Coulter et al. 1999, Cotte et al. in press).

Anticipatory and reactive guilt in particular are of interest as a recent content analysis by Huhmann and Brotherton (1997) showed them to be common appeals in popular print advertising. Of more than 2,000 advertisements processed, the content analysis found that 5.8% employed guilt appeals, of which 61.9% could be classified as anticipatory and 29.4% as reactive. In addition, research indicates that there is a differential effect in then intensity with which these two types of guilt are experienced. Giner-Sorolla (2001) found that, in the case of a short-term benefit/delayed-cost activity (e.g. going off one's diet for an immediate sugar fix), anticipatory guilt is felt less intensely and less negatively than the reactive guilt that is experienced after actually engaging in the guilt-inducing behavior. The opportunity to avoid the behavior that would cause reactive guilt also increases feelings of self-efficacy and self-control in the anticipatory condition. In contrast, in the reactive condition, having one's failure to resist temptation pointed out increases feelings of helplessness and worthlessness and overall contributes to negative affect.

Implications for Persuasion

Although guilt appeals may influence behavior, they may also elicit negative emotions. Anticipatory guilt could be construed as the most positive of the three types, since it focuses on the future and the hopeful potential of avoiding a negative emotion through some individual effort or exercise of self-control. Reactive guilt, on the other hand, can be construed as more negative, since it focuses on past transgressions and feelings of guilt in order to spur action towards avoiding that emotion again. These differences in the nature of the emotion elicited by anticipatory and reactive appeals has several implications for the persuasiveness of these appeals. The first of these concerns how consumers perceive the ad itself as well as the brand that is depicted in the ad. Since prior research has demonstrated that emotional responses to ads affects attitude towards the ad (A_{ad}) and attitude towards the brand (A_{br}) (Batra and Ray 1986, Edell and Burke 1987, MacKenzie and Lutz 1989), we would expect that consumers would respond more positively when ads used anticipatory appeals as compared to reactive appeals.

Additionally, research in the area of information processing indicates that affect plays a role in determining whether a message is processed heuristically or systematically (Schwarz and Clore 1996). In particular, the "feelings-as-information" view holds that our affective response to a target is a useful source of information when evaluating the target, and whether we experience positive or negative emotions will determine our information processing strategy. In general, individuals in a sad mood or experiencing negative emotions are both more willing to invest cognitive effort than happy individuals, as well as more likely to process information at a lower level of abstraction. This is because the negative affect cues us to a potential discrepancy between our current and our desired situation (or a "better watch out" message), and stimulates a desire for accuracy, which is in turn manifested in the systematic processing of the message (Schwarz and Clore 1996). As such, we would expect that reactive advertising appeals would elicit more systematic processing of the content of the ad than anticipatory appeals.

In order to test these propositions we conducted three experimental studies. The first examined the differential effects of anticipatory and reactive advertising appeals on various positive and negative emotions. The second study examines differences in the types of processing that consumers engage in when exposed to anticipatory and reactive advertising appeals. The third study examined differences in experienced emotions and depth of processing according to sex and need for cognition.

All the studies examined the implications that these differential effects on emotions and processing have on consumers' attitudes and behavior intentions. Our results provide evidence that anticipatory and reactive guilt appeals differ in several ways that have important implications for these types of persuasive attempts.

When Choosing Is Not Deciding: The Effect of Perceived Responsibility on Choice Outcome Satisfaction

Simona Botti, Cornell University
Ann L. McGill, University of Chicago

EXTENDED ABSTRACT

Prior research has demonstrated that when presented with all desirable options consumers are more satisfied with self-chosen alternatives than with alternatives that have been externally dictated, but that the opposite is true when the options are all undesirable. This reversal in satisfaction has been explained through an affective account: Choosers' greater engagement in the decision task causes their affective experience with the choice outcome to be more extreme than that of non-choosers (Botti and Iyengar 2004). In the present research we hypothesize that the amplification effect of choice on satisfaction is moderated by choosers' ability to differentiate among the choice options: If options are less, as compared to more differentiated decision makers would be just as happy with an externally-made as with a self-chosen option.

This prediction is based on a potential confound between the effect of choice and that of responsibility in prior findings. Research has shown that when people feel responsible for an outcome the affective experience with that outcome is magnified by either self-credit for a pleasant or self-blame for an unpleasant experience (Gilovich, Medvec, and Chen 1995; Kahneman and Tversky 1982; Landman 1987; Ritov and Baron 1992; Weiner 1981). Hence, we hypothesize that if perception of responsibility were weakened, choosers would have less of a basis on which to congratulate or blame themselves, resulting in a smaller difference between their satisfaction and that of non-choosers.

Building on prior research suggesting that choice commitment is lower in the absence of a dominating option (Dhar 1997; Shafir, Simonson and Tversky 1993), we manipulate personal responsibility by varying the extent to which decision makers can distinguish among the options and identify the more preferred one: When non-diagnostic information prevents them from identifying each option's relative quality, choosing contributes less to the ultimate experience than when differences among the alternatives are readily appreciated, influencing choosers' sense of responsibility for the outcome and reducing the gap between choosers and non-choosers' satisfaction. However, consistent with prior research showing that preference for choosing is not sensitive to the same factors that influence satisfaction (Botti and Iyengar 2004) we hypothesize that the desire to choose will not vary as a function of option differentiability.

Study 1 and 2 used a 2 (choice condition: choice vs. no-choice) x 2 (option differentiability: high vs. low) between-subjects factorial design to test these hypotheses in, respectively, a positively-valenced (coffee) and negatively-valenced (foul odors) context. High-, relative to low-differentiability participants were provided with descriptions that were more diagnostic of the relative quality of the options so that they could more easily identify the most desirable—or least undesirable—one. Choice participants selected an option, whereas no-choice participants were assigned an option at random by the experimenter. In reality, a yoked design was used so to ensure that non-choosers were assigned the same selection of their counterpart choosers; in addition, in spite of the different descriptions, all participants drank the same blend and smelled the same odor. As predicted, in the high-differentiability condition choosers were more satisfied with a pleasant and more dissatisfied with an unpleasant outcome than non-choosers, while in the low-

differentiability condition there was no difference in satisfaction. Choosers also experienced greater responsibility and credited or blamed themselves more in the high- than in the low-differentiability condition, while levels of responsibility, self-credit, and self-blame did not vary across the two no-choice conditions. Also as expected, choosers liked their choice condition better and were also less willing to switch to the other choice condition than non-choosers, suggesting that preference for choice is not sensitive to the level of differentiability of the options.

Study 3 tested for the alternative account that choosers in the low-differentiability condition in reality selected an option at random, which would explain the lack of difference in satisfaction between low-differentiability choosers and non-choosers obtained in the previous two studies. In this 2 (choice condition: choice vs. no-choice) x 2 (option differentiability: random vs. low) study involving positively-valenced options (chocolate), choosers and non-choosers in the low- differentiability choice condition were given the usual non-diagnostic information, while those in the random choice condition were given no information at all. We predicted a difference in satisfaction in the random, but not in the low-differentiability condition, a result that would confirm that these two conditions are not equivalent. In addition, we anticipated that random choosers would be less satisfied than random non-choosers. This prediction is based on prior research suggesting that choosers' responses are usually a mix of self-credit and self-blame (Brenner, Rottenstreich, and Sood 1999; Carmon, Wertenbroch, and Zeelenberg 2003; Hsee and Leclerc 1998; Kahneman and Tversky 1982; Luce 1998). Hence, we expected random choosers to not only grant themselves little credit for a positive outcome, given the lack of information on which they could base a choice, but to also harbor misgivings that however tasty their chosen chocolate, they may have inadvertently rejected a superior alternative. As a result, random choosers' self-blame may overcome self-credit, lowering their satisfaction with the chosen option relative to non-choosers. Confirming these predictions, a difference in satisfaction was observed between choosers and non-choosers in the random condition, with choosers being less satisfied with the tasted chocolate than non-choosers, but not in the low-differentiability condition. In addition, the ratio of self-blame to self-credit was found to fully mediate satisfaction with the chocolate.

As opportunities for personal choosing have been growing in modern societies, marketers seem to share with consumers the belief that choice necessarily leads to greater happiness (Schwartz 2004). However, if meaningful differences among the choice options are difficult to discern because of competitive parity in mature markets, heightened product complexity, or consumers' inability to research the alternatives, the positive effect of choice on satisfaction is nullified.

Effect of Response Time on Perceptions of Bargaining Outcomes

Joydeep Srivastava, University of Maryland

Shweta S. Oza, University of Maryland

EXTENDED ABSTRACT

Although consumers in the U. S. are predominantly exposed to fixed, non-negotiable prices, many consumer purchases including those that require substantial resources such as buying a house or an automobile involve negotiations. Despite the significance of these purchase decisions, consumer research on bargaining is relatively sparse (cf. Buchan, Croson, and Johnson 2004; Corfman and Lehmann 1993). Additionally, the few studies in the marketing literature have studied bargaining in the context of industrial purchases (e.g., Srivastava, Chakravarti, and Rapoport 2000). There is thus a need for research on bargaining from a consumer perspective.

In bargaining with incomplete information, bargainers may use features of the bargaining process as referents to infer their own and/or opponents' payoffs in at least two ways based on opponents' active or passive behavior. Bargainers may infer some information about payoffs when opponents actively respond to an existing offer positively (i.e., accept) or negatively (i.e., reject and make a counteroffer). Another important cue that may emerge from within the bargaining context, and the focus of this research, is opponent's passive behavior or the time taken by an opponent to respond to an existing offer (positively or negatively). While a few studies have examined bargainers' inferences based on active behavior (e.g., Srivastava 2001), relatively little research has focused on how opponents' passive behavior affects perceptions of bargaining outcomes.

Broadly, this research takes a consumer-focused approach to examine the effect of time taken by an opponent to respond to an offer on perceptions of bargaining outcomes, independent of actual outcomes. The focus is to identify behavioral regularities and thereby highlight the malleability of bargaining perceptions and behavior. Identification of systematic biases and their underlying reasons represent the first step towards helping consumers make wiser decisions by making them more vigilant of tactics that may be used by some to manage perceptions and behavior. It is in this spirit that this research examines the extent to which bargaining outcomes are judged comparatively as they are evaluated relative to the inferences about a bargaining opponent based on the time taken to respond to an offer.

This research argues that perceptions of bargaining outcomes may be influenced by cues that emerge from the bargaining environment, such as the time taken by an opponent to respond to an offer. Based on the idea that individuals evaluate outcomes by comparing their outcomes with those of people around them, particularly when objective referents are unavailable (Festinger 1954), the time taken by an opponent to respond to an offer may be used to infer the quality of his/her outcome, which in turn, is used in evaluating one's own bargaining outcomes. In examining the conditions under which cues that emerge from the bargaining context affect inferences about opponents and thereby perceptions of one's own bargaining outcomes, this article traces the mediating role of social comparison judgments in how cues, that are not necessarily social in nature, affect perceptions of bargaining outcomes.

Study 1 tests the hypotheses that bargainers will be less satisfied with their outcomes when their offer is accepted immediately than after a delay. We manipulate the response time using a three factor (no delay, some delay, and negotiated delay) between-

subjects design. Results of study 1 demonstrates that experiencing delay in real time, bargaining outcomes were perceived to be better when an offer was accepted after a delay than when it was accepted immediately, even though the actual outcomes were monetarily equivalent. Also, the intensity of "I could have done better" thoughts mediates this effect.

Study 2 tests the hypothesis that the influence of time taken to respond to an offer on perceptions of bargaining outcomes will be mediated by inferences of conflict within the opponent. We explicitly manipulate response time and level of opponent conflict associated with response time in a four factor (no delay, delay, no delay-associated with conflict, and delay-associated with little or no conflict) between-subjects design and show that perceived level of opponent's conflictedness mediate the effect of response time on perceptions of own bargaining outcomes for the no delay and delay conditions. However, the pattern or results is reversed for the no delay-associated with conflict and delay-associated with little or no conflict, such that the perceptions of own bargaining outcomes are superior in the no delay-associated with conflict condition as compared to delay-associated with little or no conflict condition. Consistent with hypothesis 2, these data showed that the inferred level of conflict within the opponent underlie the effect of response time.

Study 3 explores the boundary conditions for the effect of response time on perceptions of bargaining outcomes and tests the hypothesis that the time taken by an opponent to respond to an offer is likely to have a stronger effect on perceptions of bargaining outcomes in the absence (vs. presence) of an objective (or diagnostic) referent. We manipulated response time and referent presence using a 2 (response time: no delay and delay) x 2 (objective referent: present and absent) between-subjects design. The results corroborate and extend the earlier findings by showing that effect of time taken to respond to an offer is moderated by the presence of an objective referents. Individuals are thus more susceptible to cues that emerge from the bargaining environment in the absence of objective or diagnostic referents.

Together, these three studies demonstrate that the bargaining outcomes were perceived to be superior when an offer was accepted after a delay than when it was accepted immediately. The findings highlight the role of attributions for an opponent's behavior in influencing bargaining perceptions. The results are consistent with the idea that the time taken by an opponent to respond is used to infer the level of conflict within the opponent in making a decision. Specifically, the findings are consistent with the notion that immediacy is linked with little or no conflict whereas a delay in responding to an offer is linked with conflict. The level of inferred conflict, in turn, is used in assessing one's own outcomes. The finding that time taken to respond affected perceptions of bargaining outcomes in the absence versus presence of an objective referent suggests that uncertainty prompts causal analysis and individuals are more susceptible to cues when the need to seek a causal explanation for others' behavior is high.

Bidders' Regret in Auctions

Shuili Du, Boston University

Lisa J. Abendroth, Boston University

Sucharita Chandran, Boston University

EXTENDED ABSTRACT

This research investigates regret miscalibration that occurs during the bidding process: anticipated regret being greater than experienced regret, and the effects of anticipated regret on bidding decisions.

In auctions, there are two types of unfavorable outcomes that are likely to trigger regret: winning but overpaying for the auctioned item and losing the chance to get a bargain. Since regret is most commonly associated with negative outcomes, we look at regret for these two outcomes. Research on affective forecasting (Frederick & Lowenstein 1999; Wilson & Gilbert 2003) suggests that bidders are likely to overestimate their future regret. Since individuals will anticipate and act to minimize future regret (Mellers, Schwartz & Ritov 1999; Simonson 1992), we propose that anticipated regret over winning but overpaying will lead to more conservative bidding (i.e., less likelihood to bid, lower bid amount) while anticipated regret over losing the chance to get a bargain will lead to more aggressive bidding (i.e., more likelihood to bid, higher bid amount).

We also investigate the moderating role of perceived scarcity in the effects of anticipated regret on bidding decisions. We hypothesize that when the auctioned item is scarce, regret over losing the chance to get a bargain is likely to have a dominant effect on bidding, whereas when the auction item is not scarce, regret over winning but overpaying is likely to have a dominant effect on bidding.

We conducted three studies to test our hypotheses. Study 1 (n=91) looks at the effects of anticipated regret on bidding. Participants read a scenario that their university bookstore is testing a customer reward week concept where consumers can bid for various rewards using chips earned through past purchases. Participants bid on the first reward item, "dinner for two at Bertucci's," and rated their anticipated regret for winning and overpaying as well as anticipated regret for losing the chance to get a bargain. We counterbalanced the measures of bid amount and anticipated regrets; order has no effect on bid amount, suggesting that anticipated regrets occur naturally during the bidding process. Regression analysis shows that regret for winning and overpaying decreased bid amount while regret for losing the chance to get a bargain increased bid amount, thus providing support for our hypotheses.

Study 2 (n=240) examines both regret miscalibration and the effects of anticipated regret on bidding. We present a scenario where students can bid for more highly rated professors for their core courses in the next year. Each student has a total of 200 tokens to bid for four core courses and is provided with a reference price of 40-70 tokens for each course. After bidding on the first course and completing the anticipated regret measures (counterbalanced), participants spent several minutes on a filler task. Afterwards, participants are told the results of the auction: they either win but overpay for the course or they miss a spot in the course by a narrow margin, after which their regret is measured. Consistent with our hypotheses, we find that anticipated regret is consistently greater than experienced regret for both types of outcomes. Further, replicating the findings from study 1, regret for winning and overpaying decreases bid amount, while regret for losing the chance to get a bargain increases bid amount.

Study 3 (n=64) examines the moderating role of perceived scarcity in the effects of anticipated regret on bidding. We manipulate scarcity at two levels (high, low) in a 2-group, between-subjects design and measure participants' anticipated regret and bidding decisions (i.e., place a final bid or not and bid amount). Consistent with our expectation, our results show that when perceived scarcity of the auctioned item is high, anticipated regret for losing the chance to get a bargain has a dominant effect and leads to increased bidding likelihood; when perceived scarcity is low, anticipated regret over winning but overpaying plays a dominant role and leads to decreased bidding likelihood.

In sum, our findings demonstrate regret miscalibration in the bidding process and the effects of anticipated regret on bidding. Bidders overestimate their future regret; further, their anticipated regrets for the two potential unfavorable outcomes have opposing effects on bidding, that is, anticipated regret for winning and overpaying leads to more conservative bidding, while anticipated regret for losing the chance to get a bargain leads to more aggressive bidding. We also demonstrate the moderating role of perceived scarcity. When the auctioned item is scarce, regret for losing the auction has a dominant effect on bidding and leads to more aggressive bidding; when the auctioned item is not scarce, regret for winning but overpaying has a dominant effect on bidding and leads to more conservative bidding. Our research contributes to the literature on affective forecasting and regret. We document regret miscalibration and the effects of regret in the dynamic bidding decision making process. Our research also contributes to the auction literature, explaining why consumers often overpay in internet auctions (Ariely and Simonson 2003).

The Mediating Role of Arousal in Brand Commitment

Sekar Raju, University of Buffalo
Rao H. Unnava, Ohio State University

EXTENDED ABSTRACT

A well-documented finding in the commitment literature is that high brand commitment consumers show greater resistance to attitude change by generating greater number of counterarguments against negative brand information (e.g., Ahluwalia et al. 2000). This article helps us understand the motivational reasons that make committed consumers counterargue negative information and resist attitude change. Arousal is implicated as the motivating factor. This article also extends the motivational argument to suggest that arousal is affected by the ability or inability to successfully counterargue the negative message.

It was argued that high brand commitment consumers experience greater arousal compared to low brand commitment consumers when presented with negative brand information. Further, it is argued that the high arousal would decrease to more normal levels for high commitment consumers when the opportunity to counterargue the negative message was present. Study 1 tested whether arousal differed between the high and the low commitment consumers and identified the role played by arousal in affecting counterarguments and resistance to change. Study 2 and 3 tested arousal reduction when counterarguments were successful in preventing attitude change.

In study 1, participants read a counterattitudinal news article about their committed brand. The results of this study showed that arousal (self-report scale) was significantly greater in the high commitment participants than for low commitment participants. Analysis of the cognitive responses revealed that participants who were more committed counterargued to a greater extent than participants who were less committed to the target brand. A mediation analysis indicated a partial mediation by arousal of commitment effects on counterarguments. Finally, the brand attitude data showed that high commitment subjects were able to resist attitude change more successfully than less committed subjects.

Study 2 was conducted to identify the role of counterarguments in reducing the felt arousal. It is argued that successfully counterarguing negative information seems to achieve the goal of resisting attitude change. Therefore, if high commitment subjects were given sufficient opportunity to generate counterarguments and defend their attitude, arousal should decrease as the threat to the attitude is handled. On the other hand, if they were not given sufficient opportunity to generate counterarguments, the goal of defending the attitude would be incomplete and the arousal should continue to remain at the elevated level. In contrast, low commitment subjects experience lower arousal and are willing to change their attitude more readily after seeing a negative message. Thus, their arousal is mitigated without the need to resort to substantial counterargumentation. For this reason, whether they have or do not have enough opportunity to counterargue should make little difference to these subjects.

High and low commitment subjects were randomly assigned to a sufficient opportunity or insufficient opportunity condition and provided a negative news article about the target brand. Physiological measurement (skin resistance) was used as an indicator of arousal in this study. As expected, within high commitment subjects, insufficient opportunity subjects had a greater level of arousal than sufficient opportunity subjects. On the other hand, low commitment subjects did not reveal any significant differences between the time conditions. Further, high commitment subjects in the

insufficient opportunity condition had a significantly higher level of arousal than low commitment subjects, while high commitment subjects in the sufficient opportunity condition did not differ in their level of arousal compared to low commitment subjects.

The brand attitude data revealed an unexpected result where high commitment subjects in the truncated time condition showed a lack of attitude change even though they did not have sufficient time to counterargue the negative message. This result seems to indicate that counterarguments act as the primary route to resist attitude change only when provided the opportunity to process the message, but when opportunity to process the message was limited, high commitment subjects seemed to be using source derogation as the mechanism to avoid attitude change. Therefore, it seems that committed consumers use a variety of tools to protect their attitude. However, simply dismissing a source does not seem to reduce their arousal as much as being able to argue against a message.

The main purpose of study 3 was to gain a better understanding of the process by which attitude change was resisted even when high commitment subjects did not have sufficient opportunity to counterargue the negative message. The design was changed to include only the two high commitment conditions (sufficient and insufficient) and as a control group, the sufficient condition for low commitment. In addition, cognitive responses and source credibility were measured. The arousal and brand attitude results were identical to those found in study 2. Analysis of the source credibility data revealed that high commitment insufficient opportunity participants used source derogation as a means to maintain their brand attitude when not provided the opportunity to elaborate on the negative message. The cognitive responses further supported this finding.

There are three fundamental theoretical contributions of this research to the commitment literature. First, this research addresses the question of why committed consumers behave in a certain way when faced with counterattitudinal communication. By providing a motivational explanation for the earlier research findings, our research nicely complements existing research on brand commitment.

Second, the finding that high commitment subjects experience reduced arousal after counterargumentation is a relatively unique finding in this literature. The evidence that arousal reduces with increased opportunity to elaborate on the negative message implies a motivational basis for commitment effects and adds confidence in implicating arousal as a mediating variable between commitment and counterarguments and attitude change.

Finally, a third important finding in this article is that high commitment subjects resist attitude change even when not given the opportunity to process the message sufficiently. They appear to find other ways of discrediting the message (e.g., source derogation). Interestingly, while source derogation preserves one's attitude, it is not effective in reducing the arousal experienced by a committed individual. This finding implies that high commitment consumers may have multiple goals when faced with negative brand information. The primary goal seems to be to protect the attitude from change. The secondary goal seems to be removing the source of the threat and reduce arousal. It is likely that by counterarguing, both goals are met, but when opportunity to counterargue is limited, source derogations seem at best to protect the attitude without removing the source of the threat.

“The Logic of The Marketplace: How Consumers Use Metacognitive Skills to Process Brand Claims”

Christina L. Brown, University of Michigan

Discussant:

Ian Skurnik, University of Toronto

SESSION OVERVIEW

In their seminal article, “The Persuasion Knowledge Model: How People Cope with Persuasion Attempts” (1994), Marian Friestad and Peter Wright proposed that consumers’ knowledge of the marketplace acts as a defense against unwarranted persuasive attempts. This persuasion knowledge includes not only declarative knowledge of the marketplace, but also lay theories of how marketplace persuasion itself occurs; i.e. consumer metacognition. From an ecological perspective, it is hard to see how such knowledge might develop if it is not beneficial to the consumer; however, the notion that declarative and/or metacognitive elements of persuasion knowledge are effective in helping consumers “cope” has not been definitively tested. The purpose of this special session was, therefore, to determine whether and how consumers’ persuasion knowledge does indeed make them less vulnerable to persuasion. This purpose underscored the general theme of the conference, “transformative consumer research,” in its consumer perspective and its concern over improving consumer outcomes as well as those of managers.

The session addressed three fundamental questions: first, how can we assess whether persuasion knowledge has improved consumer outcomes? One standard for consumer decision-making might be reduced vulnerability to persuasion. However, when marketers offer consumers something with genuinely high value, consumers on principle resistant to persuasion will not benefit. Thus, one possibility is that persuasion knowledge improves outcomes when it makes consumers more sensitive to message quality. This possibility was explicitly explored in the first paper, “*Vigilance Against Perceived Manipulation: The Effect of Regulatory Focus on the Use of Persuasion Knowledge*,” by Amna Kirmani and Rui Zhu. In studies 1 and 2 of their paper, these authors showed that prevention-focused individuals are more alert to manipulative intent and respond by reducing brand attitudes. However, in study 3 they showed that sensitivity to manipulative intent can actually increase persuasion. Study 3 was about reading “the fine print:” manipulative intent was expressed as an asterisk at the end of an ad headline. When the supporting footnoted text cited a study by the

advertiser, brand attitudes for prevention-focused individuals were reduced. But, when the text cited a reassuring study by Consumer Reports, brand attitudes were enhanced. Thus, manipulative intent made prevention-focused consumers more vigilant and thus more sensitive to how well brand claims were supported.

Second, what is the underlying cognitive process by which persuasion knowledge may (or may not) improve outcomes? Margaret C. Campbell, Peeter W.J. Verlegh, and Gina E. Slejko addressed this question in their paper, “*Fortification or Trojan Horse? The Impact of Warnings on the Effectiveness of Product Placements*,” which studied of product placement in television shows. Using a professionally edited videotape of a TV show, the authors manipulated the presence and timing of a forewarning of product placement. Consistent with Kirmani and Zhu, they showed that concern over manipulative intent heightens attention to the product. Study 1’s results showed that pre-warnings increase the likelihood that viewers notice and remember brand placements, but the placements are less likely to be seen as manipulative. Study 2 demonstrated that improvement in brand attitudes is mediated by whether manipulative intent is attributed to the advertiser or the TV network itself.

Third and finally, in “*The Logic of The Marketplace: How Consumers Use Metacognitive Skills to Process Brand Claims*,” Christina L. Brown showed that in some cases persuasion knowledge can actually undermine decision quality by encouraging faulty logical reasoning. The author adapted the Wason four-card selection task to provide an objective measure of how advertising affects the quality of consumers’ decision-making skills. She showed that brand claims taking a conditional form (“If it’s Angelo’s, it’s got to be authentic Italian food”) are more likely to result in accurate reasoning when participants understand the claims to be advertising slogans than when the claims are heard “on the street.” This result was driven not by a general increase in consumer information search but a more domain-specific “cheater detection” algorithm (Gigerenzer and Hug 1992). She also showed that consumer persuasion knowledge improves consumer learning only when advertising claims take a familiar form; when claims are reversed (“If it’s authentic Italian food, it’s got to be Angelo’s”), decision quality was actually reduced when these claims were presented as ad slogans.

Ian Skurnik was the discussant.

SPECIAL SESSION SUMMARY

Transformative Consumer Culture Theory?

Julie L. Ozanne, Virginia Tech
Susan Dobscha, Bentley College

SESSION OVERVIEW

Eric Arnould and Craig Thompson (2005) offer a synthesizing overview of the past twenty years of consumer research addressing the socio-cultural, experiential, symbolic, and ideological aspects of consumption. By entitling their article *Consumer Culture Theory (CCT): Twenty Years of Research*, they emphasize the theoretical and conceptual contributions of interpretive research. This project is important for three reasons. First, an overview explicitly acknowledges and celebrates the many contributions of interpretive researchers. Second, this review provides a conceptual map of what has become a very complex field. This map may help newcomers better position their research for publication and funding. Finally, this paper provides an opportunity for our community to reflect upon our past and envision our future. The purpose of this session is to imagine a more transformative CCT and to chart possible courses toward this destination.

While we applaud that the CCT framework highlighted consumer resistance and ideology as one significant stream of research, the unintended consequence was an emphasis on a narrow view of critical research programs. From a critical perspective, an emancipatory interest underlies all research activities. Critical theory is more than just a critique of ideology; it is a sensibility that can be brought to a wide range of topics. Moreover, all observation presupposes interpretation, which also presupposes the freedom needed to interpret and use knowledge. Thus, empirical-analytic, hermeneutic-historical, and critical-emancipatory interests (Habermas 1971) guide the construction of all consumer culture theory over the last twenty years. Arnould and Thompson (2005) implicitly acknowledge that the empirical-analytic and hermeneutic-historical interests cut across all four categories. Yet, this same assumption is not made for the critical-emancipatory interest, which becomes encapsulated in a fourth category and bled of its transformative potential.

The three following papers are united in their transformative goal; they seek to critique consumer and social practices toward improving society and the lives of consumers. These papers draw on insights from a range of critical approaches such as, community studies, reflexive interpretive methods and action research, and feminist and critical theory research (Bristor and Fischer 1993; Hirschman 1993; Murray and Ozanne 1991; Peñaloza 1994; Stern 1993, 1996). In each of the papers, the substantive and theoretical issues discussed span across all four categories in the CCT typology. Each paper is also united in its focus on the struggle of people to control the meanings that inform their identity and sense of community.

June Francis' suggests that a field centered on the consumption of the "haves" both silences marginal voices and fails to see the harm caused to them by those people who consume the most. Eileen Fischer and Lisa Peñaloza contrast work on brand communities with communities of marginalized ethnic/racial minorities. Jeff Murray and Julie Ozanne promote and delineate interpretive structuralism as one possible method for transformational research.

This session challenges the field to think through what consumer behavior can and cannot do to transform our communities and societies. We explore how the market as an institution is configured socially and economically vis a vis public and community interests, and how these configurations impact consumer

behavior. Clearly, not all consumers are positioned equivalently in society, and thus another vital consumer behavior issue is how consumer behavior arrests and/or reproduces extant market and social relations. What is under-examined is the actual and potential ability of consumers to engage in the transformation of social practices and social structure, and to what degree this happens at the level of individual and community action.

These papers seek to explore ways to reduce human suffering (i.e., the transformative impulse) based on critique that is contextualized to the interests and historical circumstances of small, localized groups (the impulse of CCT). If suffering is caused by hegemonic meta-narratives, then this discourse can be destabilized by examining the dance between social actors' subjective understandings and social structure and by seeking to identify fissures and tensions that can be used to forge new contextualized discourses that may alleviate suffering. While this new discourse could itself become oppressive, if it arises from the voices of the participants and reduces suffering, then it is potentially better than a discourse that is imposed from outside (Agger 1994). We avoid grounding our critique on modern goals, such as rationality, and view the critical moment as never-ending; the goal is an immanent critique emphasizing freedom, justice, and equality, values that are inherent to our culture.

We anticipate that this session will appeal to researchers interested in interpretive and critical research, as well as people interested in social and public policy issues. Craig Thompson and Eric Arnould, as both authors of the CCT framework and experts in the area, are the ideal discussants who are well positioned to comment on research that seeks to extend their work.

ABSTRACTS

"We are what *They* Consume: The Neglect of the Non-consumers"

June N. P. Francis

The syntheses of the developments in the field of consumer behavior advanced by Arnould and Thompson (2005) is a timely and warranted contribution if viewed as a gauge of how far the field has come. However, the consumer research agenda suffers from "American myopia," which dictates its research approach and agenda. This synthesis still reflects the field's love affair with consumption and is rooted in the socio-cultural context of the developed world with a presumed access to the market consumption experience.

This perspective puts market consumption at the center of the discipline and, therefore, those who consume and what they consume become the focus. We are intrigued by their activities, motivations, and dispositions. We inquire into their perspectives. Certainly, the CCT research stream has served to provide even greater perspective by examining the consumer from a widened epistemological, paradigmatic, and methodological perspective, but the central actor remains the same—the consumer. This paper is concerned with one such bias, the field's focus on consumers and consumption to the neglect of the marginal or non-consumers.

The act of consumption has intended and unintended consequences on those who do not consume. Some people, given their disproportionately lesser access to consumption, for economic, political or ideological reasons, are not considered as worthy of

research attention. This approach neglects the effects of consumers on the non-consumer and in so doing adopts a capitalist driven paradigm that has consumption as the invisible hand allocating research attention and recourses. This paradigm also escapes the need for critique.

Why should consumer culture theory be concerned with the non-consumption experience? Many of the phenomena of consumption can only be understood from the perspective of the non-consumer, often those that are weaker economically or culturally marginalized. Economics determine which products gets consumed and how. When “Bob Marley” as an icon gets consumed by an increasingly global world, then the citizens of Jamaica are cornered into accepting this image as their defining brand identity. Given our current approach of focusing on the consumers, it is really not possible to understand how foreigners wearing Bob Marley locks affect Jamaican self-identity and perhaps engenders cultural alienation from ones own roots.

Consumer Culture Theory, as typified by the work of Belk (1988), points to the role that possessions and consumption play in creating and expressing identities. However, consumers not only affect their own identities but the identities of others. In describing the types of African films that get produced, Wiwa (2005) describes these films as ‘cinema village’—“films that play to the gallery with rustic, ritualized scenes, increasingly foreign and even offensive to many Africans.” He points to the appetite for these films in Europe as dictating the content and approach. The idea that the powerful dictate of market demand is, of course, not novel. However, when we focus only on the perspective of the consumers, we miss the role consumption experiences, such as these, have on those whose images are being consumed.

Power differences occur in a myriad of intercultural situations but they are perhaps most visible in tourism consumption. Here products acquired by one group from another group can serve to define the selling group’s identity. In tourists’ search for authenticity, often products or experiences that may no longer exist (Turkish Fez widely available in tourist shops in Istanbul) or never existed (feathered headdresses once sold as souvenirs by first nations tribes that had never worn such adornments) are often sought by nostalgic tourists. This search by the consumer, rather than being benign, often dictates the dimension of the culture that survives or, in some case, are even invented. Even those studies that are concerned with marginal consumers, such as Hill (1991), view the possession or loss of it. Thus they still focus on the consumption experience rather than the creation of identities among those who do not consume.

In conclusion, this paper argues for a widening of the perspective to ensure the voices of non-consumers who are significantly affected by consumption and may not qualify as consumers be examined and heard. This agenda would turn our focus to the non-western, developing world and to the culturally and economically marginalized peoples.

“Communities Beyond the Brand”

Eileen Fischer and Lisa Peñaloza

Consumer researchers have understandably demonstrated considerable interest in the phenomenon of communities based upon common consumption interests. An expanding body of work investigates the ways in which particular brands form the basis for communities (e.g. Kozinets 2001; McAlexander, Schouten and Koenig 2002; Muniz and O’Guinn 2001; Muniz and Schau 2005). As characterized by Arnould and Thompson (2005), work that focuses on marketplace cultures, of which studies of brand communities are a part, seeks to “unravel the processes by which consumer culture is instantiated in a particular cultural milieu” and to address “the ways in which consumer forge feelings of solidarity and

creates... cultural worlds through the pursuit of common consumption interests.”

In the spirit of repositioning the CCT brand to highlight more transformative aspects of consumer research than has been (and is being) undertaken, this paper re-examines research on communities that are *not* based upon brands. In particular, it examines the questions raised and the theoretical projects developed by consumer research that is concerned with communities of marginalized racial and ethnic minorities (e.g. Peñaloza 1994; Oswald 1999; Crockett and Wallendorf 2004). To be certain, the kinds of research on marginalized communities that is examined here were not ignored by Arnould and Thompson; rather, they were characterized in a manner that underemphasized the tensions and social conflicts at the heart of this work, thus compromising its critical potential.

Research on marginalized racial/ethnic communities can be contrasted with research on brand communities along multiple dimensions in order highlight this critical potential. For example, whereas research on brand communities is concerned with establishing how consumers create a sense of shared identity in relation to brands, research on marginalized communities looks at how shared identities based on race/ethnicity are configured in terms of social distinctions—exclusions and subordinations, and how/whether these social hierarchies are reconfigured in the course of community members’ engagements with market institutions and other consumers. While research on brand communities is concerned with how rituals evolve around the uses of branded products, research on racial/ethnic communities is concerned with how consumption behaviors impact patterned interactions with products and markets, subsequently reproducing and/or destabilizing the relationship of the marginal with the mainstream. And while studies of brand communities consider how a sense of moral responsibility can develop toward protecting a brand and those within the boundaries of its community, studies of marginalized racial/ethnic communities are concerned with the dynamics of community practices and ideologies as marginalized community members attempt to navigate new identities and transcend the limits of social and market representations and treatments through consumption and market engagement beyond their community boundaries.

This paper explores the transformative potential of consumer research on marginalized racial/ethnic communities, and suggests how the CCT brand can benefit from more explicitly acknowledging these social and market oppositions in advancing its critical potential.

“Transformational Theory and Methodology”

Jeff B. Murray and Julie L. Ozanne

Critical theory assumes that every form of social order includes relations of domination-subordination and that the critical-emancipatory interest underlies the struggle to change these relations. Given this basic assumption, critical theorists believe in the existence and influence of social structures, such as education, mass media, and fashion. They remain committed to some form of structuralism believing that social structures influence social actors and shape their social constructions of reality often without their knowledge or consent. In other words, critical theorists believe that part of the deep structure of every society is power and domination; it is the purpose of critical theory to excavate these relationships, reveal and explain them, hoping that awareness may eventually lead to transformation (Murray and Ozanne 1991). Thus, critical theory offers theories and methods that are compatible with the goal of transformative programs in consumer research.

Recently, in the wake of the postmodern turn, these assumptions have become increasingly difficult to justify. In fact, this is the key challenge for the most recent generation of critical theorists.

Researchers, such as Ben Agger, Stephen Best, Stephen Bronner, Douglas Kellner, and Mark Poster, are interested in reconstructing critical theory so as to embrace the critical insights of postmodernism. These theorists point to a number of primary contributions of postmodernism including an awareness of the repressive potential of meta-narratives, a critique of empiricist and realist accounts of representation, the importance of a reflexive theory of textual reading, and an emphasis on the self and identity.

This new generation of critical theorists seeks to revitalize critical theory by embracing insights from both hermeneutics and structuralism. They hold that social sciences must be based on interpretive foundations. The hermeneutical tradition emphasizes idiographic interpretations of unique social beings whose actions are contextualized and historical, and mediated through language (Arnold and Fischer 1994). But the hermeneutical tradition is silent on the goal of transformation; it refuses to engage in social critique or offer paths for social change. The structural tradition offers insights into the relationship between agency and structure and gives avenues for connecting our theories to practical social action.

In our presentation, we propose that this form of “interpretive structuralism” or “hermeneutic structuralism” (Morrow and Brown 1994) is an appropriate method for critical theory and transformative consumer research. This type of research helps to illuminate consumption cycles and marketplace behaviors. By way of illustration, we present the results of an analysis of a depth interview using interpretive structuralism. We discuss how this critical analysis fits all of Arnould and Thompson’s (2005) four categories: it is an identity project; which focuses on marketplace cultures; is part of the socio-historic patterning of consumption; and it is a critique of ideological reproduction, which enables a form of resistance. Clearly the critical transformative impulse spans substantive problems and theories.

We discuss the processes our informant used to seek out and create meaning useful for identity construction. The problems our informant encountered are all related to the struggle to maintain control of meanings needed to negotiate identity. Consumers seek and find meaning in their life world often through their consumption. These consumption signs are valuable resources for identity construction. Marketing researchers identify these signs and the “sign value” becomes systemized through marketing processes, such as appropriating the meaning of the sign and reshaping it in advertising (i.e., the sign is sanitized in order to appeal to broader market segments). The meanings are then uncoupled from the original life world of the consumer and become mobile, “floating signifiers.” These signifiers are then returned and marketed in the consumers’ life worlds, colonizing them, commodifying identity, and stripping the original meaning from their life world and identity. Thus, whoever controls the meaning of the signs influences the construction of individual and group identities.

But humans have the capacity for reflexivity; that is, they can reflect on their social behavior and change it. For example, if informants learn of the colonization of their life world, then they can jam the process of uncoupling. When humans discover that a social belief is false, they can alter their ideas and any social actions linked to these ideas. “From this it follows that criticism of false belief is a practical intervention in society, a political phenomenon in a broad sense of that term” (Giddens 1984, quoted in Morrow and Brown 1994).

In conclusion, Arnould and Thompson’s synthesis, although a useful starting point for some forms of interpretive research, does not represent the important range of alternatives for critical and transformative theory and method. This presentation will review interpretive structuralism as one such alternative.

How Time Restrictions Work: The Roles of Urgency, Anticipated Regret, and Deal Evaluations

Scott D. Swain, Boston University

Richard Hanna, Boston College

Lisa J. Abendroth, Boston University

EXTENDED ABSTRACT

Consumer promotions are a major marketing tool and have long been the focus of academic research. Recent efforts have focused more on the process by which discount size, and especially time restrictions, influence consumer responses to promotions. To date, deal evaluation has been introduced as the primary process mechanism for promotions, incorporating both discount size and any restrictions. However, evidence on the effect of time restrictions on deal evaluation has been mixed. Some research shows a negative effect of restrictions on deal evaluation (Sinha, Chandran, and Srinivasan 1999), while other research suggests a positive effect (Inman, Peter, and Raghurir 1997). Thus, the primary purpose of this paper is to extend the literature on promotional restrictions by reconciling these findings.

We develop a model in which purchase intentions during a promotion are driven by three factors: deal evaluation, anticipated regret, and urgency. We predict that shorter time restrictions lower purchase intent by lowering deal evaluations, and we provide evidence that this occurs because of greater perceptions of inconvenience (Sinha et al. 1999). Meanwhile, we also predict that shorter time restrictions increase purchase intent by creating a sense of "urgency," which we define as a felt need to initiate and complete an act in the immediate or near future.

For completeness of the model, we replicate earlier research in predicting that the effect of discount size on purchase intentions is mediated by deal evaluation (Inman et al. 1997). However, we go on to argue that deal evaluations impact purchase intent not only directly, but also indirectly by affecting anticipated regret. That is, discounts affect consumers' purchase intentions by affecting not only the perceived economic outcomes of redemption, but also the emotional outcomes of redemption. Further, we predict that more favorable deal evaluations and greater anticipated regret both serve to heighten a consumer's sense of urgency. In sum, we suggest that discount levels and time restrictions impact purchase intentions by affecting consumers' rational (deal evaluation), emotional (anticipated regret), and visceral (urgency) responses to promotions.

We conducted two studies in order to test our model. In Study 1 (N=111), we used a 2 (Discount Level: Low, High) x 2 (Time Restriction: Low, High) between subjects design. The promotional context was a simulated coupon for admission to one movie at a nearby theater. The results provide support for our model. Specifically, the constructs demonstrated good convergent and discriminant validity, the model fit the data very well, and all predicted paths were significant. Additionally, hierarchical model comparisons confirmed all of the full and partial mediations implied by the model diagram. Thus, we document the fact that shorter time restrictions can have both a negative effect on purchase intent by lowering deal evaluations and a positive effect on purchase intent by increasing the sense of urgency. We also show that anticipated regret plays a more complex role than previously believed, acting to partially mediate the effect of deal evaluation on both urgency and purchase intent.

In Study 2 (N=166), the promotional context was changed to that of a real coupon for a sandwich at a school-run sandwich shop. This allowed us to address the concern that movie theaters activate

social, rather than individual, decision making processes. The design was the same as in study 1 except that a measure of inconvenience was included to provide greater evidence for the negative effect of time restrictions on deal evaluation. Finally, external validation for the model was provided by measuring actual redemption behavior.

Study 2 replicated the results found in study 1. All paths in the model were supported and all three proposed mediators of the effects of discount level and time restriction on purchase intent (deal evaluation, anticipated regret, and urgency) behaved as expected. In addition, redemption behavior was predicted by the variables in the model; participants who redeemed the coupon had higher deal evaluation, greater anticipated regret, slightly greater urgency, and greater purchase intentions.

Perhaps the most interesting contribution of our research is a heightened understanding of the dual role played by time restrictions in the formation of purchase intentions. In its negative role, a time restriction is seen by consumers as an inconvenience, thereby diminishing deal evaluations and its consequences (anticipated regret, urgency, and purchase intention). In its positive role, a time restriction creates a sense of urgency in consumers, thereby providing an impetus for action that feeds directly into purchase intentions.

Another key contribution of this work is the introduction of a new process model where the terms of the promotion (i.e., discount size and time restriction) affect purchase intentions through three distinct processes: deal evaluation, anticipated regret, and urgency. Comparing the adjusted R-squared values from our full model to a reduced regression model with only deal evaluation provides evidence that urgency and anticipated regret add significant explanatory power above and beyond deal evaluation. Specifically, in study 1, adjusted R² increased from .329 to .480 ($F_{2, 107}=16.875, p<.001$) and in Study 2 the adjusted R² increased from .297 to .381 ($F_{2, 162}=12.055, p<.001$).

Greenleaf and Lehmann (1995) proposed that consumers delay decisions because they are too busy—suggesting that marketers should use longer time limits to accommodate consumers' busy schedules. However, as we have shown, shorter time limits create a greater sense of urgency thereby leading to higher purchase intentions. Perhaps giving consumers more time leads only to more delay and, in effect, the shorter time limit causes the promotion to gain priority on consumers' "to do" lists. However, caution is needed since, as was shown in Study 2, too short of a time limit can also increase perceptions of inconvenience, leading to lower deal evaluations and ultimately lower purchase intent.

The Impact of Certain and Uncertain Store Promotions on the Decision-Making Process in Product Choices

Cathy Y. Chen, Singapore Management University
Shi Zhang, University of California-Los Angeles

EXTENDED ABSTRACT

Store promotions presented at the beginning of a consumer's shopping trip influence the consumer's affective states during the trip (e.g., Gardner 1985). Although the promotion-induced affect should be regarded as irrelevant in subsequent product choices, previous research shows that it influences a consumer's choice decision (e.g., Heilman, Nakamoto and Rao 2002). The impact of promotion-induced affect on a consumer's product choice can find theoretical support from the incidental affect literature, which has demonstrated that affect elicited in one incident extends its effect to other unrelated incidents (Isen 2001). However, a majority of incidental affect research compares the impact of positive affect with that of negative affect and neutral state. Although this group of studies is helpful for us to predict the impact of store promotions in general, it may be insufficient to discriminate the impact of a variety of promotions which generally would make consumers feel positive, since relative pleasantness is quite unimportant to differentiate positive emotions (Smith and Ellsworth 1985).

Recent incidental affect literature demonstrates that, regardless of valence, the uncertainty associated with an affect influences the extent of systematic decision-making of a subsequent judgment (e.g., Tiedens and Linton 2001). Since promotions are different in terms of the uncertainty of the benefit provided (e.g., an instant dollar-off coupon provides more certain benefit than a sweepstakes), a promotion providing a probabilistic benefit may make consumers feel more uncertain than a promotion providing a sure and immediate benefit. Thus, focusing on the uncertainty of promotion-induced affect can be important in differentiating the impact of types of promotions on subsequent product choice process.

Although it is shown that uncertainty can decrease confidence and leads to more systematic decision making, there exist inconsistent findings which shows less systematic decision making when subjects feel uncertain (e.g., Bodenhausen et al 2000). This inconsistency may be explained by the effect of uncertainty on perceived ability. Uncertainty to which people have no control can also decrease a subject's perceived ability (Sedek, Kofta and Tyszka 1993), which, according to the ability and motivation framework, would decrease the extent of systematic decision making.

According to the affect-as-information theory (Schwarz 1990), we expect that the uncertainty can decrease perceived ability when one is ambiguous about his ability of accomplishing a task. This can be examined by varying choice difficulty. When a choice is easy, people generally perceive themselves as being capable of systematically analyzing information to make a choice. Since the ability assessment is not ambiguous, the feeling of uncertainty induced by an uncertain promotion is less likely to add any informational value for the perceived ability judgment and thus should not decrease the perceived ability. Since in this case, an uncertain promotion may decrease a subject's confidence (Tiedens and Linton 2001) but not perceived ability, it is expected that uncertain promotion would lead to a more systematic decision-making process than the certain promotion and the no-promotion situation. In contrast, when a choice is difficult, it is often ambiguous to a subject whether he/she can systematically analyze all the information to make a correct choice (Payne, Bettman and Johnson 1988). In such cases, a subject is more likely to rely on his/her affective state as an informational

cue for the perceived ability judgment. Thus, the feeling of uncertainty induced by an uncertain promotion is more likely to decrease a subject's perceived ability and lead to a less systematic decision-making process relative to a certain promotion and a no-promotion situation. The hypotheses were examined by a lab experiment.

The experiment (N= 360) investigated the extent of systematic decision making by comparing the impact of feature importance on the choice decision. Subjects who were more (vs. less) systematic should scrutinize the product features more carefully and thus be more likely to differentiate high-importance features from low-importance features. Thus, their decisions should be greatly influenced by the feature importance and more subjects should choose the option that was dominant on high-importance features (vs. low-importance features). Subjects who were less systematic, however, may not discriminate high-importance and low-importance features and may be influenced by heuristic cues like the number of dominating features. Thus, the likelihood of choosing an option that was dominant on high-importance features may not differ from that of choosing the one dominant on low-importance features.

This experiment was a 3 (promotion) x 2 (choice difficulty) x 2 (importance of dominant features) between subject design. Subjects were presented a "certain" promotion (\$50 gift certificate to Disneyland for any purchases over \$200), or an "uncertain" promotion (30% chance to win a \$150 gift certificate to Disneyland for any purchases over \$200), or no promotion. The two choice options were non-dominant to each other in the difficult choice condition and one option was superior to the other in terms of the number of dominating features in the easy choice condition. Supporting the hypothesis, the data revealed that when the choice was easy, an uncertain promotion led to more systematic processing (indicated by a higher choice proportion of the option dominating on high (vs. low) importance features) than a certain promotion and no promotion. In contrast, when the choice was difficult, an uncertain promotion led to less systematic processing than a certain promotion and no promotion. Evaluation and recall data provided converging results.

Overall, the results suggest that 1) store promotions may influence the decision-making process of a subsequent product choice through promotion-induced affect, 2) uncertain promotions influence the decision-making process differently from certain promotions and no promotion situations, 3) the impact of uncertain promotions is moderated by choice difficulty. The demonstration of the impact of promotion-induced affect on product choices enables us to go beyond the traditional view of promotion as signals for product quality and understands the effect of various types of promotions on the choice decision-making process. The comparison of the certain, uncertain and no promotion in different choice contexts lends support to the uncertainty-focused research in the incidental affect research and highlights its importance when affect management objective is not salient (Wegener et al 1995).

Price Matching Guarantees as Signals of Value: The Role of Perceived Risk and Estimate of Lowest Market Price

Sujay Dutta, John Carroll University
Dipayan Biswas, Bentley College
Abhijit Biswas, Wayne State University
Chris Pullig, Baylor University

EXTENDED ABSTRACT

Price Matching Guarantees (PMG) are tools where retailers explicitly or implicitly claim to offer the lowest market price and promise to match or beat lower market prices located by buyers. Prior to a purchase, matching or beating of lower prices is achieved by suitably lowering prices by the PMG-offering seller and following a purchase, matching or beating is achieved by issuing a refund to consumers.

Past research on PMG has generally indicated favorable effects of such guarantees on consumer pre-purchase perceptions and behavioral intentions. For instance, exposure to PMG raised consumer perceptions of offer value, their shopping intention and their belief in the overall low-priced nature of the retailer, while reducing their search intention (Biswas et al. 2002; Srivastava and Lurie 2001). Although researchers have indicated some theoretical conditions delimiting the effectiveness of such guarantees (Srivastava and Lurie 2004), no clear-cut understanding exists about marketplace factors consumers consider in their assessment of PMG. In the present research we propose a model of PMG effects and suggest that PMG favorably affects consumer perceptions when consumers perceive a low dispersion of market prices but not when they perceive a high dispersion of prices.

Till date, most researchers have conceptualized PMG as a marketplace signal (Biswas et al. 2002; Srivastava and Lurie 2001, 2004) whose primary function is to overcome information asymmetry between retailers and consumers regarding the precise location of individual retailers' offer prices in the marketplace continuum of prices. The purpose of a PMG is to inform consumers that an offer price is close to or equal to the lowest market price and to compensate consumers monetarily should that information turn out to be inaccurate.

We propose that if PMG is perceived by consumers to be truly diagnostic of the offer price's position among market prices, then exposure to PMG ought to affect consumers' estimate of the lowest market price and should also reduce their perception of financial risk involved in transacting with the retailer. Past research indicates that consumer perception of market price dispersion likely differs from an existing dispersion (Grewal and Marmorstein 1994; Urbany and Dickson 1991) and that usually consumers are not quite confident of their estimates of market prices and consequently, consumer price estimates are susceptible to external cues (e.g., Winer 1986). Hence, exposure to PMG may lead consumers to readjust their estimate of the lowest market price for the product concerned such that consumer lowest price estimate is higher when an offer is accompanied by a PMG, compared to an offer without a PMG. Also, the implicit or explicit promise of a PMG to offer a price close to the lowest market price should reduce consumer concern about overpayment; that is, an offer with a PMG should lead to lower perceived financial risk than one without a PMG. Given that the sacrificial components of an exchange are reduced in the presence of a PMG, we argue that these effects, in turn, enhance consumer perception of offer value, raise their intention to shop the retailer and reduce their intention to search for lower prices. In other words, consumers' estimate of the lowest market price and their

perceived financial risk mediate the effects of PMG on perception of offer value, shopping intention and search intention.

Finally we posit that such favorable consumer responses to PMG as outlined above are not unconditional and that these effects are less likely to occur when consumer perception of market price dispersion is high. A high price dispersion indicates the likelihood of a larger number of existing price points to consumers and given the constraints existing on consumer search ability, this is likely to be perceived as a situation where it is relatively easier for high-priced retailers to opportunistically place the signal in the market with a sense of impunity. In other words, consumer perception of the strength of marketplace disciplinary mechanisms is likely to be low thereby leading to loss of signal potency (Srivastava and Lurie 2004). On the other hand, when consumers perceive low price dispersion in the market, they are less concerned about high-priced retailers getting away with a false signal thereby enhancing signal potency.

In a preliminary one-factor (PMG: present; absent) study with 43 non-students, we found support for our proposed mediation-based model of PMG effects. In a second, 2 (price dispersion: high vs. low) \times 3 (PMG absent, PMG 100% refund, PMG 150% refund) study with 154 undergraduate students, we found that favorable effects of PMG occur only when perceived price dispersion was low. An examination of simple main effects within the low price dispersion condition revealed that the presence of an LPG was effective in influencing all dependent variables in the hypothesized direction (all F 's $(1, 44) > 4.67$, all p 's $< .05$, η^2 ranged from .10 to .30). In the high price dispersion condition, the presence of an LPG offering a 100% refund had no effect on the dependent variables of lowest price estimates, risk perception, offer value, and search intention (all F 's $(1, 53) < 3.63$, p 's $> .06$, all $\eta^2 < .06$). An LPG offering a 150% refund within the high price dispersion condition, however, was effective in enhancing shopping intention ($F(1, 53) = 4.86$, $p < .03$, $\eta^2 = .08$).

Theoretically, our findings are important in their demonstration that signal potency is not unconditional and consumers' judgment of marketplace disciplinary mechanisms delineates the boundary condition for low price signal effects (Srivastava and Lurie 2004). Particularly, our findings include that consumers are observant of the context, as defined by relevant market characteristics, in which a signal is evaluated. Further, our findings are supportive of the basic assumption of consumer rationality integral to signaling theory, in that consumers incorporate perception of seller motives in their evaluation of signals (Kirmani and Rao 2000). The most important practical implication of our findings is that retailers would be well advised to refrain from opportunistic use of PMG, as consumers are not blind to such possibilities in their evaluation of this pricing tool.

SPECIAL SESSION SUMMARY

A Variety of Explanations for Variety-Seeking Behaviors: Physiological Needs, Memory Processes, and Primed Rules

Rebecca K. Ratner, University of North Carolina, Chapel Hill

SESSION OVERVIEW

Why do individuals so often switch away from items that they liked in the past? Why is variety evaluated differently in real-time evaluations vs. retrospective evaluations? This session included three papers that reflect the quite different directions that research in this area has developed in recent years.

The first paper (by Inman, Vickers, and Maier) suggests that variety-seeking behaviors emerge when individuals have satiated on characteristics (e.g., flavors) of an initially-consumed product. This work extends the conventional view of variety-seeking as consumers' seeking to maintain an optimal stimulation level to consider the sensory satiety process whereby the pleasantness of a just-eaten flavor declines. The second paper (by Lee, Kahn, and Varghese) extends previous work in the variety-seeking literature that views individuals' preference for variety as reflecting a bias. Specifically, this work follows up on previous research indicating that when people make retrospective evaluations of options, there is a tendency to prefer options that contain greater variety, compared to when evaluations are made in real-time (Ratner, Kahn and Kahneman 1999). This paper shows that this effect generalizes to persuasive contexts and establishes ease of retrieval as the underlying process driving this preference for variety. The third paper (by Ratner, Zhang, and Fishbach) indicates that whether or not variety is viewed positively can be easily manipulated by the rule ("variety is good" or "consistency is good") that is made accessible to consumers, suggesting that even very subtle aspects of the context in which the individuals make choices can impact the amount of variety they seek, and whether they perceive "consistency" negatively (e.g., as boringness) or positively (e.g., as loyalty).

Collectively, the three papers in this special session, along with the insightful comments by discussant Don Lehmann, focused on new insights about the psychological mechanisms underlying one's preference for variety, and the extent to which variety-seeking behaviors reflect physical needs vs. primed conceptual constructs (e.g., "variety is good" or "consistency is good").

"High Satiety: The Effect of Sensory-Specific Satiety on Choice"

J. Jeffrey Inman, Zata Vickers, and Andrea S. Maier

Retailers and manufacturers continue to struggle to manage the assortment of product offerings within a given product category. For example, should the available popcorn flavors include plain, cheese, caramel, white cheese, and orange cheese, or is some subset acceptable? In the absence of established methodologies to address this issue, they largely rely on ad hoc approaches with little consideration of which attributes are more important to consumers in terms of assortment. Improved understanding of the dynamic factors that contribute to switching within a product category will better enable food retailers to set their category assortment.

We propose that sensory-specific satiety is an attribute of foods that can drive consumers to switch among products within a food category. Sensory-specific satiety is a temporary drop in the pleasantness of a food produced by eating that food. This drop in pleasantness is relative to changes in pleasantness of other foods that have not been recently eaten (e.g., Lyman 1989; Rolls et al. 1981a). For example if one eats a bowl of strawberry yogurt, liking

for strawberry yogurt drops but liking for other foods (e.g. chocolate, bananas, bread, chicken, etc.) remains relatively unchanged. Importantly, when two foods have similar sensory attributes the liking for one can be diminished by consuming the other (e.g., eating a bowl of strawberry yogurt might also diminish the liking for a strawberry jelly bean). Sensory-specific satiety differs across foods (Johnson and Vickers 1992), and it may partly explain why consumers seek variety on some attributes more intensively than others. For example, Inman (2001) reported that consumers switched more intensively among flavors than among brands in 14 of the 15 product categories examined. However, while these findings are consistent with a sensory-specific satiety explanation, this has never been directly tested.

Our objectives are twofold. Specifically, we build upon Johnson and Vickers (1992) to examine crossover effects of sensory-specific satiety as a function of the similarity between the consumed flavor and the target flavor. We also extend Inman's work (2001) by directly assessing the role of sensory-specific satiety and crossover effects on subsequent flavor choice. We draw upon the sensory-specific satiety literature to generate three hypotheses. First, we hypothesize that greater levels of sensory-specific satiety will correspond to increased switching away from a flavor in a subsequent choice. Second, we hypothesize that both sensory-specific satiety and switching among flavors are inversely related to the flavors' similarity to the consumed flavor. That is, we expect the influence of flavor consumed and similarity thereto to be mediated by sensory-specific satiety and crossover sensory-specific satiety. Finally, we hypothesize that sensory-specific satiety and switching among flavors will be moderated by liking—the effects should be stronger for less liked flavors.

We test our hypotheses in two product categories (popcorn and potato chips) across three studies, all of which are complete. The first study uses a consumption diary panel and the second and third studies employ experiments. In the first dataset, 850 participants completed a diary of their consumption occasions of several snack categories over a six-week period (see Inman 2001). The database includes measures of flavor consumed and we supplement this data with inter-flavor similarity data collected in the Food Science laboratory at the University of Minnesota. A multinomial logit analysis shows that, controlling for flavor liking and prior flavor consumed, the degree of similarity to the previously consumed flavor has a deleterious effect on the flavor's choice likelihood.

The two experiments were conducted at the Food Science laboratories at the University of Minnesota and enable us to (a) test the hypotheses in a controlled setting and (b) perform a mediation analysis. Subjects first performed a taste test in which they tasted and rated the similarity between each pair of popcorn/potato chip flavors. Subjects then participated in 5 separate test sessions—one for each popcorn/potato chip flavor, with order randomized across subjects. During each session, subjects rated their hunger, fullness, and liking for each flavor, along with a set of five control products (bread, granola bar, carrot, orange juice, and M&Ms). We then gave each subject an 80g serving of the test popcorn and instructed them to eat the entire amount. When they finished, they repeated their hunger ratings and re-tasted and re-rated a second tray of the 10 rating set foods. Immediately after re-tasting and re-rating the

foods, we presented the subjects with a tray containing five bowls of popcorn/potato chips (one of each of the five flavors) and told them they could take more of whatever they wanted. We then recorded the choice and measured the amount consumed.

The analysis revealed strong sensory-specific satiety effects for all flavors. Further, crossover sensory-specific satiety effects were correlated with similarity to the test flavor, as predicted. Importantly, a mediation analysis supports our thesis that flavor choice is influenced by sensory-specific satiety and crossover sensory-specific satiety, which are in turn driven by prior consumption and similarity to the consumed flavor, respectively. Implications for research and category management were discussed.

"Retrospective Preference for Variety: An Ease of Retrieval Perspective"

Michelle Lee, Barbara E. Kahn, and Susheela Varghese

Previous research (Ratner, Kahn and Kahneman 1999) has shown that when preferences are made retrospectively, there is a tendency to favor the more varied sequences than when preferences are made in real-time. That there is a preference for variety in memory has important implications for why consumers seemingly make choices that are sub-optimal in the sense of not providing them with the greatest utility. The reason for why it occurs, however, has not been systematically explored and provides the impetus for the current research. In addition, we explore whether this "diversification bias" extends to situations where variety is not instantiated between choices but within choices.

To date, variety-seeking behavior has been studied in contexts where variety in choices is extended in time or across consumption occasions. We examine if variety in the features of an option gives it an advantage over an option with less variety. A context that lends itself particularly well to this objective is that of persuasive appeals in the form of consumer reviews. One of the growing uses of the Internet is to provide consumer-to-consumer reviews of products and services. The website www.epinions.com, for instance, is a platform that allows consumers to share their experiences about various products. These reviews often contain variety on a number of dimensions, such as when reviewers discuss positive and/or negative aspects of the product (i.e., one-sided vs. two-sided appeals), or use different argument types (e.g., utilitarian vs. emotional arguments) to justify one's stand. The increasing prevalence of consumer reviews and the greater reliance on them as a source of information suggests the need to devote research attention to how they influence purchasing behavior.

Three experiments provide support for our hypotheses. We first demonstrate that retrospective preference for variety extends to situations where variety comes about, not as a result of choosing a sequence of different options, as is typical of studies in variety-seeking behavior, but as a result of varied features contained within an option. This is shown in the context of consumer reviews.

Similar to past research, we show that high variety reviews (that are created by adding in a mixture of positive and negative claims) are rated more highly as compared to lower variety reviews (that contain more positive claims) in memory than in real time. We then extend this finding to reviews in which the variety is created through the mixed valence of arguments, but through a mix of types of appeals, e.g., utilitarian and emotional arguments (high-variety) or arguments of a single type (low-variety). We again show a greater preference for the product featured in the high-variety review than in the low-variety review, when preference is expressed retrospectively but not when it is solicited in real-time. Finally, we demonstrate ease of retrieval as the underlying process that accounts for the advantage accruing to the high-variety option. This explanation argues that people use the ease with which they are able to retrieve information as an informative cue for what they know or their attitudes.

"Variety vs. Consistency Seeking: A Matter of the Primed Rule"

Rebecca K. Ratner, Ying Zhang and Ayelet Fishbach

In repeated choice situations, what factors compel individuals to make similar (vs. dissimilar) consecutive choices? Researchers have often assumed that behavioral consistency is desirable and rewarded by society (e.g., Aronson, 1997, Bem, 1972), thus people should prefer to make choices that mostly resemble their previous ones. On the other hand, there is also research attesting to the value of diversity or variety seeking, which demonstrates that people are less likely to choose something on a given occasion if they have just chosen something similar (McAlister, 1982). Indeed, people sometimes make varied choices even in situations where one choice alternative clearly dominates others (Ratner, Kahn, & Kahneman, 1999; Read & Loewenstein, 1995). For instance, there is research showing that people choose more variety in public than in private to convey the impression that they are interesting and open-minded (Ratner & Kahn, 2002) and the expression of variety is often meant to indicate one's uniqueness (Kim & Drolet, 2003). Taken together, these seemingly contradictory findings suggest that individuals sometimes wish to express loyalty or consistency by making repetitive choices of a single option and sometimes wish to express open-mindedness by making varied choices.

The present research explores the possibility that these opposing choice criteria co-exist, and therefore by increasing the accessibility of either one of them we can influence choice. Specifically, framing a choice sequence in terms of loyalty would encourage repetitive choices whereas framing it in terms of open-mindedness would encourage variety seeking. Moreover, merely associating variety (vs. repetitiveness) with positivity vs. negativity should have similar effects on choice. In several studies, these mental rules were primed before participants had to make choices that could either reflect a preference for high or low variety.

In one study, we presented participants with an ambiguous target person who was said to behave in a rather repetitive fashion (e.g., it was said that this person wears similar clothing, dines in the same place each day, etc.). We manipulated the primed construal of this behavior by asking participants to rate the extent to which the target person is loyal, dedicated, and reliable (i.e., repetition is good), versus the extent to which the person is repetitive, boring, and dull (i.e., repetition is bad). We then measured their liking for

the target person in addition to indicating whether they would choose two of the same type of chocolate across two choice occasions or two different types (for all participants, on the first occasion they either were randomly assigned to consume their favorite type or a less-favored type).

Participants in the repetition-is-good (*positive*) construal condition evaluated the target person as more likable ($M=5.15$) than those in the repetition-is-bad (*negative*) construal condition ($M=4.00$). Further, more participants in the positive construal condition indicated that they would choose the same chocolate on the second occasion as had been assigned for the first occasion than did those in the negative construal condition. Thus, their own willingness to make a repetitive choice was influenced by whether repetition had been primed to be interpreted positively or negatively in the initial phase of the experiment. However, this priming effect only emerged when the chocolate type assigned on the first occasion was the participant's favorite type. Therefore, the rule to "be loyal" encouraged repetitive behaviors only when individuals had a reason (i.e., underlying preference) to be loyal to the initially-consumed item.

In another experiment, we activated these choice criteria in a different manner. Participants were asked to answer various questions (e.g. "to what extent are cassette tapes and compact discs the same or different?," "how good do you think soy milk tastes in general?") by recording their responses on one of two pairs of scale labels that were placed above or below a single 7-point scale. One pair of scale labels contained the endpoints "bad" and "good" (appropriate for the question about soy milk), the other contained the endpoints "same" and "different" (appropriate for the question about cassettes and compact discs). In one condition, the scale labels "same" and "good" were placed as anchors at the same end of the scale and "different" and "bad" on the other end of the scale, thus creating an association between the terms and presumably activating the "same is good" and "different is bad" rules. In another condition, these terms' concordance was reversed, hence presumably activating the "same is bad" and "different is good" rules. This more subtle manipulation was shown to influence participants' subsequent choices across a variety of domains, such that those who saw "good" paired with "different" chose significantly more variety than those who saw "good" paired with "same" (and both were significantly different from a no-prime control condition in the expected directions). For example, participants in the "different is good" condition preferred different brands of cereals, to stay in different hotels, etc., more than those in the no-prime control condition, who preferred more variety than those in the "same is good" condition. As predicted, none of the participants suspected the connection between the two parts of the study (the priming task and the choices task). An additional study demonstrated that these effects emerge using a subliminal priming task, suggesting that these rules for consistency vs. variety can be activated completely outside of awareness.

A final study demonstrated that people's perceptions of their own levels of commitment vs. satiation mediate the effect of the primes. When primed with "repetition is good," people construe their initial choice as reflecting their underlying preference for and commitment to the item. When primed with "repetition is bad," people construe their initial consumption occasion as having fulfilled their desire for the item (i.e., satiation).

Whereas a large number of studies in consumer behavior focus on reasons why people seek variety, the present studies indicate that variety seeking can be attenuated if the salient rule is that "repetition is good" rather than "variety is good." Thus, priming these rules can influence whether individuals construe repetition as indicating

loyalty rather than closed-mindedness. These results suggest that one way to attenuate the amount of variety sought in simultaneous or sequential choice (Ratner, Kahn, & Kahneman, 1999; Read & Loewenstein, 1995; Simonson, 1990) is to activate the rule that it is appropriate or even desirable to be loyal to one's favorite items.

SPECIAL SESSION SUMMARY

Motivational Influences in Consumer Behavior: The Role of Regulatory Focus

Rongrong Zhou, Hong Kong University of Science and Technology

Jaideep Sengupta, Hong Kong University of Science and Technology

SESSION OVERVIEW

The objective of this special session is to present recent theoretical advances and empirical studies investigating the role of promotion and prevention self-regulation in persuasion and decision making. In his regulatory-focus theory, Higgins (1998) proposed two distinct self-regulatory systems. The first, called “promotion,” regulates nurturance needs and those motives related to aspiration and accomplishment. The second, called “prevention,” regulates security needs and those motives related to safety and responsibilities. These two systems are distinct, not only in the kinds of needs and motives that they regulate, but also in the types of strategies and means that these systems invoke to fulfill these needs and motives. To achieve a given desirable end-state, the promotion system relies primarily on approach strategies and means. The prevention system, in contrast, relies primarily on avoidance strategies and means. The chronic and momentary activation of these two systems has a variety of motivational consequences as suggested by the three presentations in this special session.

The first presentation by Michel Pham and Tory Higgins titled “Promotion and Prevention in Consumer Decision Making: A Propositional Inventory” advances altogether 38 theoretical propositions about the effect of regulatory focus on different stages of consumer decision making. From problem recognition and information search to choice and post-choice reaction, each stage in consumer’s decision making is posited to be differentially influenced by promotion vs. prevention self-regulation. For example, in terms of decision rules, promotion focus is suggested to be associated with greater reliance on disjunctive and lexicographic rules, whereas prevention focus is suggested to be associated with greater reliance on conjunctive and elimination-by-aspect-type rules. This presentation sheds light on many interesting areas of future research and serves as research agenda for researchers who are interested in motivational influences in consumer behavior.

Jaideep Sengupta and Rongrong Zhou examine why some people make unwise eating choices with regard to hedonically appealing but unhealthy food options. They propose that exposure to a tempting food triggers a heightened promotion focus (Zhou and Pham 2004) among impulsives. Such a promotion focus involves an emphasis on the potential upsides of consuming the food (e.g., great taste) while potential downsides (e.g., high calories) are suppressed, thus leading impulsives to choose the hedonically appealing food. Results from two experiments confirmed the mediating role of regulatory focus in impulsives’ eating behavior. Apart from identifying a psychological mechanism underlying impulsive eating, this research also suggests a way to rectify such behavior: inducing a counteracting goal, i.e., a prevention focus. Two additional experiments showed that inducing a prevention focus (using totally unrelated tasks) prior to choice would reduce impulsives’ choice of hedonic food and that inducing a prevention focus after a hedonic choice has been made would reduce the overall satisfaction associated with the earlier decision.

In the third presentation, Prashant Malaviya and Miguel Brendl examine how message framing and the regulatory goal orientation of the message recipient interact to determine the level of persuasion. In particular, they examine message framing along two dimensions: regulatory frames (highlighting a promotion versus prevention outcome), and hedonic frames (highlighting a pleasurable

or painful outcome). They conducted experiments by manipulating four message frames (gain, non-gain, loss, or non-loss) and two regulatory goal orientations of the message recipient (promotion versus prevention). Overall the results are consistent with a dis-inhibition model that they have proposed. That is, a regulatory goal orientation (e.g., promotion focus) activates mental representations that are compatible both on the hedonic dimension and on the regulatory focus dimension (e.g., gains), inhibits mental representations that are compatible only on one of the two dimensions (e.g., non-gains, non-losses), and dis-inhibits representations that are compatible on neither dimensions (e.g., losses), where dis-inhibition has the equivalent effect as activation. In a message persuasion context, activation and dis-inhibition result in greater persuasion than inhibition. Their results also suggest that the matching effect and fit effect that have been documented in previous literature can be reversed under certain conditions.

At the conclusion of the presentations, Bob Wyer led the discussion. He highlighted the similarities and differences across papers and provided insights on directions for future research.

“Promotion and Prevention in Consumer Decision Making: A Propositional Inventory”

Michel Tuan Pham, Columbia University

E. Tory Higgins, Columbia University

In a recent chapter (Pham and Higgins 2005), the authors discuss how regulatory focus theory (Higgins 1998) can be drawn upon to explain a variety of consumer decision making phenomena. They clarify some common misconceptions about the theory and draw on existing empirical evidence and new conceptual analyses to advance a series of 38 theoretical propositions about the effects of promotion and prevention on consumer decision making. These propositions are organized along the traditional stages of the decision making process postulated by standard consumer behavior theory (i.e., problem recognition, information search, consideration set formation, etc.). Some of these propositions have already received empirical support, but most await formal empirical testing in consumer research. This propositional inventory can thus be viewed as a research agenda for studying the role of regulatory focus in consumer decision making. The authors hope that this agenda will help revive consumer and marketing scholars’ interest in the motivational analysis of consumer decision making. Examples of theoretical propositions being advanced are provided below.

The authors propose, for example, that states of promotion versus prevention will result in different perceptions of discrepancies between actual and desired states, hence in different experiences of *problem recognition*. Under promotion consumers will pay relatively more attention to the desired state compared to the actual state, whereas under prevention consumers will pay relatively more attention to the actual state compared to the desired state. In general, promotion-oriented consumers will tend to experience the situation as a “need to be met,” whereas prevention-oriented consumers will tend to experience the same situation as a “problem to be fixed” (Proposition 1.1). With respect to *information search*, the authors propose that promotion-focused consumers will engage in relatively more internal search than prevention-focused consumers, whereas prevention-focused consumers will

engage in relatively more external search than promotion-focused consumers (Proposition 2.3). The authors also propose that, under promotion, information will be searched in a more global and “top-down” manner, whereas under prevention information will be searched in a more local and “bottom-level,” serial manner (Proposition 2.7). With respect to *consideration set formation*, the authors propose that the consideration set of promotion-oriented consumers will generally be larger than the one of prevention-oriented consumers (Proposition 3.1). The authors also propose that, holding the size of the set constant, the consideration set of promotion-oriented consumers will be more heterogeneous than the one of prevention-oriented consumers (Proposition 3.2). The authors further propose that under promotion, consideration sets will tend to be formed through the gradual inclusion of alternatives, whereas under prevention, consideration sets will tend to be formed through the gradual exclusion of alternatives (Proposition 3.3).

With respect to the *evaluation of alternatives*, the authors propose that under promotion, consumers will tend to rely on more heuristic modes of evaluation; under prevention, consumers will tend to rely on more systematic modes of evaluation (Proposition 4.2). The authors also propose that promotion will foster greater reliance on personal preferences and private attitudes, whereas prevention will foster greater reliance on group preferences and social norms (Proposition 4.3). With respect to *choice*, the authors propose that under promotion, choice within the consideration set will be guided by a process of selection or acceptance, whereas under prevention, choice within the consideration set will be guided by a process of elimination or rejection (Proposition 5.1). The authors also posit greater reliance on disjunctive and lexicographic rules under promotion and greater reliance conjunctive and elimination-by-aspect-type rules under prevention (Propositions 5.2 and 5.3). The authors further propose that in choices involving a default option, prevention-oriented consumers will be more likely to choose the default than promotion-oriented consumers (Proposition 5.5). The authors additionally propose that promotion and prevention will moderate the well-known context effects in consumer choice. For instance, the authors predict that the “attraction” effect will be stronger among promotion-focused consumers than among prevention-focused consumers (Proposition 5.8). However, the “compromise” effect will be stronger among prevention-focused consumers than among promotion-focused consumers (Proposition 5.9).

Finally, the authors propose that promotion and prevention will have significant influences on *post-choice processes*. For example, satisfaction from desirable outcomes should be more intense under promotion than under prevention, whereas dissatisfaction from undesirable outcomes should be more intense under prevention than under promotion (Proposition 6.1). In addition, promotion-focused consumers will be more likely to experience post-decisional dissonance and regret about errors of omission, whereas prevention-focused consumers will be more likely to experience post-decisional dissonance and regret about errors of commission (Proposition 6.3). Additional theoretical propositions are offered in the chapter (Pham and Higgins, 2005), along with detailed theoretical and empirical rationales.

“Understanding Impulsives’ Unwise Eating Choices”

Jaideep Sengupta, Hong Kong University of Science and Technology

Rongrong Zhou, Hong Kong University of Science and Technology

Around 1.7 billion people worldwide are overweight. People who are overweight are subject to higher risks of diabetes, heart disease, stroke, and high blood pressure etc. In addition, problems created by weight excess have led to huge health care costs. Apart

from physical inactivity, unhealthy dietary habit is the primary cause of overweight and obesity. Many people often seem unable to resist temptation when faced with hedonically appealing yet unhealthy food options. This research examines why some people (eating impulsives) tend to make unwise eating choices.

We draw together knowledge from three different areas—impulsive behavior, regulatory focus theory, and goal structure theory—to identify and provide evidence for one possible mechanism underlying the (usually unwise) eating choices of impulsive versus non-impulsive people. We propose that self-regulatory goals known as promotion and prevention (Higgins 1998) guide people’s choices of hedonic but unhealthy food. Specifically, we propose a mechanism whereby eating impulsives (vs. non-impulsives) spontaneously develop a promotion focus upon exposure to a hedonically tempting food. In turn, this leads to an emphasis on the potential upsides of consuming the food (e.g., great taste) while potential downsides (e.g., high calories) are suppressed, thus leading impulsives to choose the hedonically appealing food. Four experiments provided support for this mechanism and suggested ways of correcting such impulsive eating tendencies.

In experiment 1, all participants were exposed to either a hedonic snack or a non-hedonic snack and later filled out a measure of regulatory focus (Higgins et al. 1994). Results from this experiment suggested that mere exposure to a hedonic food induced a different regulatory focus for high versus low impulsives. High impulsives exposed to the hedonic snack manifested a significantly greater promotion focus, as measured by responses on a completely unrelated task (friendship strategies), compared with low impulsives. Of importance, this difference cannot be attributed to a chronic difference in regulatory focus amongst the two groups, since exposure to a non-hedonic snack did not yield any differences on the regulatory focus measure. In other words, the results confirmed that high impulsives are not intrinsically more promotion focused than low impulsives. Rather, it is the exposure to a hedonic food stimulus that triggers the observed difference in regulatory focus.

Experiment 2 was conducted to test the mediating role of a greater promotion focus in impulsives’ eating behavior. Results from this experiment suggested that faced with a choice between a tempting cake and a healthy salad, greater levels of eating impulsivity produced higher intentions to eat the cake. More importantly, mediation analyses suggested that eating impulsives’ greater tendency of choosing the hedonic food (i.e., the cake) was mediated by a concomitant increase in promotion focus.

One objective of this research is also to identify a corrective mechanism for impulsive behavior. If impulsives’ eating behavior is indeed driven by the heightened promotion focus activated upon exposure to a hedonic food, it should be possible to rectify such behavior by inducing a counteracting goal, i.e., a prevention focus, which would sensitize even impulsive people to the negative aspects of consuming hedonic food. We argue, therefore, that the situational induction of a prevention focus will reduce the propensity of impulsives to consume hedonically appealing, but unhealthy food. Experiment 3 was conducted to test this hypothesis. As in previous experiments, participants were asked to choose from a hedonic snack and a healthy snack. Before they made the choice, for half of the participants, a prevention focus was manipulated by two totally unrelated tasks: a word-categorization task and a proof-reading task. Results from this experiment showed that under baseline conditions, replicating our earlier results, high impulsives were more likely to choose the cake as compared to low impulsives. However, when a prevention focus was induced, high impulsives were less likely to choose the hedonic snack. In fact they did not differ from the low impulsives.

We have argued that impulsives tend to develop a heightened promotion focus when exposed to hedonic food; such promotion focus in turn guides increased choice of the hedonic food by highlighting the potential benefits of consuming such a food. Following this line of reasoning, after a hedonic choice has been made, if impulsive people are asked to evaluate satisfaction with their earlier choice while under the influence of an externally-induced prevention focus, the downsides arising from their earlier decision (e.g., weight gain) should become more salient. This mismatch in regulatory focus between the time of choice and the time of reporting post-choice satisfaction should lower post-choice satisfaction as compared to a situation where impulsive people stay in a promotion focus even after choice. Experiment 4 was conducted to test this possibility. Results showed that even after a hedonic choice is made, inducing a prevention focus post-choice decreased the level of satisfaction with that choice; thus providing a first step towards correcting the impulsive behavior in the future.

This research contributes to the impulsive behavior literature by identifying a possible mechanism underlying the eating choices of impulsive versus non-impulsive people. It also offers something of practical interest for those looking to correct impulsive eating behavior. Finally, the implications of this research to goal representation theory and regulatory focus theory was discussed in the presentation.

“The Influence of Hedonic and Regulatory Focus Framing on Message Persuasion”

Prashant Malaviya, INSEAD

C. Miguel Brendl, INSEAD

Research on the regulatory goal framing of persuasive messages can be broadly classified into two effects. In the matching effect, a message is more persuasive when there is correspondence between the regulatory focus frame of the message and the regulatory goal orientation of the message recipient. Thus, this effect predicts that a person in a prevention goal orientation would be more persuaded by a loss or a non-loss frame while a person in a promotion goal orientation would be more persuaded by a gain or non-gain frame.

The second phenomenon called the fit effect (Higgins 2000, 2002) posits that because people derive value from pursuing a goal with means that fit their goal, a message that conveys a means that fits the goal would be more persuasive. Specifically, a message about a promotion oriented goal is more effective when the message conveys a gain as means to approaching the goal rather than avoiding a non-gain, and a message about a prevention oriented goal is more effective when the message conveys avoiding a loss as a means to the goal, as opposed to approaching a non-loss (Higgins 2000, 2002; Lee and Aaker 2004).

Although research has provided support for the matching and fit effects, it has generally focused on one or the other. As Higgins (1997, 2000) observed, message framing based on the regulatory focus dimension is independent of framing on the hedonic dimension, with distinct effects. This suggests that understanding how frames interact with goals would require varying frames on both hedonic and regulatory focus dimensions, and varying the regulatory goal orientation of the person independently.

Research by Brendl, Higgins and Lemm (1995) adopted such an experimental design. These authors found that respondents who had a chronic promotion orientation were sensitive to monetary gains (promotion outcome) and were not sensitive to monetary non-loss (prevention outcome), a result consistent with the matching effect, but were also sensitive to losses and insensitive to non-gains, a finding that is inconsistent with the matching effect. Moreover, the assumption that gains fit a promotion goal better than non-gains

also cannot account for these results because this assumption is silent on how well losses fit a promotion goal.

To account for their findings, Brendl et al. proposed an information processing model that assumes inhibitory associations between mental representations that vary along the hedonic dimension and the regulatory focus dimension. The model posits three kinds of compatibilities that an individual in a particular goal orientation could experience when exposed to a message frame. Full compatibility occurs when there is a match between the message frame and the individual's goal orientation (e.g., goal and message are about gains). Partial compatibility occurs when the goal orientation and message frame match on one motivational dimension, but mismatch on another dimension (e.g., goal is about gains and message is about non-gains). Finally, full incompatibility occurs when the goal orientation and the message frame do not match on both motivational dimensions (e.g., goal is about gains and message is about losses). The model predicts that a goal (e.g., promotion) activates mental representations that are fully compatible (gains), inhibits mental representations that are partially compatible (non-gains, non-losses), and dis-inhibits representations that are fully incompatible (losses), where dis-inhibition has the equivalent effect as activation. Greater activation of a mental representation of a message in turn should lead to greater persuasiveness of the message advocacy.

We formally tested this model by manipulating four message frames (win, not win, lose, or not lose in a tennis match) and two regulatory goal orientations (promotion versus prevention). Respondents read an advertisement for a tennis racket (adapted from Aaker and Lee 2001), where the potential outcome of a tennis match was framed in one of the four ways indicated above. Regulatory orientation was manipulated by describing a person who either plays for him/herself or plays as a member of a team, thus varying respondent's self-construal: independent versus interdependent. Independent self-construal invokes a promotion orientation, whereas an interdependent self-construal induces a prevention orientation (Lee et al. 2000). The dependent measure was respondent's evaluation of the target tennis racket.

Consistent with the dis-inhibition model, results showed a matching effect when the message frame has positive hedonic valence (win or not lose), such that respondents in a promotion orientation were more favorable toward the target product when the situation was described in a “win” frame and respondents in a prevention orientation were more persuaded when the situation was presented with a “not-lose” frame. In contrast, when the message frame had a negative valence (not win or lose), a mismatch between the regulatory message frame and regulatory goal orientation was more persuasive. Further, when respondents were in a promotion goal orientation, the results are consistent with the fit effect, such that the “win” and the “lose” framed messages were more persuasive. However, for respondents in a prevention goal orientation, the opposite pattern was observed: target evaluations were more favorable for the “not lose” and the “not win” frames. A follow-up replication study provided convergent results. While these evaluation results are consistent with the notion of value from fit, they cannot be accounted for by current assumptions about when fit occurs, but are compatible with the inhibition-disinhibition model. Further, these results help delineate the role of two motivational principles, namely, the hedonic and the regulatory focus principles.

Of Friends and Family: How Do Peers Affect the Development of Intergenerational Influences?

Elizabeth S. Moore, University of Notre Dame
Gale D. Bowman, University of Notre Dame

ABSTRACT

This paper draws on 110 life history narratives to examine how intergenerational (IG) influences are affected as peers begin to take on a more prominent role in young consumers' lives. Although researchers have traditionally assumed that parental influence sharply declines beginning in adolescence, our findings reveal a more complex picture. Our life histories reveal that peers are readily invoked as benchmarks against which family wealth, spending patterns and lifestyle are assessed. Manifestations of the rich interplay between parental and peer influences are presented. Our study enriches conceptual models by focusing on joint parent-peer impacts rather than their separate spheres of influence.

INTRODUCTION

Traditional socialization theory suggests that childhood learning is so prolonged and powerful that the beliefs and attitudes formed during this period persist well into adulthood. Family members, peers, educational institutions, religious institutions, and the mass media each contribute in important ways to this process (e.g. Faber and O'Guinn 1988). The family is the first and typically the most powerful agent of socialization. No other source enjoys such a cumulative edge in exposure, communication and receptivity (Moore, Wilkie and Alder 2001). However, as a child matures other sources of influence such as peer groups become increasingly important. Beginning in early adolescence peers aid in the development of an individual's personal identity as well as in the search for autonomy that characterizes this life stage (Moschis 1987). Researchers have traditionally assumed that parental influence declines as peers begin to assume a more prominent role in the lives of young consumers (Ward 1974). However, more recent evidence in the social sciences suggests that rather than shifting away from parents, adolescents typically try to maintain these relationships and often consult parents when making decisions (Raja, McGee and Stanton 1992). This is consistent with studies of intergenerational influence (IG) that have revealed enduring impacts of the family on the consumer behavior of young adults (e.g., Moore, Wilkie and Lutz 2002).

To this point, consumer researchers have provided useful insights into the respective spheres of influence that parents and peers have in the socialization process. For example, some studies have attempted to quantify their relative influence in specific domains (e.g., Churchill and Moschis 1979; Moschis and Churchill 1978). Other studies have provided rich perspectives by focusing on the role of a single agent of socialization (e.g., Palan and Wilkes 1997). However, we have yet to capture the ways in which parents and peers simultaneously affect young consumers. These sources of influence may sometimes converge thus reinforcing particular actions or lifestyles, and at others provide conflicting recommendations that a young consumer must adapt to and resolve.

The idea for this paper arose while working on a larger project that examines the role of intergenerational impacts on materialism and financial well-being. In our qualitative research we found, somewhat unexpectedly, frequent mention of friends, acquaintances and peers as a general referent or benchmark. This was intriguing, and seemed to offer a valuable opportunity to learn more about how parental and peer influences operate simultaneously. Thus, our

specific goal in this paper is to explore how intergenerational influences (IG) may be affected as peers begin to take on a more significant role in young people's lives. To do so, we draw on the findings from an interpretive study using 110 life history narratives that were collected from young adult men and women.

CONCEPTUAL BACKGROUND

Consumer Socialization

Socialization is the process by which individuals learn the social roles and behaviors needed to participate effectively in society (Brim 1968). It helps people to develop their self-identities, and to assume new roles as they progress through the life cycle. Although socialization is a life long process, childhood and adolescence are thought to be particularly significant periods. Consumer socialization represents one domain within this larger process. It has been defined as "the processes by which young people acquire skills, knowledge, and attitudes relevant to their functioning as consumers in the marketplace" (Ward 1974, p.2). A number of interesting topics have been studied such as the development of consumer knowledge and decision making skills, the relative influence of consumer socialization agents, the impacts of parental style on consumer learning, and the influence of children on household buying decisions (e.g., Beatty and Talpade 1994; Carlson and Grossbart 1988; Churchill and Moschis 1979; Foxman, Tansuhaj and Ekstrom 1989; John 1999).

Intergenerational Influences in Consumer Behavior

The conceptual basis for IG influences rests within socialization theory. The term 'intergenerational influence' refers specifically to the transmission of information, beliefs and resources from one family generation to the next. Since the early 1970s, consumer researchers have shown that IG effects are both significant and potentially important in the marketplace. Although the research base remains relatively small, a number of interesting issues have been studied. Evidence of family transmission has been observed across a range of consumer skills and attitudes such as financial planning skills (Hill 1970; Moore and Berchmans 1996), consumer decision rules (Carlson et al. 1994; Heckler, Childers and Arunachalam 1989), skepticism of advertising (Obermiller and Spangenburg 2000), as well as brand and product preferences (Moore, Wilkie and Lutz 2002; Olsen 1993; Woodson, Childers and Winn 1976). Thus, theory suggests that family influences constitute a powerful socializing agent in children's lives: this has been empirically supported in consumer settings. However, there is evidence to suggest that peers also wield influence in important ways.

Investigation of Relative Influence: Parents vs. Peers

In the social sciences, family and peers have traditionally been viewed as the two most important social forces acting on adolescents, but also as competing or dissonant influences (Kandel 1996). Perhaps as a result, when these researchers have studied the relative impacts of peers and parents the primary focus has been on deviant behaviors such as drug and alcohol abuse. Research on relative influence in consumer settings has focused on explicating the

specific domains of impact for each source. For example, it has been assumed that parents influence the rational aspects of consumption while peers impact more affective dimensions, such as consumption styles and preferences (Riesman and Roseborough 1955). This is empirically supported by research showing that economic motivations for consumption are shaped by family communications, while peer communications affect social motives and materialism (Moschis and Churchill 1978). Researchers have further shown that older adolescents prefer their parents as an information source when making purchase decisions that rely heavily on price, social acceptance, and product performance while peers are preferred when decisions primarily relate to issues of social acceptance (Moschis and Moore 1979). Parents and peers may also exert different levels of influence depending on whether a product is publicly or privately consumed (Childers and Rao 1992).

Thus, there is evidence that parents and peers each possess specialized roles in the socialization of a young person's consumer skills and attitudes. Implicitly, this research stream has tended to look at the nature of these contributions in isolation from one another. Yet, there is also evidence that the extent of family and peer communications about consumption are positively correlated (Churchill and Moschis 1979). This seems to suggest that the presence of some degree of specialization does not preclude joint influence on a particular topic. As individuals we are simultaneously exposed to multiple external sources ranging from our broader culture, to various subcultures, family, and reference groups that are each acting to influence our consumer behavior (Wilkie 1994). These sources of influence sometimes converge so as to reinforce particular actions or lifestyles, and at others provide conflicting recommendations to which we must adapt. For young consumers, we know little about how the multiplicity of recommendations they encounter in their daily lives are assessed. Negotiation and resolution may be particularly challenging at this life stage when the desire for autonomy is great, yet personal experience is limited. In the next section, we turn to the unique developmental tasks of this period.

Development of the Self

Adolescence has long been characterized as a time when individuals begin to explore and examine the self as a means to discover who they are, and how they fit into their social world (Steinberg and Morris 2001). This view of adolescence as a time of self-exploration dates back to Erickson's (1950; 1968) theory of the adolescent 'identity crisis.' More recent theorizing has supplanted the notion of a crisis, and instead emphasizes the development of personal identity (e.g., Waterman 1999). Identity formation is a long process that begins in adolescence and extends well into early adulthood. Researchers have suggested, for example, that in contemporary society significant aspects of identity are still being formed between the ages of 18 and 22 (Meeus et al. 1999). Consumer behavior is a domain in which self-identity is developed and expressed (see e.g., Arnould and Price 1999). Consumers in late adolescence and early adulthood associate who they are with what they have and do (Belk 1985; 1988). This is a stage in an individual's development when financial management skills, perspectives on spending and saving, and assessments of the personal significance of material goods begin to coalesce.

Both parents and peers are potentially influential in the process of identity formation. However, conflicting conclusions have been advanced about the relationship between parents and peers in the development of personal identity. For example, based on an extensive review of the literature to that point, Gecas and Seff (1990) speculated that peers and parents act as competing influences during adolescence. They attributed this to the fact that parents and

peers may possess opposing values and opinions due to their respective associations with dominant or youth culture. Similarly, Steinberg (2001) suggested that conflict is created as children attempt to emotionally detach from parents. Other researchers have emphasized more harmonious relations. Rather than assuming conflicting impacts, parents and peers are each seen as playing unique but important roles in the process of identity development (Raja et al. 1992; Wilks 1986). Because youth become much more concerned with how the significant people in their lives view them at this stage of life (Erickson 1950), it is important to consider how the inputs from these two sources are reconciled.

Researchers in a number of academic disciplines have suggested that one of the primary ways in which individuals make sense of their lives is through the creation of personal narratives or stories (e.g., Bruner 1986; Clandinin and Connelly 2000; Polkinghorne 1988). Narratives help us to interpret, evaluate and integrate our personal experiences. More broadly, life stories are a primary venue for structuring our self-identities. When specifically related to consumption, the telling of life stories allows individuals to impose historical meaning on their consumption activities, as a means of affirming their uniqueness (Arnould and Price 1999; Thompson 1997). In this study, we draw on a specific form of narrative inquiry, the life history method.

METHOD

Research Design and Sample

The life history method belongs to a broader domain of biographical research methods which tap into personal experience through the use of narrative such as profiles, memoirs, life stories, autobiographies, and diaries (Smith 1994). This is a qualitative research method that is based on the assumption that personal narrative is a particularly useful linguistic form in which human experience can be expressed (Polkinghorne 1995). Thus, it relies upon the "subjective verbal or written expressions of informants, these expressions being windows into the inner life of the person" (Denzin, 1989a, p. 14). Here we use a topical life history approach which focuses investigation on a single phase or domain of an individual's life (Denzin, 1989b).

Life history narratives were collected from 110 young adult men and women. Posed at the threshold of independence, young adults are a particularly interesting population for the study of IG influences. All of our informants were university students living in off-campus housing. Forty percent were male, and their average age was 21. They had been living away from home for an average of 38 months at the time of the study. The majority (83 %) had grown up in households with mother and father both present. A wide range of family income levels were represented.

Our informants were asked to write personal essays in which they described how their families have affected their consumption style, beliefs and behavior. With an assurance of anonymity, informants were encouraged to share their personal story drawing on specific events in their lives. Consistent with prior research, informants were given a "life history guide" containing a large number of open-ended questions (e.g., Barnhurst and Wartella 1991; Blumer 1933). The guide was designed to direct their attention to the broad domain of interest, yet allow them great freedom to personalize the questions within their own frame of reference (Denzin 1970).

Analysis

The essays generated well over 500 pages of transcript which are the primary data from which conceptual categories and relationships were identified. We used a relatively structured process following the discovery-oriented aims and procedures of grounded

theory (Strauss and Corbin 1998). Each essay was read, and independently coded by the authors. Given our purposes in this paper, our analysis was focused on those sections of the essays in which both parents and peers were discussed. Emergent categories from the first few essays were identified by the second author, and then reviewed in detail by the first author. These initial categories then served as the structural basis for the coding of the remaining essays. Discrepancies were few and resolved through discussion. Data applicable to each category was then sorted, compiled, and evaluated for conceptual fit.

FINDINGS

The essays provide a rich set of observations into IG influences. Peers are readily invoked as benchmarks against which our informants' experiences within their own families can be understood. Their narratives move back and forth through time as they recount significant childhood experiences, and then shift into the present as they describe consumption practices which characterize their behavior now as a young adult. A range of parental influences across time are evident in our data. Friends and acquaintances are also much in evidence whether actively reinforcing IG influences, introducing divergent perspectives, or simply serving as a salient point of comparison.

Striving for Social Acceptance

The desire for social acceptance provides a significant backdrop against which our informants describe their childhood experiences. Family wealth and possessions figured prominently in their judgments about whether they were likely to fit in, and to be accepted by their peers. Perceptions of popularity were linked to having nice things, and parents sometimes played an active role in ensuring their child's acceptance, as in the following:

I always had nice clothes and shoes and expensive hobbies. This just seemed to be one factor of being "popular" at this time. Others looked up to you for having all of these things. As a family we were among the first in our area for example to have a VCR among other things. (114, M)

My house was always the house that kids came over to—they would play the new video games, play with new guns, ride a new bike, big wheel, green machine, etc. In fact, looking back at my childhood I would say that my having so many things was one reason that I was so popular (and I say this with all humbleness). And I think my parents loved buying me things not only because I loved them, but my friends loved these things too. (162, M)

Although popularity was associated with greater wealth in some cases, the relationship is not strictly linear. More commonly expressed was the desire to have an equal amount of possessions as friends and neighbors. This enabled positive social relationships and removed the potential for jealousy. Informants who had more than others as children seem to experience an "embarrassment of riches" and describe how they attempted to conceal their wealth in order to blend socially. Those from less advantaged backgrounds also expressed fear of embarrassment and rejection. For them, particularly painful are the memories when these limitations came into public view.

I never wanted to really have more than other kids. The most fun we had was when me and my friends had about the same because nobody was envious then. (121, M)

I had no clue about our finances, but I knew I had it better than other children. This also made me feel like I needed to fit in with the other children. All the way up through high school I didn't want people to think that I had more money because I guess in a small town that makes you a snob. So I generally would say I tried to keep my consumption on the level of everyone else. (018, F)

When I was younger, my mom did all the grocery shopping and always bought generic—the original kind w/ the white box and black writing—and that always made me feel insecure because all my friends had name brand cereal—and it made me feel like we were poorer than my friends—and made me embarrassed for my friends to look in the pantry. (153, F)

A range of economic circumstances are represented in our informants' descriptions of their background and experiences. However, as children they were not always cognizant of the differences that existed among families. Neighborhoods and schools sometimes created geographic and economic boundaries, such that children only became aware of differences in their family's wealth position when their circumstances changed. Many expressed a kind of awakening to their family's financial position as they entered adolescence.

When I think about it now, my family was pretty well off, but I never realized it when I was younger. This had a lot to do with the fact that I went to a private school for kindergarten through high school. As I looked around everyone had pretty much everything they wanted without thinking about it twice. (058, F)

As a child, I did not have a lot of material things. I certainly had plenty of toys and such, but I didn't have a lot. I think other kids my age that I played with had about the same amount, but that can be attributed to the neighborhood I grew up in. (063, F)

I didn't realize until junior high, when my best friend had everything, how poor we really were. (010, F)

Parents as Supporters of Social Acceptance

How childhood experiences have been interpreted by these young adults appears to be driven more by the level of parental involvement and support they remember, than by the absolute level of household wealth they enjoyed. Our informants describe varying involvements of their parents, both as facilitators of peer acceptance and as teachers of consumer skills and preferences. Parental support was manifested in many different ways. Some parents were actively involved, and sympathetic to the social pressures that their children felt, while others expected their children to fend for themselves. Levels of IG influences apparent today, appear to be linked to these early experiences.

Some parents tried to overtly facilitate their child's social success by providing material goods that were similar to friends' and classmates'. Even if parents didn't necessarily like the significance being placed on possessions, the desire to help their child fit in with peers seemed to outweigh hesitations they might have. In some cases, mothers and fathers did not agree between themselves that this was the best use of family resources, yet one parent would act as the primary facilitator. In contrast, other informants feel that their parents discounted the social pressures they encountered as a child, and this continues to influence their behavior today.

The only reason my mother bought us extra things and spent more than my dad wanted her to was because she knew we could afford it and she wanted us to have the things our friends had. (014, F)

My dad would prefer it if we put our money in the bank and never spent it, whereas although my mother was interested in encouraging us to save our money, she would still want us to have things that we wanted so that we wouldn't be too different from other kids. (130, M)

I think that I grew up in a time where you had to be fashionable to be "cool." My parents would grill me on why I needed the \$60 Nike instead of the \$20 Payless shoes that looked almost the same. I carry on this trend today in my daily spending. I still try to buy the best that my money can buy even though I don't have much of it. (144, M)

Not surprisingly, our informants describe occasions when they were disappointed by the amount of money and material goods that their parents made available to them. Whether these disappointments later translate into a rejection of parental values seems to be more a function of the motives they attribute to their parents, than the amount of money and goods involved. Even when money was limited, if they believed that parents were not withholding resources they tended to accept their situation with gratitude, and are now more likely as young adults to adopt similar monetary perspectives. In these cases, informants recount being asked to contribute money for major purchases, and the important lessons they learned from doing so (even if painful at the time).

My parents did the best they could with the money they had. (006, M)

Growing up, when we were not as well off as we are now, I was taught early the benefits versus costs of extra unnecessary items such as fancy erasers and pencil sharpeners at school. In the end I wasn't denied things that I wanted. I was just asked to think about it. So I can't exactly place where, but somewhere some time we learned to spend very wisely from my parents. (154, F)

One thing that I appreciate from my upbringing is my parent's example of a good work ethic. I have had a part-time job since I turned 16 and had to buy a car. My sister and I were both expected to purchase our own vehicles, and my parents covered the insurance. As my high school friends were getting new cars for their birthdays or a hand-be-down from older siblings, I thought my parents were the meanest in the world. Looking back, I took better care of my car than most of my friends did. (149, F)

Other respondents recount quite disparate experiences. Rather than feeling supported and encouraged by parents, these young adults expressed feelings of isolation and resentment. Some respondents believe that their parents didn't trust them as children, and as a consequence deliberately withheld information. Others feel that their parents were simply unwilling to provide money or goods, though they clearly had the means to do so. Feelings of being left out, or unfairly criticized are also apparent. When expected to learn on their own, they report turning to peers for guidance.

I was insatiably curious about money back then but my parents said they couldn't tell me how much they made cause I would

run and tell my friends. This lack of trust to discuss money matters always bothered me and I've always wished they could be more open about money with me. Perhaps I would have developed a more frugal spending style if they had. I never truly learned the value of money in terms of saving for future needs. I didn't even have my own savings account until late high school. Friends of mine were encouraged to put money into a saving's account even as early as five years old. (124, F)

As a child, my parents weren't ones to give me everything that I wanted. It was especially hard when all my friends would get it (e.g., a Cabbage Patch doll), and knowing that they had the money to afford it, but didn't want to spoil me. (140, F)

My dad says that I am spoiled but I don't think I am as spoiled as a lot of people I know. I hope that I don't act like they do. (135, F)

My parents never really taught or told me anything about shopping that I really remember. I think I just went off on my own and did it. When I first started shopping my friends influenced me a lot. (176, F)

These characterizations of parent-child relationships reveal clear differences among families in the ways in which questions of independence and autonomy are negotiated. For some, the transition into adolescence and then into adulthood is marked by parental conflict or laissez faire attitudes. For others, warm, supportive relationships facilitate the acceptance of parental beliefs and values. This is largely consistent with the research findings on parental styles (e.g., Carlson and Grossbart 1988). Overall, it is apparent that the young adults in our study retain powerful feelings—both positive and negative—about their childhood experiences. These memories and their emotional connotations are now being carried forward into adulthood, and are helping to shape their self-identities.

Manifestations of IG Influences: The Good, the Bad, and the Ugly

Evidence of continuing IG influence in our informants' lives is readily apparent in the life histories. Many of the IG impacts observed in our study are related to savings and spending behavior. Generally, parents are viewed as positive role models and the primary source of input on financial management. This is consistent with early theorizing that parents influence the rational aspects of consumer learning (Riesman and Roseborough 1955). Peers also continue to serve as important benchmarks in young adulthood. However, by this point in their development social acceptance is not the driving issue. Rather, peers are a salient comparison against which they can assess their own financial management behavior. Though our informants report significant similarities to their parents, their friends and acquaintances also stimulate new opportunities and desires. Subtle tensions between these two sources of influence are evident.

I try to deposit as much of my money as possible and occasionally will spend money on a dinner or movie or a night out with friends. I think I spend a little less on clothes and other possessions than many of my friends. Therefore I think I am similar to my parents. (064, F)

I hate to buy things that aren't on sale. I think that is definitely one thing that I've gotten from my parents. The values that they have installed in me are saving your money and shopping

around. I do save more than most of my friends, but nowhere near as much as my parents. I think that would be hard. (052, F)

I am more like my parents than I am to my friends. When my friends and I go shopping, they buy anything and everything that is on sale, regardless if they need it. (111, F)

Parental influences are not always positive however. IG influences are sometimes associated with personal anxieties, poor decision making and dysfunctional behaviors (Moore and Wilkie 2005). Evidence of “dark side” IG influences is apparent in our data, particularly with regard to poor financial management, overspending and credit abuse. Poor financial management is an IG influence that may continue to create savings and spending problems for future generations (Hill 1970). These problem behaviors can be very painful to these individuals who are highly cognizant of the problems, yet may feel unequipped to resolve them.

My mother let me have a credit card when I was 17 years old. Most of my friends didn’t have one until they went to college. Looking back, it may have been a really young age to teach me about the buy now, pay later idea. That way of thinking has gotten me into a lot of trouble. (136, F)

As a child I was what many would consider “a spoiled brat.” Any new toy, game, sport, or pastime, I had to have it. And, I got it. I was the envy of most of my neighborhood friends. This feeling grew on me to my near demise. I now feel I must have the latest greatest in technology to get the same attention I once did. I was an only child, misunderstood by my peers because of my family being wealthy, most children were jealous and had little to do with me. So, the only way I could get attention from my peers was to have a cool toy. I soon learned that money and monetary items get people’s attention. And so I have since lived with my desire to buy and impress my friends who undoubtedly are quite sick of my toys, but I cannot quit buying. (027, M)

Overall, the manifestations of IG influences in our informants’ lives are rich and varied. Significant aspects of their savings and spending patterns, desires for material goods and financial management skills are grounded in their experiences growing up within their family households. Having moved out of the household, it is with friends and acquaintances that they now have the most frequent daily contact. As young adults, they are largely independent. They are in a position to either act on, or disregard what they have learned from their parents. To the extent that these influences are now embedded in their self-identities, they may be difficult to isolate. At the same time, peers introduce new ideas, preferences and approaches. In our final section, we consider how these may work to sustain or disrupt IG bonds.

Peers as Sustainers and Disruptors of IG Bonds

Although the influence of peers in the maintenance of IG impacts has not been investigated in depth, researchers have reported that these “new influencers” can have disruptive effects (Moore, Wilkie and Lutz 2002). Our data suggests that peers may help to sustain IG bonds, as well as facilitate their disruption.

Disruptive Impacts. We observed situations in which peers are exerting influences that are in conflict with parental views. They may encourage or facilitate behavior that parents find not only less preferred, but also potentially objectionable. Although we should

be careful to recognize the limitations of our research design, it is interesting to note that when our informants indicate they are engaging in behaviors that deviate from parents these are generally instances of “misbehavior”—primarily overspending, gambling, or overeating. They are well aware that their parents disapprove, and try to hide these activities from them. Though often motivated by simple pleasure seeking, over-consumption is sometimes used as a vehicle for rebellion. Thus, deeper family conflicts may surface in their consumption choices.

My bank account is still in my hometown therefore all of my money transactions have to go through them. This became a problem when I lost a little bit of money gambling on the riverboats this summer. It turns out that I really didn’t lose that much money but to my parents it was a lot. My dad could not understand how I could just throw my money away like that. I was just having fun with my friends. (144, M)

My parents would probably have a heart attack, (knock on wood) if they knew how much money I spend when I go out to the bars with my friends. (026, M)

I have trouble saving money, and that scares me for the future. It seems as though no matter how much I make, I manage to spend it all. My parents have always taught me to save money. I think that I learned from my friends. (139, F)

I think my father would be shocked and really upset if he knew how much I eat out. First because it’s so bad for you and second because it’s so expensive. My friends say that I’m just trying to rebel against them by eating out and eating so much junk food. (152, F)

Sustaining Impacts. We also observed many instances in which the influence of parents and peers are mutually reinforcing. Perhaps the most powerful way in which peers sustain IG influences, is by providing opportunities for these beliefs and attitudes to be enacted. IG impacts are now well-integrated into their identities, and become the norms for behavior. Although they acknowledge the roots of these beliefs in their parents’ model, they now view these as a natural and appropriate way to engage the world. Gift giving, shopping strategies and product preferences are all now reinforced and strengthened via their interactions with friends. The mechanism may be as simple as being the willing recipient of a gift, or more involved as in the shoe shopping ritual noted below.

I think that because I remember the activity so fondly from when it was a tradition with my mother, I enjoy it so much now. I admit that I have a thing for buying shoes. In fact, my best friend Nikki and I have sort of a competition going as to who has more pairs of shoes. At this point, I am at 56 pairs, while she has 59. We have discussed this and we figure that shoes can never look bad on you. (136, F)

I have also picked up lots of gift giving techniques from my parents. Pictures, making dinner for friends who have experienced a loss of a loved one, birthday gifts, etc. I love to give heartfelt gifts. Things that are important to me and can be symbolic. I also like to give things to people that they really want. (052, F)

My mom’s generous and supportive use of money has influenced me to do the same with my family and friends. (003, F)

It is funny how I am always in amazement with my boyfriend about his ridiculous purchases, just like my dad would be with my mom. (140, F)

CONCLUSIONS

This exploratory study highlights how IG influences are affected as peer groups begin to take on a more prominent role in young people's lives. Although consumer researchers have often assumed that parental influence sharply declines in adolescence due to the countervailing influence of peer groups (e.g., Ward 1974), a richer and more varied picture emerges here. Peers serve as an important frame of reference beginning in childhood. They are used as a benchmark against which family wealth, spending patterns and lifestyle are assessed. IG influences were manifested in a number of ways related to financial management and material possessions in our study. Interestingly, the level of perceived parental support, not in terms of tangible resources, but on emotional dimensions emerged as the key sustaining force for IG influences. Peers also help to sustain IG, via shared shopping rituals and by providing venues in which to enact lessons learned at home. These findings extend conceptualizations that have tended to focus primarily on the disruptive impacts of "new influencers."

Our findings are of course subject to the limitations of this study's scope, sample and method. Nonetheless they are informative and potentially useful for future research. Because our study centered on IG influences related to financial well being and material goods, it is likely that the scope of peer influences in consumer settings is underrepresented here. Our substantive domain of interest focused on what might be considered the "rational aspects of consumption," thus we would expect parental impacts to be particularly salient. Future research might be directed toward designs that capture the broader domain of peer influences, as well as potential interdependencies with IG impacts.

More generally, the significance of parental support (or the lack thereof) that was observed in this study seems to suggest a direction for future IG research studies. Greater understanding of the factors within the parent-child relationship that strengthen or weaken IG impacts would be useful. The literature on parental styles seems to offer a useful starting point for conceptualization (e.g., Carlson and Grossbart 1988). More broadly, it would seem that there is much to be learned about the interdependent actions of parents and peers in the consumer socialization process. The depth of insight provided by our informants reinforced for us the richness of this topic, and the potential for future advancements.

Dependence in Consumer Behavior Research: Exploring Measurement

T. Bettina Cornwell, The University of Queensland
Cameron Newton, Queensland University of Technology
Robert Lawson, University of Otago

ABSTRACT

This paper proposes that healthy, normal dependency is a construct that would be valuable in consumer behavior research. The area of family life cycle research has always considered the very important implications of the dependent child but other areas of normal dependency have not been examined. Based on a survey of 97 undergraduate students, a dependency scale having three factors: social, financial and physical; is shown to have some value in predicting several recent purchases.

INTRODUCTION

Healthy normal dependence has perhaps not gained popularity as a construct of interest in consumer behavior research because it has historically been associated with abnormal or over dependence and codependent personalities. Only recently has dependency been "depathologized" as a concept and healthy dependency measures developed in psychology (Bornstein 1998). Exploring dependence as a meaningful underlying construct related to consumer behavior liberates the discussion from normative overlays of dependence within traditional frameworks such as the family life cycle. In addition to capturing the dependency found in provision for and in care of a child, a basic concept of dependence could be useful in understanding consumer behavior related to other relationships including but not limited to those with elders, pets, significant others, and even organizations. The purpose of this paper is to outline the aspects of dependency that might be incorporated into the study of consumer behavior and to explore one possible approach to measurement of dependency.

From a social policy perspective, dependency has been defined as "a state in which an individual is reliant upon others for assistance in meeting recognized needs" (Wilkin 1987, p. 868). Consumer behavior requires a broad based conceptualization of dependence, one that allows for all the variability found in normal behaviors and one that is flexible enough to encompass dependent relationships outside of human to human interactions. Memmi (1984) defines dependence as a relationship with a real or ideal being, object, group, or institution that involves more or less accepted compulsion and that is connected with the satisfaction of a need. He explains dependence as a trinitarian relationship where there are two partners and an object. Memmi contends that it is constructive to ask three questions about the trinitarian relationship: "Who is dependent? On whom? And for what?" (p.18). Before outlining the categories of dependency that might be considered in consumer behaviour research, it is useful to establish a theoretical jumping off point and that is the family life cycle research.

Family Life Cycle Research

The family life cycle has been a standard conceptual template in consumer behavior and marketing for decades. It is of interest here, in part because it has housed accounting of the influence of dependent children on family expenditures and constitutes the main contributions to our understanding of dependence and consumption. Due to space limitations, the history of the family life cycle will not be reviewed, rather, we will consider the most recent significant development, and that is argued to be the Gilly and Enis (1982) "redefined" modernized family life cycle. The model adds to the modernized model of Murphy and Staples (1979) the influ-

ence of timing of marriage and children, divorce/death and aging and results in the following 16 categories:

Under age 35 and single
Under age 35, married with no children
Under age 35, married with a child under six
Under age 35, married with a child six or older
Under age 35, divorced with no children
Under age 35, divorced with a child under six
Under age 35, divorced with a child six or older
Age 35 or older and single
Age 35 or older, married with no children
Age 35 or older, married with a child under six
Age 35 or older, married with a child six or older
Age 35 or older, divorced with no children
Age 35 or older, divorced with a child under six
Age 35 or older, divorced with a child six or older
Age 35 or older, retired and single
Age 35 or older, retired and married

Even those making strong past contributions to the literature on household life cycle stages (Wilkes 1995) now, readily admit that the concept is overly narrow (excluding for example, gays and lesbians, see Wilkes and Laverne 2002) and thus exclusionary. Moreover, extrapolations of the original idea are not parsimonious and it could be argued that the family life cycle is declining in explanatory usefulness as fewer and fewer households are constituted as traditional families.

Development of a dependency construct in consumer behavior research offers several advantages over the family life cycle (authors working paper, 2005) including (1) movement away from the terminology of "stages" and "cycles" which did not receive universal support even when it applied to majority of living arrangements (Murphy and Staples 1979); (2) recognition of multifarious dependencies such as present in relationships with significant others, elders and organizations; (3) acknowledgement of the increasing complexity of living arrangements in terms of both their constitution and duration; and (4) potential reinvigoration of a research area that has declined and become repetitive (Commuri and Gentry 2000). Moreover, development of a dependency construct would allow a move away from defining the behavior of groups of individuals as "non-traditional" (and thus "other") as contrasted to a historical and dwindling mainstream.

Categories of Dependence

As a starting point, three broad categories of dependence are offered here as those which encompass the spectrum of human dependence:

Financial/Economic-This type of dependence is mainly concerned with the provision of tangibles and commercially available services. Financial dependence is a more individual (micro) concept whereas economic dependence is a more societal (macro) concept. From the financial dependence perspective, the United States Internal Revenue Service (1996), states that a dependent must be a live relative (by blood or marriage) without sustaining income for which the claimant provided over half the person's support in the previous year. Support includes food, a place to live,

clothing, medical and dental care, and education. For the purposes of consumer behavior researchers, dependents need not be blood or marriage relatives but financial dependence is characterized by the provision of the support discussed by the IRS. From the economic perspective, ideas such as the company town (towns with one dominant employer), urban decay and rural poverty create types of dependence that strongly influence consumer behavior. For example, residential segregation has been associated with the development of an American underclass which experiences among other things welfare-dependence (Massey 1990). From the macro perspective, individuals are dependent on the overall business climate, the value of their currency, and the success and failure of public policies at the broadest level.

Physical/Time- Physical dependence of a general nature has seen very little research within consumer behavior. Research on consumers with disabilities was inspired by the 1990 US Americans with Disabilities Act (Kaufman 1995) but prior to that, consumer behaviors of the disabled or physically dependent received only tangential mentions. For example, Gelb (1978) found that retirement age shoppers value retail store promotions that consider their physical limitations (e.g., offering early opening hours so that they can avoid crowded shopping situations). In particular, the relationship between marketing and the physically disabled (e.g., Burnett 1996; Mueller 1990) and the challenges faced by individuals with particular disabilities (e.g., visual impairments; Baker, Stephens and Hill 2001) have been examined. However, given their focus on disabilities, these studies particularize physical dependence rather than develop general applicability of the concept.

Time is grouped here with physical dependence in that the single most important aspect of physical dependence is time as the dependent object. Unlike physical dependence, a great wealth of literature and theory on time use is available and important links to consumer behavior have already been made (e.g., Jacoby et al. 1976, Hornik 1982; Kolodinsky 1990). Over several decades of research the concept of time has moved from having a primarily economic meaning (family production variable) to conceptualizations as a constraint (as in "time pressure," Suri et al. 2003) and "timestyles" (Cotte, Ratneshwar and Mick 2004) and to consideration of polychromic time use (Kaufman, Lane and Lindquist 1991; Linquist and Kaufman-Scarborough 2004).

Psychological/Social- Psychological and social dependence has the richest literature from which to draw. Bornstein (1993) found more than 500 published studies examining the antecedents, correlates, and consequences of dependent personality traits in children and adults. Even though a great deal of literature may focus on abnormal aspects of psychological and social dependency, almost all aspects of these dependencies have less extreme, normal counterparts. For example, Hirschfeld et al. (1977) defined the interpersonal dependence found in the normal adult personality structure as follows.

Interpersonal dependence is a complex of thoughts, beliefs, feelings, and behaviors which revolve around the need to associate closely with, interact with, and rely upon valued other people. The thoughts concern views of self and one's relationships with others. The beliefs pertain to the value one places on friendship, intimacy, interdependency, etc. The feelings include both positive and negative emotions. The behaviors seek to maintain interpersonal closeness, for example, by being 'pleasant,' giving or requesting advice, or helping others (p. 610).

In psychology, Bornstein and Languirand (2003) have considered dependency as a full spectrum ranging from destructive overdependence to healthy dependence (they also consider dysfunctional detachment). Destructive overdependence is characterized as maladaptive and inflexible dependency whereas healthy dependency is characterized as flexible, adaptive and help- and support-seeking (Bornstein et al. 2003). The focus of Bornstein and his colleagues is on the person and the personality, the ability of an individual to form a healthy dependent relationship.

Given the macro nature of economic dependence, and the potential overlaps of social with psychological dependencies, and time with physical dependencies, this first attempt at measurement was limited to financial, social and physical dependence. The following sections describe development and testing of a scale to capture these three dimensions of dependency.

Measurement

The survey instrument had three sections. The first of these asked respondents about themselves and included a question regarding their family life cycle stage as measured by the 16 categories found in the Gilly and Enis work (1982). This question offered the life cycle categories as response alternatives but also allowed respondents the opportunity to explain if they felt that their current household situation was not described in those categories offered. The second section asked respondents a series of questions regarding particular purchases made in the last year and others made in the last month drawn from Wilkes (1995). The third section contained a battery of five-point semantic differential questions each anchored by "strongly agree" and "strongly disagree". These items were developed following the "item pool" as suggested by Churchill (1979). After a large number of items were generated by the authors, they were reviewed by six students in a PhD seminar in consumer behaviour for their wording and responsiveness to the categories outlined. This section included a reduced set of eight items tapping financial dependence, eight items designed to capture physical dependence and seven items measuring social dependence. These items are shown in Appendix A.

Study Participants

Undergraduate students at a large state university attending introductory marketing and consumer behaviour classes were invited to participate in the study. Participation was voluntary and students were not compensated for their participation. They were debriefed regarding the study objectives after participation. Overall, nearly 60% of the respondents were female, and the majority were between the ages of 20 and 24 (75%). A total of 97 surveys were distributed and all were deemed usable in the analysis.

RESULTS

Not surprisingly, 87% of this student sample reported that their family life stage was that of "Under age 35 and single." This suggests a high degree of homogeneity amongst study participants, at least as far as traditional measures are concerned. Since the remaining responses were distributed amongst the Gilly and Enis categories, it also suggests that the stages approach could distinguish few differences in this particular sample.

Overview of the Data Analyses

Research questions were addressed via two categories of analysis. First exploratory and confirmatory factor analyses were conducted in order to develop an appropriate dependency scale. Second, logistic regression was employed to determine the predictive ability of dependency factors on purchasing behaviours.

TABLE 1
Descriptive statistics and zero-order correlations

Scale	Mean	SD	1	2	3
Social Dependency	3.50	.7438			
Financial Dependency	3.51	.93969	.248*		
Physical Dependency	1.8118	.77088	-.044	.023	

* $p < .05$

TABLE 2
Items and standardized estimates resulting from CFA

Item	Standardised Estimates		
	Factor 1 – Social Dependency	Factor 2– Financial Dependency	Factor 3– Physical Dependency
I'm the kind of person that needs strong interpersonal relationships.	.96**		
I need to have dinner with friends or family regularly in order to feel close.	.43*		
I need strong social relationships.	.60**		
From a financial perspective, I am not self-sufficient.		.71**	
I am receiving financial support.		.68**	
I do not have financial independence.		.83**	
I look forward to the day when I am financially independent.		.54**	
Because of a physical condition, I must often depend on others for help			.79**
Getting out and about is difficult for me.			.59**
With regard to my personal care, there are some things I can't do without help.			.66**
Coefficient alpha	.65	.78	.71
Highest item SMC	.926	.696	.618
Lowest item SMC	.180	.288	.344

** Significant at $p < .001$

* Significant at $p < .01$

Scale Development

SPSS 13.0 was used to conduct an exploratory factor analysis on the student sample ($N=97$) to determine how the various dependency items loaded onto factors. An oblique rotation using principal axis factoring extraction was requested. Investigation of the pattern matrix identified the variables that loaded onto the three factors at a level above .5. Descriptive statistics and correlations relating to factors are displayed in Table 1.

Using AMOS 5.0 (Arbuckle 1986), a confirmatory factor analysis (CFA) was conducted to further assess the fit of the exploratory model to the data (Anderson and Gerbing 1988). Issues relating to sample size, normality of data, and missing data are addressed. Initially, maximum likelihood (ML) estimation was employed in the analysis. Indeed, reliable estimates have been obtained by ML estimation based on sample sizes as low as 50 (Gerbing and Anderson 1985). This method assumes normality of the data which was an assumption that was violated in this sample (all variables: Shapiro-Wilk; $p < .05$). To ensure non-normal data did not influence the results, a Bollen-Stine bootstrap procedure (500 iterations) was employed. This analysis was not significant

indicating that the chi-square indicator of model fit was not inflated. Lastly, missing data was inspected and considered to be missing at random. As per Allison (2002), an EM algorithm was used to replace missing data via MVA in SPSS. Fit indices relating to the CFA are displayed in Table 2 and indicate a reasonable fit of the model to the data based on conventions (Hu and Bentler 1999).

Predictors of Purchasing Outcomes

Several binary logistic regression analyses were performed to investigate the predictive ability of self-reported ratings of dependency on past purchasing outcomes. In all, 97 participants were surveyed, with missing data apparently randomly scattered amongst categories and subsequently listwise deleted (Tabachnick & Fidell 1996). The independent variables proposed as important with respect to predicting purchasing outcomes were (a) social dependency, (b) financial dependency, and (c) physical dependency. Table 4 displays regression coefficients, standard errors, Wald statistics, significance levels, and confidence intervals for significant and near-significant predictors of purchase outcome variables. Table 5 shows base response rates for the behaviors examined.

TABLE 3
Goodness of fit statistics for confirmatory factor analysis

Goodness of Fit Statistics	Value
Chi-square	54.32
DF	32
CFI	.91
NFI	.81
RMSEA	.085
Standardised RMR	.072

TABLE 4
Regression weights, standard error, Wald chi-square, df, significance, and confidence intervals relating to logistic regressions

Variable	<u>B</u>	<u>S.E.</u>	Wald	<u>Df</u>	Sig	95% C.I. for Exp(B)	
						Lower	Upper
<i>Purchase of dinner in a restaurant in the past month</i>							
Social Dependency	1.664	.579	8.268	1	.004	1.699	16.427
Physical Dependency	-1.434	.488	8.647	1	.003	.092	.620
<i>Purchase of dry cleaning services in the past month</i>							
Social Dependency	1.048	.406	6.670	1	.010	1.287	6.320
<i>Purchase of automobile in the past year</i>							
Physical Dependency	.713	.378	3.562	1	.059	.973	4.276
<i>Purchase of power tools in the last year</i>							
Social Dependency	.917	.520	3.108	1	.078	.903	6.941

From Tables 4 and 5 we can see that while the models did not improve our prediction over the base rates, the models do tell us something about the dependencies influencing the reported behaviors.

Purchase of dinner in a restaurant in the last month. A test of the full model with the predictors (social, financial, and physical dependency) against a constant-only model was statistically reliable, $\chi^2(1, N=96)=37.37, p<.001$, indicating the set of predictors reliably distinguished between students that had or hadn't purchased dinner at a restaurant in the month prior to completing the survey. Prediction success was 85.4%.

According to the Wald criterion, both social and physical dependency predicted dinner purchasing outcomes. First, higher levels of reported social dependency significantly predicted the purchase of dinner in a restaurant in the last month, $z=8.27, p<.010$. Conversely, higher self reports of physical dependency significantly predicted not purchasing dinner in a restaurant in the last month, $z=8.65, p<.010$.

Purchase of dry cleaning services in the last month. Testing the full model with the predictors (social, financial, and physical dependency) against a constant-only model was significant, $\chi^2(1, N=96)=28.22, p<.001$. Based on the composite set of independent variables, prediction success was 85.4%. As per Table 4, those reporting higher perceived levels of social dependency were sig-

nificantly more likely to purchase dry cleaning services in the month prior to surveying, $z=6.67, p<.05$.

Purchase of an automobile in the last year. Based on automobile purchase, full model analysis with all predictors against the constant-only model was statistically significant, $\chi^2(1, N=94)=38.66, p<.001$. Prediction success was 87.2%. Overall, this analysis showed that higher self levels of physical dependency neared significance in the prediction of an automobile purchase in the past year, $z=3.562, p=.059$ (see Table 4).

Purchase of lawn or power tools in the last year. Analysis of the intercept-only model was statistically significant, $\chi^2(1, N=95)=40.98, p<.001$ with an overall prediction rate of 89.5%. Whilst a marginal result, the results revealed that higher self-reported levels of social dependency neared significance in the prediction of purchases relating to lawn or power tools in the past year: $z=3.108, p=.078$ (see Table 4).

DISCUSSION AND CONCLUSION

While only a first empirical examination of the potential value of a dependency measure in consumer behavior, the scale, or at least the idea of development of a scale of dependency, must be considered viable and potentially useful. A reasonably well estimated set of three factors was shown to have some predictive value within a relatively homogenous sample. Particular prediction of recent

TABLE 5
Base response rates to purchase behavior questions

Variable	Yes	No
<i>Purchase of dinner in a restaurant in the past month</i>	82	14
<i>Purchase of dry cleaning services in the past month</i>	20	76
<i>Purchase of automobile in the past year</i>	12	82
<i>Purchase of power tools in the last year</i>	10	85

consumer behaviors was not our objective in this study, rather, prediction was only utilized to support the usefulness of the scale and thus only purchases of potential interest to the sample were considered. Although the research could be criticized for using a student sample, the use of this sample actually represents a strong test of the potential value of such a measure since the student sample offers so little variance.

Development of a dependency construct in consumer behavior has been positioned as a possible alternative to the analysis of household or family life cycle but it is also the case that this type of measure might work well within that paradigm. The more important value, however, is the potential to dispense with the "traditional versus non-traditional" distinction, especially when each particular "non-traditional" group (e.g., gays, lesbians, single fathers, displaced homemakers, committed pet owners, returning adult children, elder care-givers) is treated as unique and isolated. The challenges faced by individuals often emanate from some of the same central dependencies.

APPENDIX A
Items Measuring Dependency in Three Areas

Social

Every once in a while I just need to get out with a group of friends.
I prefer to be by myself. (R)
I need strong social relationships.*
Before I plan a social event, I usually ask my friends for advice.
I need to have dinner with friends or family regularly in order to feel close.*
I am the kind of person that feels alone if I do not get to socialize regularly.
I am the kind of person that needs strong interpersonal relationships.*

Financial

I make my own money.
I support myself financially.
I do not rely on anyone for financial support. (R)
I have to rely on others financially.
From a financial perspective, I am not self-sufficient.*
I am receiving financial support.*
I look forward to the day when I am financially independent.*
I do not have financial independence.*

Physical

Physically, I am able to go and do easily. (R)
I have a physical dependency.
I often have to rely on others to get where I need to go.
I often must ask others to help me do things around the house.
Because of a physical condition, I often times must depend on others for help.*
With regard to my personal care, there are some things that I can't do without help.*
Getting out and about is difficult for me.*
I really don't have any physical limitations. (R)

Brands and the Identification Process of Children

Angelique Rodhain, University of Montpellier 2

ABSTRACT

Literature shows a growing interest in the role played by brands in the everyday life of consumers. And identity construction is often underlined since brands are recognized to be linked to consumers' own identity. Yet, even if this link occurs at an early age, few studies deal with children. That is why this paper aims at identifying the role played by brands in the identification process of 10-11 years children. Thanks to a qualitative research led in schools, this article suggests that brands intervene in the sexual identification, the identification of an age group, of a peer group, of the family and of a whole community.

INTRODUCTION

"Identity is a keyword in contemporary society" (Howard 2000). In a society where change rapidly occurs, individuals have difficulties in building their own identity, what is particularly true during transition periods, such as pre-adolescence. That is what was remarked from the ground while leading observations of 10 to 11 year-old children at primary schools. This research comes from a qualitative study which objective was at the beginning to understand the brand relationship (Fournier 1998) between brands and a particular consumer (the child) in a specific environment (at school). In so doing, during the observations and interviews led, the research question of the identity conveyed by brands emerged from the ground. Indeed, during the last year children spend at primary schools, they are about to build and transform their identity of children into an identity of pre-teenagers and brands (particularly of clothes) play an important role in this identity construction.

The aim of the present paper is then to propose a comprehension of brands as playing a role in the identity construction of children in the natural context of schools.

The structure of the article is as followed. First, identity is defined and presented as the result of the socialization process of children. Second, the research question and the methodology are briefly exposed to finish third with an explanation of the results proposing that brands take part in the identification process of 10 to 11 year-old children.

LITERATURE REVIEW: IDENTITY AND SOCIALIZATION

After having defined identity in general, the particular case of the child's identity is approached before revealing the marketing literature treating about the role played by products and brands in the identification process.

Definitions

There are multiple definitions of identity, which can be understood as a structure, a function, a result or a process. Our purpose here is to focus on identity as a process. There are different levels of studying identity: at the level of the individual, of the interaction between two persons, of the group and of an ideology (Baugnet 1998). We will focus here on the identity of the self but evolving thanks to interactions. One global definition is Harter's¹ (1983, in Adamson, Hartman and Lyxell 1999) who defines identity from its three components: the subjective feeling of *unity* among one's self-conception, a sense of *continuity* of these attributions over time, and a sense of *mutuality* between the individual's conception of the self and the conception held by others. Then even the individual identity cannot really be disconnected to others. As a matter of fact, the

individual does not construct her/his identity in a social emptiness. On the opposite. According to Chappuis (2002), "being oneself is inseparable of being with... the individual exists only inside and thanks to her or his relationships with others" (p.48). Identity formation is viewed as a reciprocal process between the psychological interior and her/his socio-cultural environment. Then, emphasizing the close link between individual's identity and relationships highlights its evolution: if identity supposes to follow a certain continuity in time, it is not fixed forever but does evolve too, according to the interactions and meetings with others. That is why identity can be studied as a process, by which others (another person, a group of persons, a celebrity or a character) are used as a model.

Dealing with identity is far from being new, but is particularly in fashion nowadays, in sociology, psychology as well as in the media. Traditional cultures do not ask the question of identity, which is "taken-for-granted" (Bendle 2002). On the opposite, identity is a cultural problem which emerged during the evolution of a modern society, becoming more and more individualistic. Giving individuals more choices to become what they want, modern society gives freedom (allowing a certain social mobility), but at the same time makes the construction of identity difficult (putting forwards the value of realization of the Self) (Mead 1979).

Identity and children

The construction of identity is guided by the research of an ideal after which one aspires and tries to conform to. If the individual judges her/himself through other valuable people's eyes, it is because she/he tries to be accepted by them. The quest is then guided by the desire of being recognized as a valuable person. If identity is in evolution all along the life span, it is all the more significant during childhood, while the child is in construction and socialization. Erikson (1972) built a model of the progressive evolution of identity composed of eight stages (with the first four stages happening during childhood) that lead to a "sane adult personality".

According to the author, as soon as during her/his first months (until 18 months), the child accedes to the feeling of confidence that she/he gains through her/his first interactions with her/his mother, receiving and accepting what she gives. The second stage (from 18 months to three years old) consists of acceding to autonomy thanks to the opposite feelings of ability and inability. During this period, the child begins to experiment her/his autonomous will even if she/he is still extremely dependent of others. During the third stage (from three to five years old), the child needs to discover who she/he wants to become. She/he makes comparisons in order to understand which classes and groups she/he belongs to. This period is characterized by the realization of actions. The last stage of childhood identity (from five to 13 years old) is linked to the identification to specific tasks. This emerging desire to make things well, and even perfectly, is called the "sense of industry". The child tries to identify to adults who have knowledge and know-how. While the child spends most of her/his time at school, the identification to the teacher is important.

¹Harter, S. (1983). Developmental perspective on the self system. In: P.H. Mussen & E.M. Hetherington (Eds.), Handbook of child psychology (Vol.4). New York: John Wiley & Sons.

The environment of the child is essential for the good development of her/his identity and it becomes more and more complex over time. First, only the interactions with the mother are really important (during the first months), then both parents (the first three years), then the whole family (until five) and at last the neighborhood, the teacher and peers at school.

If the identity construction relies on interactions with emblematic persons, it can also be conveyed by things, such as brands and products, which represent these persons. That is how brands and products can become media for children's identity construction too.

Brands and products, media of children's identity construction

Research about materialism tried particularly to understand how people attach themselves to special objects in order to construct their identity. Any commercial product bears a symbolic sense (Levy 1959) and when buying one, one judges implicitly or explicitly if it suits to her/his own image. The object is thus a mean to express oneself, the self being defined as: "a sense of who and what we are" (Kleine, Kleine, and Kernan 1993). From Sirgy's works (Sirgy 1982; Sirgy and Danes 1982) about congruence between the image of the self and the image of the product, Belk (1988) proposes that the objects we use and choose are part of a significant world we create around us that serve as an "extended-self". We transcend the immediate limits of our bodies incorporating in our identity construction objects from the physical environment. In so doing, the chosen objects play the role of a mirror reflecting a part of our life history (Kleine, Kleine, and Allen 1995). And the sense we give to these objects can at the same time be private or public (Richins 1994). These meanings can refer to different personal events and be a media for nostalgic feelings (Belk 1990; Wallendorf and Arnould 1988), and being a support during transition periods (Chang and Arkin 2002; Kamptner 1995; Noble and Walker 1997) or during the realization of rites (Schouten 1991). We particularly attach to objects during moments difficult to live, like the little kid who needs her/his first transitional object that represents her/his mother to reassure her/himself when she is absent. If Baudrillard (1968) qualifies this act as being "regressive", it can nevertheless help the individual to get over the worst.

Even if defining a border between brands and products is not easy-if a border does exist-brands particularly play the role of mediating the identity (Kapferer 1998). The brand, in itself is proven to convey and express the self identity (Fournier 1998; Fournier and Yao 1998), the family identity (Olsen 1993), or a community identity (Kates 2000; McAlexander, Schouten, and Koenig 2002; Muniz and O'Guinn 2001; Schouten and McAlexander 1995).

Elliott and Wattanasuan (1998) having studied teenagers, highlighted that their representations are mostly social ones (conveyed by the media) and from these common representations, brands are used as symbols in order to, in the one hand construct their identity of teenagers and in the other hand communicate this identity to others (Elliott 1994, 1997). According to Elliott and Wattanasuan (1998), the brand gains a strong significance once it is part of a socialization process thus when attitudes and behaviors take shape. But this phenomenon has not been studied yet with younger children.

RESEARCH QUESTION AND METHODOLOGY

This research follows the principles of grounded theory (Glaser and Strauss 1967). I was actually leading a first research whose objective was to understand the way sponsored educational materials used at school could create a child-brand relationship. When observing and interviewing children at school, the question of the construction of identity appeared prevalent, if not inevitable. Intu-

tively, brands indeed seemed to strongly intervene in the identification process of the children encountered. Literature helped then to specify the research question. It allowed to justify that brands and products do play a role in individuals' identification and that an individual's identity is socially constructed thanks to the multiple interactions with others. But if it is recognized that brands are linked to consumers' identity particularly from "Golden Age", there are no research describing how this process occur during childhood. From these points, it seems that, if this research deals with children, it is necessary to study them in their natural environment (at school) and to pay attention to all the persons important in their socialization process. These factors are: parents, sisters and brothers, the media, peers and school (the teacher) (Brée 1993; McNeal 1992). Then the present research question was to understand the role played by brands in the identity construction of 10-11 year-old children² in the natural social context of school.

The methodology is composed of two main phases. Following the principles of grounded theory (Glaser and Strauss 1967), from the first exploratory phase emerged the research question. It consisted of interviewing 15 children and their mother at home³. Then a case study aimed at observing everyday life of children at school. Six classes of the 5th grade were observed in two kinds of schools: Three in Priority Educational Zone (ZEP)⁴ schools (where children come mainly from poor families) and the other three were composed of children coming from middle class families. The case study is mostly based on two methods: observations and interviews. The six classes were observed during six months (in class and on the playground). All in all, 112 pupils were observed. During the non participating observations (Delalande 2001), methods recommended for observations at school were followed (Postnic and de Ketele 1988). I led 36 days of non participating observations, while sat at the corner of the class or of the playground, I noted in a note book: the way children were dressed, any game they use, any sentence and discussion dealing with brands, etc... Then in each of the six classes, four children were interviewed twice (at 6 months inter-

²The age of 10-11 year old, often called pre-adolescence, was chosen because the environment of the child is indeed particularly complex, composed of all the factors: the child is still interested in the media (while during adolescence, he/she is less attracted by them), he/she begins to act like other children who seem more affluent (sisters and brothers and other peers), and at the same time, have not yet established a break-up with their parents and their teacher (what they are about to do during adolescence). This is the period of time when they look for their place in the adults' world. The age studied is limited to 10 to 11 years old, that is the last class of primary school, in order to at least "control" the variable of the age and of cognitive development, and not to multiply the observations. Moreover, this age is chosen because this is the last year during which the teacher is still important for them (because they have the same referent professor the whole day) and the children are old enough to be studied (in order to respond to interviews, to be able to make introspections, etc...).

³During the semi-directive interviews, children were especially asked to draw their preferred product and to realize Chinese portraits: imagine this brand is a person, how would you describe this person?

⁴In France, the term ZEP (for Zone d'Education Prioritaires) is used for schools situated in poor suburbs where the population comes most often from the immigration. The State makes a supplementary financial effort in order to help these schools: there are fewer children in each classroom, the teacher has more money to buy supplying, etc.

vals): two boys and two girls, more leader or more isolated (according to the teacher). At the end of the case study, a group interview with four other children was led in each class. Moreover, implicit discussions were led with the six teachers as often as possible outside the class after school⁵. 9 parents (among the 24 children interviewed) were interviewed at home at the end of the study. The approach is hermeneutic-like, that is signs are interpreted as being symbolic meanings of the culture studied (see for example Thompson, Pollio, and Locander 1994). Each interview is entirely taped and transcribed before being analyzed in two steps. First, each given case is analyzed globally (this is the intra-case analysis where the individual story of each child is approached) and second the cases are compared two by two (the inter-case analysis). The notes written during the observations are associated to the collective interviews and are analyzed jointly in order to understand the social aspect of the identification to the brand.

RESULTS: BRANDS, AT THE CENTER OF THE IDENTITY CONSTRUCTION OF CHILDREN

Brands seem to intervene at five levels in the identification process of the children met. Each level is first presented linearly and then a dynamic process of identification is proposed.

Brand as a gender identification medium

The first level of identity borne by brands (and mainly brands of clothes⁶ and sportswear) is gender identification. Different factors converge in order that the sportswear brand (such as *Nike*, *Adidas* or *Reebok*), represents for children the male power: the pregnancy of sports stars, the fact that leaders (who try to already play the role of small gang leaders at school) wear those brands, as well as older, and thus stronger, boys do. In that case, the product is not really important (sportswear in itself) without the brand. Male power is conveyed only by the brand. This association between brands and male power is perceptible in boys and girls' own definitions of brands and in their Chinese portraits. Wearing branded clothes is associated to adjectives such as "*superior*", "*strong*", "*gang leader*", "*richer*" and "*being at the centre of attraction*". Paradoxically, "*those who wear brands*" fascinate the others and are respected but at the same time are not particularly loved: "*those who wear brands are loud*", "*If Nike was a person, he would be self-centered*". Then, most of the boys still want to identify to "*leaders who wear brands*", even if they do not like them, because they represent the male power: they are those who are listened to and feared. Not to wear brands is then reserved to boys who hang along with girls:

Clément: If there's a boy who wears brands and who goes along with girls, he looks really weird to me, yes really weird...

- The researcher: Why?

- Clément: Because the one who wears brands is like a gang leader, he's a bad boy who walks weirdly and if he goes with girls, it's not right, it's strange!"

Then wearing brands (let's understand in their words "brands of clothes") is a way for boys to stand as boys in opposition to girls. And their manliness can be questioned by others if they do not wear brands, except in certain cases⁷. Nevertheless the reverse logic is not necessary true: this is not only because a boy wears brands that he becomes powerful. For example, *Thomas* who is quite smaller and younger than the others (nine years old), bought one day only *Nike* products from head to foot, because the gang leaders put pressure on him everyday in order to make him do so. And after this purchase, *Thomas* remained an isolated child, but became just a

little more respected. But he felt stronger and proud of himself and became the first to criticize other boys "who do not wear brands"...

As for girls, the dynamic is quite different. They are considered by boys-and they consider themselves-as less concerned by brands:

"Boys do wear brands to be remarked by the others, but girls rarely care about that" (Sarrah).

"When I buy something, I'm interested in the whole class' s opinion.... well, when I say "the whole class" I don't include the girls of course, because they know nothing about brands" (Jean-Christophe).

"The researcher: According to you, what is a brand, what it is for?"

- Oh, this is a question to rather ask boys, because we, girls, are more interested in the kind of clothes we wear, the kind of sweat, of jeans or things like that, but we don't care about the brand like boys. Except sometimes for tracksuit..." (Elise).

"If I were a boy, I would be the leader, I would be naughty when necessary and I would always wear brands like Nike and Reebok..." (Chloë, in a essay).

According to girls' words, brands are not that important for them... And indeed they have many other different ways to position themselves in opposition to boys, wearing female clothes (skirts, dress) which boys have not access to. Whereas boys can hardly differentiate themselves from girls since the latter wear also jeans, sweats, sportswear and sport shoes like them. Then girls easily identify themselves to stars who wear clothes in fashion with no particular brands. The girls met are more sensible to the type of product than to brands. Even girls who are considered as leaders do not exert an influence on the others in order to make them wear a specific brand⁸. Girls who are interested in brands, mostly of

⁵The objective of these implicate discussions was to better know the children and the interactions between them. Important facts were transcribed afterwards in the notebook.

⁶Even if, with the children interviewed, different product categories were dealt with, brands which play a more important role in the identification process are those of categories that, according to children, "we can see", that is mainly clothes and shoes.

⁷For example, *Abdellatif* and *Youssef* who are considered by others as "gang leaders" do not wear brands at all. But, being older than the others (12 years old) and being a little bit quarrelsome and strong, the others are persuaded that they do wear brands... because they are strong! In other words, the other children do not change their idea that "brands=male power". On the opposite, they do not remark at all that *Abdellatif* and *Youssef* do not wear brands because they are powerful, and they even let them make fun of them about the way they get dressed!

⁸Nevertheless this is perhaps inherent to the kind of girls encountered because there exist many brands of clothes that are particularly for girls (like *Chipie* or *Caprice de Filles*), but these brands were very rarely seen in the classes observed. It is supposed that either these branded clothes are too much associated to younger girls or they are bought by richer families (and here only poor and middle-class children were encountered). For example, *Cecilia* exposes her experience lived in another school where brands were important for girls too: "Here girls don't care about brands but in my former school they did. There were two groups: the first used to wear only athletic brands like Nike and could go with boys, and the second used to wear brands like *Chipie*, and we didn't like each other and always quarrelled".

sportive brands are considered-and consider themselves-as tomboys who play only with boys. But boys are less exigent with girls than with boys about the way they get dressed⁹.

Brands as an age group identification medium

The brand (and once again particularly the sportswear brand) symbolizes the identification to an age group. Brands of clothes are indeed worn by older children, because of their high price. Then for kids in the 5th grade, wearing brands is assimilated to older children and is a way to get ready for the important passage to high school. Children in the 5th grade identify to their older brothers and sisters and peers in the neighborhood. They imitate the way they are dressed to get ready to be soon part of the teenagers' world. Those who do not wear brands yet are hence considered as "*the young*". They are called "*the small kids*", "*the weak kids*" or "*the oversensitive babies*". The more expensive the branded clothes are, the more they are valorized. The cheap clothes are bearable for "*little children*" but they are no longer once children get older. To be respected as a future teenager, it is necessary to wear more expensive branded clothes.

The identification to age group follows the same force for girls as for boys. Girls get prepared to the fact that, once in high school, they will have to "*wear brands*" too: whatever the type of product, it will have to bear a brand. Girls in the 5th grade already know that from their older sisters and peers' experience. Nevertheless, once again the influence is less strong between girls than it is for boys. As a matter of fact, girls have many other ways to identify to older girls: they can wear high heels, jewels, making up, short skirts... what they could not do in elementary school. On the opposite, clothes for boys do not really evolve. They still have to wear jeans, sweats, sport shoes like before and that is why brands play a more important role in order to mark a change.

The identification to the age group is similar to a rite of passage, like Le Breton (2002) observed for corporal brands. First a personal rite that the child imposes her/himself in order to prove her/himself she/he is getting older. And second a social rite that the child uses in order to show the others she/he has changed. The child tries to surpass her/himself through the identification to an older age group, and brands intervene in this identification process, for they symbolize teenagers, high school and "valuable people".

Brands as a peer group identification medium

Brands can convey the identification to a group of peers, and particularly the peers of the class. Among the class, three variables play a role in the identification process to peers: the personality of the leader, the teacher and the class atmosphere.

The leader, first, plays a major role. Leaders are valorized because they are supposed to be more successful and popular. They often represent an ideal the other children want to reach (even if they are not really good friends). And, since most of the leaders of the classes wear branded clothes, a way to identify to them is to wear the same brands. A brand can hence become the symbol of a whole class by this game of influence. In a class where the leader is particularly valorized by others, he exerts his influence in three ways:

- he often wears the latest models of the fashion brand;
- he is the first to be consulted by others as for the branded clothes to buy;
- he fixes standards about which brand is good or not and who is "cool" or not.

Each of the six classes observed has its girl and boy leaders, but not all of them play the same role. The most influent leaders are those who are considered as "*bad boys*". They are usually bad pupils, violent, not really liked but very respected anyway. The "*bad boys*" are often associated to the most famous sportswear brands.

Second, the atmosphere among the pupils of the class seems important too for the identification to the peers is possible. Among the classes observed where the atmosphere was very friendly (where boys and girls respect each other and where there was less social differences between children' origin), the role of the "*bad boy leaders*" was diminished. On the opposite, in the classes where children do not get on well, the leader is empowered and brands intervene in the identification process to the peer group.

And third, the teacher plays a role in the identification to peers according to the way she/he teaches (if she/he is authoritative and talks or not about the brands and the game of influence among children) and according to the relationship she/he maintains with the pupils (if she/he can play the role of an ideal for children, letting more or less the leader influence the other pupils). Let us consider the two opposite examples as follow:

In class A, "bad boy leaders" wear essentially Nike clothes and shoes. But they are not really powerful and they do not try to influence the others to wear brands because they are "controlled" by their teacher. This fifty-year-old man plays indeed a very important identification role in the class. He is loved and respected because he takes as much as he can care of the pupils, but at the same time he is feared because he is authoritative. Yet this teacher puts forwards Faïçal, the best pupils of the class and disparage the "bad boy leaders". In so doing, he reduces their influence and makes Faïçal being the leader of the class, but a leader who is recognized and loved by the others for being "a good person". And Faïçal does not really care about brands. He has his own theory on brands: good persons do not wear brands, or only very rarely (for example he only wears Adidas shoes) whereas bad boys are found of brands like Nike. Faïçal is then an identification model and those who want to imitate him do not care either about brands. And "bad boys" cannot exert their influence on this class because the teacher plays a strong gatekeeper role (the children say that "if he hears a child making fun of another about the way he or she is dressed, he would violently kicked her/him off!"). Moreover, this teacher tries to educate the pupils about values such as respect and he diffuses the idea according which, for example, isolating a child because he does not wear brands is a kind of racism. In class A, there is a good atmosphere: all the children are quite similar (they come from poor and Arabic families), they are respectful to each other.

In class F, Kevin, the leader, is really strong, respected and feared by the other children. He pays a peculiar attention on the wearing of brands by others. Nike is particularly appreciated. Then he exerts a strong influence on the way kids are dressed. Those, like Nicolas, who respond to his requirements are valorized and can take part of the central group. Those, like Mathieu, who do not wear brands, are isolated. The

⁹For example, *Kevin* is the gang leader of the class that everybody fears. He can be very aggressive with boys as for their clothes (because, he says, "*if boys don't wear brands, they are not cool like me*") but says nothing to *Linda*. She is "authorized" to play with boys because she is good at sports, and even if she never wears brands, she is respected. Nobody request her to do so.

teacher, a forty-year-old woman, does not want to intervene into the children relationship. She does not play any identification role model either. In so doing, she lets Kevin exert his power and fix his standards on the whole class. In class F, to be “cool and popular”, pupils have to wear sportswear brands, and particularly Nike and Reebok. The atmosphere in this class is quite bad: children insult each other even during lessons. The origin of the children is diverse: few of them come from Arabic and poor families while the majority comes from French middle class families.

Since these three variables (the atmosphere, the power of leaders and the role of the teacher) intervene at the same time in the observations led, this is not possible to elaborate a hierarchy among them.

Brands as a family identification medium

Parents are the first identification models for children. Then, if the child associates her/his parents to a specific brand, she/he will want this brand too. Nevertheless, the identification process to adults is more complicated than to other children, since adults have access to products that children cannot obtain (for example alcohol or cars). Yet, with a specific brand of car, parents can convey a certain value (for example, power). And the child, who would like to identify to her/his parents through consumption will try to find a brand which convey the same value but in a product category she/he can reach (waiting for the time when she/he can buy a car...). In this case, parents intervene in the identification process of the child where brands play a role, even without using and even liking the same brand as the child.

Moreover, when the child feels she/he is closely linked to their parents' choices, she/he feels that these choices are common to the whole family. As Franck says: “We are all Renault in the family” or Abida's mother: “I don't know why, but we are all Colgate, my husbands, all the children and I. We only like Colgate. Everyone. Always. It's like that!”. The central role of the brand in the family identity is highlighted by the use of the auxiliary “to be” rather than “to have”. The brand links the family, and liking the brand is a way to feel part of it.

Parents play another role in the identification process of their children, since they remain their “gatekeepers”. The child cannot make autonomous consumption choices yet. Then if parents accept to buy whatever the child wants, they do not play a role in the identification process to peers and to the age group. On the opposite, if they refuse to buy their children the brands they want and if they explain their choice, they can play a moderating role in the identification function of the brand.

Brands as a cultural identification medium

Children also need to feel that they are part of a bigger community or culture. Children construct an ideal of a culture or of a community they want to take part. To this culture, they associate products and brands. Then they will use the associated brand in order to feel part of the chosen community and in order to communicate their membership to others. This search to be part of a culture was particularly obvious for Arabic children. They often refer to certain products and brands' origin to justify their choices. For example:

“The researcher: Which car do you prefer?

- Faïçal: Renault, it is better.

- the researcher: Why?

- Because when I went to Algeria, there were only Renault cars, the Megane, the Clio, the Laguna. All the others were

old-fashioned cars. They don't have much money in Algeria. The brands of cars I know to be strong are Peugeot for the engine and the coachwork, and Renault. The French brands are better cars. Well...of course there are brands like Mercedes that are better, but I do not think that this is the better choice anyway... and if you take a car too high in quality, you take the risk not to see it again the day after...”.

This example is eloquent because Faïçal is a child who particularly wants to be part of the French society but whose origin is at the same time really important. And Renault allows him to make a link between both cultures, even if it is not the best brand of cars. On the opposite, other children choose brands, even without knowing their real origin, but thinking that they are “from somewhere else”, to claim their no-membership to the French community: “What I prefer is Sergio Blanco, Eden Park and Lacoste. I like these brands because they are not from France. They come from other countries, it is better...” (Nourredine). Even if Nourredine is wrong about the origin of these brands, he uses them as a way not to be a member of the French society, but of another one (likely the American one). For these Arabic children, it appears that few alternatives are possible: most of the sportswear clothes represent an occidental model, either a European or an American one. The adhesion to American brands is then the only way (except not wearing branded clothes at all) to be in opposition to the French culture. That is why the new brands that appeared recently at the effigy of Arabic culture (*Mecca-cola* for drinks and *Muslim* for sportswear) will probably have success in the future among these children looking for a contra-culture. In reverse, some children can reject a brand because it represents a community they dislike. For example, Elie says he does not like Adidas because “this is a Moroccan brand”. If he is wrong about the origin of the brand but Elie associates Adidas to Morocco because the children who wear this brand in his class come from this country. Then, rejecting the brand, he rejects this peer group but also the whole community.

The identification process

The identification process has been exposed linearly in order to simplify the purpose. Nevertheless, the process is a lot more complex since all the levels are interconnected and all the socialization factors intervene at the same time. Let's only take the example of the gender identification process. All the socialization factors of the same gender than the child (and in opposition, the persons of the other gender) intervene in the gender identification process: parents, siblings, the teacher, peers, stars, etc... Through the image conveyed by all these factors of same gender, the child constructs an ideal image of her/his gender. And brands can intervene in this ideal image. If a brand is associated by the child to her/his gender, she/he will want to possess it in order to feel reassured, to claim her/his membership to the gender and to communicate it to others. And to do so, the brand must be visible. The ideal model is like a mosaic constructed by the child, taking only pieces of important persons.

Then the socialization factors intervene in a complementary or a contradictory way. The identification is easier for the child if all the factors converge and if the same kind of brand, or of value, is highlighted by the factors of the same gender. When the factors are in opposition, the child is likely to follow the factor the most important to her/him. When there is an opposition among factors, this is often when parents and teachers play a role of moralizing gatekeepers preventing the child from using the brand in the identification process, in opposition to peers, siblings, and stars. Then the less parents and teachers play their educative role, the more the brand is used as an identification mark. Then, the identi-

fication process is particularly complex first because each socialization factor intervenes on all the identification levels, and second because all the identification levels are interconnected. For example, wearing a certain brand of shoes is a way to identify to a gender, but also to a peer group, an age group, the family group or a whole community...

CONCLUSION

The child's identity is constructed through the interactions with others who are important for her/his development. For 10 to 11 years-old, those are parents, siblings, peers (particularly at school) and the teacher as well as other persons that they cannot directly meet but they know from the media (stars, characters, ...). The child's identity is partly constructed like a mosaic, taking piece after piece, ideal people's characteristics. And brands intervene in the process for they can symbolize these people, groups or culture the child wants to identify to. Once obtained as a symbol, brands allow the child to assert her/himself and to communicate this gender, age group, peer group, family and cultural identity to others.

The implications of the research stand at a theoretical, managerial and social levels. From a theoretical point of view, the research highlights the complexity of consumer socialization where all the factors intervene in a complementary or contradictory way. The role of teachers, almost never studied, is underscored. Then it presented more generally the brands as intervening in the children's identification process. Brands' and children's identities are then linked, but not in an exclusive person-brand relationship and rather on a person-brand-person basis. The identification process must then be analyzed in the complex social context of the child's everyday life.

From a managerial point of view, the research offers reflections especially about brand extension since it appears that the child can be attached to and would like to gain adults brands she/he has not access to (like a brand of car). Moreover, the research offers the opportunity to show that brands convey identity values. From a societal point of view, the research offers the opportunity to question the role of educators (parents and teachers) in children socialization. The role of peers and media-and corollary of brands-seems indeed empowered when educators let them fill the gaps.

This research offers many ways for future research. For example, the identification to the peer group needs to be deepened. The simultaneous role of leaders, of the teacher and of the class atmosphere has been remarked. It appeared that the leader was empowered as soon as the atmosphere was bad among the pupils... but what constitutes a good atmosphere? The balance between boys and girls? Socially mixed or homogeneous classes? Rules stated by the teacher? The leaders' personality needs also a better understanding. And more generally each result is not fixed but deserves a fertile deepening in order to better understand the role played by brands in the children's identification process. And this process is likely to become more and more pregnant, as Le Breton (2002) explains: "Because the crisis of sense and values makes the relation to the world more problematic, the individual is cautiously looking for her/his brands and tries to brave her/his discomfort constructing a more favorable identity" (p.17).

Children's (Mis)understanding of Nutritional Information on Product Packages: Seeking Ways to Help Kids Make Healthier Food Choices

Sabrina M. Neeley, Miami University
Brienne Petricone, Miami University

EXTENDED ABSTRACT

According to the U.S. Centers for Disease Control and Prevention (CDC), overweight and obesity has reached epidemic proportions after rising dramatically since the 1970s. Nearly 59 million adults are obese and approximately 9 million young people ages 6-19 are overweight as well (NCCDPHP 2004). The CDC acknowledges that promoting healthy eating, and creating an environment that supports this behavior, is essential to reducing this epidemic of overweight and obesity.

Encouraging people to eat healthier foods requires that basic information about food nutrients and healthy diets is available, and understandable, to consumers. While adults may understand nutritional guidelines but not put them into practice, kids may have difficulty even understanding basic nutritional information that can help them make healthy food choices. The Nutrition Labeling and Education Act of 1990 (NLEA) was implemented by the U.S. government with the goal of providing more complete, useful, and accurate nutrition information that had previously been available on food packages so consumers would have the information needed to make healthy food choices (U.S. Food and Drug Administration 1995). However, despite the increased efforts to provide standardized, accurate information about nutrients in food and nutritional guidelines, the U.S. faces even higher rates of overweight and weight-related health problems than ever before, and public health officials are alarmed at the rapidly rising rate of weight-related health problems in children.

This study examines how much 7-12 year old children understand about nutritional information and labeling on food packages. Previous marketing and developmental psychology research has demonstrated that kids have difficulty understanding information that requires abstract or hypothetical thinking, as much of the nutrition guidelines and information require. We would expect some type of comprehension deficit in kids, but we lack studies that examine the nature of these deficits or how we can provide more appropriate information to kids to guide their food choices.

This study qualitatively explored kids' knowledge and understanding of nutritional information, and their use of nutritional information appearing on food packages. A snowball sample of 7-12 year olds resulted in four split-gender focus groups (20 children) and ten one-on-one interviews. Focus group participants were shown empty packages from foods commonly consumed by kids their age and were asked to show and talk about the nutritional information on the package. In the interviews, participants were asked questions about their general nutritional knowledge, perceptions, influences, inferences, and decisions.

Results of this study reveal that kids demonstrate wide variance in their levels of nutrition knowledge. This variance is often related to educational situation factors such as where nutrition is taught in the curriculum and whether the child attends public school, private school, or is home schooled. Both nuclear and extended family members appear to have significant influence on children's nutritional knowledge and the kids often go to a family member who they believe is most knowledgeable for guidance on food choices. Children also are very attentive to parents' discussions of nutrition, foods, and diets and could identify and discuss extensively the various diets their parents were using. Nutrition

information learned at school is often reinforced and validated at home, but mostly through pejorative statements about "fat people" and the relationship between food and disease.

Participants stated that they do not read food package information, unless they are bored while they are already eating, and they do not use package labeling to make food choices. They rely on schema (i.e., "fruits are healthy") or they ask a parent if they can eat a particular item. They have simple knowledge of basic nutritional markers such as calories and sugar, but express great confusion about the extended information on food labels. They have great difficulty understanding the various types of nutrients listed on nutrition labels and they do not understand % RDA recommendations. When the children could not understand the nutritional label information, they often turn to other visuals on the package and use these as cues for nutritional quality (i.e. pictures of fruit, marshmallows, cartoon characters, or pictures of children on a package).

These findings suggest that marketers, food companies, and health officials need to seek better ways to communicate nutritional information to kids via product packaging. Perhaps the use of a more visually-presented model can do a more effective job of providing information. Additionally, more research is needed to help researchers and health officials understand how kids interpret abstract information such as calories and even serving sizes, in order to provide kids with better tools for managing portion control. There also appears to be a need for attention to mandatory nutrition education standards.

Do Products Smile? When Fluency Confers Liking and Enhances Purchase Intent

Aparna A. Labroo, University of Chicago

SESSION OVERVIEW

A recent ad for a tri-zone watch (where the face of the watch is split in three sections corresponding to three different time zones) carried a picture in which all three zones were simultaneously set at 10:10 am. Other watch-advertisers follow similar practice, employing ads showing several watches all set at 10:10 am, and car manufacturers sometimes curve the edges of the front grill up at the sides just a little. Whereas some suggest aesthetic or functional reasons for these practices, marketing folklore advocates that this makes the product appear as smiling to the consumer, and enhances liking and purchase intent of the product. Academic research based on processing fluency, however, suggests that this is not the case and that although liking and purchase intent sometimes increases, this is not because the product is smiling.

In investigating factors that enhance liking and purchase intent, three papers in this session build on the processing fluency model. The fluency model posits that liking of objects is influenced by the ease (or difficulty) associated with processing physical features of the object (perceptual fluency, e.g., Zajonc 1968) or in assigning meaning to the object (e.g., Whittlesea 1993). Adding to this literature, in the first paper, Labroo, Dhar, and Schwarz show that liking judgments are enhanced from perceptual ease of processing the target, and further suggest that perceptual ease can be manipulated through closely-related specific concepts. They find, in three studies, that prior exposure to a watch enhances later liking of the watch. However, a minor mismatch (displayed time 10:10, resembling a smiling face, vs. 8:20, resembling a sad face) between the watch at exposure and evaluation eliminates this fluency effect. Similarly, overexposure to the watch decreases liking; but again, a minor mismatch (displayed time 10:10 vs. 8:20) eliminates this disfluency effect. Finally, conceptual priming (“watch” and “smile” words) enhances liking of a “smiling” watch (10:10 display), relative to non-specific activation (“watch” related words only) or baseline conditions.

In the second paper, Aggarwal and McGill test two competing explanations—mimicry versus fluency—for differences in consumer responses to products that have human-like features, such as a smile or a frown. Mimicry-based explanation suggests that people will evaluate an object more positively when it is perceived to be smiling than frowning and that this difference will be larger when the object is seen as a living being. Fluency-based explanation suggests that smiling leads to higher evaluations than frowning when perceived as a living being (people smiling are likely more common than frowning ones) but the reverse when perceived as an inanimate object (if frown is more compatible with product features or goals of the perceiver). Results of a laboratory study provide support for the fluency-based explanation over its alternative.

Extending fluency effects to likelihood of engaging in a behavior, the final paper by Janiszewski and Chandon presents evidence from seven studies showing that processing fluency also contributes to the mere measurement effect. Previously, the mere measurement has been attributed to the increased accessibility of the information supporting the attitude toward the behavior. Janiszewski and Chandon suggest that a second source of the mere measurement effect may be the redundancy in the processes used to generate the mere measurement response and the processes used to decide whether or not to engage in the behavior. Process redun-

dancy creates a fluency that can be interpreted as supportive of the behavioral tendency. That the degree of overlap between the two sets of processes affects extent of behavioral intent is compatible with data reported in this session by Labroo et al. wherein liking of products emerges from an exact match between the prime and target.

Stijn van Osselaer served as discussant on this session. Van Osselaer’s research focuses extensively on understanding memory processes, in particular, how accessibility toward cognitive constructs affects consumer judgment, and the three papers included in the session form a cohesive set within this area, but each with unique findings.

“Of Smiling and Frowning Watches: Stimulus Specificity in Perceptual Fluency”

Aparna A. Labroo, University of Chicago

Ravi Dhar, Yale University

Norbert Schwarz, University of Michigan

Several studies suggest that liking of objects is influenced by the ease (or difficulty) experienced by consumers in processing information relating to the product (see, Schwarz 2004). This facilitation (impairment) is associated with the ease of processing physical features of the object (perceptual fluency, e.g., Zajonc 1968) or in assigning meaning to the object (e.g., Whittlesea 1993). Whereas perceptual fluency is stimulus-specific and sensitive to changes in features (e.g., Mandler, Nakamura, and Van Zandt 1987), conceptual fluency arises without prior exposure to the stimulus, although those results are more mixed. Some authors report enhanced liking from prior conceptual activation (e.g., Lee and Labroo 2004), others do not always find the effect (e.g., Nedungadi 1990). Note that the former authors induced specific expectations of seeing the target by manipulating the context; however, this was not the case in the latter studies. It is possible that conceptual fluency is also stimulus specific and enhances liking only when the primed concepts are closely related to the target. Three studies were designed to investigate this and examine the extent of match required between a prime and a target to enhance liking.

Experiment 1 followed a 3(prime: control; watch set at 10:10, resembling a smiling face; watch set at 8:20, resembling a sad face) x 2(target: watch set at 10:10, watch set at 8:20) between-subjects design. The experiment followed a two-stage procedure whereby participants first evaluated one of three prime-storyboards and then indicated liking toward the target watch. The results indicated that prior exposure to the 10:10 watch increased liking of the 10:10 but not of an 8:20 watch. Similarly, prior exposure to a watch set at 8:20 increased liking of the 8:20 but not of a 10:10 target. Note that the evaluation of storyboard prime did not differ, nor did mood or involvement differ across conditions. The data thereby indicated that an exact perceptual match is required to enhance liking of a target and that a minor mismatch of features can remove any enhancement in liking. Furthermore, conceptual fluency effects were not observed in these data and a single prior exposure of the mismatched watch did not enhance liking of the target over baseline liking. In particular, prior exposure to the 8:20 watch, relative to not seeing any watch, did not increase liking of the 10:10 target; nor did prior exposure to the 10:10 watch enhance liking of the 8:20 target.

It is possible that conceptual fluency requires more extensive elaboration of the prime-watch to enhance liking of other (mismatched) watches. Also, it is possible that participants generated prime-specific meaning (e.g., “10:10 is in the morning and...”), and so liking of the matched but not mismatched watch increased. It is not clear why participants should elaborate specifically about the time and not watches in general; however, experiment 2 was set up to rule out these possibilities. Elaboration was manipulated by number of prior exposures, and the experiment followed a 2(prime: 10:10 vs. 8:20) x 2(target: 10:10 vs. 8:20) x 2(exposure of prime: one vs. seven) design. If the results of experiment 1 are a matter of calibration, then seven (vs. one) exposures should enhance liking of the mismatched target (via enhanced elaboration about watches). Also, if prime-specific meaning was generated by participants, then seven (vs. one) exposures should enhance liking of the matched target (via enhanced prime-specific elaboration). However, if the results are from perceptual fluency, then overexposure of the prime (e.g., Kruglanski, Freund, and Bar-Tal 1996) will enhance boredom and decrease liking of the matched but not mismatched target. Indeed, seven relative to one exposure decreased liking of the matching targets. Moreover, liking of the perceptually-mismatched targets was not affected by number of prior exposures. This enhances our confidence that the observed effects are perceptual, not conceptual.

Experiment 3 was designed to test whether perceptual-fluency effects are also stimulus specific when conceptual cues are employed to prime the perceptual features of the target. Participants first completed a word-jumble task (priming phase) in a 2 (prime words: smile versus frown) x 2 (prime words: control versus watch-related) x 2 (target watch: 10:10 versus 8:20) between-subjects design. The data indicate an enhancement in liking of the 10:10 watch when people are primed with words relating to “smile” and “time,” but an enhancement in liking of the 8:20 watch when people are primed with “frown” and “time.” This suggests that conceptual fluency, like perceptual fluency, is stimulus specific and requires prior activation of meaning that is specific to subsequent processing of the target. As a set, these studies speak to the specific nature of perceptual fluency.

“Is That Car Smiling at Me? Schema Congruity as a Basis for Evaluating Anthropomorphized Products”

Pankaj Aggarwal, University of Toronto

Ann L. McGill, University of Chicago

Anthropomorphizing, that is, seeing the human in nonhuman forms, pervades human judgment (Guthrie, 1993). Furthermore, marketers commonly encourage consumers to see their products in human terms. Hence, people sometimes see their cars as loyal companions; they argue with, cajole, and scold malfunctioning computers and engines. Prior research also reveals that products may be seen as having consciousness or a soul (Gilmore 1919), an underlying defining essence, analogous to a genetic code (McGill 1998), personalities (Aaker 1997; Keller 2002), and relationships (Aggarwal 2004; Fournier 1998). In addition, people apply social norms of reciprocity in their interactions with computers (Moon 2000; Moon and Nass 1998).

Although the tendency to anthropomorphize is pervasive, people do not anthropomorphize all objects nor are they able to anthropomorphize different objects with equal ease. The ability to anthropomorphize depends on the presence of specific features. For example, movement in an object can often create the impression that it is alive (Hieder and Simmel 1944; Tremoulet and Feldman 2000) as can sounds/voices, facial features, intentionality, imitation, and communication ability (Dennett 1996).

The primary questions that this research attempts to address are whether an anthropomorphized presentation of a product affects its evaluation and, if so, how? Our central hypothesis is that when marketers encourage consumers to anthropomorphize a product, consumers bring to mind their schema for human beings and that the product is evaluated in part by how well its features fit that human schema (Fiske 1982; Mandler 1982; Meyers-Levy and Tybout 1989). Depending on the characteristics of the object, therefore, consumers may or may not be able to see the analogy suggested by the marketer to successfully anthropomorphize the product. Thus, this research proposes schema congruity as a theoretical basis for examining the effectiveness of marketers' efforts to anthropomorphize their products.

This overall hypothesis is examined in two laboratory studies. In these studies, a human or an object schema is first triggered by encouraging participants to think of the product as being like a person or an object. Next, a new product is presented to them with a feature that is more or less congruent with the human schema. Finally, the dependent variables are administered.

Study 1 uses a car as the target product. Prior research suggests that smiling faces are more familiar (Baudouin, et al. 2000), and that smile is part of the human face schema (Martin and Rovira 1982). We manipulate the shape of a front grille of the car visual so that the edges point up to resemble a smile or down like a frown. We expected that the “smiling” car would be a better fit with the human schema than the “frowning” car. As a consequence, we predicted that when primed with a person schema, participants would be more likely to perceive a smiling car as a person and evaluate it more positively than a frowning car. The study was a 2 x 2 x 2 design with schema prime (person, object), facial feature (smile, frown) and car model (Lexus, Thunderbird) as the between-participants conditions with 120 undergraduate students as the participants. The results confirmed our hypotheses: participants primed with the human schema (but not the object schema) were more likely to see the car as person (2-item anthropomorphism score) and evaluate it more positively (15-item scale) when the target feature was more congruent (smiling) than less congruent (frowning) with the human schema. Further, the anthropomorphism score partially mediated the product evaluations. Finally, there were no differences across the conditions on an 11-item affect score—ruling out mood as an alternative explanation.

In order to get deeper insights into the underlying mechanism and further validation of the schema congruity hypothesis, study 2 was conducted. Thus, Study 2 also incorporated participants' thought protocols. We also wanted to rule out two alternative explanations: 1) product mimicry—which suggests that participants mimicked the smile of the car in the human schema condition, and this mimicry resulted in more positive evaluations (Chartrand and Bargh 1999), and 2) contingent quality—which suggests that a smile is seen as a better quality feature than a frown.

In study 2, we primed participants with a person or an object schema by telling them about the product “family” or the product “line” of a new beverage. The visual showed four bottles that were either identical in size, or they differed in size as well and placed in a way so as to suggest different individuals (much like different members of a family). A pre-test confirmed that people expect members of a family to be different sized—suggesting different sized bottles to be congruent with the human schema. As before, we expected participants primed with the human schema to be more likely to see the product as a person and evaluate it more positively when the feature was congruent (different sizes) than incongruent (same sizes). Also, since the bottle sizes (same vs. different) could not be mimicked, nor were they inherently better (or worse), this study rules out the two alternative explanations suggested earlier.

Ninety-two undergraduate students participated in this 2 (schema prime: person, object) x 2 (bottle sizes: same, different) between-participants study. Results showed that participants in the person prime (but not the object prime) condition who saw different sized bottles were more likely to perceive the beverage as a person and evaluate it more positively relative to the other conditions. Further, coding of the thought protocols showed that these participants made more schema-match related comments compared to the others. Finally, the anthropomorphism score (3-items) partially mediated the product evaluation (18-item) score.

Our research offers a framework to better understand the phenomenon of anthropomorphism. Two studies provide support for schema-congruity theory as the underlying theoretical basis for explaining consumers' evaluations of anthropomorphized products. Our findings also offer marketing managers specific guidelines of how to ensure a successful anthropomorphism of their products. Future research that delves more deeply into the evaluation of anthropomorphized products is awaited.

“Transfer Appropriate Processing, Response Fluency, and the Mere Measurement Effect”

Elise Chandon, University of Florida

Chris Janiszewski, University of Florida

There is considerable evidence that the mere measurement of intent influences subsequent preference judgments, behavioral intent, and behavior (cf. Morwitz and Fitzsimons 2004; Spangenberg and Greenwald 1999). Specific intent questions can influence specific behavior (e.g., Greenwald et al. 1987; Sherman 1980) or general behavior (e.g., Spangenberg and Obermiller 1996) and general intent question can influence general behavior (e.g., Morwitz, Johnson, and Schmittlein 1993) or specific behavior (e.g., Fitzsimons and Morwitz 1996; Morwitz and Fitzsimons 2004). Moreover, mere measurement influences the performance of shopping behaviors, health-related activities, and pro- or anti-social behaviors (cf. Morwitz and Fitzsimons 2004).

The pervasiveness of the mere measurement effect makes the identification of a single underlying process difficult. Short-term, ephemeral mere measurement effects have been attributed to semantic priming and information accessibility. For example, Fitzsimons and Shiv (2001) propose that prior consideration of information about a target will influence subsequent judgments about the target because the prior information remains accessible and contaminates the subsequent judgment (see also Fitzsimons and Williams 2000). Long-term, persistent mere measurement effects have been attributed to the increased accessibility of attitudes (Fitzsimons and Morwitz 1996) and the increased accessibility of normative beliefs (Spratt, Spangenberg, and Fisher 2003). Morwitz and colleagues (Chandon, Morwitz, and Reinartz 2004; Dholakia and Morwitz 2002; Fitzsimons and Morwitz 1996; Morwitz and Fitzsimons 2004) provide evidence suggesting preexisting attitudes exert a strong, long-term influence on brand loyalty and consumption as a consequence of being measured.

It is possible that there is an additional source of the mere measurement effect. There is now considerable evidence that people are not only sensitive to the content of the information generated in cognition, but also to the characteristics of the processes used to generate the information (Klinger and Greenwald 1994; Schwarz 2004; Whittlesea and Leboe 2000). Processing fluency refers to the ease of executing a cognitive activity, whether it be the generation of a perception (i.e., perceptual fluency), the retrieval of information from memory (i.e., retrieval fluency), or the assigning of meaning to an event (i.e., conceptual fluency). Attributions about processing fluency have been shown to influence judgments about preference, truth, and memory (Hasher, Goldstein,

and Toppino 1977; Mandler, Nakamura, and Van Zandt 1987; Whittlesea, Jacoby, and Girard 1990) as well as influence eating behavior, social interaction, and compliance with requests (Burger et al. 2001; Capaldi 1996; Zajonc 1968). We propose a similar bias, based on the processing fluency of response planning, can contribute to the mere measurement effect.

This article investigates the influence of mere measurement on subsequent intentions to purchase the product. Our objective is to show that attributions about the processing fluency experienced during response planning, termed response fluency, can contribute to the mere measurement effect. We will show that response fluency effects are independent of information accessibility and attitude accessibility effects, while acknowledging both information content and attributions about process contributed to mere measurement effects. In experiment 1, we show that response fluency increases a subsequent purchase intention. Experiments 2A and 2B show that it is the degree of overlap in the processing activities used to answer the mere measurement question and the processing activities used to respond to the purchase intention question that creates the response fluency responsible for the mere measurement effect. Experiment 3 and 4 identify a boundary condition of the response fluency effect, showing attributions about response fluency are limited to situations where response fluency is high relative a baseline. Experiment 5 documents that people will not rely on attributions about response fluency when more diagnostic information is available.

Joint Versus Separate Evaluations of Mental Accounts

Subimal Chatterjee, Binghamton University

Junhong Min, Binghamton University

EXTENDED ABSTRACT

We can measure preferences one alternative at a time (*separate evaluations*, e.g., Choose Brand A or not choose Brand A; Choose Brand B or not choose Brand B), or many alternatives at a time (*joint evaluations*, e.g., Choose Brand A, or choose Brand B, or choose neither). Research typically shows that if one alternative is more attractive in a particular evaluation (say, Brand A is more popular than Brand B in separate evaluations), it is less so in the other evaluation (Brand A is less popular than Brand B in joint evaluations; see, for example, Hsee and Leclerc, 1998). Such preference reversals often occur because consumers shift from a within category processing in separate evaluations (consider Brand A only, or consider Brand B only) to reconciling across category differences in joint evaluation (how Brand A compares to Brand B; Bazerman, Moore, Tenbrunsel, Wade-Benzoni, and Blount, 1999).

In this paper, we extend the study of joint versus separate evaluation effects to mental accounting, a form of cognitive book-keeping that consumers often use to evaluate transactions (Thaler, 1980, 1985). In mental accounting, consumers organize the costs and benefits of a transaction within that transaction's mental account. If separate evaluations encourage consumers to look only within one mental account, but joint evaluation encourages broader across account comparisons (e.g., how the costs in one account compare to the costs in another account), it is conceivable that the mental accounting process itself may be susceptible to separate and joint evaluation effects.

In the first experiment, we consider the theater ticket problem from Kahneman and Tversky (1984). Upon entering the theater, Consumer A discovers that she has lost the \$10 ticket, and Consumer B discovers that she has lost a \$10 bill. Mental accounting predicts that B is more likely to buy the theater ticket than A because B will organize the lost \$10 bill in a wealth account (and keep it separate from her theater decision), but A will organize the lost \$10 ticket directly into her theater cost. We, however, expect that the mental accounting prediction will hold in separate evaluations but not in joint evaluation. In separate evaluations, we can make out that there is a qualitative difference between A's theater decision (\$10 cost) and B's theater decision (\$0 cost). In joint evaluation, however, as our focus shifts to comparing the costs across the two consumers, we can see that both consumers are equally worse off (A is \$10 poorer in her theater account, and B is \$10 poorer in her wealth account). To test our predictions, we have three separate groups of participants read about (1) Consumer A, or (2) Consumer B, or (3) both Consumer A and Consumer B. As predicted, we find that the mental accounting prediction is supported in separate evaluations but not in joint evaluation.

In the second experiment, we consider the basketball game problem from Thaler (1980). Here, Consumer A has to decide whether or not to brave a snowstorm and drive to a basketball game for which she has already paid \$40, whereas Consumer B faces the same decision, except that she got the ticket for free. Mental accounting predicts that A is more likely to drive to the game because closing the game account, with a \$40 cost already in it, is too painful. B, on the other hand, is not wasting money by not going to the game, so she has, in that sense, nothing to lose (other than the enjoyment of the game). In this case, we expect that the mental accounting prediction will hold in joint evaluation, but not in separate evaluations. Unlike the \$10 bill in the previous example,

which could have been used for any purpose, it is difficult to separate the cost of driving to the game from the game itself. In separate evaluations therefore, we cannot easily distinguish between A's tradeoff (risking a dangerous drive to get the satisfaction of not wasting \$40) and B's tradeoff (risking a dangerous drive to enjoy the game). When the scenarios are presented jointly, however, all other costs and benefits remaining the same, the paid ticket becomes salient when it is compared to a free ticket. To test our predictions, we have three separate groups of participants read about (1) Consumer A, or (2) Consumer B, or (3) both Consumer A and Consumer B. As predicted, we find that the mental accounting prediction is supported in joint evaluation but not in separate evaluations.

In Experiment 3, we make one change to the basketball game problem. Instead of reading about a snowstorm, participants are told that the consumer will have to spend \$40 in transportation should she want to go the game. Thus, Consumer A must spend \$40 for transportation in addition to the \$40 for the ticket, while Consumer B, with a free ticket, must spend \$40 on transportation. Mental accounting predicts that, in this case, A is less likely to go the game. Making the expenses easy to track, the extra \$40 transportation costs de-escalates the sunk cost faced by A (Heath, 1995). However, as before, we expect that the mental accounting prediction will be supported in joint evaluation but not in separate evaluations. In joint evaluation, when the two amounts are presented together, we can see that the cost of attending the game is double for A relative to B. In separate evaluations, however, since the two costs cannot be compared, it is hard to judge who is spending more money (i.e., \$80 is a lot of money, but so is \$40). To test our predictions, we have three separate groups of participant read about (1) Consumer A, or (2) Consumer B, or (3) both Consumer A and Consumer B. We find that the mental accounting prediction is supported in joint evaluations, but not in separate evaluations.

Our results cast the normative status of mental accounting in doubt. It appears that consumers are unable to decide whether mental accounting is good for them or bad for them, as is evident by their shifting preferences across joint and separate evaluations. This, however, offers an opportunity to educate consumers. If some outcomes of mental accounting are not desired, encouraging consumers to think in both separate and joint evaluation modes may show that what they think is attractive in one condition is not so in the other.

The Effects of Mixed Bundling on Consumers' Inferences and Choices

Rebecca W. Hamilton, University of Maryland

Nevena T. Koukova, Lehigh University

EXTENDED ABSTRACT

For several product categories like cars, computers, vacation packages, and new homes, consumers choose not only the product itself, but also various options for the product. When sellers offer such products to consumers, they make decisions about presentation format. For example, a computer manufacturer like Dell can offer different models of computers featuring different options, or they can offer a base model and give consumers a choice of options (Huffman and Kahn 1998). Further, if the seller offers a base model with options, the options can either be offered individually or in bundles of multiple options (Venkatesh and Mahajan 1993).

Economic theory predicts that when bundles are not discounted, consumers' option choices should be the same regardless of whether options are presented individually or in bundles. However, this prediction assumes that consumers' reservation prices for individual options do not change across presentation formats. Empirical evidence suggests that consumers' valuations for options can be influenced by the presentation format (e.g., Huffman and Kahn 1998; Park, Jun and MacInnis 2000). In this paper, we examine how cues such as whether the options are offered as part of an option package and how the option package is labeled, affect consumers' inferences and choices.

While there is a substantial body of research considering incentives for sellers to bundle products and options, and optimal bundling strategies in various situations, there is much less research considering consumers' inferences when they encounter bundles of options. For example, suppose that a computer manufacturer offers Microsoft Office software, a modem, an extended warranty and a printer as an option package in addition to offering these options and other options individually. If customers can purchase the bundled options individually, and the options in the bundle are not discounted, then offering the bundle does not materially change the consumer's choice set. However, we argue that as consumers evaluate an offer, they make inferences about the options that are offered based on various cues, such as whether certain options are bundled together into option packages, and how these option packages are labeled. Consumers may infer that these options are bundled together because they are more important or because the package was designed to target certain groups of consumers. Such inferences are argued to change consumers' valuations for the bundled options.

We test our predictions in a series of three studies. Study 1 shows that offering an option as part of a bundle significantly increases the likelihood that the option is chosen relative to otherwise similar options that are not part of the bundle. Participants were more likely to choose options that had been included in the bundle than options not included in the bundle. Providing evidence for the robustness of this effect, the same pattern was replicated for three different products categories.

The description of the option package further affects consumers' valuations for options that are bundled together. For example, if an option package is labeled "Collegiate Package" instead of "Option Package," consumers are likely to infer that college students—but not necessarily other consumers—would find these options particularly useful. Therefore, this label is expected to increase the number of college students who buy at least some of the options in this bundle, but decrease the number of non-college students who purchase options included in the bundle.

Studies 2 and 3 demonstrate that the way an option package is labeled can change consumers' perceptions of the appropriateness of the bundle for them, resulting in changes in the purchase likelihoods for options in the bundle. Consumers draw inferences about the value of the options to them based on the presence of the bundle and the label of the bundle, and these inferences influence their choices. The results of studies 2 and 3 suggest that the label of the bundle moderates the effect of presenting options as part of a bundle that was shown in study 1. Moreover, we show that study 1's effect is not due to anchoring or salience, because the inferences and the labels given to the bundles affect the options selected.

Our findings from these three experimental studies underscore the importance of the presentation format in influencing consumers' choices of options for products. Because consumers make inferences based on cues such as whether certain options are bundled together into option packages, and how these option packages are labeled, these cues can systematically affect their choices. These inferences may explain why consumers continue to encounter many examples of mixed bundling even when online ordering and flexible manufacturing reduce the costs of customization.

On-Line versus Memory-based Information Credibility Inferences: Implications for Memory-based Product Judgments

Mario Pandelaere, Catholic University Leuven
Siegfried Dewitte, Catholic University Leuven

ABSTRACT

Product quality judgments based on retrieved information should take the credibility of the information source into account. We used information complexity to manipulate cognitive resources during information processing and used information processing goals to trigger either on-line or memory-based information credibility assessments. Our results suggest that consumers may take source credibility into account if they assess it on-line or if they have the cognitive capacities to store the source during information processing. Otherwise, source credibility may have no impact on product quality judgments. In addition, our results suggest that source credibility effects on perceived quality may be mediated by information trust.

INTRODUCTION

Consumers often have to make quality judgements with respect to products of which they have received information in the past. Obviously, to make adequate memory-based product judgements, consumers need to retrieve as much information about the product as possible. In addition, as the information may stem from multiple sources (e.g. from advertising, consumer reports, friends, ...) that may vary in credibility, consumers have to take the information into account to the extent that the retrieved information is trustworthy, or, equivalently, to the extent that its source is credible. This implies that, for each retrieved piece of information, people also need to retrieve the source of the information and assess its credibility. Studies on the sleeper effect (Kumkale and Albarracín 2004) have shown that people may not always be able to do so. In fact, it appears that persuasive information may have an increasing impact over time, simply because people forget the source of the information, or, at least, are no longer able to match the various pieces of information with the various sources.

Drawing on the distinction between on-line and memory-based (product) judgments (cf. Hastie and Park 1986), we propose that people may make either on-line or memory-based inferences with respect to the credibility of the information they receive. On-line credibility inferences are inferences that are made while the information is being received, whereas memory-based credibility inferences are inferences that are made when the information is retrieved from memory. Clearly, accurate memory-based credibility inferences require that consumers are able to recall the source of each specific piece of information that is retrieved. The proposed distinction between on-line and memory-based credibility inferences may help to identify the conditions under which source credibility may affect memory-based product judgments. There are two possibilities. First, if consumers have made an on-line credibility inference, we assume that they integrate and code this information with the product information. As a result, consumers will be able to take into account the credibility of the information upon retrieval. Whether or not they can retrieve the source of the information should not affect the ability to retrieve credibility information. Second, if consumers have not made an on-line assessment of the credibility of the information, adequately judging the credibility of the information requires that they can retrieve the source of the information. Clearly, retrieving the source of the

information, in turn, requires that consumers have stored the source in the first place. Therefore, whether or not they can retrieve the information source should strongly affect the ability to retrieve credibility information in this case. If consumers lack the cognitive resources at the time they process the information, they may not store the source of the information at all. As a result, they will not be able to adequately account for the credibility of the information later on. Their memory-based product judgments, then, will not be affected by the source credibility.

In sum, the proposed distinction between on-line and memory-based credibility inferences implies that if consumers make an on-line credibility inference, their subsequent memory-based product judgments will reflect source credibility, irrespective of cognitive load. In contrast, if consumers have not made an on-line credibility inference (i.e. have to make a memory-based credibility inference), their subsequent memory-based product judgments will reflect the source credibility only if they had sufficient cognitive resources to process the information and store the source.

In studies on product judgments and person impressions, processing goals are used to have participants make either on-line judgments or memory-based judgements (e.g., Lichtenstein and Srull 1987). Likewise, we asked half of the participants to assess the information credibility of the information they are presented with (credibility condition) in order to trigger on-line credibility inferences. We asked the other half to assess the comprehensibility of the information for average consumers, which reduces the need for on-line credibility judgments (comprehension condition).

The information credibility was manipulated using 'suspicions of ulterior motives' (cf. DeCarlo 2005; Fein 1996). Although information credibility may depend on various source factors, like source expertise or source liking, suspicions in ulterior motives may be more interesting for our research. In particular, inferences about ulterior motives may be cognitively more demanding than inferences about source expertise and source liking. In fact, inferences about source expertise and source liking may be made somewhat automatic (i.e. on-line), whereas inferences about ulterior motives may require more controlled processes (i.e. made either on-line or memory-based, depending on the goal one has while processing the information).

Cognitive load may be induced in various ways ranging from very artificial (e.g. memorizing 7 digits, Shiv and Fedorikhin 1999) to natural (e.g. time pressure, Park, Iyer, and Smith 1989). We decided to manipulate cognitive load by using complex versus simple information, based on the fact that, in natural settings, information varies considerably in complexity. Processing complex information requires more cognitive resources than processing simple information (Daneman and Merikle 1996). Therefore, source information may not be stored spontaneously in complex information conditions. Taken together, source credibility should affect product judgments if consumers focus on credibility, irrespective of information complexity. In contrast, if consumers focus on information comprehensibility, source credibility should affect product judgements for simple product information but not for complex product information.

METHOD

Participants

For a participation fee of 6 Euro, 157 students from the University of Leuven took part in a one-hour experimental session that included the current experiment (mean age=21.77 years; 23% male).

Procedure

Participants arrived at the lab in groups of 5 to 8 and were seated in separate cubicles. They were told that they would receive information about a product or service. Half of the participants had to assess how understandable the information was for average consumers (comprehension condition) whereas the other half had to judge how credible the information was (credibility condition). Participants received either uniformly positive information about a 'new food supplement that could diminish the effects of aging' or uniformly positive information about an established restaurant. The food supplement was described in terms of chemical substances and their purported beneficial effect on various old-age illnesses (complex information). In contrast, the restaurant was described in very simple terms (simple information). Half of the participants received the information from a source that stood to gain from it (the firm that made the food supplement or the restaurant owner: dependent source condition) or from an independent source (FDA and a restaurant guide, respectively: independent source condition). After participants received the information and gave their credibility or comprehension judgment (depending on their processing goal), they were also asked to rate how well they had understood the information. The program then closed and participants engaged in an unrelated task that lasted about 5 minutes. Afterwards, participants were asked three questions about the product/service on which they had received information. They were asked to indicate on an 11-point scale (ranging from 0 to 10) how good they thought the product/service was, how good they thought it would be compared to competing products/services and how convinced they were that the product/service was good. They then were asked to type in as much information they could still remember. Finally, they were asked three questions about their trust in the information they had received. They were asked to indicate on a 11-point scale (ranging from 0 to 10) how objective they thought the information was, how much they would trust the information, and how much they would trust the source of the information.

RESULTS

Manipulation checks

Information complexity. We analyzed the participants' self-proclaimed understanding of the information using a 2 (processing goal: credibility versus comprehension assessment) x 2 (information complexity: simple versus complex) x 2 (source: dependent versus independent) between-subjects ANOVA. Complex information ($M=5.74$) was judged to be less comprehensible for the participant than simple information ($M=9.03$), $F(1,149)=88.39$, $p<.001$. The other factors did not affect comprehensibility.

In the comprehension condition, we had also obtained ratings of how well the average consumer would understand the information. We analyzed these ratings using a 2 (information complexity: simple versus complex) x 2 (source: dependent versus independent) between-subjects ANOVA. Consistent with the previous, complex information ($M=4.29$) was judged to be less comprehensible for average consumers than simple information ($M=6.89$), $F(1,76)=19.28$, $p<.001$.

Information credibility. In the credibility condition, we had obtained information credibility ratings. We analyzed these ratings using a 2 (information complexity: simple versus complex) x 2 (source: dependent versus independent) between-subjects ANOVA. Information from a dependent source ($M=5.50$) was judged to be less credible than information from an independent source ($M=6.60$), $F(1,73)=5.59$, $p<.05$. Information credibility, then, seems to be affected by the source manipulation as intended. Unexpectedly, information complexity also affected information credibility, $F(1,73)=10.35$, $p<.01$. Complex information ($M=5.29$) was judged to be less credible than simple information ($M=6.80$). Although one must be cautious to interpret this difference as such because the complex information involves another domain than the simple information, a reading of the recall protocols does support our interpretation: Quite a few participants commented that the technical jargon in the 'food supplement information' may have been used to persuade people through authority arguments that preclude potential consumers to critically process the information. This apparently raised suspicions about the product. Note that this counteracts our hypothesis, because complex information apparently raises suspicion in itself, which probably facilitates the encoding of consistent (suspicious) source information. Finally, it is important to point out the total lack of interaction between source and information complexity, $F(1,73)=0.08$, $p>.77$. This suggests that the source affected information credibility similarly in the simple information condition as in the complex information condition.

Trust ratings

The three judgements with respect to information and source credibility were averaged to form a general index of 'information trust' (Cronbach alpha=.80) that was analyzed using a 2 (information complexity: simple versus complex) X 2 (processing goal: credibility assessment versus comprehension assessment) X 2 (source: dependent versus independent) between-subjects ANOVA.

Not surprisingly, we replicated the effect of information complexity that was obtained for the information credibility judgements, $F(1,149)=5.35$, $p<.05$. Complex information ($M=4.82$) was trusted less than simple information ($M=5.48$). More pertinent for our research question, a main effect of source was obtained, $F(1,149)=16.91$, $p<.001$. Overall, information from an independent source ($M=5.74$) was trusted more than information from a dependent source ($M=4.56$). A planned contrast revealed that the source affected the trust ratings in the two credibility conditions and the comprehension condition involving simple information, $F(1,149)=16.70$, $p<.001$. Moreover, the source effect did not differ over these three conditions, $F(1,149)=0.19$, $p>.83$. Another planned contrast showed that the source had no significant effect in the comprehension condition involving complex information, $F(1,149)=1.04$, $p>.30$. These results suggest that source affected trust in the credibility condition, irrespective of information complexity. In the comprehension condition, however, source affected trust only in the simple information condition.

Perceived quality.

The average of the three product/service quality judgements (Cronbach alpha=.84) was analyzed using a 2 (information complexity: simple versus complex) X 2 (processing goal: credibility assessment versus comprehension assessment) X 2 (source: dependent versus independent) between-subjects ANOVA.

The results parallel the results for the trust ratings. Information complexity affected perceived quality, $F(1,149)=53.45$, $p<.001$. Complex information ($M=4.97$) led to lower quality ratings than

TABLE1
Trust & Perceived quality as a function of Processing Goal, Information Complexity and Source
(dependent vs. independent)

Information:	credibility judgment		comprehension judgment	
	simple	complex	simple	complex
Source:	Information Trust			
dependent	4.73	4.32	4.77	4.41
independent	5.95	5.59	6.47	4.94
	Perceived Quality			
dependent	6.21	4.56	6.27	5.05
independent	6.86	5.26	7.16	5.00

simple information ($M=6.62$). In addition, a main effect of source was obtained, $F(1,149)=5.83, p<.05$. Overall, information from an independent source ($M=6.07$) led to higher perceived quality than information from a dependent source ($M=5.52$). A planned contrast revealed that the source affected perceived quality in the two credibility conditions and the comprehension condition involving simple information, $F(1,149)=7.65, p<.01$. The source effect did not differ over these three conditions, $F(1,149)=0.07, p>.93$. Another planned contrast showed that the source had no effect in the comprehension condition involving complex information, $F(1,149)=0.02, p>.89$.

Mediational analyses

We investigated if the effect of source on perceived quality was mediated by trust. Baron and Kenny (1986) suggest testing mediation using four steps. Above, we already showed that source (independent variable) affected trust (mediator) as well as perceived quality (dependent variable). Further, trust was highly correlated with perceived quality ($r=.58, p<.001$). Finally, a 2 (information complexity: simple versus complex) X 2 (processing goal: credibility assessment versus comprehension assessment) X 2 (source: dependent versus independent) between-subjects ANCOVA with trust as covariate and perceived quality as dependent variable, revealed that trust had a significant effect on perceived quality, $F(1,148)=65.41, p<.001$, whereas neither the main effect of source, nor any of the interactions involving source was significant, all $F_s<0.63, p>.42$. Information complexity continued to affect perceived quality, $F(1,149)=50.29, p<.001$. This direct effect of information complexity is probably due to theoretically unimportant differences between domains: People may perceive an established restaurant as being of (relatively) high quality where they may refrain inferring this level of quality for a new food supplement.

DISCUSSION

We hypothesized that consumers may infer information credibility on-line or memory-based. In addition, whereas on-line assessment of information credibility may not be affected by the cognitive load that is present during product information processing, memory-based information credibility inferences may be affected by the cognitive load that was present during product

information processing. We manipulated the cognitive load in processing the information using an intrinsic quality of the information, namely information complexity. In addition, on-line credibility inferences were elicited by asking participants to judge the credibility of the information whereas memory-based credibility inferences were elicited by asking participants to judge how well average consumers would understand the information. Our results are entirely consistent with our hypothesis. The source affected both trust in the information and perceived product/service quality in all conditions, except in the condition designed to trigger memory-based information credibility inferences when the information was hard to process (complex information). Moreover, mediational analyses revealed that the source effect of on perceived product/service quality was due to its effect on trust.

Whether or not consumers make on-line credibility inferences may depend on a variety of factors. The persuasion knowledge model (e.g., Friestad and Wright 1994) suggests that consumers may make on-line credibility inferences if a persuasion attempt is very blatant. For more subtle persuasion attempts, consumers may be able to make on-line credibility inferences only to the extent that they have sufficient cognitive resources. In addition, product involvement may also determine the likelihood of on-line credibility inferences. Indeed, on-line credibility inferences may be especially likely if people have already decided to buy a product from that category or if they have a strong interest in the product (i.e. if they have a high involvement in the product [category]). Finally, consumers may also differ in the extent to which they take information for granted: Some consumers may chronically be very sceptical of any information they receive, whereas others may, as a default, readily accept the information they receive. However, depending on the situation (salience of the persuasion attempt and product involvement), even less-sceptical consumers may become more sceptical when processing information.

Of course, several questions remain for future research. First of all, on-line inferences were triggered very directly by asking participants to assess information credibility. It remains to be seen whether on-line credibility inferences can be triggered more subtly through priming of scepticism or through alternative information processing goals. A related question is to what extent credibility inferences occur spontaneously in natural circumstances. Second, we obtained a direct effect of information complexity on trust and

perceived quality. As information complexity was confounded with information content, it appears necessary to replicate the current experiment using either a constant script and manipulate cognitive load externally, or continue to manipulate load internally through information complexity but keep the content of the script constant (e.g., using a simple and a complex food supplement script). Finally, our framework suggests that sleeper effects may be obtained particularly when consumers have failed to make an on-line credibility inference, but, nevertheless, had sufficient cognitive resources to store the source and the association between the source and the information. Consequently, it would be interesting to investigate how judgment delay affects trust and perceived quality in the various conditions that were used in the current experiment.

Looking for Lake Wobegon: Why Sometimes We Are All Below Average

Katherine Burson, University of Michigan

Joshua Klayman, University of Chicago

EXTENDED ABSTRACT

In many product domains, consumers must evaluate their abilities as they compare to others' abilities. For instance, two consumers who disagree about which restaurant to visit together need to determine which of the two consumers is better at picking restaurants. However, evidence suggests that consumers cannot accurately gauge their own relative standing in many contexts (see Alba and Hutchinson 2000 for a comprehensive review). Kruger (1999) and others show that people are influenced by the difficulty of a task when they make estimates about their relative standing. When tasks seem easy, people on average believe they are above average. When tasks seem difficult, people on average think they are below average. Many researchers posit that this bias is due to an egocentric focus on the target of social predictions. People appear to attend to themselves and neglect information about the group average. Researchers point to strong correlations between participants' estimates of absolute ability and their estimated percentile and a weak or nonexistent correlation between estimates of average ability and estimated percentile. We will call this pattern of correlations "asymmetric weighting". In this paper, we explore the idea of asymmetric weighting in two ways: We identify one cause for asymmetry and we determine if this pattern is an error or not.

First, we determine whether or not the type of absolute estimate elicitation has an impact on asymmetric judgmental weights. We hypothesize that absolute estimates generated about one's "skill" evoke comparative rather than truly absolute judgments while absolute estimates generated about one's "score" will not show this tendency. In the first study, we manipulate how absolute estimates of performance are elicited on three different tasks—in terms of "skill" or in terms of "score". We find consistently greater asymmetric weighting when absolute estimates are provided on a "skill" measure than when they are provided on a "score" measure. This finding suggests that participants asymmetrically weight absolute information in judgments of relative standing only to the extent that this information is redundant with their subsequent relative estimate. Presumably, comparative thoughts ("skill") do not need to be supplemented with thoughts about the group average while singular thoughts ("score") must be composed of estimates of own and average performance. Since the "score" absolute measures were truly singular, participants should not *and did not* show egocentric attention to their absolute estimates.

In the second study, we test the hypothesis that symmetric weighting is "ideal" weighting of absolute information. We suggest that symmetric weighting does not necessarily produce accurate percentile estimates. Previous research has argued that a more normative weighting strategy (equal weight on one's own score and average person's score) would improve the accuracy of participants' percentile estimates and make biases less likely to occur. However, estimates made about others are surely less accurate and reliable than estimates made about oneself. We predicted that even a substantial amount of asymmetric weighting would not necessarily hurt participants' accuracy in percentile estimates. In fact, we expected that when the absolute information being weighted by participants was perfectly accurate, percentile estimates would be quite accurate despite some asymmetry.

To test this hypothesis, we varied the amount of feedback participants received about their own and the average participant's scores on a task. Then we ran regressions for each individual across

ten trials in order to determine how they weighted this information. We compared these weights to the *best* weights that they could have used with the provided information—the weights that would produce accurate percentile estimates. We found that participants were essentially weighting information about themselves and others in an "ideal" manner. While these weights were not symmetric, the weight given to the provided information was proportionally correct when it was compared to the ideal weights. Participants' error seemed to be simply too much weight on that information in general, not too much asymmetric weighting. Furthermore, as expected, accuracy in percentile estimates improved as each absolute estimate was replaced with actual absolute score.

These two studies shed light on the process decision makers use to evaluate themselves relative to others. Consumers do not necessarily egocentrically focus on themselves in this process. To the contrary, they symmetrically weight information about themselves and others when that information elicited in terms of "score"—a singular estimate. The second study demonstrates that "ideally", judges should employ some asymmetric weighting of information in most cases. Study 2 shows that, when consumers have no truly certain information about their or others' absolute performance, asymmetry is ideal. This makes sense given that information about oneself is more accessible than information about others. However, when consumers have access to both their own absolute ability and that of the group average, they are better off estimating their relative standing using both pieces of information to equal extents.

Of course, in life, consumers rarely have access to information about the performance of their reference group. Marketers can choose, however, to help consumers more accurately predict their relative standing. Because consumers will incorporate information about the median performance into their comparative assessments when that information is diagnostic, marketers may choose to provide it to their customers. The pro shop that tells the disappointed putter that the average person performs below her level can correct an irrationally low self-assessment. Similarly, the ski resort that takes the time to inform skiers that the average skier cannot ski down a triple black diamond slope can prevent its customers from a disappointing and dangerous experience. For these reasons, we believe that our results are an important addition to the growing body of research on consumer calibration.

SPECIAL SESSION SUMMARY

Public Policy Prescriptions from Consumer Research

Nina Mazar, MIT Sloan School of Management

SESSION OVERVIEW

In what ways can research on consumer behavior inform public policy and help to design more effective and more efficient policies? In the session “public policy prescriptions from consumer research” three papers that deal with a variety of consumer research topics exemplified their possible contribution to theory and demonstrated the overall applicability of research on consumer behavior for policy.

The field of consumer research continuously produces papers that give other researchers valuable new insights in understanding motives, goals, and reasons for why consumers act in certain ways under certain conditions. Surprisingly, little of this knowledge has ultimately been applied in real world to improve the quality of individual consumers’ decisions, their life in general, or our society’s welfare. The goal of this special session was to bring together research that has examined more directly questions related to social policy in an attempt to promote not only the particular topics of research (which are very interesting in and of themselves), but also the general theme of pursuing public policy as a goal for research.

The particular topics of the three papers are moral behavior, health, and fund raising. In essence, all three papers deal with the multiplicity of goals consumers face, their attention to these goals, and their pursuit of them—with the recognition that some of these goals represent the public good and some do not. The question of interest then is how to align the actions of the individuals with those of society at large. Joel Cohen, who is the editor of the *Journal of Public Policy and Marketing* and who has been involved in this intersection between consumer behavior research and public policy for a long time, discussed the three papers.

We hope that our call for more collaboration between these fields will invoke fruitful follow-up thoughts and discussions that will ultimately result in a larger role of consumer research in politics.

“Almost Honest: Internal and External Motives for Honesty”

Nina Mazar, On Amir, Dan Ariely

The standard rational model of human behavior in philosophy as well as economics assumes that individuals are motivated to maximize their selfish needs. In the domain of honesty and deception this representation of homo economicus means that individuals are honest only to the extent that the cost-benefit analysis of the dishonest act points in favor of honesty. In other words, the standard rational model of decisions about honesty and dishonesty is one in which these decisions are no different from any other decisions. In contrast, we sketch a psychological model in which we assume that decisions about honesty also include considerations of internal reward mechanisms. Such considerations imply that even without any external downsides to a dishonest act, individuals will consider being honest. Our current work tests the existence of such internal mechanisms by manipulating one factor that the standard rational model predicts would largely influence the tendency to be dishonest: the probability of being caught in the dishonest act, and one factor that the standard rational model predicts would not influence the tendency to be dishonest: awareness of the dishonest act (e.g., religious priming or having individuals sign a bogus honor code).

Our experimental results support our hypothesis that individuals possess internal reward mechanisms for honesty. In particular, first we show that when given the opportunity and incentives to be dishonest individuals do exhibit dishonest behavior but that this dishonest behavior is limited in its extent (limited by the degree to which dishonesty activates their internal reward mechanisms). Second, we show that when the probability of being caught further decreases, the tendency for dishonesty does not change substantially (we argue that this is based on the fact that the probability of being caught only changes the external, but not the internal rewards from honest behavior). Finally, our third finding is that increasing awareness of motivation for honesty dramatically decreases the tendency for dishonesty. This last finding seems to be in line with the notion that higher awareness might cause the internal mechanisms for rewards from honesty to be more active or to “kick in” earlier (see related experiments by Duval and Wicklund [1972] with, for example, mirrors).

We would like to argue that these results could offer a different perspective when thinking about how to design policies for punishments. If we were to adopt the standard rational model when designing policies, we would subscribe policies in which the expected magnitude of punishment is set to be larger than the possible benefits of a dishonest action (another option would be to increase the probability of being caught). In principle, such setups will make the cost of the dishonest act higher than the expected reward, and hence there should be no dishonest acts. To the extent that the standard rational model is incomplete, it might be useful to reconsider punishment policies. Such considerations would set the magnitude of punishments to be smaller than the possible benefits of dishonest actions in order to take into account not only the effects of the external rewards but also of the internal rewards. To illustrate this point imagine that for a particular possible crime the expected benefit is Y , and the internal positive reward for honesty is X . In this case the standard rational model would prescribe a punishment with expected magnitude of $-Y$ to offset Y , while the model that includes internal rewards would prescribe $-Y+X$ under the assumption that the joint magnitude of the two components influenced the decision to commit the dishonest act.

Another interesting difference between the standard rational model and our extended version of it relates to how both models treat cases in which crime and dishonesty do exist. In such cases, the standard rational model would suggest that the expected magnitude of the punishment is not sufficiently large, and it needs to be increased in order to prevent further crime. From the perspective of the model that includes internal rewards, the existence of crime and dishonesty could just as easily be attributed to low activity in the internal reward mechanisms. The recommendations under these conditions would be to invest in educational efforts to increase the internal mechanisms for rewards, which in turn would decrease the tendency for dishonest acts.

Finally, the perspective that includes internal reward mechanisms also suggests that there are immediate changes one could implement in the environment that would increase honesty. Much like the honor code manipulation in one of our experiments, one could imagine to ask people to sign an honor code just before starting to fill out their tax return forms. Similarly, for universities

and other educational institutions that are considering whether and how to implement an honor code the recommendation is simple: Implement the honor code and use an explicit and salient signature as an invoking cue for honesty.

“A Repeated Decision-Making Framework for Understanding Decisions about Protective Measures: The ‘Magical Thinking’ Model”

Barbara E. Kahn, Mary Frances Luce

We believe that the use, and neglect, of protective measures is an issue with crucial public policy implications. As just one example, nationwide accidents from bicycle riding cause more childhood injuries than any other consumer product except automobiles but only 41% of children use bicycle helmets while riding. Clearly, it is in the public interest to encourage and reinforce helmet use. Most strategies for doing so focus on education as to the benefits of helmets. As such many people are aware of the advantages of bike helmets and own helmets, but still do not ensure that their children wear them every time they ride. In other words, educational campaigns have focused on motivating initial *compliance* and have not focused on the repeated *adherence* in use every time a child rides. Our research addresses this problem of repeated adherence to protective measures over time. We will review and provide empirical support for a model of adherence focused on the segment of people who are educated, and largely persuaded, about the benefits of protective measures (e.g., screening tests, safety precautions) and who have not experienced the relevant threats (e.g., disease diagnosis or accidents). This is a situation where a marketing approach is particularly relevant to public policy considerations (see Rothschild (1999) on distinctions among marketing, education, law).

We are concerned with the problem of lapsed use, whereby consumers who have initially adopted protective measures become less vigilant over time. We apply our model to two major classes of chronic behaviors. First, we have data from several experiments (published as well as ongoing) that address adherence and delay in the context of medical screening tests such as mammograms. Second, we will discuss extensions of our model and experimentation to non-medical protective measures such as bike helmet, car seat, or sunscreen use.

Our “magical thinking” model focuses on two problematic classes of events and their implications for repeated decision behavior. First, we focus on “false positive” events where the protective measure is used, the relevant threat does not occur, and there is some “hassle” associated with use of the protective measure (e.g., a false positive in mammography screening). For instance, our prior published work indicates that false positive mammography test results can reduce intentions to engage in cancer screening, unless coping resources are bolstered (Kahn & Luce 2003). Data collection that is currently underway suggests that these processes are moderated by individual difference factors as well as by one’s prior medical history.

We are currently extending our model to include a second set of problematic “false security” events. In work that is currently underway, we extend our focus to include situations where the protective measure is not used but again the threat is not realized. Initial tests of this model will occur within the domain of bike helmet use, focusing on why and how adherence declines as a function of previous behavior. In this domain, we hypothesize that declines occur because (1) if there is discomfort or stress involved

with wearing of the helmet and an accident does not occur, the perceived efficacy of the helmet diminishes and (2) if a helmet is not used, and an accident does not occur, perceived vulnerability to the threat diminishes. Although experiments currently in development focus on use of bicycle helmets, we suggest that our model will generalize to the patterns of behavior that exist for a wide variety of preventative measures (e.g., seatbelt use, cars seats, etc.) and screening behaviors.

Our theoretical approach to the effects of false positive and false security events on adherence begins with a normative, decision tree structure for the value of protective measures. We then augment that analysis with a more descriptive process model that has two components. First, we argue that incorrect causal inferences occur due to “magical thinking” or the erroneous interpretation of causality between two closely occurring events. We suggest consumers may incorrectly infer a causal relationship between the “false positive event (hassle)” or the “false security they feel” and subsequent evaluations of subjective probabilities associated with the decision to use the preventative measure. For instance, decision makers may incorrectly infer, or over-infer, from “failure” associated with hassle of a protective measure to relative efficacy. As another example, decision makers may incorrectly infer reduced vulnerability from a “false security” event. For instance, an individual may infer that it is generally acceptable to neglect bike helmets simply because negative outcomes do not follow from an instance of neglect. Second, we believe it is important to understand decision makers’ processes of emotion and coping, as protective measures address anxiety-provoking events (cancer, car accidents). We will also discuss how our model overlaps with, and diverges from the traditional health belief model, and similar approaches to health related decisions.

Our theoretical model provides several avenues for public policy application, as understanding the causes of adherence declines will allow us to suggest specific strategies and tactics to reverse these declines. First, because our approach relates behavior to a normative framework, it allows for calculation of normative, rational actions (some protective measures are not worth taking) and for comparison of actual behavior to model predictions. Further, it provides an “as if” framework for individual consumer behavior that may directly suggest avenues for intervention. We believe that there are three main classes of approach for public policy interventions following from our work. First, there is a “cognitive” debiasing approach rooted in the behavioral decision theory literature. This approach may allow for identifying and correcting biased interpretations people draw from prior behaviors (e.g., biased judgments of vulnerability). Second, there is an “emotional” approach based on emotional appeals and specific appraisal dimensions. This approach may suggest specific emotional appeals to signal goal relevance and mitigate the impact of reactions to “problematic” (False Positive or False Security) events. Finally, there is also a “behavioral” approach acknowledging that it may be possible to generate behavior that bypasses intention by creating habits. This could be beneficial in that it might provide some resistance to impact of factors such as negative evaluation given hassle or reduced subjective vulnerability given neglect of measure. More generally, we believe that by addressing the problem of repeated adherence to protective measures over time, we can uncover interventions with public policy benefits.

“Social Psychological Motivations in Nonprofit Marketing”

Jen Shang, Rachel Croson

Recently funding for public goods such as education, healthcare, and other public services have become more dependent on local and voluntary funding sources, especially individual contributions, and less reliant on taxation and government grants. Local governments, schools and other nonprofit organizations have increasingly turned to private donations as a source of funding for public goods. In 2003, individual giving accounted for 74.5% of donations to nonprofits. One challenge facing policy-makers is to evaluate the effectiveness and permanence of this funding source, and to decide how much of its limited budget to allocate toward making nonprofits more effective in their fundraising as opposed to funding the nonprofit providing the public goods directly.

We identify social psychological motivations that impact the extent of voluntary funding through a survey of contributors to public radio stations. We use results from this survey to suggest interventions that can be used to increase this funding source, and use a field experiment to test these interventions. Our results suggest both tactics that nonprofits can use to increase their voluntary contributions, and publicity campaigns that policy-makers can use to increase voluntary contributions to these nonprofits (and thus decrease their reliance on governmental funding).

In the survey of current and lapsed members of public radio stations we elicit ratings of various motivations for giving, then correlate those ratings with self-reported contributions and actual contributions (matched back to the radio station's historical database). As expected, we find that individuals over-state their actual contributions; claiming that they contribute more than they actually do. However, we also find that the motivations that correlate with reported contributions are not the same as the motivations that correlate with actual contributions. Thus in addition to the substantive contributions, this part of the project also makes a methodological contribution to research in this area; the type of response seems to interact with motivations for giving.

One motivation identified in the survey is that of social norms (Fisher & Ackerman, 1998); individuals contribute because they believe others contribute, or because it is the appropriate thing to do. In the field experiment, we focus on the impact of social information and its impact on voluntary contributions to fund public radio. We test the impact of providing social information about another donor's contribution to targets in both on-air fund drives and mailing campaigns. We find that contributions are extremely responsive to this social information; they increase their contribution when the social information is higher than their previous contribution, and decrease it when the social information is lower. When social information is omitted or is the same as their previous contribution, they contributed the same amount as they did the year before. The differences in these changes are statistically significant ($F(2,296)=3.03, p=0.05$), and economically significant; the difference in the average contribution between the high and the low social information condition is over \$30 per donor, representing a 15% increase in contribution revenue.

It is also heartening to note that this social information effect is long-lasting. Having been exposed to higher social information does not affect the retention rate (likelihood of contributing the next year), and generates higher revenue in the subsequent year as well. Thus this intervention does not simply shift future intended contri-

bution to the present; it actually increases overall contribution and thus the extent of the public good provided.

A follow-up lab study searches for the causes of this effect. We find that the effect of social information on behavior is fully mediated by beliefs in the social norm (what others contribute and what is appropriate to contribute). Identifying this mechanism has the potential to help policy-makers in designing publicity campaigns encouraging voluntary contribution (and thus reducing the reliance of nonprofits on government funding); highlighting others who contribute high amounts or influencing beliefs of appropriate contribution is likely to have an impact on revenue from individual contributors.

In this research, we use field surveys and field experiments to investigate the motivations for, and impact of social psychological factors on, donors' contributions to nonprofit organizations that provide public goods. Increasing our understanding of these motivations can help policy-makers to make better decisions about designing publicity campaigns to increase nonprofit's effectiveness in fundraising, and how to allocate limited budgets between these activities and direct funding.

Special Session Summary

Word-of-Mouth and Word-of-Web: Talking About Products, Talking About Me

Andrea C. Wojnicki, University of Toronto

EXTENDED ABSTRACTS

“Subjective Expertise and Word-of-Mouth”

Andrea C. Wojnicki, University of Toronto

Consumer-to-consumer communication or word-of-mouth (WOM) is an impactful marketplace force that has been studied for decades by academics. Two prevalent constructs in the WOM literature are “opinion leaders” (Rogers and Cartano 1962) and “market mavens” (Feick and Price 1987). It makes sense that consumers who give and are asked for information regarding certain product categories (opinion leaders) or the marketplace in general (market mavens), are also likely to be experts. While the relationship between WOM and expertise is backed by very little empirical evidence (see Jacoby and Hoyer 1981 for exception), it remains as a common and non-contentious assumption in the WOM literature.

Why are these experts talking? Researchers have suggested a few motivations that may encourage consumers to generate WOM, including involvement, altruism, reciprocity, cognitive dissonance, and self-enhancement (cf. Feick & Price 1987, Gatignon & Robertson 1986). This last motivation, self-enhancement or status-seeking, may be particularly compelling in the context of WOM and expertise. Consumers may use WOM as a means to gain attention, social status, superiority, or power by showing off what they have bought, what they’ve been doing, or to enhance their reputation as an expert.

According to self-enhancement theory, people strive to associate themselves with the positive and avoid the negative (cf. Baumeister ’98). It follows then that consumer experts may be motivated to self-enhance by talking about their positive (satisfying) experiences. But this would only be the case if these experiences were diagnostic of or attributable to the consumer’s expertise. One way of operationalizing this attribution is with choice. If the consumer chose the product to consume, the outcome may be attributable to their expertise. If, however, the product was imposed, the outcome would be attributable to something else, such as chance. Study 1 will test the hypothesis that satisfied experts generate the most WOM, but only when they had choice. Based on the insight that the salience of consumers’ identities can affect their behaviors (cf. Tybout and Yalch 1980), Study 2 will test whether this effect is intensified when consumers’ expertise status is primed. It is predicted that the same pattern of results described above will persist in both the primed and not primed conditions, but they will be exaggerated in the primed condition such that satisfied experts will generate even more WOM when their expertise status is primed versus when it is not primed.

Study 1

Subjects from an online subject pool were emailed an invitation to participate and given a 72 hour window to complete the study. 449 subjects completed the study and were mailed a \$5 money order as compensation. When they logged on to the experiment website, they first read a hypothetical restaurant scenario that was randomly assigned to the choice or imposed and the satisfied or dissatisfied conditions. Following a distraction task, subjects answered questions regarding subjective expertise (Mitchell & Dacin 1996), opinion leadership (Childers 1986), involvement (Higie & Feick 1988), all specific to restaurants, as well as the market maven scale (Feick & Price 1988).

Consistent with predictions, the two-way interaction between outcome and expertise was significant in the choice condition ($p=.042$) and an analysis of simple effects revealed that satisfied experts generated more WOM than any other group. The main effect of expertise was also significant, and expertise, opinion leadership and WOM are all positively and significantly correlated, even after controlling for involvement. In the imposed condition, the interaction between outcome and expertise was not significant ($p=.283$).

Study 2

459 subjects from a different, independent online subject pool completed this study. A third factor, salience (primed versus not primed) was added to the design. Subjects in the not primed condition followed a procedure very similar to Study 1. Subjects in the primed condition first answered the expertise scale questions and were then explicitly labeled as a restaurant expert or non-expert. They were also reminded of this status before they indicated how much WOM they would generate regarding the hypothetical restaurant scenario.

Results confirm hypotheses—the three-way interaction between salience, outcome, and expertise was significant ($p=.001$). Importantly, the simple effect of salience for satisfied experts was significant ($p<.001$), as was the main effect of expertise ($p<.001$).

Discussion

This research demonstrates self-enhancement as a viable and significant motivation for consumers’ WOM behaviors. Based on their desire to enhance their expertise status, satisfied experts generate the most WOM, but only when they can take credit for a positive outcome (Study 1), and even more so when their expert status is salient (Study 2).

This research also demonstrates new and nuanced evidence in support of the relationship between expertise and WOM; the main effect of expertise on WOM was significant in both studies. It should be noted though that it is satisfied experts who are driving this main effect. These results may also illuminate previous inconsistencies regarding prevalence of positive versus negative WOM in the marketplace—a question that has received some attention, but with ambiguous results. Here, we see that consumers who are satisfied generate more WOM than those who are dissatisfied, but only when they are experts, and only when they had choice.

"Word-of-Mouth in Virtual Communities: A Netnographic Analysis"

Kristine de Valck, HEC School of Management-Paris

Online forums, boards, list servers, chat rooms, newsgroups, and blogs provide consumers worldwide with the ability to share their knowledge, experiences, and opinions. The popularity of electronic consumer exchanges is reflected in the vast number of virtual communities that specifically focus on consumption-related interests. When making a purchase decision, consumers may turn to the community to gather information, ask for advice, or review experts' opinions. Post-purchase, they may communicate their own experiences to the community. The result is an ongoing process of interpersonal influence and online word-of-mouth recommendation. As information exchange between consumers via the Internet continues to grow exponentially, spheres of influence will become increasingly virtual. Marketers are challenged to cater to this development. It is therefore important to acquire systematic knowledge about this process of online interpersonal influence within virtual consumption communities.

Considering existing research efforts, we start to understand why people participate in and contribute to virtual communities (e.g., Dholakia, Bagozzi and Klein Pearo 2004; Hennig-Thurau, Gwinner, Walsh and Gremler 2004), with what effect (e.g., Algesheimer, Dholakia and Hermann 2005; Bickart & Schindler 2001; Muniz & O'Guinn 2001), and how we can measure that effect (e.g., Godes and Mayzlin 2004). However, what is still lacking is a deeper understanding of what people talk about and how they try to influence each other online. This study applies the method of netnography (Kozinets 2002) to investigate interaction dynamics between virtual community members. The main goal of the study is to analyze how the discussants communicate with and influence each other.

The community under study (www.SmulWeb.nl) is organized around culinary matters attracting around 30,000 unique visitors per month. It consists of theme pages, member pages, discussion forums, chat rooms, and databases for articles, reviews, and recipes. I made my entrance in the community and started informal observation of the forums in September 2000. I reviewed a range of member contributions, conducted in-depth interviews with members and administrators, and participated in offline community gatherings. After three years of knowledge building, I intensified my monitoring by systematically reviewing all topics discussed in the forums in 2003. In several rounds, I made a purposeful selection of 53 discussion threads for further analysis. The total research volume amounted to 3161 postings generated by 82 distinct contributors. The conclusions are based on an iterative content analysis. My interpretation of the data has been constructed through continuously moving between individual postings, chunks of postings, entire discussion threads, and the emergent understanding of the complete data set. The evolving netnography has been posted in its

entirety to the community to elicit member feedback. In total, sixteen members (active discussants and lurkers) reacted. All reactions were positive and affirmed the analysis and interpretation.

First and foremost, the netnography has given insight in the character of the virtual community as a reference group. SmulWeb consists of a varied member database. Participants differ with respect to gender, age, race, nationality, education, income, profession, family situation, and lifestyle. No real life counterpart of SmulWeb (e.g., cooking club or wine course) shows this level of diversity. Offline reference groups are geographically more restricted, but they also tend to be more limited in terms of economical, social, racial, and ideological characteristics according to the principle: birds of a feather flock together. Online, these feathers are not directly apparent. They are also less relevant because members have one important thing in common: their passion for the community's topic of interest. Although they share this passion, their related opinions and behavior diverge due to their different backgrounds. It is these differences that are the motor of the community's processes of interpersonal influence and WOM recommendation, because the community members actively learn from and influence each other.

The netnography has revealed four main frames of discussion. The discussants engage in communicative acts to (1) share knowledge, (2) negotiate norms, (3) oppose values, and (4) celebrate similarities. These labels do not only exemplify the aim of discussions (to share, negotiate, oppose, and celebrate), but also what is at stake (knowledge, norms, values, and similarities). The categorization is valuable for researchers and marketers alike, because it highlights the complexity of online forums as sites of interpersonal influence between consumers. It is not just about information exchange related to specific purchase decisions, but discussants engage in far more encompassing communicative acts to define, negotiate, argue, and cheer about value systems surrounding the community's focal topic of interest. Furthermore, discussants have several tactics to influence each other. They call upon authority to convince others of their expertise. They tell stories about other people's deviating behavior to express and reinforce their shared norm, and they contextualize their own behavior whenever it deviates from this norm. Finally, the 'virtuality' of the community stretches the unifying character of the discussions, because members more easily let go of their decorum, and show their true selves to an audience of like-minded individuals to whom they confess secret passions.

"Viral Marketing Mavericks: Capturing Word-of-Web"

Janghyuk Lee, HEC School of Management, Paris & Korea Advanced Institute of Science and Technology (KAIST)
Judith Lynne Zaichkowsky, Simon Fraser University

Viral marketing refers to the strategy of encouraging consumers to sell a product on behalf of the company that creates it. The effectiveness of viral marketing on-line has been well documented in the business community. Some examples include WD-40, which quadrupled visitors to its website by giving away 1,000 radios shaped like its product to those who signed up 10 other members (Business Wire, 2002); or Listerine which created a game called Germinator on its web site and encouraged players to email their scores to friends (Neff, 2001). Other viral marketing programs are loyalty or fidelity programs. Consumers can earn points for every contact person they give the company. They can then trade their points for company merchandise. The web documents both the sender and receiver of that information.

Encouraging current consumers to tell their friends about one's brand and encourage purchase is about the most trusted form of product endorsement. Consumers who tell others about products can be classified into four categories, depending upon the amount of information they give and receive. Consumers who both give and receive a great deal of product-based information are called socially integrated. Those who mainly give information, but do not care to receive it are called socially independent. Those who like to receive information, but rarely give information are deemed socially dependent. Finally, consumers who give and receive low amounts of marketplace information are deemed to be socially isolated (Schiffman et. al, 1975). The web has made the social aspect a virtual aspect because consumers can both send and receive a great deal of information without the face-to-face contact, and in fact may be socially isolated on a face-to-face basis, but be socially integrated on-line.

Therefore the computer and the World Wide Web have added an extra layer or dimension of explosion to WOM, creating "word-of-web." Consumers are now able to send the same message to dozens or hundreds of consumers at a time through a click on their address book. They are also able to link the company of interest to their own web site, which may be deep linked to certain key words in search engines. This web-imbedded information has the potential to be seen by thousands or more. The question is who are these consumers who practice word explosion and what motivates them to link and share company information. As a first step to answering this question, the network behavior of customers of an on-line company is documented.

The Study

An electronic greeting card company (established in 2002) supplied the following data: the number of subscribers; the number of e-cards sent on monthly basis; a list of paid subscribers to their service; the start and expiry date of their subscription; and a list of all cards sent to other members from July 2004 to January 2005. Due to the nature of this business, the volume of e-cards sent is subject to seasonality. There was a low of 0.41 cards sent per member in September and a peak of 12.38 cards sent in December. November and April showed minor peaks, 5.41 and 3.64, due to Thanksgiving and Easter.

Exploratory analyses showed the following: (1) During the peak season (November and December which accounted for 78.1% of e-cards sent), new customer acquisition was more effective (22.3 cards sent to acquire each new subscriber) than during the off-peak season (33.4 cards). Less cards were sent to non-subscribers compared to existing subscribers (the ratio of e-cards sent to non-subscribers from existing subscribers was significantly lower during the peak season (0.25) than during the off-peak season (0.31)). These results show the importance of timing to diffuse word-of-web. The impact on new customer acquisition can be maximized if it is diffused when consumers are in the same buying mode. (2) Heavy senders and heavy receivers can be very important. Our e-card data confirmed the well known Pareto law of 20/80, as 20% subscribers sent 75% of the e-cards. The cross tabulation of heavy senders and heavy receivers showed that heavy senders also tended to be heavy receivers. (3) Heavy senders are less likely to exit the company than light senders. Cox-regression analysis showed the significant impact of the number of e-cards sent on the survival probability. This result was confirmed from two different subscriber cohorts starting in November and December 2003. However, the number of e-cards received showed a negative impact on likelihood to continue as a customer. This needs to be explored in future research.

Stage Left, Stage Right? Position Effects on Perception of a Spokesperson

Nancy M. Puccinelli, Suffolk University

Linda Tickle-Degen, Boston University

Robert T. Rosenthal, University of California, Riverside

EXTENDED ABSTRACT

Imagine that as you read reviews of a celebrity's TV appearances, you are struck by how the reviews differ. On *The Tonight Show* the celebrity is seen as a leader, steering the interview. However, on *Larry King Live* she is seen as passive and as if bullied by Larry King. Your first inclination is to attribute the effect to the respective hosts, however, might the differences be accounted for by the position of the celebrity - on the *Tonight Show* the celebrity appears to the left of Jay Leno and on *Larry King Live* to the right? The present research sought to investigate this question.

It is proposed that the specialization of the right hemisphere in processing faces (Gazzaniga 2000) and nonverbal behavior (Benowitz et al. 1983) mediates the effect of target position on observer perception. When an observer's attention is drawn to the left visual field, person perception processing in the right hemisphere is activated and leads to greater recall of visual information of the target (Taylor and Fiske 1975) and perception of the target as more instrumental in the interaction.

Experiments 1 and 2

Experiment 1 Method. Forty-eight participants were randomly assigned to sit on the left or the right while engaging in a puzzle (time 1) or discussion (time 2). Thirty-two observers rated 15-second clips from each of the interactions on 38 behavior variables ranging from "Friendly" to "Similarity in movement" which were combined to form Critical, Dominant, Interpersonally Skilled, Polite, and Tempo Setting.

Experiment 2 Method. To control for any position effects due to differences in target behavior, 29 observers in experiment 2 rated the mirror image of the target videos shown in experiment 1.

Given the similarities across experiments 1 and 2 a 2 (target position: left or right) x 2 (target task: puzzle or discussion) x 2 (partner presence: alone or with partner) x 2 (experiment: 1 or 2) repeated-measures ANOVA was calculated using target pair as the unit of analysis (Rosenthal 1991).

H1: Targets positioned to the observer's left will be seen as more instrumental in the interaction compared to targets positioned to the right.

H2: The effect of target position will be stronger when a target is viewed with a partner than when the partner is obscured.

H3: The effect of target position will be stronger when a target is viewed during an externally-focused, puzzle compared to an internally-focused, discussion interaction.

Consistent with the hypotheses, ratings were higher for targets on the left for Tempo Setting ($p < .001$), Interpersonally Skilled ($p < .001$), Critical ($p < .001$), and Dominant ($p < .001$) (H1) and this effect was stronger when the target was viewed with a partner for Tempo Setting ($p < .001$), Critical ($p < .01$), and Interpersonally Skilled ($p < .05$) (H2) and during an externally-focused puzzle interaction for Tempo Setting ($p < .01$), Critical ($p < .01$), and Dominant ($p < .01$) (H3).

Experiment 2 also examined the moderating role of gender.

H4: The effect of target position will be stronger for male observers than female observers.

Consistent with H4, when targets were observed by men the target position effect was stronger for Tempo Setting ($p < .001$) and Interpersonally Skilled ($p < .01$).

In sum, targets positioned to the left were seen as more instrumental in the interaction as suggested by higher ratings on Tempo Setting, Critical, Interpersonally Skilled and Dominant. Further, it appears that this effect was moderated by presence of a partner, type of task, and observer gender.

Experiment 3

In experiment 3, it is suggested that observers will be more persuaded by a target on the left and sought to explore recall as a mediator of observer judgment.

H5: Observers will indicate greater willingness to pay for products endorsed by targets positioned to the left.

H6: Observers will judge targets positioned to the left as more convincing than targets positioned to the right.

H7: Observers will recall more visual information about the target when the target is positioned to the left than when the target is positioned to the right.

The materials were virtually identical to those used in experiments 1 and 2. Sixteen participants viewed each of the videoclips and indicated the persuasiveness of the target as well as his/her memory for target attributes that contributed to their judgment (Fiske et al. 1982). Consistent with H5, participants indicated a greater Willingness to Pay for products when the target was positioned to the left ($p < .001$). However, contrary to H6, targets positioned to the right were judged as more Convincing ($p < .001$). Consistent with H7, more neutral and negative information was recalled for targets positioned to the left ($p < .001$ and $p < .01$, respectively), however, more positive information was recalled for targets positioned to the right ($p < .001$). Moreover, more positive, neutral, and negative information was recalled about targets positioned to the left when the observer was male as compared to when the observer was female ($p < .001$; $p < .001$ and $p < .001$, respectively).

Thus, it appears that the results from experiments 1 and 2 extend to observer judgments of Willingness to Pay. Interestingly, the results for judgments of Convincing appear moderated by gender. While men show no effect of target position on judgments of Convincing, women do. Moreover, women tend to judge the target to the right as more convincing. This may be related to the differential recall observed and valence-specific laterality in women (Rodway et al. 2003).

In conclusion, this study finds strong evidence for an effect of target position on the impression formed of a target individual and suggests a hemispheric specialization and recall interpretation of this result. The implications of such a result are both important and

far-reaching, opening a new window of insight into the complexity of consumer perception with applications to perceptions of spokespeople in advertising and salespeople in service settings.

Music-Visual Congruency and its Impact on Two-sided Message Recall

Karen Becker-Olsen, Lehigh University

EXTENDED ABSTRACT

Two of the greatest challenges facing advertisers today are credibility and clutter (Marney 1996; Zanot, 1984)—both of which can negatively impact advertising recall. Thus, creative tactics that help to combat these problems are prevalent in today's advertising. For example, a two-sided message can help to increase credibility (Pechmann 1992; Swinyard 1981), whereas music can serve as an attention getting agent (Kroeber-Riel 1979). In this work we look at the impact of music-visual congruency on two-sided message recall.

Theoretical Foundation

Two-sided Advertising Messages

Two-sided advertising messages present both positive and negative information about a given product, service, or even situation (Hovland, Lumsdaine and Sheffield 1949). Extant research shows that two-sided advertising is viewed as more credible (Kamins and Assael 1987; Smith and Hunt 1978; Swinyard 1981). However, to date there has been minimal work which has evaluated processing biases related to two-side advertising. In this study we are interested not in the credibility of the claim, but in the viewer's ability to recall certain portions of the message. Thus, we present viewers with a list of five negatively correlated words (e.g., love/hate) imposed on an advertising image and then measure recall of these words across conditions of music-visual congruency and incongruency.

Music and Advertising

Music functions on many levels to positively influence advertised brands and their messages. From an elaboration likelihood perspective, music is viewed as a peripheral cue, which helps to gain attention for the brand and create positive affect. In fact much of the music and advertising literature focuses on music's ability to create a positive mood state (see Bruner 1990 for a review). There is substantial evidence that a positive mood state improves recall as encoding is more efficient (Isen 1993 and 1999). In this work we expect that the calm music will induce a more positive mood state than chaotic music or even the control condition where no music is present. Thus,

H1a: Calm music will lead to greater total word recall than chaotic music.

H1b: Chaotic music will diminish total word recall.

Further, mood congruency processing states that processing is selective and biased toward cognitions that are congruent with our mood state (Bower, Gilligan and Monteiro 1981; Parrott 1991). If we are in a positive mood (calm in this study), we are more likely to process information which is positive. Conversely, if we are in a negative mood state (chaotic in this study), we are more likely to process information which is negative. Thus,

H2a: Calm music will lead to greater word recall of positively valenced words than chaotic music.

H2b: Chaotic music will lead to greater word recall of negatively valenced words than calm music.

Further, we believe the mood state is intensified when the visual and musical cues are congruent. Thus,

H3a: Calm music-visual congruency will lead to greater recall of positively valenced words than calm music-visual incongruency.

H3b: Chaotic music-visual congruency will lead to greater recall of negatively valenced words than chaotic music-visual incongruency.

Divided attention and Incongruity

There is significant evidence that when attention is divided between two or more tasks (e.g., resolving the incongruity and processing words), recall is diminished (see Naveh-Benjamin, Guez and Marom 2003). Thus, total recall should be enhanced when music-visual congruency exists because cognitive resources are not expended trying to resolve the incongruity between the music and the visual image.

H4a: Music-visual congruency will increase total word recall.

Study

The study is a 3 (calm music, chaotic music and no music) by 2 (calm picture and chaotic picture) completely randomized between subjects design. The music selection (original guitar music) is consistent within the calm condition and within the chaotic condition, while there are two exemplars of calm (smiling baby and landscape) and chaotic (crying baby and exploding building) visual images.

Two hundred forty subjects participated in this study. Subjects were randomly assigned to an experimental condition and participated in the study via a blackboard site. Subjects logged onto the site where they accessed directions, their advertisement and a response form. Our primary dependent measure is word recall, including total recall, positive recall and negative word recall.

Results

Manipulation checks reveal that perceived congruency varies as expected ($M_{\text{incongruent}}=2.39$ and $M_{\text{congruent}}=6.16$, $F_{1,239}=1876.00$, $p<.0001$) and does not vary by example ($F_{1,239}=2.87$, $p>.26$). Further the images that are suppose to be chaotic or calm were perceived as such ($M_{\text{calm}}=5.06$, $M_{\text{chaotic}}=5.46$, $F_{(1,239)}<1$) as are the music selections ($M_{\text{calm}}=4.75$, $M_{\text{chaotic}}=5.02$, $F_{(1,239)}<1$.)

Music Effects. In support of H1a, total recall is greater for the calm music than the chaotic music ($M_{\text{scalm}}=6.312$, $M_{\text{schaotic}}=4.49$; $F_{(1, 159)}=51.697$, $p=.000$). Similarly, H1b is supported ($M_{\text{schaotic}}=4.49$, $M_{\text{scontrol}}=6.25$; $F_{(1, 159)}=47.082$, $p=.000$), indicating that the chaotic music diminish total word recall.

Mood congruency. As predicted by H2a, total positive word recall is greater when calm music is present than when chaotic music is present ($M_{\text{scalm}}=3.61$, $M_{\text{schaotic}}=2.12$; $F_{(1, 159)}=77.80$, $p=.000$). Contrary to our predictions, total negative word recall is not greater when chaotic music is present.

When we add the visual image to our analysis, we find strong support for H3a and marginal support H3b. Calm music-visual congruency leads to greater recall of positively valenced words than calm music-visual incongruency ($F_{(1,79)}=14.274$, $p=.000$). Chaotic music-visual congruency leads to marginally greater recall of negatively valenced words than chaotic music-visual incongruency ($F_{(1,79)}=5.149$, $p=.026$).

Incongruency and Divided Attention. We do not find support for H4, which predicts that music-visual congruity will lead to increased recall ($MS_{\text{congruent}}=5.55$, $MS_{\text{incongruent}}=5.25$; $F_{(1,159)}=1.06$, $p=.305$). What we do find is that total positive recall is increased in cases of music-visual congruency ($F_{(1,159)}=11.908$, $p=.001$).

Conclusions

These results suggest that temporary mood states can influence processing and are likely tied to underlying cognitions. These findings are important in that we are able to demonstrate how advertisers can potentially capitalize on processing biases of two-sided messages and mood-congruency. The pattern of recall results in this study, suggests that advertisers can present two-sided messages and bias processing beyond simple credibility effects.

“Now That’s What I Call Music!”

An Interpretive Approach to Music in Advertising

Matthias Bode, University of Hanover¹

ABSTRACT

Music is a fundamental feature of commercials. Despite its significance, advertising research into this area is underdeveloped; furthermore, it is fragmentary and contradictory. This paper puts it down to misunderstandings of how music works. Instead of reducing music to an affective stimulus, a socio-semiotic model of music as a cultural system with an expressive potential is developed, based on contemporary studies in musicology and popular music studies. The reference point is interpretive consumer and advertising research, that so far has focused on text and visuals. An interpretive approach is introduced that integrates music based on its specific socio-semiotic potential of making meaning possible.

INTRODUCTION

In 2001, the Wieden & Kennedy advertising agency developed the acclaimed “freestyle” commercial for Nike Inc. It featured basketball players showing off their moves. The sound editing constructs a steady beat made up with the sounds of squeaking shoes and the ball hitting the floor. Besides the acoustic link to hip-hop, the visual quotation of typical hip-hop dance moves intensified the close association. The longer version replaced the final “swoosh” logo with the typical music video credits for song title, musician and director. There were considerable discussions if the music video version could run as part of the programming or as a commercial (Elliott 2001). For most of the literature on music in advertising, this spot would not even be considered as “music”, as it misses such characteristics as harmony, melody or modality.

The purpose of this article is to advance research on music in advertising by proposing a new conceptualization of music as a cultural system with expressive potentials. As Scott (1990) criticized, studies on music in advertising are characterized by mechanistic stimulus-effect models, focusing on music as a nonsemantic affective stimulus. The implicit concept of music is based on 19th century psychoacoustic and psychophysiological music psychology, exemplified by scholars such as Helmholtz or Wundt and the empirical-experimental American music psychology of the beginning of the 20th century. The methodological procedures are still the same: musical reception is analyzed experimentally in laboratory environments; short acoustic stimuli are controlled and modified to detect a shared reaction pattern. Early on, Susanne Langer (1942, 211) noted the lack of knowledge gains with these approaches: “this approach has not taken us; it seems to be an essentially barren adventure.” The fragmentary and inconclusive research on music in advertising (Kellaris, Cox, and Cox, 1993, 114) proved Langer right. Here it is argued that the problem cannot be solved with improved measurement methods. Before one can decide *how* it is best to measure something, it should be clear *what* one is trying to measure. In that sense the music anthropologist Merriam (1964, 84) warns: „Without understanding of concepts, there is no real understanding of music.“

FALLACIES IN THE TRADITIONAL MUSIC CONCEPTUALIZATION

The conception of music in advertising research is stuck between adhering to classical music theory while focusing on popular music as the typical type of music in advertising. The lack of explicit definitions of music seems to be less bothersome, as it is assumed that popular music does not require much effort to define: it is pleasing and understood by ordinary people (Roehm 2001, 49). This view neglects the long and still much debated discussion about the definition of popular music (Middleton 1990, 4) and leads to theoretical misconceptions that can be described according to the following issues (see also Meyer 1956, 5; Scott 1990, 225f.).

Music as ahistorical

Advertising research is still using the Hevner and Rigg experiments from the 1930s to support links between musical elements and effects (e.g. Alpert and Alpert 1990; Bruner 1990; Kellaris and Rice 1993; Morris and Boone 1998). Instruments and their tunings, performance rituals, listening modes, everyday soundscapes, the availability of music and the media have all changed. However, research on music in advertising insists on universal reactions to timeless music elements. This attitude also becomes apparent in the common practice of referring to the utilized musical stimuli in publications as “pleasant” or “unpleasant” music. These musical stimuli are perceived differently today, and definitions and evaluations of “pleasant” “unpleasant,” “dissonant” or “consonant” are also changing (Attali, 1985, 35). In popular music genres such as “noisemusic,” the nerve-racking sound qualities even gain a special relevance for the enjoyment and symbolic valence of music (see also Gracyk 1996, 99ff.). This phenomenon is not unknown in consumer research. From an experiential point of view, Hirschman and Holbrook (1982, 96) explicitly mentioned the aesthetical pleasure of a confrontation with the unpleasant and discomforting in their hedonic consumption model.

Music as emotional engineering

One of the main qualities of music in advertising is often seen as triggering moods and emotions. This romantic notion of music as the language of the heart is deeply ingrained in Western civilization. It assigns music to the expression of subjective feelings, to the “objectless inner” (Hegel), and separates it from the external social world. In advertising research, this shared credo has the tendency to blur the differences between emotions represented and felt. Bruner (1990, 95) exemplifies this widespread confusion when he summarizes the research on rhythm and emotions as: „fast music *is considered* to be more happy (...) slow tempi tended to *evoke* tranquil (...) sorts of *description*; fast tempi *elicited responses* relating to exhilarating (...) sorts of *feelings* [emphasis by the author].“ But already the often cited Hevner (1935) and Rigg (1964) explicitly point out that their results refer to the identification of emotions and not to experienced emotions. Pratt (1931/1968, xxv) famously explained the confusion between description and experience by saying “Music sounds the way emotions feel.” We tend to describe musical elements with the same words as emotions, but they are still two separate processes. It is expected that we would identify deep sadness in Bessie Smith’s blues songs; even so,

¹I am grateful for helpful comments and support from Linda Scott and the ADV 487 Masters class at UIUC in 2002.

listening to them could deeply satisfy us and make us happy. As Tagg (1993) showed in his cross-cultural research, the musical articulation of emotions is based on conventions, rules and codes. This is also supported by neuro-physiological research, which refutes the old assumption of a direct affective impact of music without any cognitive involvement (Maeß, Kölsch, Gunter, and Friederici 2001). Cognitive processes are already relevant during the first unconscious acoustical perception in structuring sounds, comparing them with expectations, separating them from background noise and connecting them to learned schemata (Bregman 1990). So far, modern music psychology is rejecting the mechanistic assumption of directly manipulating emotions with music.

Music as acoustic stimuli

Other than research that codes music as absent/present (e.g. Gorn et al. 1991; Park and Young 1986; Stewart, Farmer and Stannard; Olsen 1995), the main approach is to examine the effects of structural musical elements (Alpert and Alpert, 1990, 115f.). Bruner (1990) grouped these studies according to time-related findings (e.g. tempo, rhythm, phrasing), pitch-related findings (e.g. modality, melody, harmony) and texture-related findings (e.g. orchestration, volume). As a research leitmotif he formulates "Music is not simply a generic sonic mass, but rather a complex chemistry of controllable elements." (Bruner 1990, 94). But already the interaction of two controllable elements like tempo and modality (Kellaris and Kent, 1991) exhibits a complexity that is hard to control and to interpret. While the control of all structural elements seems to be infeasible, it also appears to be futile. The music psychologist Serafine (1988, 53) rejects the atomistic approach in emphasizing the perceptual perspective: "Scales and chords do not exist in music." Structural elements are theoretical artifacts that are useful for analyzing intermusical structures, but for most recipients isolated structural elements will be understood as acoustic stimuli and not as music.

Music as an abstract artifact

To extract music from its context of production, transmission and consumption means to reduce music to an abstract, fictional, and theoretical entity. The possibility that the same music, heard in a laboratory, on an mp3-player, in a club or in a commercial, might be perceived differently is seldom mentioned (see as an exception Macklin 1988, 242). The separation of music from its context is based in the music theory tradition in which music as absolute music, expressing only itself and depleted from its social and cultural traces, became a regulative concept (Goehr 1992, 121). This ideological frame impedes research on music in advertising. Acoustic stimuli only become music in certain contexts: „by removing the bare score from its context in order to examine it as an autonomous organism, the analyst removes that organism from the ecology that sustains it.“ (Kerman 1985, 72). One example is the utilization of interpretive frames by listeners that differentiate between noise and musical experience. The same phrase, overheard from a practicing neighbor or attentively listened to in a concert hall, will be experienced in different ways. The interpretive frame applied to a song used in advertising can even totally reverse the musical experience. Favorite songs, listened to in an ad, can elicit the most negative feelings (McLaren 1998, 10).

A NEW CONCEPTUALIZATION OF MUSIC AS A SOCIO-CULTURAL PHENOMENON

Several authors have written about the obstacles encountered with the present conceptualization of music (Alpert and Alpert, 1991; Hung 2000; Murray and Murray 1996; Scott 1990). The basic

hope was to develop an approach that acknowledges music as a cultural and social phenomenon. Scott, as a reference point, mentions advances in the areas of visual and verbal rhetoric. However, a meaning based model for music in advertising is still missing. Here it is argued that the application of a verbally- or visually-biased methodology might not be appropriate for making sense of music. In the following section, a new interpretive framework is developed, using the assumption that music is a symbol system with its own specific qualities that has to be approached from a music point of view.

What is music?

When adolescent music aficionados have to defend their preferences from adults who roll their eyes and say "you call that music?", they might find a word of comfort in music ethnology. Cross-cultural research has shown that there is no single and universal concept of what music might be (Nattiez 1990, 55). What is called music differs in demarcations between environmental noise and music (Feld 1988), as well as in the context of rituals, social or behavioral functions that are responsible for the inclusion of sound into music or not (Blacking 1981). A general framework for music was developed by Merriam (1964, 32ff.) who suggested three necessary analytic levels: an acoustic, a behavioral and a conceptual one. In reference to this framework, music can be defined as the cultural and social structuring of sound, materialized in the process of composing, performing and listening. Besides personal elements, the shared reference to specific cultural conventions is necessary (see also Blacking 1973, 92; Moisala 1995, 17).

The expressive qualities of music

As an element of the Geertzian web of significance (Geertz 1973, 89), music as a cultural system incorporates expressive potentials. This resonates in the everyday understanding of music ("this music expresses exactly how I feel;" "this band articulates the zeitgeist of a whole generation") and has a long intellectual history. Our understanding of the sad minor key can be traced back to the ancient Greeks, for whom specific musical modes implied a certain ethos. The theory of affects in Baroque music constituted a further refinement. Music should represent affects, with close analogies between musical figures and rhetorical (verbal) principles (Blake 2001, 262). The rise of instrumental music in the second half of the 18th century challenged the tight connection between the verbal language and music. Music in itself was seen as a superior language, able to express the most subjective, transcendental and romantic sentiments (Motte-Haber 1994). While still connected with the Baroque ideas, romanticism indicates a vital shift away from the social coding of music. The interpretation of music as rhetoric was finally lifted with the move towards autonomous, absolute music, free from any extramusical implications. However, it is only a small step from the concept of music expressing the unspeakable to the idea of music as a pure interplay of "forms moved by sound" (Hanslick 1854, 32).

In music theory, this shift is reflected in the dominance of approaches focusing on intra- and intermusical meanings (Davies 1994). From this perspective, musical meanings refer only to the music itself. Whenever listeners incorporate their own extramusical associations into the music listening experience, their interpretations are discredited as "misunderstandings," as deviations from the "correct," analytic understanding of music (e.g. Lissa 1973, 221). This normative position is problematic not only for the analysis of popular music but especially for the analysis of music in advertising. Here, the commercial contextual setting triggers certain interpretive frames, similar to the concept of schemer schema (Friestad

and Wright, 1994), and the link to extramusical associations as "a grist of significance for the ad mill" (Williamson 1978, 19) is intentional. To conceptualize these meanings, a semiotic approach to music is developed.

The semiotics of music

Semiotics, understood as a "science that studies the life of signs within society" (Saussure 1966, 16), claims universal applicability. Only music, however, shows considerable resistance to becoming "readable." The semiotics of music, especially popular music, is one of the least developed fields in semiotics, without consensual terminology, approaches or even agreed on areas. It seems that "music and semiotics do not make comfortable bedfellows" (Gronow 1987, c7). The uniqueness of the musical signification process is identified as the main obstacle (Lidov 1986, 577). Different attempts to develop music sign typologies reached a dead end when the linguistic anchor of the iconic, indexical, and symbolic sign structure proved to be restraining (Stefani, 1973). A problem is the semantic vagueness of the musical sign. The more musical signs get meaningful, as in iconic sound imitations, the less they are able to stand as a foundation for a general meaning model. They are considered to be semantic enclaves.

There are two basic positions in music semiotics on how to approach the problem of vague musical meanings. One strategy is to further work on substantiating the meanings, while another strategy accepts the vagueness as the essence of the musical sign system.

Until the 1980s, the formal study of musical syntax was the dominant approach in music semiotics to further clarify musical meanings (Ruwet 1967). If music is the structuring of sound material, than the meaning should be located in this syntactical structure. In general, the syntactical approaches are technical, formalistic and focus only on the absolute, intramusical meanings. Closely following linguistic methods, the idea is to find musical equivalents to nouns, verbs, predicates and grammar (Bernstein 1976). Though recently changes have become visible, the syntactical approaches are criticized for their lack of incorporating music perception (Echard 1999, 8).

The second strategy is to qualify music as necessarily semantic vague (Monelle 1996). Especially in Germany, this position is linked with Adorno's aesthetic theory, that music as true art will always have an enigmatic quality, like an unsolvable riddle. As an ideological concept, this indissoluble quality also separates high art from "industrial products" like popular music. Theoretically more promising is the position that the concept of semantic vagueness in music stems from the reference point of verbal language. Langer (1942) especially tried to develop a "wordless" semantics that she labeled presentational symbolism in opposition to the discursive symbolism of the verbal language. However, a general difference between verbal and musical meaning does not necessarily imply a uniqueness of musical symbolism. From a semiotic point of view, meanings as mental concepts are part of the sign process, but they are not the same as words (Mick 1986, 198). In each sign system, verbalizations can work as proxies for meanings, which are again acoustic or visual signs. Furthermore, the definition of a musical meaning as something distinct from the definiteness of a verbal meaning misjudges the verbal sign system. The verbal language also has ambiguities and needs situational and contextual anchors. In a provocative way DeNora (1986, 90) even inverts the comparison: "it actually may be more appropriate to treat language 'as a species of music'."

In this paper, Langer's basic idea is adopted, without sharing her music philosophy. She coined the expression that music is the

"unconsummated symbol" (Langer 1942, 240). To consummate the musical sign system, it needs a contextual semiotic approach that acknowledges the social and cultural dimensions of music and the distinctiveness of popular music.

The socio-semiotics of popular music

The traditional analysis of music in advertising was criticized for referring to classical music theory, while trying to make sense of popular music. Likewise, almost any semiotic approach to music refers to classical music of the functional-tonal era. Here it is argued, that such a focus distorts, discredits and misjudges popular music by a) inadequate analytic methods and b) a false fixation on the written score as the primary text. To make sense of popular music, one has to focus on the lived experience of a dynamic sound space.

a) Traditional music theory has primarily emphasized pitch organization with the analysis of intervals, melody and harmony. This dismisses essential structuring principles of popular music genres such as blues, hip-hop or electronic music that prioritize rhythmic structures and repetition. In a traditional harmonic analysis these genres are indeed simplistic and almost meaningless. However, traditional music theory lacks the analytic tools necessary for perceiving the significance of irregular rhythms, poly-rhythms, deferred phrasings or overlapping rhythmic structures (Middleton 1993, 180f.). There is a prevailing illusion that elements that are not so easily classified or controlled, for instance a groove, must be irrational and irrelevant (McClary and Walser, 1990, 281). An example of this fallacy is the problematic understanding of lyrics in songs, when they are seen as the meaning vehicle, and analyzed using traditional content analysis. But in popular music, voice and lyrics work differently. Lyrics are words in performance, defined through the relation of the voice and words, dependent on specific genre conventions, and specified by the sound of the specific song. In popular music it is the "grain of the voice" (Barthes 1977, 157) with different timbral qualities and microtonal inflections that makes singer like Billie Holiday, Janis Joplin or Will Oldham so special.

b) A semiotic analysis starts with a text to identify potential meanings (McQuarrie and Mick, 1992). In traditional music semiotics, the text in question is the score. Written notation represents the core ideas, the intention of the composer and the musical meanings. But even in classical music, the authority and accuracy of the score is disputed. Gustav Mahler warned that the music is not in the notes. Here it is argued that notation is an ethnocentric language, appropriate to represent music based on scale systems of equal temperament and square metric systems (Tagg 1987, 281). For the music orally and aurally conceived, as in popular music and most non-European music, with improvised elements, distortions of pitch and flexible rhythms, written notation actually misses the music itself. The constructed text is not the text to which anyone else is listening. Rather, popular music is based on the materiality of sound as the primary text (Middleton 1990, 220ff.; Moore 2001). In the performance or in the studio recording, the essential sonic structure is created. The studio especially can be classified as one of the most important instruments in popular music (Frith 1996; 233). Recording defines a whole musical aesthetic and makes record producers like Sam Phillips, George Martin, Phil Spector, or Trevor Horn as famous as the musicians they produce. In most classical music, the recording works as an acoustic snapshot, trying to produce a realist, naturalist representation of an actual performance. In popular music, the sound of the recording defines the aural qualities of the music, which often are not even reproducible in a live performance.

The musical sign system as a nexus of inter- and extramusical references

In traditional music theory, the supposedly superiority of classical music is ascribed to the autonomy of society. This normative view is reflected in the positivist research on music in advertising in its tendency to isolate music from its social and cultural embeddedness. If we accept the resonating cultural meaningfulness of music, the decontextualization tends to eliminate exactly the specific qualities of music, especially popular music. Popular music is inherently socially mediated and formed through a dialogical process between the participants of the popular music system. Popular music is functional music in the sense that it is used by the listeners, for making everyday life more controllable, navigable and worth living, as well as refining a sense of collectivity. Because of this social and cultural charge of the popular sonic sphere, it tends to be more easily incorporated into the extended self (Belk 1988). The materiality of this sonic system is intensified by the "politics of jousiance" (Hawkins 2002, 28), the physical-affective pleasures of popular music. It is argued, that this charge of popular music is not a certain attitude or an interpretive frame brought onto music. Rather, it exemplifies a semiotic process in music in which the relevant musical text is an amalgam of inter- and extramusical signs.

In this sense, music per se does not have to be meaningful. Its main capacity is to make meaning possible. Actual music, that is alive and meaningful, is always integrated into a nexus of cues that are hints for the appropriate context in which to develop interpretations. Contrary to other semiotic systems, this contextuality does not reduce the multivocality of signs but is a prerequisite for meaning. Only in-between the cue nexus can music be experienced as meaningful. Verbal and visual contextualization cues (Gumperz 1982) are the most significant cues. *Verbal cues* can include the title of the song, program-notes, booklets, the performers name, lyrics, artist statements, liner notes, music criticism, and informal talks about the music. *Visual cues* can include record covers, music videos, performance imagery, visual hooks, corporate design of musicians, the appropriation of music in video games and movies, and associated fashion and body codes (see for a detailed discussion Bode 2004, 365ff.).

Consequences for advertising research

The basic idea of the proposed approach is that meaningful music cannot be limited to the acoustic sphere. As a sign system, it exists only in form of a multimedia nexus, with verbal and visual cues (Cook 1998). This has consequences for the analysis of music in advertising, especially for the research on the interaction of the acoustic, verbal and visual levels in a spot. This process cannot be understood as adding up several meanings, but as the emergence of a new meaning constellation based on a multi-level rhetoric. The conceptual equivalent for this process in traditional research on music in advertising is "fit" or "congruence." As it turned out in experimental research, the affective and cognitive impact of music depends on actual music-spot combinations. MacInnis and Park (1991, 162) define the fit as the "subjective perceptions of the music's relevance or appropriateness to the central ad message." But in using songs with lyrics, a verbal appropriateness for music and the spot was tested. Furthermore, why participants assumed a fit, on what levels and what that meant for them remained unclear. A refinement of fit is the congruence concept by Kellaris, Cox, and Cox (1993), who focus on the relation between pure musical information and the verbal ad message. However, the concept of musical information is not further developed, and the dimensions of congruence are reduced to binary oppositions as "yes" or "no."

To clarify these interactions, based on the musical sign system, it is important to distinguish the steps of a) coding, b) functionality and c) interaction.

a) *Codes* are socially shared rules of organizing single signs into sign systems (Hall 1980/1993, 98). To ensure the intended communicative effect of a text, an adjustment between the encoding and decoding practices is necessary. One adjustment refers to the appropriate coding level. A basic code model for music was developed by Middleton (1990, 174), who distinguished the levels from the most abstract codes with basic conventions to sub-norms, dialects, styles, genres, sub-genres and finally idiolects, the level of a concrete song. These codes structure the significance of certain parameters as well as the accompanying extramusical cues. For advertising, it is important to decide on what code level music is applied, e.g. on a stylistic level as a rock'n'roll song or on an idiolect code level of Elvis Presley's "Blue Suede Shoes." The code level does not only influence the rhetorical function of the music. In regard to different code competences (Stefani 1987) of target audiences, it also shapes the potential encoding and decoding overlaps. An example of this is the song "Respect" by Aretha Franklin, that when used in a beer spot, it was encoded primarily on a stylistic soul level, while in a spot for the UN Refugee Agency, the song was encoded on the idiolect level, referring to the feminist and civil rights movement's origin of the song. Therefore, typology and characterization of music in advertising go beyond music's intrinsic aspects to explain different impacts of the same music.

b) The *functionality* of music describes the basic way music is integrated within the visual level of a spot. The main categories are foregrounding and backgrounding. The background use resembles the techniques of film music. Here, music's function is primarily the emotional, social, and narrative framing of the image (Gorbman 1987). The background use leads to the musicalization of the image. Here, music works as a guide through the images, it helps to anchor basic interpretations of the image, without necessarily being listened to. The foreground use leads to a visualization of the music while the images guide through the music. Instead of a fit, here it is more appropriate to analyze the music-image relations along the diverse lines as illustrations, amplifications or resonance by incoherence (Goodwin 1993, 86ff.). A paradigmatic model for foregrounding is the music video format.

c) The *interaction* step is the primarily level for a meaning-oriented music analysis, as it is the music-spot context where the specific nexus of inter and extramusical references becomes fleshed out. Hung (2000) experimentally showed some basic interaction effects and the necessity to analyze the meaning potentials of the different modes not separately but through their interaction. Still, the conceptual framework was missing. The suggested model highlights the significance of a double interaction effect, once in-between the musical sign system and then in relation to the verbal, acoustic and visual elements of the spot. This can e.g. incorporate rhetorical elements already on the sound level, like a Hip-Hop song in a scratchy old gramophone sound or a heavy metal song played by a string quartet. In the interaction of the musical sign system and the spot, a multi-level rhetoric unfolds, based on stressing, accentuating and deferring diverse verbal and visual contextual cues of music. Here the work on resonance (McQuarrie and Mick, 1992) is important as a starting point to conceptualize not only the semantic consequences of the text-image interaction, but of the verbal, visual, and musical levels interaction in a spot.

Conclusion

Though estimations indicate that more than 70% of all commercials have music, neither traditional nor interpretive approaches

have dealt more in depth with music. The few empirical results are so far inconclusive about music's impact. Linda Scott (1990, 234) proposed a new way of approaching music, consistent "with the way we experience the phenomenon in everyday life." There might be a "spine-tingling sense of esthetic excitement" or an almost "shattering electric charge," as Holbrook (1981, 37) reminded consumer researchers in his aesthetic imperative. Those experiences are a far cry from the acoustic stimulus manipulation of traditional advertising research. Though most of the time an ad will not be able to elicit such responses, these potential experiences frame the phenomenon of music. Interpretive approaches to the question of "how music works" were also not pursued further. This paper has argued that in both paradigmatic research streams, the main problem was the faulty conceptualization of music. In traditional research, the problem is the decontextualized analysis of acoustic stimuli. In interpretive research, the problem is the focus on literary and visual methods. It is time to realize the expressive potentials of music and to apply methods that can conceive these specific musical qualities. This can make the difference between acoustical stimuli and meaningful music, as a sonic space embedded in a nexus of inter- and extramusical references. Therefore, the intention of the paper is not to call for research on a supplementary musical rhetoric. Instead it is necessary to develop an integrative approach to the verbal, visual and sonic world we live in.

It Seems Factual, But Is It?

Effects of Using Sharp versus Round Numbers in Advertising Claims

Robert M. Schindler, Rutgers University-Camden
Richard F. Yalch, University of Washington-Seattle¹

ABSTRACT

This paper compares sharp versus round numbers in advertising claims. Round numbers have a salient conceptual basis (e.g., 10 years are a decade). Sharp numbers do not (e.g., 11 years). Estimates tend to be expressed with round numbers. An experiment is described that examines whether consumers make the false assumption that claims using sharp numbers are less likely to be estimates (i.e., are more factual) than those using round numbers and, if so, whether this makes sharp-number claims more believable. The results demonstrate that such assumptions do occur, even for those consumers considered to be advertising skeptics.

INTRODUCTION

A newspaper advertisement for a career-training program highlighted the claim that their recent graduates were earning between \$43,000 and \$57,000 per year. This salary claim could have just as easily been expressed using the phrases such as, “are well-paid,” “earning around \$50,000,” or “earning from \$40,000 to \$60,000.” The advertising copywriter had to make a decision as to which wording would be best received. Current views of advertising effectiveness stress not just what the advertiser claims, but what inferences are made about these claims by the consumers (e.g., Kardes, Posavac, and Cronley 2004). The present paper explores one type of inference that consumers might make about an advertiser’s claim—that it is based on actual empirical data and not just on the advertiser’s general impressions.

LITERATURE REVIEW

The study of persuasive communications has identified numerous factors that affect whether or not the audience accepts the information and recommendations offered in the message (e.g., MacInnis, Moorman, and Jaworski 1991). One relevant factor is the choice to present advertising claims in a numerical or verbal form. For example, research by Yalch and Elmore-Yalch (1984) established that numerical messages (“many people do 95% of their banking ...”) were better received than an equivalent verbal claim (“many people do virtually all of their banking...”) when attributed to expert sources but not when presented by nonexpert sources. Other research supports the finding of a numerical-superiority effect (Scammon 1977; Viswanathan and Narayan 1994). Childers and Viswanathan (2000) attribute some of this superiority to the fact that numerical evidence is processed at a surface level, making it faster to recognize and compare numerical information compared to the equivalent verbal information.

Related to the above discussion, Darley and Smith (1993) draw a distinction between objective and subjective claims. Objective claims are those that have an element of verifiability and cite specific factual information. On the other hand, subjective claims rely on emotions and impressions. Their manipulation of the presence of objective information consisted of the use of numerical descriptors (“Loom woven of a 75% acrylic and 25% wool blend for shape retention and softness”) versus only verbal descriptors (“Proudly woven with the very finest shape-retaining material; the

blanket is unusually soft and delightfully elegant”) for the subjective message. They found that objective claims were more persuasive than subjective claims, especially when based on factual evidence.

In thinking about numerical claims, we propose that there may be differences between numerical claims much as there are differences between numerical and verbal claims. In particular, we are interested in the distinction between round numbers and the other numbers, which could be called “sharp numbers” (Dehaene 1997, p. 108). Round numbers are those whose conceptual status gives them mental salience. For example, numbers such as 10, 20, and 30 receive salience by initiating decades in our base-ten number system, and numbers such as 15 and 25 receive salience by being midpoints of these decades (Dehaene and Mehler 1992; Schindler and Kirby 1997). Some numbers have salience, and thus roundness, only in certain contexts. For example, in time estimation, the period of seven days is salient because it represents a week (Huttenlocher, Hedges, and Bradburn 1990).

As a result of their salience, round numbers are the numbers that are most likely to come to mind when a person is trying to estimate a quantity that is uncertain. For example, in a variety of numerical estimation tasks, people show a strong tendency to produce 0- and 5-ending numbers (e.g., Hornik, Cherian, and Zakey 1994; Kaufman et al. 1949). This use of round numbers leads them to become indicators of the use of an estimation process rather than actual counting. Thus, if it is said that there are 100 people in a room, the use of the round number would lead listeners to interpret the statement as an approximation. The true number could be perhaps anywhere from 80 to 120 people. On the other hand, if it is said that there are 106 people in a room, the use of the sharp number would suggest that some counting has occurred.

It is interesting that the tendency to interpret a round number as a result of approximation is so pronounced that to communicate otherwise requires some additional wording. For example, if a count has determined that there are 100 persons in the room, one would have to say that there are *exactly* 100 individuals in the room to indicate that this is not an approximation (Dehaene 1997, p. 109).

Our research combines the round-versus-sharp-number distinction with Smith and Darley’s objective-versus-subjective distinction. We propose that sharp numbers are assumed by consumers to be objective and factually-based because they imply a high level of accuracy that could be achieved only through an empirical analysis. On the other hand, round numbers suggest an approximation that is likely to be a subjective estimate that may bear little relationship to reality. For example, a claim that a new allergy drug is 46% more effective than a popular competitor implies that the claim is based on some clinical research whereas the claim that it is 50% more effective indicates that the communicator lacks knowledge of the true level of differential effectiveness.

RESEARCH QUESTIONS

On the basis of the preceding literature review, a series of research questions were developed related to the relative effectiveness of advertising claims expressed with sharp numbers compared to round numbers.

1) Are numerical claims judged differently than equivalent verbal claims? Prior research has established that numerical claims

¹The authors thank Hiralkumari Udawat for her assistance in the data collection for this study.

are superior to equivalent verbal claims, especially when used by high credible sources (Yalch and Elmore-Yalch 1984). As both sharp and round numbers are numerical, it was expected that they would be judged more believable than an equivalent verbal claim.

2) Are numerical claims judged differently when a sharp rather than a round number is used in the claim? The belief here is that consumers will infer that the advertiser's use of a sharp number is the result of an empirical analysis and not merely an approximation or a number that the advertiser has made up in order to impress the consumer. Consequently, it was expected that consumers would judge the sharp number as being more accurate and empirically-determined relative to the round-number claim.

3) If sharp numbers are assumed to be more empirically-based, will that make the overall claim more believable and persuasive? Prior research has shown that the use of objective evidence (claims based on empirical testing) enhances the persuasiveness of an advertising message (e.g., Darley and Smith 1993). However, this prior research used multiple verbal claims compared to multiple numerical claims as the objective evidence manipulation. No study has looked at the more subtle difference between round and sharp numbers in making a single claim. Here, there is a minimal implicit suggestion that one claim is more credible and persuasive than the other.

4) Does advertising skepticism, an individual difference in the overall belief in the honesty of advertising, moderate the effects of numerical-versus-verbal claims and of sharp-versus-round numerical claims? Prior research has established that consumers differ in their general skepticism toward advertising and advertising claims. Obermiller and Spangenberg (1998) developed a nine-item scale to measure consumers' tendencies to question advertising claims. Their research demonstrated substantial construct validity, with advertising skepticism being positively associated with unfavorable attitudes toward marketing and advertising in general. The scale developers speculated that high skeptics would reject testimonials and many other forms of advertising, such as demonstrations. However, it was not determined if they would reject all forms of advertising. We propose that because advertising claims expressed with sharp numbers are interpreted as being more likely to result from authentic empirical analysis than those using round numbers, that advertising skeptics may be less inclined to reject them than round-numbered claims. Consequently, we predicted an interaction between the type of number used in a claim and advertising skepticism. Specifically, we expected that high skeptics would be less likely than low skeptics to accept a round-number claim but equally likely to accept a sharp-number claim.

METHOD

The above-mentioned research questions were explored in an experimental study of consumer responses to paired advertisements. Subjects were asked to compare two color advertisements for the same product that differed only in the main claim made on behalf of the product. In all cases, one of the two advertisements used a verbal format. The second advertisement in the pair was varied such that one third of the subjects saw the claim expressed with a sharp number that was slightly lower than a round number, one-third saw the claim expressed with a sharp number that was slightly higher than the round number, and the remaining third saw the ad's claim expressed with the round number. After examining the pair of advertisements, the consumers responded to a three-page questionnaire.

Test Advertisements

We decided to use a fictitious body-spray deodorant as the advertised product, because the product category could plausibly

support an objective claim and because it is a category relevant to most people. The ad we constructed featured a young man and woman dancing on an outdoor deck. The key claim was that the brand, Amor, was a long-lasting body-spray deodorant. The claim using the verbal format was, "Lasts far longer than any other deodorant." The three numerical claims were, "Lasts [47%, 50%, or 53%] longer than any other deodorant." The claim was made in both the headline and the last line of the body text of the advertisement. The ads were presented side-by-side to facilitate comparisons. The verbal message was paired with one of the three numerical messages. Half of the time, the verbal message was on the left and half of the time on the right. Although hemispheric lateralization studies suggest that verbal and numeric information may be processed differently depending on the field of vision, an analysis revealed no position effect so the data were combined across the two positions.

Measures

Immediately below the two advertisements was a set of nine questions asking subjects to compare the two ads. These looked at two aspects – credibility and perceived accuracy. Credibility was assessed using four items (more true, more believable, more trustworthy, and more convincing). Perceived accuracy was assessed using four items (more accurate, more exaggerated, based on actual scientific evidence, and better documented). The last of the nine items asked which of the two ads in the pair made the subjects more interested in trying the product. All items were judged using 5-point scales with the labels Ad A definitely, Ad A probably, Both ads are about the same, Ad B probably, and Ad B definitely.

The second page of the questionnaire included the nine questions making up the Obermiller and Spangenberg (1998) ad skepticism scale. The items included statements such as "Advertising is generally truthful" and "I feel that I am accurately informed after viewing most advertisements." A 5-point response scale was used with the labels Strongly agree, Somewhat agree, Neither agree nor disagree, Somewhat disagree, and Strongly disagree.

The third page of the questionnaire asked about the subjects' interests in solving problems and thinking about situations. Neither proved useful in understanding the phenomenon of interest. The last item was an open-ended question regarding the purpose of the study. No subjects indicated that it involved sharp-versus-round numbers in claims. This is not surprising since no subject was exposed to both a sharp- and a round-number claim.

Subjects

One hundred and ninety-nine university students served as subjects in this study. They were recruited by campus advertising to report to a testing room where they completed the questionnaire for this study along with questionnaires for two unrelated studies. They were paid \$10 for their participation in the three studies.

RESULTS

The responses to the four items making up the determination of the ad's credibility were combined (Cronbach's $\alpha=.85$) to form a credibility scale, CREDIBILITY. Three of the other four items were combined to form the perceived accuracy scale, ACCURACY. The fourth item, more exaggerated, was deleted because the reverse wording appeared to confuse many subjects as they rated claims they considered more accurate, more likely based on scientific testing, and better documented as more, not less, exaggerated. Both a factor analysis and the reliability analysis argued for not including this item with the others. The reliability of the three-item scale was low (Cronbach's $\alpha=.52$), but still usable. The nine items related to ad skepticism were summed to form an overall advertising-skepticism score (Cronbach's $\alpha=.86$). A median

FIGURE 1
Message Evaluations by Ad Claim

split was made such that those scoring 3.25 or less were grouped and labeled low skeptics. Those scoring above 3.25 were labeled high skeptics.

Figure 1 shows the results for the perceived accuracy and credibility scales by the three message conditions. The first research question as to whether numerical claims are evaluated better than verbal claims was tested with a t-test of the perceived accuracy and credibility scores versus the null hypothesis value of 3 (equivalent to judging the numerical message the same as the verbal message). The results ($t=21.5$ for ACCURACY and $t=13.2$ for CREDIBILITY, both $p's < .001$, $n=199$) strongly support the view that numerical claims were judged to be more empirically-based and more credible than an equivalent verbal claim.

The second research question related to whether sharp numerical claims would be judged as being more accurate and empirically-determined than round numerical claims. A one-way ANOVA compared the three group means for the ACCURACY measure. The result was statistically significant ($F(2, 196)=7.48$, $p < .001$). A post hoc comparison of the means showed that the sharp-numbered claims (47% and 53%) were judged to be more likely based on empirical evidence than the round-numbered claim (50%), using a Student-Newman-Keuls test ($p < .05$). The difference between the two sharp-numbered claims was not significant, indicating that the inference that a sharp number was more likely to be empirically-based did not change when the comparison claim was rounded up or rounded down.

The third research question considered whether being seen as a claim that is more accurate without an explicit statement that this was the case would translate into greater credibility for the claim.

A one-way ANOVA compared the three group means for the CREDIBILITY measure. The differences were not statistically significant ($F(2,196) < 1$), indicating that the implicit belief that there was evidential support for the claim did not make the claim more believable. Similarly, there were no significant differences between the three groups in the subjects' interest in trying the advertised product.

The final research question concerned ad skepticism and whether or not it moderated the relationship between using sharp-numbered claims and judgments that these claims were based on empirical evidence. This question was addressed using a two-way ANOVA on the perceived accuracy measure. The independent variables were type of claim (47%, 50%, or 53%) and ad skepticism, with groups assigned on the basis of a median split of the subjects' self-reported beliefs about advertising. The results revealed a main effect of the type of claim ($F(2, 193)=5.98$, $p < .01$) and a marginally significant interaction of claim type with ad skepticism ($F(2, 193)=2.51$, $p < .09$). As shown in Figure 2, the cause of the interaction was the tendency of the high ad skeptics to doubt the evidential basis for the round-numbered claim relative to the low skeptics but to not do that for the sharp-numbered claims. However, as was true for the combined sample, the interaction effect between claim type and ad skepticism for perceived accuracy was not significant for claim credibility of the messages (claim type by ad skepticism, $F(2, 193)=1.67$, $p > .1$).

DISCUSSION

The results of this experiment support the conjecture that advertising claims stated in terms of sharp numbers are more likely

FIGURE 2
Perceived Accuracy for Claim by Ad Skepticism

to be judged by consumers as having originated from some empirical data and therefore are more accurate than equivalent round-numbered or verbal claims. The effect is particularly noteworthy in that it appears to be due primarily to those consumers who consider themselves to be highly skeptical of advertising claims. Although these high skeptics indeed showed a smaller advantage of numerical over verbal claims when round numbers were involved, they were just as likely as the low skeptics to make the unjustified inference that a sharp-number claim is empirically-based. This finding suggests that Obermiller and Spangenberg's (1998) view that advertising skeptics tend to be suspicious of advertising devices such as testimonials and demonstrations should be modified to state that ad skeptics are not more skeptical of everything advertisers do. This research shows that more subtle methods used in advertising may not be as readily rejected.

The evidence in this study that the use of sharp numbers suggests the involvement of detailed, empirical analysis may also be applied to our understanding of everyday verbal communication. Consider, for example, how you might perceive a friend if, rather than saying, "I'll be back in a half hour," the friend said, "I'll be back in 27 minutes." Santos, Leve, and Pratkanis (1994) found that a panhandler can get more money by asking for 17 or 37 cents rather than requesting a quarter. Although they explained this phenomenon by the attention-getting properties of the sharp numbers, the results of the present study would suggest an alternative explanation. It may be that when one is approached for 37 cents, the sharpness of the number suggests that there is a very specific need, say, that the requestor is only a few cents short of what he needs to buy a bus ticket home. By contrast, the request for a round amount of money might suggest that there is no specific need – rather, the requestor just wants money.

LIMITATIONS AND FUTURE RESEARCH

The present research is exploratory, and the conclusions must be judged tentative since only one ad with only one headlined claim was tested. Further, ads were compared directly against each other, making it likely that the subjects would focus on the numerical claim. As this should increase scrutiny of the numerical claim relative to a more natural exposure situation, this provides a strong test of the proposition that audiences infer an empirical basis for claims stated in terms of sharp numbers. In a more complex exposure situation, where consumers typically do not expend the resources to consider the possibility that the claim is being falsely stated to look like it was empirically-based, the possibility of such an unwarranted assumption should be greater.

Individuals concerned about truth in advertising should be heartened by the finding that the sharp-numbered claim was not judged to be highly persuasive. There may be a countervailing influence whereby consumers may be more suspicious of advertisers who use empirically-based claims such that the greater credibility of the claim is countered by a lowered trustworthiness. This could easily be tested by varying the perceived trustworthiness of the source to see if there is an interaction between source credibility and type of numerical claim.

It would also be useful to determine whether the effects are enhanced when consumers lack the resources or motivation to properly evaluate sharp-number claims. As noted by MacInnis et al. (1991), advertisers should recognize that there are tradeoffs such that an executional device designed to attract attention (sexy models or humor) may interfere with the processing of brand information. The mere fact that a numerically-stated claim appears more accurate and factual than a round-number claim because it is

assumed to be empirically-based may cause the audience to pay less attention to the message, thus reducing comprehension and storage of the information. It would be useful to determine whether there is a memorability difference between sharp and round numbers. Childers and Viswanathan's (2000) research comparing the representation of verbal and numerical information is a good reference for thinking about this issue.

CONCLUSIONS

Advertisers have used sharp numbers for many years. Proctor & Gamble's trademarked claim that Ivory soap is 99 and 44/100% pure dates to the 19th century and may be one of the best-known examples of a sharp-number claim. Interestingly, this claim is based on a chemist's analysis of a sample of the product (<http://www.ivory.com/history.htm>). Other advertisers use similar numerical claims that also appear highly precise but may not be based on scientific research. The present research shows that even in the absence of a clear reference to an empirical basis for the numerical claim, consumers are likely to assume that it is based on research when the claim is stated in terms of a sharp number rather than a round one.

ROUNDTABLE
Philosophy and Consumption
Janet L. Borgerson, University of Exeter

This session's purpose was to survey recent efforts by consumer researchers to draw upon philosophical concepts and theories in accomplishing consumer research. Turning to philosophy can help clarify assumptions, theory, and methods within consumer research. Initial examples of areas that could benefit from such philosophical grounding included research on consumer objects—or material culture—as resources for consumer identity work (Marcoux 2005; Miller 1987); brands as resources in symbolic consumption (Holt 2002); and constituting consumer subjectivities, including gendered and racial identities, through interaction with marketing representations (Schroeder and Borgerson 2005; Borgerson and Schroeder 2004). Indeed, the roundtable gathered together over forty researchers engaged in philosophically informed consumer research; provided a platform for learning about attendees' ongoing projects; and pooled knowledge, offering suggestions regarding theoretical resources for future research.

Clearly, the concerns of philosophy and the marketplace intersect. Some of the most famous philosophers have backgrounds in economics and political theory. Historically, these writers engaged with labor, production, and value issues, and the economic interactions—broadly conceived—of individuals, particular cultures, and the world as a whole. Further, many theorists in economics, management, and finance look to, reflect on, and write documents based in philosophical concerns for global justice, human capabilities, and cultural practices. At a more pragmatic level, philosophical considerations and ethical investigations, and the ability to undertake both, allow for thoughtful, careful, and aware research, including an understanding of epistemological and ontological issues regarding, e.g. consumer identity, corporate social responsibility, and consumption generally.

Issues around agency and materiality provide but one illustrative example of the work philosophy does in consumer research (Borgerson 2005). One might ask, What do consumer researchers mean when they claim that consumer selves are “transformed”, “created”, “expressed”, or “emancipated” in relation to consumer objects and contexts, such as branding, in consumer culture? What are the relations between subjects and objects, or to put it another way, what versions of materiality are being proposed, called upon, or assumed in such consumer research? How does consumer research conceptualize the self? How much agency should be attributed to objects and subjects in becoming who and what they are?

Assumptions about who or what the consumer *is* matters. How consumer researchers conceptualize consumers, consumer identity, and consumer self crucially impacts upon appropriate research assumptions, contextual understandings, and potential insights and outcomes in consumer research: Yet, effects of agency and materiality-related assumptions often remain undertheorized, or simply absent, leading to conceptual confusion, inaccurate description, and simplifications rather than complexity even in sophisticated attempts to understand relationships between humans and life contexts.

This is not to claim that attending to the relation between philosophy and consumption leads only to a single version of subject constitution. Many theoretical conceptions exist; and these are drawn upon, often, in qualitative, interpretative research focused, for example, upon branding, retail environments, material culture, and research methodologies, especially that which is in-

formed by social sciences and humanities disciplines (e.g., Thompson, Locander, and Pollio 1989). The goal is to widen the conversation among scholars with a variety of interests and approaches, providing support and resources for interested researchers.

The researchers who attended the roundtable introduced themselves and briefly discussed a topic with which they were engaged and indicated how particular philosophers or philosophical notions and concepts helped them think through complexities, or made certain questions and insights possible. A number of philosophers were mentioned, from historical figures Plato, Hume, and Kant to twentieth century names, such as, Pierre Bourdieu, Michael Foucault, and Donna Haraway. One researcher suggested that contemporary philosopher Judith Butler's work *Bodies That Matter* (1993) helped her conceptualize the constitution of ‘consumers that matter’. Another researcher warned against looking only to long dead canonical or typical philosophers (the usual suspects, as it were), urging instead turning to plentiful contemporary sources of philosophical and ethical ideas and innovations. This means taking into account work in *feminist philosophy* (e.g., Oliver 1998; Young 1990) and *philosophy of race* (e.g., Goldberg 1993; Gordon 1997), as well.

Materiality, as mentioned above, and related concerns for co-creation, interrelationships, and intersubjectivity emerged as a topic of particular interest among several participants. Issues of meaning construction, aesthetics, mundane practices, and identity also sparked a turn to philosophy and philosophical thinkers. Further, philosophy sheds light on methodological concerns: moreover, philosophy questions, and thus adds rigor to, the coherence of arguments. Future roundtables will offer opportunities to focus in on particular topics or figures and extend this fruitful, yet often missing, conversation in consumer research.

SPECIAL SESSION SUMMARY

Marketplace Motives and Consumer Meta-Skepticism

Barbara Bickart, Rutgers University-Camden

SESSION OVERVIEW

Over the last ten years, there has been increasing attention focused on understanding how consumers' beliefs about a firm's motives affect consumer response to marketers' actions. Much of this research has focused on beliefs about the persuasion process, or persuasion knowledge (Campbell and Kirmani 2000, Friestad and Wright 1994, 1995). Specifically, consumers often appear to question marketers' motives, resulting in diminished trust and skepticism about relationships with firms (Fournier, Dobscha, and Mick 2000). Fournier et. al (2000) suggest that in order for companies to build strong relationships with consumers, they must be honest about their motives. Further, a consumer's ability to accurately perceive a firm's motive and respond accordingly is important from a consumer welfare perspective.

The papers in this session examine how consumers' make inferences about a marketer's motives and how skepticism about such motives affects consumers' reactions to a firm's marketing efforts. Building on an idea suggested by Wright (2002), the research in this session investigates theoretically and empirically how meta-skepticism influences the manner in which the consumer interprets a firm's actions. In fact, the research presented in this session suggests that marketing tactics can have a very different impact depending on how the consumer views and interprets the motives of the influence agent.

The first paper, by Dan Ariely and Ayelet Gneezy establishes in a convincing way the extent of consumers' meta-skepticism about marketers' actions and statements. In three studies, they show that consumers' default view is to be skeptical about marketers' offers and to distrust statements made by companies. Importantly, this skepticism about marketers stands in contrast to peoples' inherent trust of others in interpersonal relations. Skepticism about a firm's motives can also influence how specific marketing tactics (i.e., changes in price) influence attitudes toward the company, as shown in the paper by Priya Raghurir and Meg Campbell. Their research shows that depending on the types of inferences consumers make about the marketer's motives, price increase announcements can result in either positive or negative attitudes toward the firm. The third paper, by Barbara Bickart, Mimi Morrin, and Ratti Ratneshwar, examines salesperson communications. They show that the effect of admitting a lack of knowledge to a consumer's question (versus obfuscation) depends on whether or not consumers question the salesperson's motives. They also show that the effects of persuasion knowledge operate not only through skepticism (that is, lack of trust in the salesperson), but also via feelings towards the salesperson (i.e., the likeability of the agent).

To summarize, we hope that by presenting these papers in a single session, we encouraged further dialogue on the role of meta-skepticism in consumer behavior. The session included a lively discussion led by Connie Pechmann.

SHORT ABSTRACTS:

“Truth and False in Marketing”

Dan Ariely, MIT

Ayelet Gneezy, University of Chicago

In social interaction it was shown that people first believe others, and disbelief is triggered only as a result of a correcting procedure. We hypothesize that, in contrast with the standard

finding from social interaction, consumers are primarily disbelieving and distrusting of information provided by marketers. One field study and two lab studies support this hypothesis. The results show that ambiguous (experiment 1) and unambiguous (experiment 2) statements that are endorsed by a firm are judged as false more frequently, and that when they are judged as true, they are judged more slowly.

“Benefit of Doubt or Betrayal? The Effect of Priors And Reasons on Response to Price Increases”

Priya Raghurir, University of California at Berkeley

Margaret C. Campbell, University of Colorado at Boulder

Four studies show that fee increases are ambiguous events that can be perceived as positive depending on the customer's inferences based on priors about the company and its competitors, and the reason provided for the fee increase. When reasons are perceived to be valid, then priors act as a buffer, allowing customers to give a company the benefit of the doubt. However, when the reasons appear to be an infraction, there is a feeling of betrayal. The fee amount has a limited downside, and a potential upside effect: with improved attitudes with higher fees for customers with a positive prior.

“Does it Pay to Beat Around the Bush? Salesperson Motives and the Effects of Obfuscation versus Honesty in Communications”

Barbara Bickart, Rutgers University-Camden

Maureen Morrin, Rutgers University-Camden

S. Ratneshwar, University of Missouri

Communication between a salesperson and a consumer plays an important role in how long-term relationships are developed and maintained. In two studies, we show that consumers' beliefs about a salesperson's motives affect how consumers' interpret communication with the agent. Specifically, when the salesperson's motive is to earn a commission (versus provide information), consumers believe the agent is more likely to obfuscate versus admit not knowing the answer to a question. Further, when the agent is on commission, behavioral intentions and satisfaction are significantly higher when the agent admits to not knowing an answer relative to obfuscating. We discuss these findings in the context of the Persuasion Knowledge Model (i.e., Friestad and Wright 1994, 1995).

SPECIAL SESSION SUMMARY

Emerging Perspectives on Self-Control

Ran Kivetz, Columbia University
Yuhuang Zheng, Fordham University

SESSION OVERVIEW

In their everyday lives, consumers face many self-control dilemmas between immediate pleasures and long-term interests. There is growing evidence that consumers often fail to exercise the appropriate level of self-control. However, despite the voluminous and interdisciplinary research on self-control, there is still much to be learned about how consumers could improve their self-control decisions. The present session introduces three current programs of research that offer emerging perspectives on consumer self-control. The three presentations highlight the key role of construal level, justification, and mood-regulation and together offer descriptive and prescriptive insights into self-control failures and their possible remedies.

In the first paper, Fujita, Trope, and Liberman propose a model of self-control based on the tenets of construal level theory (Trope & Liberman, 2003). The authors propose that decisions that result in increased self-control involve acting in accordance with high level, rather than low level, construal. Therefore, the authors argue that activation of high level construal (which captures the primary, central features of an event) should lead to greater self-control than activation of low level construal (which captures secondary, incidental features). The authors demonstrate across three experiments that priming high level construal leads to increased self-control in the form of decreased preferences for immediate over delayed outcomes, greater physical endurance, and less positive evaluations of temptations.

In the second paper, Kivetz and Zheng build on an alternative perspective that suggests that people also experience a reverse self-control problem, namely excessive farsightedness and over-control — in short, “hyperopia” (Kivetz & Simonson, 2002a; Kivetz & Keinan, forthcoming). The authors examine two major justification routes that consumers can employ to relax their self-control and enjoy the pleasures of life. Specifically, they propose an “entitlement” route that involves working hard or excelling and another complementary route that entails indulging without depleting income. Consistent with these two justification routes, a series of experiments with actual effort tasks and real choices demonstrate that higher effort or (bogus) excellence feedback enhances choices of vice over virtue; further, these effects are reversed when the interchangeability of effort and income is implied (by providing the effort’s typical, yet unavailable wage).

The third paper, by Zemack-Rugar, Bettman, and Fitzsimons, examines how consumers make self-control decisions in the service of mood-regulation and demonstrates several novel findings. The authors propose a strategic view of self-control, whereby self-control levels are increased or decreased in the service of emotion-regulation goals. As a result, contrary to the prevalent view that negative emotions lead to failures in self-control (e.g., Tice et al., 2001), it is demonstrated that negative emotions can sometimes lead to increases in self-control.

The papers presented in this session are unique in their conceptual treatment of consumer self-control. Overall, the session provides new insights into the key factors that affect consumer self-control and the mechanisms that consumers could employ to resolve such dilemmas more effectively. The session has both

theoretical and practical implications in that it presents new theories regarding the conditions in which consumers succeed or fail at self-control; such consumer failures (both myopia and hyperopia) have particularly detrimental societal implications.

EXTENDED ABSTRACTS:

“Construal Levels and Self-Control”

Kentaro Fujita, New York University
Yaacov Trope, New York University
Nira Liberman, Tel-Aviv University

People often fail to do what they want to do, despite possessing the knowledge, opportunity, and skills required. Such self-control failures are pervasive and the focus of a multi-disciplinary research effort. Most models of self-control posit conflicts between automatic versus controlled psychological processes (e.g. Baumeister & Heatherton, 1992), long-term versus short-term motives (e.g. Ainslie & Haslam, 1992), or impulsive affect versus rational cognition (e.g. Loewenstein, 1996; Metcalfe & Mischel, 1999). We propose a general theoretical framework based on the tenets of construal level theory (Trope & Liberman, 2003), which builds upon and integrates these previous approaches.

Construal level theory posits individuals can represent the same event at multiple levels (Trope & Liberman, 2003). High level representations, or construals, capture the primary, global, central features of events, whereas low level construals capture the secondary, local, peripheral aspects. As the valence of high and low level features is independent, individuals’ evaluations, preferences, and decisions can change systematically as a function of construal level. More weight is given to high level features in preferences and decisions when high level construals are activated, whereas more weight is given to low level features when low level construals are activated. Empirical research has supported these theoretical assertions, demonstrating that high and low level construals are distinct, and that they predict different preferences and decisions (Trope & Liberman, 2003).

A construal level analysis of self-control suggests that self-control conflicts arise when the valence of high and low level construals motivate opposing action tendencies. Self-control is defined as making decisions and acting in accordance with high levels construals rather than low level construals. Failures of self-

control, on the other hand, occur when individuals make decisions and act in accordance with low level construals rather than high level construals.

One implication of this model is that the activation of high level construals should promote self-control. We present three experiments designed to test this hypothesis. In all three studies, we enhanced the tendency to construe events at high versus low levels using an experimental priming manipulation. We then observed the “carry over” effects that these primed construal levels had on subsequent self-control tasks. Importantly, high level construals were activated without activating more deliberate, “cool,” rational, and long-term thinking. These studies thus directly test the unique effect of construals on self-control. High level construals, however, are frequently associated with these factors, which are proposed as critical variables by other approaches, and we believe they represent instantiations of the more general model of self-control we propose.

In Study 1, we manipulated the tendency to construe events at high versus low levels by having research participants consider why or how they engaged in some activity. Previous research has demonstrated that considering why one engages in an activity activates a tendency to construe at high levels, whereas thinking about how one engages in an activity activates a tendency to construe at low levels (Freitas et al., 2004). As a measure of self-control, we then observed participants’ preferences for immediate over delayed outcomes. As predicted, participants primed to high levels of construal demonstrated a reduced tendency to prefer immediate over delayed outcomes, suggesting greater self-control.

Using a similar manipulation of construal levels, we replicated these results in Study 2 with a behavioral measure of physical endurance. After primed to high versus low levels, participants were asked to hold a handgrip, an exercise tool that taxes one’s physical endurance, while connected to a computer with electrodes, ostensibly to receive feedback about their personality via a new psycho-physiological measure. Participants were told that although uncomfortable, holding the handgrip for longer durations would lead to more accurate feedback from the computer. Results revealed that participants primed to high levels of construal demonstrated greater physical endurance, suggesting that they exerted greater self-control.

In Study 3, to manipulate construal levels, we had participants either generate category labels (high level representations) or exemplars (low level representations) for a series of common objects. Participants, who were all students, were then asked to evaluate a list of words, some of which were temptations that undermine the goal to study. Self-control would be revealed through less positive evaluations of temptations. We also had participants indicate how important the goal to study was for them, as the temptations we presented would represent self-control conflicts only to those who value studying. As expected, high levels of construal led to less positive evaluations of temptations (with no differences between levels on non-temptation words). Moreover, the effect was limited to those who experienced those temptations as self-control conflicts, i.e. those who valued studying. These results replicate the previous two studies, and provide evidence that impact of construal levels is indeed specific to self-control conflicts.

The results of these studies suggest that high level construals do lead to greater self-control. They provide preliminary support for a construal level analysis whereby self-control is defined as making decisions and acting in accordance with high level rather than low level construals. As factors that other models propose enhance self-control are often related to high level construals, whereas factors that impair self-control are often associated with

low level construals, a construal level analysis provides an integrative theoretical framework for understanding the critical variables in self-control proposed by previous approaches. Although often highly correlated, however, low level construals are not necessarily affective, visceral, short-term, and automatic, nor are high level construals always cool, rational, long-term, and controlled. Both high and low level construals can be affective and visceral (versus cognitive and rational) and automatic (versus controlled). Moreover, a construal level analysis can capture self-control conflicts for which time is not an issue. A construal level analysis therefore represents a new approach to studying and understanding when and why individuals fail to exert self-control.

“Determinants of Justification and Self-Control”

Ran Kivetz, Columbia University
Yuhuang Zheng, Fordham University

Consumers often face a fundamental self-control dilemma between indulging and delaying gratification. How decision-makers resolve this dilemma is a central question in the voluminous and interdisciplinary literatures on self-control and time-inconsistency, which examine tradeoffs between immediate pleasures and long-term interests (vices versus virtues, respectively). Prior research and common sense suggest that people are more likely to relax their self-control and select vices when they have a compelling justification (e.g., Prelec & Herrnstein, 1991; Shafir, Simonson, & Tversky, 1993). However, a critical question that has not yet been studied is how such justifications are constructed. Accordingly, the main goal of the present research is to shed light on the antecedents of justification and their impact on self-control.

Building on prior analyses in the social sciences (e.g., Kivetz & Keinan, forthcoming; Kivetz & Simonson, 2002b; Maslow, 1970; Scitovsky, 1992; Thaler, 1985; Weber, 1958), we propose two complementary routes to justifying self-gratification: one through hard work or excellent performance (i.e., an entitlement or deservingness justification) and the second through the attainment of vices without the depletion of income. A synthesis of these two routes suggests that the preference for vice over virtue will increase with the expending of resources perceived as effort but will decrease with the expending of resources perceived as income or money. We test this and other related propositions in a series of studies with real effort activities (e.g., completing a computerized letter recognition task) and real choices between relative virtues and vices.

Studies 1a-1c show that perceiving oneself as having invested higher effort enhances the likelihood of choosing (a) to subsequently participate in a fun study with no delayed benefits rather than in a painful self-assessment study with long-term benefits; (b) lowbrow over highbrow movies; and (c) a delicious chocolate cake over a healthier fruit salad. Importantly, these self-control dilemmas were adopted from prior research on self-control (Fujita et al., in press; Read, Loewenstein, and Kalyanaraman, 1999; Mischel 1974; Shiv and Fedorikhin, 1999; Trope and Liberman, 2000; Trope and Neter, 1994). Studies 1a-1c also demonstrate that self-control choices are influenced by effort investment that is either absolute or relative (i.e., to the effort invested by others) and regardless of whether the effort activity and the self-control decision are related (as in effort-reward contingencies) or unrelated (as in two ostensibly separate studies). Further, consistent with the proposed conceptualization, higher effort is shown to have a stronger effect on people who perceive the choice as involving a conflict between short- and long-term interests.

In Study 2, we manipulate participants' guilt by asking them to recall either few or many instances of choosing vice or virtue (see Schwarz et al., 1991). We find that stronger emotions of guilt magnify the impact of effort on subsequent self-control decisions. This finding is consistent with the conceptual framework because it implies that a greater need to justify self-gratification sensitizes people to the presence of justification cues.

Studies 3a and 3b show that, although greater effort enhances the preference for vices, this effect is reversed when the interchangeability of effort and income is implied (by providing the effort's typical, yet unavailable wage). Study 4 extends the entitlement justification by demonstrating that participants who are led to believe that they excelled in an effort task are more likely to select vice compared to participants who are provided with mediocre or no performance feedback; we also re-examine the attenuating effect of alluding to the interchangeability of effort and income.

The last two studies investigate the implications of the two justification routes for willingness to expend different resources to attain either vices or virtues. In particular, Study 5 shows that people are willing to pay in effort more for luxury than for necessity but are willing to pay in money less for luxury less than for necessity. Study 6 generalizes this finding by holding constant the actual resource investment and framing it as either effort (solving anagrams) or income (by providing the typical, yet unavailable wage per anagram solution). Consistent with the results of Study 2, in which we manipulated guilt, throughout Studies 3-6 we find that the predicted effects are more pronounced among individuals who suffer from stronger chronic guilt. The final section highlights the unconscious nature of the two justification routes and their ability to explain the findings of prior research on self-control.

"The Conscious and Nonconscious Use of Self-Control for Emotion-Regulation"

Yael Zemack-Rugar, Duke University

James R. Bettman, Duke University

Gavan J. Fitzsimons, Duke University

Although self-control is a critical foundation of social and personal functioning (Baumeister 1997; Mischel 1996), we often fail at it. Existing research shows that we most often fail at self-control when we are in a bad mood (Baumeister 1997; Bushman et al. 2001; Heatherton et al. 1998; Leith & Baumeister 1996; Tice et al. 2001). Theories as to why this occurs range from distraction, to intentional self-harm, to inability to reason or assess risk (Leith and Baumeister 1996).

In this paper we present a strategic view of self-control and argue that people strategically increase or decrease self-control based on their need to regulate (different) negative emotions. The present theory and findings add to existing literature in several respects. First, existing theories argue emotion-regulation and self-control goals are antithetical and cannot coexist; whenever emotion-regulation goals are present, self-control goals are overridden (Tice et al., 2001). The present theory argues emotion-regulation and self-control goals not only coexist, but also interact strategically. That is, individuals adjust their self-control levels depending on whether self-control is deemed useful for emotion-regulation.

This "adjustment" of self-control depends on individuals' beliefs regarding the degree to which self-control is useful for emotion-regulation. Our theory accounts for such beliefs regarding goal-achievement (Carver and Scheier 1998) and examines the moderators that affect both beliefs and behavior. A more nuanced picture of the effects of negative emotions on self-control is drawn by accounting for belief and behavior (self-control) moderators,

including emotion type, emotion strength, and individual coping characteristics.

Additionally, we demonstrate in 3 studies that individuals can either decrease or increase their self-control in negative emotional states. This finding is contrary to existing literature that argues self-control inevitably fails in negative emotions (Tice et al., 2001). Finally, in four additional studies we demonstrate that the use of self-control for emotion-regulation can be pursued automatically, without conscious awareness.

In our first study we vary the need to regulate emotion by using sad (salient emotion-regulation goal) vs. neutral (no emotion-regulation goal; Wilson et al. 2003) conditions. We then directly manipulate participants' belief regarding whether self-control will help/hurt their emotion. We find a significant interaction of Emotion*Belief. Neutral consumers' self-control is unaffected by self-control beliefs, as they have no active emotion-regulation goal. However, sad consumers increase or decrease self-control depending on whether they believe indulging (in a guilty-pleasure food item; Giner-Sorolla 2001) will help/hurt their emotion. Consequently, individuals in a sad mood who believe indulging will hurt their emotion show *higher* self-control than their neutral counterparts. These results support a strategic emotion-regulation view in which self-control is "recruited" to the service of emotion-regulation based on cognitions. Additionally, showing increased self-control in a negative emotion (i.e., sad) runs contrary to existing findings and theories.

In our second study we indirectly manipulate beliefs by eliciting two different negative emotions, sadness and guilt. In a pretest, we demonstrate that beliefs regarding the utility of self-control for emotion-regulation differ across these emotions. Consistent with these beliefs, guilty individuals indulged less than their sad and neutral counterparts (in a CD/DVD purchase coupon). As in study 1, individuals in a negative (guilty) mood show an *increase* in self-control as compared to the neutral baseline. Moreover, individuals in different negative moods espouse different cognitions regarding the utility of self-control for emotion-regulation, and these cognitions correspond to the level of self-control seen in those specific emotions.

In our third study we examine the moderating effect of emotion strength and individual coping characteristics. We examine guilty, sad, and neutral participants and measure guilt-proneness, an individual difference variable that measures coping with guilt (Tangney, Wagner, and Gramzow 1992). In this study, we induce a strong emotional state by requesting autobiographical stories for guilt and sadness. As predicted, we find an Emotion*Guilt-Proneness interaction for both beliefs and behaviors. Individuals low in guilt-proneness believe increasing self-control is useful for emotion-regulation and show increased self-control on a grim-necessity task (Boster et al. 1999; Bybee 1998; Estrada-Hollenbeck and Heatherton 1998; Giner-Sorolla 2001; Tangney 2001) compared to sad or neutral individuals. However, individuals high in guilt-proneness believe self-control will not help emotion-regulation and show less self-control than sad or neutral people. This backlash of high-guilt prone individuals is consistent with clinical literature suggesting that when high guilt-prone individuals experience acute guilt (as in this study), they tend to engage in denial and avoidance behaviors (Kubany and Watson 2003) and behave antisocially (Harder 1995; Harder and Lewis 1987) with low self-control. This backlash effect is neither predicted nor found in studies where guilt is milder, as presented next.

In four additional studies we demonstrate that the use of self-control for emotion-regulation can become automated. If individuals consistently enact the same behaviors in a given situation, the behavior can become automatic. We argue the emotion-behavior

link between specific negative emotions and self-control should be activated even when individuals are not fully aware of their emotion-regulation goal. We examine both guilty and sad emotions and we include a measure of guilt-proneness.

In these studies we subliminally prime either guilt or sadness and measure behavior on either a guilty-pleasure or grim-necessity self-control task. We find no conscious reporting of an emotion-regulation goal. Moreover, we find no differences in the conscious, subjective emotion reported across the sad vs. guilty conditions (Winkielman et al. 2005). However, we find predictable differences in self-control behaviors. Specifically, we find a consistent Emotion*Guilt-proneness interaction. Guilty individuals high in guilt-proneness, who repeatedly tend to associate guilt with self-control behavior, show higher self-control than individuals in all other conditions. These results persist even following the addition of a time delay, suggesting they are not purely semantically driven, but rather are driven by a goal (Bargh et al. 2001).

In sum, this research suggests consumers can use self-control as a tool for emotion-regulation based on what they *believe* will make them feel better. As a result, self-control can and does increase in negative emotions. Moreover, self-control varies across different negative emotions, their strength, and individual coping characteristics. Finally, these emotion-regulation strategies can become automated over time and can be elicited non-consciously.

How Single and Married Women Organize to Get the Food on the Table Every Day: Strategies, Orientations, Outcomes and the Role of Convenience Foods

Louise Heslop, Carleton University
Judith Madill, Carleton University
Linda Duxbury, Carleton University
Melissa Dowdles, Carleton University

ABSTRACT

How single and married mothers approach food preparation tasks was determined from reports of activities and attitudes around food preparation. The patterns of these activities and attitudes were used to develop meaningful typologies of food preparation orientations and strategies. These strategies and orientations were then explored in terms of their association with various work-family outcomes and convenience food use. There are many similarities in approaches used between single and married women, but also some differences. Work and family outcomes, such as role interference, stress, strain, and life satisfaction are related to several strategies and orientations, as is convenience food use. Clearly some approaches work better than others in terms of life balance.

INTRODUCTION AND LITERATURE REVIEW

Even if employed full-time outside the home, women carry most of the family care responsibilities (see e.g., Cowan and Cowan 1999; Duxbury, Higgins, and Lee 1993). Probably the most difficult and time consuming tasks center around the constellation of activities involving food buying and preparation. Most studies have looked at parts of these linked tasks as isolated specific activities. However, it is likely there are underlying patterns among the food task activities reflective of strategic approaches, interests, and orientations to work and family. This study expands the knowledge of food-related task accomplishment by identifying and examining strategies in food preparation. It looks at the relationship of these strategies to food task orientations, to the use of convenience foods, and to demographic characteristics of the mothers and their households, the work patterns of the mothers, measures of work and family involvement, stress, strain, and life satisfaction. Further, it compares these across two family types, single and married mother households. The research contributes to theories of household task accomplishment and work-family balance, and informs marketers of convenience foods.

Numerous studies document that the difficulties faced by women in managing their personal and work lives generate time pressures, role conflict, role interference, role overload, stress, life dissatisfaction and affect performance both at work and at home (see for example, Duxbury, Higgins and Lee 1993; Gutek, Repetti and Silver 1988; Lewis and Cooper 1988). Emmons et al. (1990) suggested the pressures of managing multiple roles are greatest and the psychological benefits from employment are least when heavy family responsibilities involve younger children and less support from one's spouse. The management and performance of food preparation roles has been found to be a significant stressor for women in all work-family situations (Marshall, Duxbury and Heslop 1992). In particular, consumer researchers have taken the most interest in this area because of its direct relevance to consumption behaviors. Research has focused on three major subthemes of purchase of convenience foods (e.g., Jackson et al. 1985; Schaninger and Allen 1981; Strober and Weinberg 1980), food services (e.g., Bellante and Foster 1984; Nickols and Fox 1983), and durables (e.g., Bryant 1998; Weinberg and Winer 1983).

Wife's employment appears not to be a determinant of the purchase or ownership of labor-saving durables, the use of frozen

foods, grocery or clothes shopping behavior, or other types of purchases (see for example, Rubin, Riney and Molina 1990). Jackson et al. (1985) noted that working wives were more likely to dislike food shopping and cooking because of time pressures and to be less concerned with the impact of their food activities on other family members. Overall, research suggests working wives may respond in strategic ways to the stress of multiple role demands by disengaging from the tasks mentally and/or physically, e.g., by shifting tasks to other family members or downplaying the importance of the task. However, Strober and Chan (1999) noted women who preferred to do a task were not interested in bargaining it away to others. To some, cooking is a disliked chore; to others, it is a creative stress reliever (Hendrix and Qualls 1984).

Both Strober and Weinberg (1980) and Nickols and Fox (1983) proposed the individual decisions made by working wives may be guided by "global" time buying and time saving strategies, such as using capital equipment or the labor of others or reducing the work standards. Bird, Bird and Scruggs (1983) found this generalized strategy-based approach more insightful than individual product-use analysis to understanding the behavior of women who were or were not employed outside the home. Hermann and Warland (1990) studied organizing and planning practices and noted that orientations to the tasks of meal preparation, such as enjoyment and concern for aspects of the task, and feelings of time pressure did differ across the typologies they developed. These results support a relationship between orientations to the task and approaches to task performance. Finally, Carter (1990) found that households which did more in-home food preparation reported more enjoyment of cooking. Convenience food users were more likely to be in two-adult households and held more positive attitudes towards the quality of such foods.

There has been little research on single mothers and food tasks. Kushnir and Kasan (1993) report that single mothers believed their time is very limited and that they had less control over their lives because of limited resources. Sinkula (1984) (as reported in Ahuja and Walker, 1994) found an inverse relationship between the preplanning shopping efforts of single parents and their purchase of frozen foods. Both McCracken and Brandt (1990) and Burden (1986) found single employed mothers spent less time than married mothers on household tasks, especially food-related ones.

Methodology

Data were collected from a sample of 390 married and 91 single mothers who were employed full-time in five federal government departments and had one or more children under age 19 living at home. The questionnaire included sections on:

- 1) personal and household demographics—marital status, education, income, number and ages of children
- 2) hours spent in work and work status, broadly classified into two categories of professional/managerial career and technical, clerical and semi-skilled earner
- 3) work and family involvement—the former measured using the Lodahl and Kehner (1965) scale and the latter using the technique of Yogev and Brett (1985)

- 4) work interference-using the nine statement measure developed by Kopelman, Greenhaus and Connolly (1983) with such statements as, "My work schedule often conflicts with my family life,"
- 5) role overload-using the measure developed by Reilly (1982) with twelve scales such as: "There are too many demands on my time"; "Sometimes I feel as if there are not enough hours in the day"
- 6) stress-using the Perceived Stress Scale (Cohen, Kamarck and Mermelstein 1983). PSS scores of 2.8 or above are generally considered "high," levels of stress, and PSS scores of 1.5 or lower are considered "low" stress
- 7) time strain-using a measure of extent of being bothered by the adequacy of time available for eleven activities, including community involvement, spouse, children, sleep, friends
- 8) life satisfaction-using the 5-item Quinn and Staines (1979) measure
- 9) food preparation strategies-Based on the work noted above by Strober and Weinberg(1980), Nickols and Fox (1983) and additional approaches to this activity identified in depth interviews preceding the survey, a list of twelve food preparation behaviors and activities for single mothers and thirteen for married mothers were developed (the extra strategy involved delegating to spouse)
- 10) food preparation orientations-extent of agreement with ten scales for single mothers and twelve for married mothers, including "I like serving unusual dinners;" "I am a good cook;" "I have better ways to spend my time than cooking."

Principle Components Analysis with Varimax rotation, eigenvalue cutoffs of 1 and loadings of .4 was used to examine for patterns that would describe overall strategies and orientations for the last four measures.

RESULTS

Sample Description

The mean age of married women was 41 and of single women was 39. Although both families had an average of two children, the mean was statistically significantly higher for married women (2.1 vs. 1.8 for single mothers). A higher percentage of married women (26.5%) had completed university than single women (11%). There were no differences in the average weekly hours worked (39), occupation classification, or personal income (2/3rds earning \$30-60,000). However, 83% of single mothers vs. 39% of married women had family incomes of less than \$60,000. Stress levels of married women were slightly higher than those of single mothers, and single mothers rated considerably lower on overall life satisfaction.

Food Preparation Orientations and Strategies

To determine food preparation orientations and strategies, the responses to food preparation attitude scales and concerning the performance of several food preparation activities were analyzed using Principle Components Analysis to determine interrelated patterns of behaviors. Eigenvalue cutoffs were set at 1, and varimax rotation was used to clarify the loading patterns at .4 or above. For convenience of discussion, names were developed to reflect the patterns seen in each of these identified factors. Factor scores were developed for the orientations and strategies seen and correlations with demographic, work and family variables were used to search for associated life experiences.

Food preparation orientations. Ten statements for single mothers and twelve for married mothers about attitudes to food preparation were analyzed revealing two similar and two different factors for both groups as presented in Table 1. The extra scales for married women concern the role of the spouse. The first factor for both groups was a "Happy Cooker" orientation that featured interest in cooking and no interest in decreasing time spent. Also, both groups have a "Disengage" orientation of not worrying about food preparation or judging oneself on performance of this task. Also, for single mothers, preference for quick meals and feeling there are better ways to spend one's time loaded here. For single mothers, the two other food preparation orientations were labeled the "Family Focus" orientation, because family wishes are an important consideration, and "Cheap Gourmet," because it included high loadings on interest in serving unusual dinners but also concern for cost. For married women, the other two factors included one not available to single mothers, i.e., a spouse who enjoyed cooking and was good at it. The second involved concern for both cost and family preferences and was termed the "Carefilled."

Food preparation strategies. Twelve food preparation activities for single mothers and thirteen for married revealed four factors for the former and five for the latter. For single mothers, the first factor suggested a "Harried Juggler" strategy involving working hard, sleeping less, looking for time saving tips, and polychronic time use. The second factor depicts the "Do Less" strategy, including items of cooking simpler meals, lowering standards, and decreasing meal preparation time. This strategy is similar to the reduction of responsibility strategy discussed by Bird, Bird and Scruggs (1983) and the coping strategy classified by Nickols and Fox (1983) of reducing the quantity and quality of household production. The third factor was termed the "Organize" strategy, including planning meal preparation, organizing time to allow for cooking, and a secondary level loading for working harder. This strategy resembles the "organization" role management strategy addressed by Bird, Bird and Scruggs (1983). Finally, the last strategy was called "Food Bank" because it involves time shifting of work by stockpiling meals through weekend cooking and preparing in larger quantities.

For married mothers, two factors are the same as for single mothers, "Do Less" and "Food Bank." The second factor for married mothers includes the three scales of working hard, organizing and planning and has been called the "Do It All" strategy, in contrast to the "Do Less" approach. A pattern of polychronic time use has been labeled as "Crunch Time." The final factor for married mothers is a "Delegate" strategy, comparable to the "delegate" role management strategy discussed by Bird, Bird and Scruggs (1983) and the "substituting the labor of others" coping strategy of Nickols and Fox (1983). Interestingly, single mothers do not seem to use this strategy, in their case, not using the help of children. Married women have more options with another adult available in the household.

Food preparation orientations and life situations. Table 2 contains information on the correlations between factor scores of the orientations and demographics (education, personal and family income, number of children), work-family situation (work status, hours worked, work and family involvement) and outcomes (work interference, role overload, time strain, stress, life satisfaction). For single mothers, the "Happy Cooker" orientation was associated with higher personal incomes. Those with lower work involvement and work status but longer work hours were associated with the "Disengage" orientation, perhaps reflective of a less than fulfilling work experience. The "Cheap Gourmet" also had lower work involvement but more work interference and role overload, possibly reflecting a great involvement in household activities. For

married mothers, the “Happy Cooker” orientation was positively correlated with higher education but also with work interference and role overload. Those who were good cooks and enjoyed looking for recipes and preparing interesting, new dishes did find difficulties juggling work and family time commitments. Delegating to a spouse who was good at food preparation tasks and enjoyed them was associated with lower levels of role overload, time strain and stress for the wife. Working mothers with higher hours in the labor force and high work involvement were more likely to disengage from the food preparation task. The “Carefilled” mother seems to be in the worst situation with lower income, work involvement, work status, more children and higher role overload. This seems to be a married mother with many conflicting demands but fewer economic resources, no spousal support, and lower life satisfaction.

Food preparation strategies and life situations. For single mothers, the “Harried Juggler” strategy is positively correlated to family involvement, work interference and role overload, suggesting that those using this strategy feel pressured from being highly involved with their families and finding work conflicts with family responsibilities. The “Do Less” strategists experience high work interference and role overloads but not family pressures, so their approach to food preparation reflects this lower concern for tasks of feeding the family. The “Organize” strategist has higher education levels and family involvement, suggesting the food preparation task will be demanding and her organizational skills are called to the fore to deal with them. For married mothers, the “Do Less” strategy appears to be adopted by those with higher education, incomes, work status, hours worked, work interference, role overload, time strain, and stress. The high performance job of this type of person is balanced by a minimalist food preparation task performance. The “Do It All” strategy is also positively correlated with work interference, role overload and time strain, but also life satisfaction. This type of mother has many stresses in her life but appears to be happy with a frantic work and home life pace. The “Food Banker” deals with high work interference by scheduling time for food preparation around her workweek. The “Crunch Time” strategy is associated with lower family incomes and lower role overload. Perhaps the time efficient strategies help best in the balancing of time demands in the lower income households. Those women who delegate to other family members and share food preparation with their spouse are more likely to have higher personal incomes, work involvement and hours worked. This willingness of other family members to share household tasks is more apparent where the wife’s work status is higher.

As indicated from the previous analysis, the “Happy Cooker” who tries to “Do It All” experiences very high stress, role overload, strain and work interference levels, but the food banking and time efficiency strategies are not associated with such problems. Similarly, those mothers who are highly concerned with controlling costs but keeping family members happy will find different strategies yield different results in terms of handling the multiple roles with ease. Given these women are working long hours, have high levels of work-family conflict and aren’t interested in food tasks, this is not a surprising outcome.

Strategies, orientations and convenience food use. Convenience food usage was measured by reports of frequency of use of five types of foods (baked goods, prepared mixes, prepared dinners, prepared meats, prepared/frozen vegetables) and also the use of convenience goods in recipes rather than on their own. Overall, there is considerable use of convenience foods. Prepared or frozen vegetables were used most frequently (45.5% of single and 51.2% of married), while mixes were used the least (48.9% of singles and 48.8% of married never used them). Prepared dinners were also relatively frequently used (40.0% of single and 36.2% of married

weekly or more) but baked goods much less often (56.7% of single and 51.3% of married). Many women did use convenience goods as recipe adjuncts more than once a week (25.5% of singles and 37.3% of married).

As seen in Table 2, no significant relationships were found between the food preparation orientations of married mothers and their use of convenience foods. However, for single mothers, the “Happy Cooker” orientation is negatively correlated with the use of prepared dinners and meats. In contrast, the “Cheap Gourmet” may feel that convenience foods are a good way to get inexpensive variety into the meals she prepares. This orientation is positively related to the use of convenience foods in recipes and with total convenience food use.

There were many significant correlations of the various types of convenience food use and strategies, particularly for married women. High usage of all types of convenience foods and total usage is found among the “Do Less” Strategy for both single and married women. Here convenience foods are alleviating work and helping in getting a job done that is seen as a waste of time. These women do not see anything special about the food preparation task. In contrast, the “Do It All” strategy is associated with lower usage of most products and total usage. The women using this strategy plan, organize and give up personal time to get the job done, rather than resort to using convenience foods. One other negative correlation was found between the use of prepared dinners and the “Food Bank” strategy where women using this approach would rather spend weekend time cooking than opt for grocery store meals.

In summary, single mothers who use a lot of convenience foods are likely to have low work involvement, lower family incomes, and dislike preparing food. For those who dislike and feel food preparation is a waste of time, convenience foods are found to be useful to meet their goals. However, those with quite a different food preparation approach, the “Cheap Gourmet,” may find convenience foods useful not so much to save time and work, but as an inexpensive way to enhance meals. For married mothers, total convenience food usage is highest among those who do not enjoy cooking and are experiencing work interference and stress and low life satisfaction. Married women with strategic approaches to doing less food preparation accomplish this through higher use of convenience foods. Others who have high commitments to doing food preparation themselves work harder and organize more and avoid convenience foods in their approaches. An alternate strategy only available to some women is to delegate the task to the husband who is handy in the kitchen.

DISCUSSION

The findings indicate that what women do in accomplishing food-related tasks can be identified as patterned around strategic approaches that are associated with orientations to the task and to work and family situations. The identification of these strategies is an important contribution of the research to the field of study. Moreover, it is important to note that there are many points of similarity in strategies used by single and married mothers. Both groups include those for whom food preparation is enjoyable and who are likely to cook in quantity to time-shift the daily food preparation chores. Both also have their disengaged members who work away from home more hours and do fewer food tasks, keeping things simple without worrying about it. The remaining groups of women are all highly engaged and trying many tactics to get a lot done. The “Harried Juggler” single mothers are very much like the “Crunch Time” married women, employing polychronic time use to balance work and family demands. However, the single mothers do not have the Do It All “Super-Mom” strategy seen among the married women. Perhaps, the single mothers are being more realis-

TABLE 2

Correlations of Strategies and Orientations with Demographic Characteristics, Convenience Food Use, Family and Work Situations and Outcomes

Marital Status	Strategy/ Orientation	Demographic	Work/Family Situation	Work-Family Outcomes	Convenience Food Use

	Do It All			Work interference (.14), Role Overload (.18), Time strain (.19), Life satisfaction (.12)	dinner (-.20), meats (-.19), in recipes (-.12), all (-.15)
	Food Bank			Work interference (.10)	dinners (-.13)
	Crunch Time	Family income (-.14)		Role overload (-.11)	
	Delegate	Personal income (.15)	Work involvement (.20) Hours (.16)		

tic here about what can be accomplished with one adult in the household. However, they do have their own high stressor strategies and orientations, including the Cheap Gourmet who wants great meals on a limited budget, and the Harried Juggler who works harder, sleeps less, and crunches time.

The research findings also suggest that some strategies are associated with different levels of stress and strain. High scores on work interference, role overload, and time strain were associated with several orientations and strategies. Since these are correlation measures, no direction of causation can be assured. However, in some cases, some speculation may be supportable. For single mothers, the "Harried Juggler" food preparation strategy has multiple associations with high stress levels. For married women, two apparently contrasting strategies, the "Do Less" and the "Do It All," were associated with high work interference, role overload, time strain, and stress. However, the latter was associated with high life satisfaction, suggesting a "Super Mom" typology who is satisfied with a "high octane" lifestyle. There were no negative correlations with any orientations or strategies for food preparation and shopping among single mothers. For married women, if the spouse takes on the food tasks and likes to cook, the wife feels significant reduction in all of the stressors and life satisfaction is higher. Interestingly, she may not actually delegate the food preparation to him, since this strategy was not associated with less stress, strain and overload. Rather, he may shop and they may cook together, or he may be involved in some other way with meal preparation.

For marketers of convenience foods, two disparate markets suggest themselves. Working women, whether married or single, do not rush to embrace convenience foods as a panacea. The most successful products in terms of frequency of use are those that completely eliminate most of the task of food preparation because they involve the whole meal. There is also a growing market for products that enhance the preparation of more complex dishes, making gourmet results easier and cheaper to obtain. This appeals to certain groups of women who are looking for unusual meals. Convenience food use is a way to decrease the task of food preparation among those who wish to do less and also by those who have a family focus. They are rejected by those who see themselves as high achiever "Super Moms" and by those who enjoy cooking. Positioning convenience foods as a means to increase time with family while still producing a high quality, high variety menu may remove some of the stigma that still appears to be associated with these products. However, it is clear that convenience foods are not the salvation for today's double-duty mother balancing work and family responsibilities.

The Meanings of Family Dinners for Young, Affluent Families in Urban China

Hongyan Yu, Jilin University
Alvin C. Burns, Louisiana State University
Ann Veeck, Western Michigan University

EXTENDED ABSTRACT

While in recent years the pace of life for urban Chinese families has become much busier, due to more competitive work and school, the family dinner remains a mainstay of daily family life (Veeck and Burns 2005). Exactly how do family dinners fit into modern life in China? In the face of hectic lives, why do family members continue to make time for family dinners and its associated tasks? To answer these questions, we conducted comprehensive, semi-structured interviews with a targeted sample of seventeen young, affluent families in Changchun, Jilin Province, P.R. China. Through these interviews, we hoped to illuminate the meaning of meals to family members and the role that home serves as a consumption site during times of change. by analyzing meals as family rituals.

Family rituals can be defined as patterned interactions among family members that are repeated over time and serve both an instrumental and a symbolic function (see Fiese et al. 2002 for a review). While rituals are naturally occurring events in family life, the extent to which rituals are practiced, as well as the manner in which they are conducted, have been found to be related to the health and well being of the family members. Rituals are influenced by changes that occur in the life course of families, such as changes in residences, work patterns, and family members (births, marriages, divorces, illnesses, deaths). In addition family rituals can be affected by forces external to the family, including social, political, and economic changes (Pleck 2000). During times of stress and transition, rituals can serve a central purpose in maintaining family relationships and roles (Bossard and Boll 1950). As such, studying family rituals is important for understanding how the home functions as a consumption site (Valentine 1999).

Family meals, in particular, can be viewed as ritualized, symbolic events that serve to reproduce social capital and reinforce family unity (Devault 1991; Douglas 1974). According to Wolin and Bennett's (1984) typology, family meals can be classified as "patterned family interactions," that serve to define the roles and responsibilities of family members and organize daily life. A number of important studies in the West have shown the importance of family meals in molding family identities and contributing to family unity. Further study is needed to investigate the role of family meals in maintaining family stability during times of stress and transition, created by both internal and external events.

Toward this end, we conducted semi-structured interviews with younger (parents <age 50), affluent (household annual income >30,000 yuan) families in Changchun. All seventeen of the interviews were conducted in the families' homes, to facilitate interviews of the entire family and to allow the research team to take photographs and collect observational data of the families' residences. The participants were asked a series of questions related to the routines, responsibilities, and affective responses that accompany their meals. The interviews were audio-taped, transcribed, and translated. To focus this inquiry, we analyzed family dinners as rituals, interpreting the data via the major components of rituals (see Fiese and Kline 1993).

The findings substantiated the importance of family meals in urban China today for fostering family identity, improving communication, facilitating socialization of children, and allowing the

transfer of social capital. We learned that family members view dinner as an important transitional time following work, allowing them a regular, defined period of time to relax in the stability of family life. Another important finding is that, even while the women perform most of the food tasks related to meals, men and women seem to place equal importance in the role of the family dinner for "producing family" (DeVault 1991). Men, in particular, often view regular attendance at family meals as a measure of the quality of a family. Finally, it should be noted that the smaller, three-member families common in urban China today allow for easier accommodation of all family members' schedules.

Food consumption patterns are an excellent window through which to view social change, in general, and family change, in particular (Mintz and DuBois 2002). In this study, the ritual of the family dinner serves to illuminate the routines and responsibilities of family members as they navigate between the outside world and home. The family members we interviewed continue to believe it is both their duty and their pleasure to convene as a family once a day and eat dinner together. However, as work and leisure activities continue to change in response to the socioeconomic environment, the patterns of the family dinner could be altered. As China continues to experience economic and social change, it will be worthwhile to monitor the status of the family dinner.

Foodsigns on the Highway of Life: The Semiotics of the Diner

Elizabeth Hirschman, Rutgers University

ABSTRACT

This inquiry examines a long-running retail form - the diner - from multiple perspectives: historical evolution as a commercial response to industrialization, an icon of modernism, a nostalgic symbol of retro-marketing and a site of consumer communalism and personal transition. Historical documentation, popular culture texts, consumer interviews and participant observation are utilized for constructing the analysis.

"Now this golden age is all but gone.... The highways have fallen into disrepair, superceded by freeways with no recognizable character. Many diners have served their last special, and a large number of ma-and-pa hotels have been swallowed up into chains.... Small towns, with the whole of life encapsulated on Main Street, are a far cry from the soulless shopping malls of today. And the cars - oh those glorious, gas-guzzling monsters - have been replaced by sensible, compact, economical models with dull names" (Moss, 2000, p. 7, *Diners: American Retro*).

INTRODUCTION

In this brief passage, Moss (2000) places the retail form known as the *diner* in the nostalgic epoch of the Fifties, together with small town shopping streets, state highways (e.g., Route 66) and gas-guzzling, chrome-laden automobiles (Flink 1975, 1988). While it is certainly true that diners evoke that mythic near-past of post-World War II Americana, it is incorrect to view them as a vanished or even fading retail form. Indeed there are currently 5,000 diners in operation in the United States, and they are even being exported to Western and Eastern European countries seeking to patronize this retro retail icon (Baeder 1995; Gutman 1993).

Our present inquiry seeks to serve two agendas. First, we extend the retro-marketing thesis put forward by Brown, Kozinets and Sherry (2003) to a consideration of how retailing forms may also serve as nostalgic icons for consumers. Second, we seek to direct theory construction toward the contemplation of retail forms as carriers of deeply metaphoric cultural meaning, rather than solely as profit-generating business ventures. Investigating the semiotic qualities of the American diner should help us achieve both goals.

FROM WHENCE THEY CAME: DINER EVOLUTION

In their recent article, Brown, Kozinets and Sherry (2003) present a theory of retro branding and then instantiate it using the Volkswagen Beetle reissue and "Star Wars: Episode One" as exemplars. Drawing upon earlier work by marketing scholars such as Penaloza (2000) and Holbrook and Schindler (1989, 1994, 1996), as well as their own inquiries (Brown 1999, 2001; Sherry 1990), these researchers develop a conceptualization which describes the anchoring of revived or retro brands in consumers' memories of the past - memories which are almost always tinted with feelings of warmth, security, simplicity and authenticity. As Brown, Kozinets and Sherry propose, brands associated with the past - whether historically grounded (Volkswagen) or mythically imagined ("Star Wars") - benefit from our personal and cultural tendency to bathe them in a utopian glow (Davis 1979).

Perhaps no retailing form is better positioned by its historic evolution and utilization as a popular culture signifying device to

exemplify retro-retailing than the diner. In this section of our inquiry, we present a selective overview of diner history and develop the thesis that diners evolved both functionally and semiotically as *icons of modernity*. Ironically, or as B-K-S would put it, antinomically, it is postmodern nostalgia for modernity that now serves to enhance the diner's appeal, both as an actual retail presence and a cultural icon.

Diners are Born

Diners came into being as a direct result of America's rush into modernity at the turn of the century. Urban manufacturing centers in the Northeast had become electrified, permitting operations to be conducted twenty four hours a day. Night shift workers - offered no food services by their employers - had been bringing boxed meals to the plant. Sensing a marketing opportunity, a man named Walter Scott began selling sandwiches, boiled eggs, pies and coffee to factory workers on the night shift in Providence, Rhode Island, in 1872. His restaurant-on-wheels, termed a night lunch wagon, was the forerunner to the diner (Gutman 1993).

The standardization and mass production of early stage capitalism soon encompassed the late night lunch wagon business. By 1891, Charles Palmer had patented his design for a night lunch wagon that would be manufactured in a factory assembly line procedure; his new model restaurant had a kitchen section and a dining room section containing stools or chairs for patrons (Gutman 1993). Affirming modernity, the production and consumption of meals had been wrested from workers' homes and relocated at their place of work.

By the early 1900's industrialization had spread to such an extent that three companies came into existence whose sole purpose was to mass produce lunch wagons - now termed *diners*: the Tierney Company, the Worcester Lunch Car Company and the O'Mahoney Company (Witzel 1999). Reflecting the modern ethos of standardization and efficiency, these mass produced diners had a stereotypical appearance:

Within this category one finds the classic diner structures exemplified by respected industry manufacturers.... Of course, all these came to life as distinct, self-contained units in a factory. Workers assembled the majority of their interiors, exteriors, and structures ahead of time. A truck or a train hauled them to their intended site of business, where owners connected them to plumbing and utility lines and opened for business. All the proprietor had to do was add the utensils and foodstuffs....

These portable eateries feature at least one or more of the standard interior and exterior components characteristic of the diner stereotype. One of the most important elements is that the overall design and layout of the dining building follows the lead of a train car (short or stretched). Regarding the roof, only a barrel-style cover or monitor treatment qualifies. At the same time, it's important that the building feature a preponderance of windows and a generous application of stainless steel or porcelain-clad panel. Preferred details include a Formica counter, private dining booths, pedestal-style stools, table-top jukeboxes, and a dramatic application of neon lights (Witzel, p. 6).

And yet, despite their standardized structure, individual units could be, and were, made distinctive by their proprietors using exterior signage and decorative motifs and offering unique 'house specialty' menu items; a feature we term *standardized authenticity*. In Brown, Kozinets and Sherry's (2003) retro terminology, this phenomenon of distinctiveness within conformity would serve as an example of antinomy.

By the 1920's and the emergence of middle-stage capitalism, the diner had come to signify not only standardization but also the embrace of technological innovation: it was an icon of modernism. As Gutman (1993, pp. 62-63) reports: "In interior appointments, innovation was the rule. A new emphasis on cleanliness and ease of operation was touted.... White tile floors were predominant. Countertops were often of white marble or white opalite, an opaque glass. Some... even had white metal ceilings. Behind the counter, all manufacturers offered a built-in refrigerator, steam table, gas stove, grill, dessert display cases, coffee urn and exhaust hoods fabricated of gleaming German silver, an alloy that was the precursor to stainless steel."

The 1920's - perhaps the core decade of American modernism - also witnessed the widespread adoption of the automobile and the construction of coast-to-coast and border-to-border road systems. The new national highway system was accompanied by motels, service stations and diners, all of which were intended to assist the modernist rush to personal mobility: social, geographic, and economic. Diners served 'home cooked food' hundreds, or even thousands, of miles from one's home (Gutman 1993).

The 1930's witnessed the introduction of aerodynamics into both popular culture and national ideology. Futuristic designs inspired by the possibility of space travel (e.g., Buck Rogers) and the reality of intercontinental air carriers and diesel locomotives led to widespread design mimicry in automobiles and, ultimately, diners. "By the end of the thirties, surfaces and textures were brushed, polished, rounded or wrapped (Gutman 1993, p. 113.)"

Materials generated by advances in technology and chemistry were quickly incorporated in diner design to further signify their status as icons of modernism; most important among these were Formica and stainless steel. The aesthetic effect was one of ultimate smoothness and glistening functionality. Art Deco was celebrated in many diner interiors as a series of stripes and circles of complementary colors; surfaces were sleek, unadorned and contoured.

By the 1950's, economic prosperity enabled families to dine out more frequently and to travel great distances on annual family vacations (Jewell 1966). Diners actively sought out family patronage by featuring 'children's menus' and offering more women and child-friendly interiors. Indirect lighting was used, Naugahyde cushioned booths were introduced, mirrors along the walls created a greater sense of spaciousness, and terrazzo floors replaced the tile floors of a decade earlier. Pastel color schemes softened and feminized the interiors, creating a more 'family friendly' aesthetic. Wood-grain Formica was used to create table and counter accents (Gutman 1993).

The Death of the Diner and Rebirth as Retro-Chic

By the close of the 1950's, however, the era of Aerodynamic Moderne with its commercial beacon, the diner, was coming to a close. Two intertwined events led to this demise. The first was the birth of fast food, carryout restaurants; the second was the institution of the interstate highway system. McDonalds served as the fulcrum of this retailing transformation (Love 1986). Mac and Maurice McDonald had been operating a successful drive-in restaurant on Route 66 in Arcadia, California. Following consumer preference for faster, more efficient forms of retailing, such as the

emerging use of self-service gasoline stations and express checkout grocery lanes, the McDonald brothers created a novel restaurant format which they termed the "Speedy Service System" (Luxenberg 1985). This was premised upon the same assembly line manufacturing process, emphasizing standardization and uniformity, that had birthed the industrial revolution and brought diners into being. Yet now, ironically, diners were made obsolescent by the ultimate expression of industrialization in the food service business. Further, unlike the individually owned and operated diners, fast food restaurants such as McDonalds and its competitors Burger King, Hardees and, later, Wendy's, were corporate chains, able to expand their assembly-line, standardized units nationally (Luxenberg 1985).

Concurrent with the advent of the fast food restaurant chain was a second key event - the Interstate Highway Program which was formalized in 1956 and called for "40,000 miles of widened, four-lane routes that would link together 90 percent of major US cities (Wirtzel 1999)." By their primary completion in the late 1960's, the interstate highway system had effectively created retail conformity from coast to coast, as interstates led travelers around downtown areas and toward the standardized off-ramp offerings of fast food restaurants, filling stations and regional shopping malls (Lewis 1980; Luxenberg 1985; Marling 1984).

In decline as a retail form during the 1970's, the diner re-emerged as a symbol of nostalgia for, of all things, *modernism*, during the 1980's and beyond. As one observer (Genovese 2002) noted, the 1950's became imbued with the "golden glow of yesterday," for despite their Cold War, atomic bomb, mass conformity dimensions, they were an era "when we lived in blissful ignorance; we just didn't know any better..."

Diners, because of their close association with modernism and its utopian sense of the perfectibility of the world, "came to signify something unique in the twentieth century. Through their unusual form and distinctive appearance, they had earned a special place in the hearts of the public. When you drove up to a diner, you knew what to expect: good, home-cooked food and plenty of it at a good price. Though a stranger, you immediately felt at home when seated at the counter alongside one of the regulars. Diners could bear a strong resemblance to each other and at the same time possess personalities of their own. The families that operated them... invariably put their own imprints on the food, the décor and the conversation (Gutman 1993, p. 170)." Or as Moss (2000) put it, diners meant "good and wholesome food, always (p. 23)...", "and the *whole* of society can be found in a small town diner (p. 50)," implying that the *soul* of society could be found in a small town diner, as well.

Even minute aspects of diner furnishings became imbued with a comforting, protective, home-like ambience. Kittel (1998, p. 5) writes: "The sense of comfort and cheer that any good diner radiates is an amalgam of the actualities of the diner itself - the blunt faces of the salt and pepper shakers, the menus above the grill with their square, white capital letters, the steam rising from the coffee urn, the clunk of cheap, solid china being slapped down on Formica - and of memory." The melancholy, luminous and utterly precise vision of Americana that only a diner can signify.

DINERS AS POPULAR CULTURE SIGNS

The second part of our inquiry deals specifically with diners as signs. We have argued that this retail form evolved to signify a certain epoch of American history; that of Twentieth Century modernism with its ethos of mechanized progress. Yet, with an ironic turn of meaning, it was the bypassing of diner modernism, with its small town and highway trappings, by the turbocharged innovations of fast food restaurants and interstate superhighways

that triggered the recasting of diners as a nostalgic relic of a 'bygone' (for thirty years) imagined age of innocence and simplicity. "Diners came to signify the time when apple pie - no longer home cooked by Mom, but baked even more deliciously at the local diner - could be had in the company of friends and companions, while lingering over a second, or even third, cup of percolated coffee (Kittel 1998, p. 32)." It was the place which was always safe, warm and inviting; where personal-favorite omelettes could be ordered twenty four hours a day; where the booth seats were comfortable and snug and there was no pressing urgency to be on one's way to somewhere else (Everett 2002).

This retro view of the diner - so at odds with diner origins and evolution as a modern retailing form - was (and is) encoded in multiple popular culture representations (Everett 2002). From television shows such as 'Happy Days' to 'NYPD Blue' to 'The Sopranos', diners are cast in key roles as cultural anchors and emotional touchstones (Everett 2002). Advertisers, as Genovese (2002) comments, have been quick to incorporate diners as contextualizers in commercials ranging from heartburn remedies to health insurance. But it is perhaps in motion pictures that their essence has been used most evocatively. For example, organized-crime films from 'Good Fellas' to 'Donnie Brasco' to 'Pulp Fiction' have called upon diners to create a blue-collar, urban ambience in which violence can be planned and even enacted.

Yet, more prominently, diners are cast in motion pictures such as "What's Love Got to Do With It" and "City Hall" as locales in which characters can meet and discuss deeply personal issues. They are used as safe havens and places of social intimacy. Let us briefly consider perhaps the centerpiece of the diner film genre: *Diner* (1982). Directed by Barry Levinson, *Diner* featured performances by the (then) unknown actors Kevin Bacon, Mickey Rourke, Steve Guttenberg, Daniel Stern, Timothy Daly and Ellen Barkin (Silverman 1989). The narrative was set at Christmastime 1959 in Baltimore, MD. Pointedly, Levinson placed his story at the close of the modern era, just as America was making its uneasy transition to the Sixties, that semi-mythical time when many social groups - Blacks, women, Gays, Chicanos - so long submerged beneath the Formica-clad surface of Fifties conformity - burst forth with their revolutionary agendas, challenging America's suddenly quaint and self-deluded view of itself as a 'fair and open' society.

Yet here at the fictitious Fells' Point diner, Levinson shows us a modernist microcosm collected together for the last time before entering the Sixties abyss. A group of five, sometimes six, white guys have graduated from high school and gone on their separate paths to adulthood. Six months have now passed and they have recollected at 'their' diner, in 'their' booth, and attempt to recapture their teenaged selves over coffee and French fries covered in gravy. Levinson presents the semiotics of diner-dom brilliantly: cigarettes are smoked (smoking was legal then); ketchup bottles are refilled by middle-aged waitresses clad in light green uniforms who write orders in pencil on white pads. The Greek diner owner wears a black suit and skinny necktie, yells at his non-English speaking cooking staff, and rings up customers on a manual cash register.

The interior and exterior features of the diner also are accurately evoked: the red, flickering neon sign, the crunchy gravel parking lot filled with streamlined Fords and Chevys, the brilliantly lit interior with its plastic-clad booths and sleek countertops, refrigerated dessert and salad cases, pale orange Naugahyde benches, thick, sturdy glass sugar pourers and heavy white crockery. Late at night, as the film shows, this was primarily a man's world. Businessmen and clumps of teenage boys gather in booths and at the counters, "not ready to go home yet," as one says. The diner was a refuge *from* responsibility, a haven *from* home, a place to go when

jobs, parents, spouses and children were too demanding. The diner provided a simultaneously communal, yet liminal, space. The characters communicated to us that this was only a temporary respite on their way to adulthood, yet we understood very well why they wanted tarry there a little longer.

As the film documented, the world outside the diner required a lot: adult sexuality, paying bills, making and then keeping commitments. How much better it was to hang out with one's pals, discussing which girls in high school were "easy," handicapping local sports teams, mooching food and reading the newspaper. And as was true for the Fifties, in general not much of note happens in the film - just regular people leading regular lives; life went on.

CURRENT CONSUMER UNDERSTANDINGS OF DINERS

Thus far our inquiry has considered the meaning of diners as seen by historians and creators of popular culture. From these sources we have gained insights regarding the economic and social evolution of the diner as a cultural signifier. Yet we are missing a central voice regarding diner semiotics - that of the consumer. How are diners seen, experienced and remembered by those who patronize them? What roles have diners played in their lives, if any? How do current customers utilize diners vis a vis available competitors such as fast food restaurants? What distinctions are seen as characterizing diners? To learn this, we conducted interviews with seven diner patrons, ranging in age from 11 to 51 and including four men and three women. The interviews were conducted at the informant's place of residence, audiotaped and transcribed under conditions of informed consent.

We supplemented these materials with visits to three local diners conducted over a two-week period and including day and evening, weekend and weekday visits. Here is what we gleaned *from* and *as* consumers.

The Diner as Cornucopia of 'Home Cooking'

Perhaps one of the great ironies - or antinomies - of the diner is that it is viewed by customers as a favorite locale for out-of-the-house 'home cooking.' This metaphor was expressed by informants in a variety of ways: "It's like going to grandma's house to eat, only better," "It's like they take normal meals and they make them special somehow." The home cooking available at the diner, however, was seen as superior to that actually available at home, or even at grandmother's, for several reasons. First, the normal rules of breakfast, lunch and dinner 'appropriate' foods were suspended. One could, for example, have dessert or eggs or waffles or spaghetti "anytime" - often 24 hours a day. So, diners were ideal for assuaging food 'cravings' or 'moods.' "I guess for breakfast I'll take a Spanish omelette with cheese usually, maybe a steak sandwich sometimes, whatever I'm in the mood for" (Jason, 22). "I get strawberry pancakes with fresh strawberries" (Ralph, age 51). "For breakfast... I had a cream cheese bagel and a Belgian waffle... for lunch I always have some kind of sandwich and dessert; I just pig out on dessert, ha, ha!" (Tommy, 11).

A second desirable trait of diner cuisine, according to our informants, was the sense that normal food quantity rules are also suspended. Diners serve very large portions and consumers seem to experience little guilt in eating the entire serving. "I can fill myself up for a max of \$15.... [At] a diner you get more of that homey quality meal thing" (Jason, 22).

One informant claimed hyperbolically that diners had "thousands of items on the menu;" she was overstating the matter, but not by much. It is the enormity of the selection combined with an emphasis on 'comfort foods' such as cheeseburgers, milkshakes,

pies and starches that contributes to diners' hedonic appeal. Although some informants reported that the typical diner menu was a prime example of confusing overchoice, most experienced the selection as delightful; an opportunity (like at the proverbial grandmother's house) to indulge whims, be spoiled and overeat in a guilt-free atmosphere.

Closing out our discussion of this theme is one final point. Not only were mealtime rules suspended, but a lenient, casual attitude toward customer dress and behavior prevailed as well. As 11-year-old Tommy put it, "I don't have to get dressed up or act stupid and fancy. I can just be myself... people don't care how I act at a diner. It's more comfortable." Emily, 25, elaborated on this same idea, "Employees at a diner are more lenient. At restaurants there seem to be more rules to follow. Like at a library, you have to be quiet. At a diner not every time do people order food. Many times people just go there to hang out and that is accepted.... Restaurants are more of a business." Significant here is the distinction that Emily draws between diners - which are accepting, relaxed and indulgent toward customers - versus 'restaurants' which she views as more formal, ordered and business-like. As we shall see in the next section, diners are seen to act in loco parentis for adolescents and teens making their transition from childhood-home to adulthood-public life.

Diners as Rite of Passage

As discussed earlier, the motion picture *Diner* (1982) portrayed the transformation of six self-indulgent 'boys' into responsible men; serving as the central set-piece, the eponymous diner of the film acted as the fulcrum for each set of moral challenges confronting the main characters. It was at their regular booth, over piles of food, that each dilemma would be communally addressed and mulled over. Although in the narrative occasional emotional trauma and even violence marred the characters' lives, within the safe stainless steel walls and beneath the bright fluorescent lights of the diner interior, no ill could befall them. It was a haven, a clubhouse, hideout and launching pad simultaneously.

Similarly, our informants expressed the same sentimentality regarding their favorite diners' role in their own lives. In essence, they viewed the diner as a home away from home: the indulgent middle-aged waitresses were Mom; the usually-ethnic, middle-aged, always-rushed owner/manager was Dad, and their 'crew' or 'posse' of friends were siblings.

"So how often do you go out to diners?"

Jason (22), "Well probably I end up there about twice a month now, but back in high school me and my boys would go at least three times a week.... [We] usually go really late at night - when nothing else is open.... The atmosphere is cool ... you can dress how you want, but still get good food."

Lorraine (50) recalls going to diners with her girlfriends in high school as "an important part of growing up for kids. All kids go to diners to hang out at one point in their lives.... It's almost like they [diners] are a part of the culture.... When I go there now, I look at all of the kids and remember when I was 20."

Often, in part because of these nostalgic recollections, customers would continue to return to "their" diner throughout adulthood:

"Do you ever think you'll stop going to the diner?"

Ralph (51), "Not unless all my friends stopped. I don't wanna go there by myself. But I think no matter how old I am, I will always have someone to go to the diner with...."

Diners are sites where intimacy is constructed in a public place. They encode a particular time in a given individual's life when she or he is venturing into the world, but does not yet want to fly solo. Diners also provide exposure to some of the ills and dangers of the outside world, yet in inoculating doses that strengthen, rather than sicken, the young adventurer.

Several informants spoke of occasionally seeing "drunks" or "scumbags" or "sleazy people" at their diner. Especially during late night hours, the flickering red and blue neon signs of the diner seemed to serve as a beacon to transients, cross-country truckers, deadbeats and drunks seeking a place to eat, rest, or sober up. The presence of such persons was seen as undesirable by adult patrons, but provided some sense of tantalizing voyeurism to the clusters of teenagers we observed. Intriguingly, cops and firefighters, coming off duty, would also arrive in the late night hours at the same diner as the vagabonds. Yet no hostilities broke out; it was as if everyone was taking a "time out" from their regular roles. The teenaged groups also engaged in some quasi-nefarious activities of their own. The most common of these was underage cigarette smoking. Stoked by contraband tobacco and legal cups of caffeinated coffee, heavily sugared milkshakes and desserts, the teenagers could linger for hours, their conversations intermittently exploding with loud laughter.

Diner Topography

Our observations of diners and their patrons also led to some insights regarding their topography, or internal space usage patterns. As shown in Diagram One, most modern-day diners have a distinctive layout.¹ First, from the exterior, they face the highway, their large neon signs calling to drivers-by. The door is placed at the center of a long, one-story building that has banks of windows along the front and side walls. A vestige of their origins as wheeled lunch wagons, even contemporary diners have small porches that must be accessed via steps in front of the entry door.

As one enters, generally the right side of the diner has booths and a counter with a row of stools/chairs. The counter service area is nearest the kitchen and generally floored in terrazzo or ceramic tile for easy cleaning. Smoking, if it is allowed, and drinking, if alcohol is served, usually occurs in the booth area immediately adjacent to the counter and stools. This high traffic area can be easily cleaned after a night of cigarettes and drinks before the morning breakfast crowd arrives. The counter stools are usually most heavily occupied at night and in the early mornings as truckers, cops and workmen stop in to grab a quick meal. The booths are most heavily used late at night by clusters of teens and college students who arrive en masse, eat large quantities of food and may linger for one or more hours.

Most modern diners are now "double-wide," providing room for a partition and a carpeted area with tables near the windows. Couples, senior citizens, mothers with children, and empty nesters generally choose to sit here. Perhaps visually the service may seem quicker, since these tables are within eyesight of the kitchen - as well as the dessert and salad display cases.

On the side left of the entry door is a "new" (circa 1970's) addition to the diner. This is a carpeted, less glaringly lit family area that features small and large tables (some circular) at which family groups can sit and enjoy an away-from-home home-cooked meal. These extended family gatherings usually occurred on weekends. Empty nest couples and business colleagues out for a working lunch would sit in this section, as well. In all the various seating areas,

¹Older, mass-manufactured diners have only a kitchen, counter service and booths.

however, the tables were clad in neutral or wood grain Formica, and the chairs were deeply cushioned Naugahyde. A distinctly postmodern addition at one of the diners was a salad bar located in the aisle separating the family seating area from the booth seating area. Though clad in 'diner-correct' stainless steel, the inclusion of a salad bar is a competitive response to chain restaurants that uniformly provide such an offering to consumers.

Yet, despite this nod to conformity, most diners still retain several of their distinctive features. Those we visited all were equipped with table-mounted jukeboxes in the booth-and-table area; available songs ranged from Fifties doo-wop to Billy Joel to Britney Spears. There were no hip-hop or hard rock offerings; likely these musical genres were not popular with the clientele. Two of the three diners visited still prepared soda drinks (e.g., milkshakes) and egg dishes directly behind the counter, permitting customers to see their food 'being made', especially if they were seated in a booth or at the counter. This feature adds to the homeyness of the diner, as it seems to make it more kitchen-like.

A final distinctive topographical feature of diners is their placemats. Once seated, each patron, regardless of where s/he is sitting, is issued a paper placemat. These 1940's-era accoutrements usually feature a pen-and-ink or photographic image of the particular diner in the center and have a border composed of small print advertisements for other local places of business (e.g., service stations). At each of the four corners of the placemats are tear-off coupons for, say, photo processing, dry cleaning, and so forth. Essentially, these seem to constitute a banding-together of small, independently owned, personally operated businesses in the area. Again, this reifies the iconic position of the diner as a hold-over from an earlier era in which small towns and their local businesses were seen as the core of American economic life.

What Diners Are Not

Finally, from our interviews and observations we gained some notions of what diners are not; or more pointedly, how they are believed to differ from other types of restaurants. For example, as one informant put it: "A diner is not Burger King," when pressed on this, he added, "'cause a diner has waitresses... people come, they get their coffee; they have plates and silverware. The feeling is just different... I love its (the diner's) variety and the way it smells... the coffee, the kitchen. Diners are diners."

A second informant characterized fast food restaurants, such as Burger King and McDonalds, as "shitty food that's dirt cheap; whereas at a diner you get more of a homey quality meal..." However, this same informant also made it clear that he did often eat fast food: "It's still food, and my ultimate goal is not to be hungry."

This same informant also contrasted diners with corporate chain restaurants, saying "[diners have] that community feeling; people I guess like the purity aspect - you know, it's not some big chain like Applebees or Bennigans.... It's more like going to someone's house for dinner, only you have a full menu to choose from.... You go to a diner for the experience, the chill feeling you get there."

Still, diners were often contrasted negatively to what informants termed "real" or "good" restaurants, i.e., those that were privately-owned and served excellent specialty foods. Though requiring more formality and adherence to stricter rules of behavior and dress, "good" restaurants were those chosen for special events, such as anniversaries, birthday parties and graduations. Diners were deemed inappropriate for such exalted occasions because they were, in fact, too home-like and therefore mundane.

DISCUSSION

Sherry's (1990) article on flea markets proposes a retail marketplace structure made manifest along two continua: formal/informal and economic/festive. He locates flea markets in the festive/informal area of this structure. Diners would be positioned within this same structural locale, as they are seen as casual and communal gathering places. What is also striking is that some of Sherry's (1990) informants voiced descriptions of the flea market that echo sentiments expressed by our informants about diners. One said, "The flea market is not as *sterile* as a mall. You don't get the same franchises over and over again. There's lots of different people around the flea market - it's more of a *social* atmosphere..." (Sherry 1990, p. 17)." And also echoing our informants' perceptions, Sherry's interviewees found some customers of the flea market to be "a sleazy element... people on the shady side (p. 17)." In essence, both diners and flea markets appear more representative of 'real life' with its oddities, authenticities, risks and rewards. The sterilized monotony and predictability of the shopping mall and fast food restaurant - with all their standardized perfection - offer only cookie-cutter experiences.

In keeping with Arnold and Reynolds' (2003) article on hedonic shopping, diners also seem to provide "enter-tailing" to consumers. That is, they provide "higher levels of service, highly-trained staff and an entertaining and fun retailing environment (p. 77)." With regard to the hedonic motivations identified by Arnold and Reynolds (2003),² diners would appear to be capable of satisfying the desire for *socializing* (spending time with friends and family members) and also for *self-gratification* (to relieve stress, improve a bad mood, treat oneself).

But perhaps most profoundly, the diner represents *retro-retailing*. Likely the longest running exemplar of modernism in retailing, the diner has now - in the era of postmodernism - become a simultaneously iconic and ironic statement of commercialized homeyness, of replicated authenticity, of multiplied uniqueness. Each diner is idiosyncratic, individually owned, personally named and carries a (somewhat) distinctive lineup of foodstuffs; yet because of their mass-manufactured format, their standardized aesthetic and their uniform meaning in the minds of consumers, each diner signifies "the" diner. As Brown, Kozinets and Sherry (2003) remind us, diners are among that select group of commercial entities that have a "vital essence" and "have existed as an important icon during a specific developmental stage for a particular generation or cohort (p. 30)." Diners have served as places of passage for generations of American consumers since the early 1900's; they will likely continue to carry on this role as long as there are teenagers to claim them, and adults to reminisce.

Consuming, Studying, and Regulating Genetically Modified Foods: A Case for Transformative Consumer Research

Ahmet Ekici, Bilkent University

ABSTRACT

ACR 2005 North American Conference calls for Transformative Consumer Research (TCR). Based on the principles of TCR, the objective of this paper is to provide a platform to involve consumers more directly with public policy issues related to food biotechnologies, so that this technology can actually make positive impacts on consumers' lives, both present and future generations. More specifically, through an iterative and rigorous multi-stage research design, we aim to provide valuable insights for consumers, for the academic community, and for public policy makers with respect to genetically modified foods.

INTRODUCTION

ACR 2005 North American Conference calls for Transformative Consumer Research, TCR. TCR aims to "make a positive difference in the lives of consumers, both present and future generations, through the chosen focus and conduct of specific research, and in the communicating of its implications and usefulness" (ACR 2005). An ideal TCR is one that both scientifically rigorous and practically useful to consumers. In addition, TCR aims a heightened relevance and value related to consumer research to business executives and public policy administrators (ACR 2005). Based on the principles of TCR, the objective of this paper is to provide a platform that involves consumers more directly with public policy issues related to food biotechnologies, so that this technology can actually make positive impacts on consumers' lives, both present and future generations. More specifically, through an iterative and rigorous multi-stage research design, we aim to provide valuable insights for consumers, for the academic community, and for public policy makers with respect to genetically modified foods (GMF).

This paper clarifies consumers' perceptions of the food system and particular elements of the system with respect to food safety in general and food biotechnologies in particular, and provides consumer input for the policy issues surrounding the future of genetically modified foods. Understanding consumer perceptions of this technology can have important global ramifications. Agriculture and food applications of biotechnology promise solutions for feeding an ever-growing global population. This promise may particularly be important to underdeveloped countries where there is an immediate need not only for increasing productivity in agricultural output but also for nutrition-rich food. Consumers' views in developed countries (where most biotechnology research is conducted) are likely to affect the extent to which public and private organizations commit to biotech research. For example, consumer reactions toward GMF in many European countries have reduced funding for biotech research over the last two years (ISIS Press Release, 2001). Private organizations conduct and therefore control most biotechnology research and its outputs (including various consumer products). Even though many underdeveloped countries look favorably upon food and agriculture applications of biotechnology, it will still be in the hands of consumers in developed countries to encourage or discourage biotechnology research. Results of this study can provide much needed consumer voice in the biotechnology policy debate, and in the long run our findings can contribute to regulation and communication efforts.

The policy issues (e.g. communication, education, and regulation) of GMF can be seen as a problem of the government, biotech researchers, seed/chemical companies, farmers, food producers, retailers, environmental groups, and mainstream consumers. We argue in this paper that in the heart of all these interest groups lie ordinary consumers. Once consumers' problems are identified and addressed then other interest groups' problems may be addressed adequately and fairly. Further, treating the issue as a problem of mainstream consumers would have advantages to remain "neutral."

When identifying and addressing policy problems (of consumers in this case) there seem to be two fundamentally different approaches. Those who favor the "engineering model" view social science as a means of providing technocratic solutions to problems. A problem—whether pollution, poverty, alcohol, or tobacco—can be safely agreed to be a "bad" thing by all, and the social scientist is then brought in to treat the problem in the manner that the doctor diagnoses illness. The employment of such engineering models can be disconcerting and perhaps dangerous if the social scientist points out the "right" course of action when there are conflicting interests, lack of consensus, social cleavage, and (international) political conflicts surrounding the problem (like in the case of GMF). In such cases, the "enlightenment model" can accommodate better in establishing the role of researcher who attempts to provide an intellectual background of the problem using the domain of his/her discipline.

Morris Janowitz argues that the social scientist is part of the process which he or she is studying, not outside it. In other words, under the enlightenment model it is assumed that the social scientist recognizes that he/she is interacting with his subject and a variety of publics to which he must be responsible. His work has an impact on himself, and his findings influence his subjects and his public in an ongoing fashion. The enlightenment model assumes the overriding importance of the social context, and focuses on developing various types of knowledge that can be utilized by policy-makers and professionals. "While it seeks specific answers its emphasis is on creating the intellectual conditions for problem solving" (Janowitz 1972, p5-6). Research (of enlightenment model) provides the intellectual background of concepts, orientations, and etc. that inform policy. It is used to orient decision-makers to problems, to think about and specify the problematic elements in a situation, and to get new ideas. Policy-makers use research to formulate problems and to set agendas for future policy actions. Much of this use is not direct, but a result of long-term infiltration of social science concepts, theories and findings with the general intellectual culture of a society.

OBJECTIVES OF THE PAPER

As stated earlier, the broad objective of this study is to investigate consumers' views of and expectations from various key social institutions of the food system with respect to food safety and food biotechnologies in order to provide background information and insights to public policy makers with respect to the regulation efforts of food biotechnologies. These social institutions include regulatory agencies, food manufacturers, farmers, the scientific community, consumer activist groups, and media. Since we are following the footsteps of Janowitz (1972) and adapting the enlight-

ement model for social knowledge, we first seek to obtain information about the “background” of consumers. Table 1 provides information about the specific objectives of this paper.

METHODOLOGY AND METHODS

Our research is based on focus groups and in-depth interviews with consumers on topics surrounding GMF. The research design used in this study is an adoptive and emergent one. In other words, the design unfolds as fieldwork unfolds and the emergent nature of the design affects decisions regarding sampling, data collection and analysis. Our design involved a three-stage data collection process. The first stage involved seven depth-interviews with consumers in a Midwestern state on their awareness, beliefs and attitudes toward GMF. For the first study conducted in 2000, we sampled relatively educated consumers because at this time both academic and popular press noted consumers’ awareness of GMF was very limited (Kilman 1999). By 2001 consumer awareness of GMF had increased from 12% in 2000 to over 70% largely due to the Starlink[®]-corn fiasco and debates on stem-cell research. Therefore, our emergent theoretical perspective on factors that influence beliefs and behaviors related to GMF drove sampling decisions for the second stage. We sought to include informants with diverse orientations to GMF based around underlying differences in family stage, health concerns, social and political beliefs. The second stage involved 17 depth-interviews and four focus groups conducted in four different cities in Western and Midwestern states to understand in detail consumers’ view of food safety and their expectations from various institutions they see as responsible for food safety. The third stage was conducted in 2002 and involved 10 depth interviews focusing on uncovering consumers’ trust in the quality and safety of their food and whether and how that is related to GMF and institutions they identify as playing a role in food safety.

Data analysis was a process of gradual induction. Analysis of textual data proceeded through two distinct stages of iteration: intra-text and inter-text (Arnold and Fischer 1994; Spiggle 1994; Thompson 1997). Intra-text analysis asks a set of questions to identify the codes and categories of the findings. Once codes and categories have been identified, the researcher uses inter-textual analysis to look for patterns of relationships within different interviews (Thompson 1997). Thus, intra-text analysis addresses the extent to which general themes are shared by different respondents, and patterns of difference.

FINDINGS

The data gathered throughout the course of this research are exhaustive. Findings we report here, however, due to page limitations, will be an abbreviated version of the data. We intend to summarize the data mostly using tables and save the space for discussion.

Stage 1

Our specific objective in stage 1 was to identify consumers’ knowledge, conceptualizations, overall views, and concerns about these products. We have identified more than twenty categories of the findings, however; due to page limitation, in this section we focus on the following a few themes.

- a. Even though consumer knowledge and awareness of GMF is very limited, they still speculate, guess, and make assumptions as to how genetic modification of foods could be done.
- b. Consumers don’t seem to have well articulated preferences for GMF products. As a result consumers do not

have clear categories of these foods. They are ambivalent and confused. This confusion seems to affect consumers’ potential concerns about various types and applications GMF products.

- c. GMF products create ambiguous consumer experiences (both in terms of product attributes and information environment) and consumers seem to use various types of analogies in making sense of their ambiguous experiences. This tells us several very interesting things about how consumers draw inferences to novel product categories (Mick and Fournier 1998) as well as their constructive choice processes (Bettman, Luce and Payne 1998). Like Mary Douglas’ penetrating discussion of food that is dirty or clean (see Douglas 1966) and Levi-Strauss’ (1975) classic distinction between raw and cooked food, our respondents seem to have constructs about food and food safety that they use in making decisions about this new food category.
- d. Consumer education may not result in behavior change. One may argue that through provision of verbal information consumer can be “taught” about the facts of GMF and this education could benefit the providers in the long term. However, as we found out, consumers tend to link attributes of GMF to some (intended or unintended) consequences, and further linked these consequences to deeply held and enduring personal values. When these personal values “disagree” with the providers’ intention, it seems very difficult (if not impossible) to make any change in consumers’ beliefs and attitudes toward such food applications.

Stage 2

The findings of the first stage suggested that a more comprehensive and holistic look at the potential public policy issues surrounding these products may be beneficial. For example, the finding that consumer know very little (if not nothing) about GMF makes it very difficult to identify specific regulation (such as labeling) questions. When level of awareness and knowledge is very limited, consumers seem to use their experiences in other technology and/or food products and transferring this existing knowledge to this new yet unknown domain (a type of analogical learning). In order to provide a more detailed information environment for policy decision maker, one should try to understand these broader associations and linkages consumers make with GMF products. Therefore, the specific objective of the second study is to understand consumer background not particularly on GMF but on other related issues. These issues are numerous. However, based on the findings of the first study, we focus on consumers’ overall food purchasing concerns, and consumers’ views on food safety.

Consumers’ Food Shopping Concerns:

Table 2 is the summarized version of responses consumers provided as their most important concerns in food shopping. Identifying consumers’ food shopping concerns can provide insight into priorities consumers have when they purchase food products. We can have a general understanding regarding what consumers are looking for when they purchase food.

Consumers’ Concerns about Food Safety:

Although Table 2 offered some insights into the degree to which consumers are concerned about their food supply, we could still know little if we don’t look at the elaborated responses to consumers’ view on food safety. In other words, Table 2 suggests that consumers didn’t seem to worry too much about health and safety aspects of the food they purchase. However, there is still

merit in examining consumers particular food safety concerns. Such an examination can provide information regarding the sources of consumers' suspicion and/or confidence about the food they purchase and consume.

Stage 3

The objective of stage three was to explore in detail consumer trust and distrust in social institution and in the food system. In this section, we first report our findings related to consumer trust and distrust in social institutions¹ and then we report consumers' views of the food system.

Trust in Social Institutions: The analysis of data reveals that trust in social institutions can be categorized mainly into two: confident beliefs that are based on competence/assurance (CA), and the beliefs that are based on faith and hope (FH) in particular institution. The CA aspect of trust can be characterized as knowledge and experience-based trust and therefore, more to do with consumers' own (and perhaps direct) experiences with the target of trust (e.g. manufacturers). In other words, buying (using) particular brands for years gives informants a first hand experience/reason to trust the manufacturers of these brands. Similarly, knowing that government enforces rules (such as limits on chemicals use or crop

rotation) once again gives the informant a first hand reason to trust government. FH-based trust, on the other hand, is characterized as more perception-driven, indirect experience and generalized expectations with the target of trust. For example, informants can trust farmers based on the perception that farmers would not see food as a commodity and care more about the land, the earth and ultimately about consumers. Table 4 provides details about the types and sources of consumer trust in social institutions.

Distrust in Social Institutions: Coding and analysis of data reveal that there are mainly three categorizes of distrust: skepticism/cynicism-inducing distrust (SC); fear-inducing distrust; and vigilance/ watchfulness-inducing distrust (WW). Similar to those of sources of trust, informants' distrust in social institutions is mainly direct and indirect experience-based. For example, the source of distrust in media can come from direct experiences (e.g. watching inconsistent health reports in the news media for years). At the same time, consumers can have perception driven distrust (e.g. believing that most research in universities is done through grants provided by "big business" and therefore biased). Our data analysis revealed that the informants develop a number of coping mechanisms in the presence of distrust (regardless of whether based on direct or indirect experiences). We categorize these strategies (consequences of distrust) into three: skepticism/cynicism (SC), fear, and, vigilance/watchfulness (VW). Fear-inducing distrust is conceptualized as repeated and long-term experiences of suspicion that leads to great concern about the safety of food supply. When a respondent's distrust is fear-inducing, he/she intends to completely

¹Due to page limitation, only a general framework for the findings of institutional trust and distrust is presented here. Detailed excerpts for each category and code listed in Table 4 and Table 5 are available upon request.

TABLE 3
Concerns About Food Safety

Resp.	Worry about food safety?	Rationale
1	Yes: things at home in the fridge No: things in grocery store	
2	No	Check the dates, Everything is safe
3	No	Pick, wash, cook properly
4	Yes	Not natural, insecticides
5	Yes: things in the fridge No	Stays long time (e.g. mayonnaise) Cook really good, don't eat rare.
6	Yes: when there is a scare No: (mostly meats)	Buy fresh
7	Yes: things sitting out too long	Can spoil
8	No	Have faith in supermarkets, government, and I know how food is prepared
9	Yes: when hear on the news	
10	Yes: things at home for long time No, in general	May past expiration date
11	Yes: (meat and milk)	May past expiration data
12	No	Trust supermarkets
13	No	Usually eat healthy
14	Yes No in general	When I cook the food
15	Yes (meat) No	Texture, smell, fat, the blood, all gross Don't eat meat
16	No	" I" buy and store my food, know where its been
17	No	Trust people to make food correctly

disregard information that comes from the target of distrust. The difference between SC and VW is that with VW-inducing distrust, informants are able to provide particular methods/strategies that help them deal with the distrust-creating situation. In other words, when distrust is VW-inducing, informant becomes active (i.e. they take an action) to overcome the situation that created distrust in the first place. For example, when an informant believes that a big food manufacturer should be distrusted because they are unable to prevent bacterial contamination (coded as VW-inducing distrust) then she takes an action and decides to buy ground beef from the grocery stores who grind their own meat, instead of buying as already grounded from big meat manufacturers. Table 5 provides more details about various types and sources of consumer distrust in social institutions.

Trust in the Food System: With respect to food system beliefs, our findings are intended to illustrate the range of beliefs and behaviors associated with food safety in general and GMF in particular among U.S. Midwestern consumers. Table 6 provides a summary of the types of informants who rely (or not) trust and

distrust for food safety. As can be seen in Table 6, many informants look at a "system" for food safety. Some of them (two columns on the right) trust the system, and some of them (first column on the left) distrust the system. However, as can be seen in Table 6, not all of the informants rely on a "system" to ensure the safety of the food. For some informants, trust in one institution (e.g. the watchdog or a high authority) can be sufficient to feel safe about the food. Similarly, for some respondents, distrust in one institution would be sufficient to feel unsafe about the food supply. In addition, some informants do not rely on trust/distrust when they think about food safety. They have other ways to ensure the safety of the food they eat.

DISCUSSION

Our objective in this paper is to utilize a multiple-stage *Transformative Consumer Research* to provide insights for consumer, for consumer researchers and for public policy makers. In the following sections we offer some concluding remarks about our findings.

TABLE 4
Trust in Social Institutions

Target of Trust	Type of Trust	Sources of Trust
Manufacturers	Competence/Assurance	Competence through brand names and expertise Through inspection of products through packaging: packages product, inspected product Accountability Confidence through product testing
	Hope/Faith	Fiduciary obligations Benevolence Reputation to hold (perceived check and balance) Their business to take care
Government	Competence/Assurance	Enforcement of rules Sufficient regulations Overseeing industry operations, watching the companies Enforce recalls of problem products Government research process Motive is ensuring public safety (no profit motives)
Scientific Community	Faith/Hope	Intentions are good (to make food safer) Technology is both for producer and for consumers
Consumer Groups	Competence/Assurance	Objective, consumer oriented motives, non-profit nature Credible source of information Public education efforts
Farmers	Faith/Hope	They see food not just as commodity (closer to production, different meaning to farmers) It is their business to keep (by offering healthy products) Won't produce things that are harmful to consumers) Doing their best for humanity
Media	Faith/Hope	Relies on press to be a watchdog Reliance (making food news available)

For Consumers:

In spite of their low awareness and limited knowledge on the issue, our informants are able to make elaborate distinctions among various genetically modified foods. In the case of GMF products, consumers do not have well articulated preferences and therefore, they construct their own categories that can help them identify their preferences. This is consistent with explications of constructive consumer choice processes (Bettman, Luce, and Payne 1998; Coupey 1994). Due to a lack of cognitive resources to generate well-defined preferences consumers tend to “construct” categories and identify preferences based on these “constructed categories of preferences” (Bettman et al. 1998, p. 187). Consumers are most likely to have well articulated preferences when they are familiar and experienced with the preference object, and the rational choice theory (Wright 1975) is most applicable in such situations.

At the very aggregate level, consumers see differences (make categorizations) between genetically modified meat and genetically modified plants. This categorization is important because, it appears that consumers use such categorization to assess how and to what extent they would be concerned about the fact that the food is genetically modified. They raise both health and moral issues as the bases for their categorization. It is also apparent that consumers use these categories to shape their GMF behaviors.

As evident from our interviews, consumers with very little knowledge of GMF products draw on existing categories to con-

sider how to respond to these foods. This tells us several very interesting things about how consumers draw inferences to novel product categories (Mick and Fournier 1998) as well as their constructive choice processes (Bettman et al. 1998). Like Mary Douglas' penetrating discussion of food that is dirty or clean (see Douglas 1966) and Levi-Strauss' (1975) classic distinction between raw and cooked food, American consumers have meaningful categories about food and food safety that they use in making decisions about this new category of GMF products.

One interesting distinction of several of our informants parallels Mary Douglas' (1966), but expands her categories to include “junk food.” American food that is labeled junk food has the peculiar characteristic of making consumers indifferent about the actual ingredients of the food. That is, once consumers view a food category as “already polluted” like junk food (the hygienic component of the pollution theory), then they might perceive that category as less threatening even if the foods within that category include genetically modified ingredients. This is an interesting finding considering some “junk food” producing companies like Frito-Lay and MacDonald's have recently elected to cut their “bio-tech” corn and potato suppliers assuming that consumers would be concerned about the ingredients of their products.

One of the most interesting aspects of our study was to uncover consumers' reactions to GMF products when they find out that they have been consuming GM foods for a long time. The basic informa-

TABLE 5
Distrust in Social Institutions

Target of Distrust	Consequences of Distrust	Sources of Distrust
Manufacturers	SC-inducing	Unjustified practices (e.g. the use of antibiotics)
	Fear-inducing	Hide information from consumers, cover things up Motivated by greed Immoral motives
	VW-inducing	Big operations can get out of hand out of control Insufficient prevention of contaminations
Government	SC-inducing	Setting low standards for food safety Setting wrong farm/food policies Surface treatment of problems (not creating real solution to problems)
	VW-inducing	Insufficient inspection of food products on the market Slow responding to reality Non regulated areas of food production
Scientific Community	SC-inducing	Creates suspicion about food quality (limiting consumer choice) Questionable findings (one-sided research) Arrogant scientists (some scientists have blinders) Research funded by big business (results skewed)
Consumer Groups	SC-inducing	Sometimes deal with unimportant issues They can create misinformation which is damaging for society Overdo things (overreact to things)
Farmers	VW-inducing	The use of potentially damaging substances in food production Overdosing chemicals (financial pressures, profit motives)
Media	SC-inducing	Irresponsible reporting (can be more damaging to society)
	Fear-inducing	Too many reports on food/health (not worthy of attention)

TABLE 6
Trust, Distrust, and Beliefs About Food Safety

Column 1	Column 2	Column 3	Column 4	Column 5	Column 6
System Distrust (Distrust Reinforcing Properties)	Distrust a particular component	Do not rely on trust or distrust	Trust a particular component	System Trust (Trust Reinforcing Properties)	System Trust (Offsetting properties)
Perceived negative synergetic interactions among the components of the system	Incompetent (weak) watchdog	Up to the consumer to ensure the safety of the food. Don' t have to trust	Competent (strong) watchdog	Perceived positive synergetic interactions among the components of the system	The use of balancing strategies

tion that we provided to the informants midway through the interview was that the majority of grocery items are already genetically modified. The responses to this additional information can be summarized in one word: “surprise.” As indicated earlier, most consumers believed that they weren’t eating any GMF products. More elaborate response categories to the new information are “ignorance,” “irritation,” and “making peace with the current condition.” Overall, our informants didn’t indicate a resistance to the current situation. They provided various reasons why they would continue buying these foods even though now they know these foods are most likely genetically modified. These reasons (we call them “sources of comfort”) are “the practice of food safety,” “maladaptive behavior,” and “trust in systems or social trust.”

For Academicians:

We believe that approaching policy research through the enlightenment model can lead to the discovery of various important questions of social sciences. More specifically, we believe that our findings are closely linked to various fundamental consumer behavior concepts and theories, and therefore can open up perspectives and newer ways of thinking about these concepts.

First, as indicated earlier, GMF consumption creates ambiguous experiences. Literature on ambiguous experiences suggests that when there is ambiguous evidence about the product performance consumers rely on advertising (ad-induced expectations) in making consumption decisions (Deighton 1984; Hoch and Ha 1986). Similarly, providers of these technology (food) products have mainly relied on traditional means (advertising and opinion leaders) of “reaching” consumer. For example, advertising campaigns in UK and in the US aimed at “teaching” consumers various benefits of and “easing” consumers’ possible concerns with these products. Ever growing concerns about these food products (both in UK and recently in the US) may suggest a different process consumers go through when they learn and make decisions about such products.

Second, we argue that the adoption decisions surrounding these products pose challenges for innovation researchers. The innovation-decision model (Rogers 1995), and correspondingly most innovation research, is grounded in the assumption that individuals seek for information, go through persuasion, and make adoption or rejection decision about the innovation before any kind of experience with the innovation/product. The innovation-decision process seems to overlook the individual’s potential “unconscious” experiences with the innovation *during* the knowledge, persuasion, and decision stages. Since these GMF products have already replaced the existing ones (according to a USDA survey, approximately 70 per cent of all food in grocery stores are already genetically modified) and hence consumers have already been consuming (have unconsciously adopted) them, the decision-making regarding further adoption (continuation) or disadoption (discontinuation) may be different. We believe that studying consumer of GMF would provide an understanding to these direct experience-based innovation-decision making processes.

Third, as the findings suggested, consumers seem to go through an analogical learning when they try to deal with GMF products. Our conceptual understanding of analogical learning has been limited to technologically complex and less fundamental product categories (e.g. Gregan-Paxton and Roedder-John 1997). However, when we deal with learning about products that are not only technologically complex (making most consumers novices and naives) but also its consequences are ambiguous (the “true” consequences cannot be determined), the frameworks such as Gregan-Paxton and John (1997) might not be sufficient. Further, genetically modified “food” is a prime example of a socially and culturally

fundamental product category. We argue, in such situations, there is scope for studying consumer learning in its broader context to include social and cultural impacts.

Our findings offer valuable insights about the concept of trust and distrust. The findings suggest that public trust in various social institutions may be conceptually different, coming from different domains. For example, when an informant says “I trust government” this, according to the findings, is not exactly same as when he/she says “I trust farmers.” In other words, trust in government and trust in farmers may come from two different directions, while the source of trust in government is mostly confidence based (and therefore, based mainly on direct experiences), trust in farmers is largely faith based (based on indirect experiences, perceptions, and inferential beliefs). This finding is important and should have implications for research that aims at “measuring” public trust in social institutions.

Further, the finding that informants trust various social institutions based on different domains may suggest different strategies for these institutions to reinforce public trust. For example, since trust in government has been mainly identified as confidence based (and therefore, based on direct experience and exposure with the government’s activities), it may become crucial for governmental agencies to have direct and clear communication with the public in policy design and implementations. Encouraging the public’s direct participation during the policy debates, and communicating the results of enforcements with the public (in the form of product recall, bans, and so forth) appear to be effective strategies government agencies can use to enhance public trust.

The findings with respect to distrust in social institutions are important for many reasons. First, as argued earlier very little attention has been paid to the concept of distrust. In addition, most research has treated trust and distrust as mutually exclusive constructs (conceptualize distrust as the negative of trust and assumed low levels of trust would indicate distrust). Our findings suggest that this notion in fact may not be correct and individuals can have both trust and distrust toward the same target at the same time. The idea of simultaneous existence of trust and distrust has been conceptualized (e.g. Lewicki et al 1998; Luhmann 1979), but relatively little empirical evidence had been produced in its favor.

We believe this study is one of the first empirical studies that deals with the concept of distrust. The qualitative nature of the study makes it even more useful in that it empirically identifies three dimensions (in the form of consequences) of distrust within which social institutions of the food system can be viewed. From a practical point of view, identification of these dimensions could potentially help design strategies to reduce citizens’ distrust in various institutions.

For Public Policy Makers:

Some of the broad public policy implications of the study has been implied in the preceding (“for consumers”) section. First, from the public policy point of view, consumers’ meaning making about GMF products seems alarming. Consumers tend to think that such food safety practices as cooking and washing can take care of potential negative health consequences of consuming these products. Similarly, it appears that consumers are making analogies between GMF and other food categories (e.g. junk foods). Parallel to Douglas’ (1966) account of dirty vs. clean food, consumers seem to believe that such food categories as “junk foods” are already “polluted.” Therefore, marginal (potential) danger of GMF seems ignorable.

When we connect the findings of stage 1 and stage 2, we observe that consumers’ views on GMF products are closely related to broader issues such as how they view food safety, technology,

and the interaction between food and technology. From the policy point of view, it is imperative to identify such linkages and focus on the impact of such linkages to consumer learning, unlearning, and fail to learning.

Further, stage 2 suggests that consumers are preoccupied with the cost of the food and rely (and trust) heavily on the integrity of the providers and regulators of these products. This further suggests that consumers expect a well-integrated and open communication among various types of providers and regulators to ensure the safety of GMF products. Consumers seem to extend a time credit to providers and policy makers in order for them to act in the best interest of the consumers.

Now, we would like to conclude this paper with a few specific implications of GMF policy debates. The main biotechnology debates are over the novelty of modern genetic engineering, debate over pre-release testing, debate over labeling, constitutional debate, and debate over transparency (public information). In addition, there are two fundamental debates that shape the current regulatory regimes on agriculture biotechnology applications: debate over substantial equivalence doctrine and debate over the precautionary principle.

Perhaps the most important implication for public policy of GMF comes from the finding that, as opposed to the existing views on the subject, the relationship between consumer trust/distrust in the food system and their beliefs about the safety of GMF may not be strong. For example, those who trust the system (e.g. Amanda) can still strongly demand labeling for GMF for many other reasons such as ecological, moral, and ethical reasons. At the same time, a respondent who distrusts the system (e.g. Pam) would not have health/safety related concerns with GMF.

Our study also suggest the importance of designing public policies by distinguishing between health related and other social, economic, ecological and moral concerns consumers have about GMF. Thus, regulatory agencies should broaden their scope of what is a reasonable regulatory regime for GMF. Our findings suggest there is not a failure of trust among the American public as regards regulatory agencies' dealings with GMF and other food safety issues. This is in contrast to findings in other countries and consistent with previous quantitative results. However, we find consumers favor a precautionary principle rather than a substantial equivalence doctrine as a foundation for regulating GMF, primarily because of non-food safety issues associated with GMF. The substantial equivalence doctrine was adopted by the US, Canada, and Japan following the OECD-Edinburgh Conference. However, currently the US is the only country that still relies on this doctrine to regulate GMF. EU has always been skeptical, and recently both Canada and Japan have decided to reexamine and change their underlying foundation for regulating GMF.

In addition, more research should be funded by the federal government. As one of our respondents (Pam) suggested, she would have like to see more research be done through "independent academicians" who are purely funded by the federal government. Independent academic research sponsored by the federal government is an essential component of a protective regulatory system. Unfortunately, the federal agencies that fund scientific research are not the agencies that need it for regulatory purposes. Of the three agencies with primary responsibilities for regulating GM foods, only USDA has a significant program for supporting academic research, and as Gutterman (2000) argued in her recent article, the USDA is devoted primarily to developing new applications of biotechnology, not to discovering the adverse health and environmental effects of the products of the new technologies. I believe that, in order to boost consumer trust in the scientific communities, the US Congress, for example, should create a separate program

through the EPA to fund research on the potential environmental effects of GM crops and animals. As suggested in this paper, it is possible that such interactions between government and scientific communities (consumer perceptions of positive synergetic interactions) can also boost trust in the system.

Finally, our study suggested that informants see "industry" as the key player of their perceptions of negative synergetic interaction (distrust reinforcing properties) among the component of the system. At the same time, some informants see government as very important component of their confidence in the food safety system. As a result, we suggest that that public education programs should be prepared and run by governmental outlets (e.g. NPR or PBS). A relatively successful example of this suggestion was executed about two years ago. "Frontline" and "Nova" combined their efforts to produce *Harvest of Fear* aired on PBS in the fall of 2000, incidentally during the most intense days of the Starlink[®]-corn fiasco. According to the critics, the program was "a better presentation of the controversy surrounding biotechnologies" and applauded even by the opponents of the biotechnologies (McCullum 2001)

SPECIAL SESSION SUMMARY

Culture and Cognition: The Case of Irrational Beliefs about Luck

Rashmi Adaval, Hong Kong University of Science & Technology

SESSION OVERVIEW

*Fortune is merry,
And in this mood will give us anything.
- William Shakespeare*

People often attribute life's vicissitudes to luck. Such attributions are particularly common among certain Asian cultures where fortuitous events are regularly attributed to luck or fate. Even if an event occurs randomly, individuals' implicit beliefs about luck might lead them to contradict the claim that this event occurred purely by chance. Further, anecdotal evidence suggests that people are also irrational in their interpretations of situations involving luck or chance. For example, some poker players talk to the dice before throwing it (Hayano 1978) perhaps believing that they can influence the outcome. Yet, the systematic investigation of why people behave in these ways has received scant attention from researchers.

Beliefs about luck play an important role in a number of consumption situations. For example, shoppers in Hong Kong pay very high prices for license plates that are considered lucky (Vanhonacker 2004) and a large number of retailers use the lucky number "8" in the prices and phone numbers. More importantly, both retailers and manufacturers in China use luck-based promotional games and events to boost sales, and many marketers depend on such tactics for their promotional strategies. An understanding of how consumers interpret these luck-related offers has obvious implications for consumer welfare. In addition to the typical consumption situations described here, luck-related behaviors have a dark side. In several other countries, addiction to gambling is a social problem that affects large sections of the population. Many such addictive behaviors result from a lack of self-control and irrational beliefs that the next attempt at the wheel will be lucky. As large sections of the population in several countries succumb to the gambling addictions and various "come-ons" that lure them into thinking that today will be their "lucky day", policy makers need to be aware of tactics that are used to exploit vulnerable sections of the population. To be fair, however, beliefs in luck are not necessarily always bad for the individual. In some cases they might serve as a sort of positive illusion (Darke and Freedman 1997), an important source of optimism for people in their daily lives and, therefore, might be functional to a degree.

Our session provides a theoretical understanding of luck-related phenomena using existing models of information processing. The first paper in the session by Valenzuela, Darke and Briley investigates whether cultures with different control orientations (American vs. Chinese) differ in their sensitivity to luck. Beliefs in luck and personal self-esteem are relied on differentially in these cultures and this difference might influence the extent to which they rely on luck in opting for a risky choice. The paper reports findings from two cross cultural studies and shows that people from cultures that have an internal locus of control are likely to engage in more risky decision-making when self-esteem is enhanced. On the other hand, cultures with an external locus of control make more risky choices when they feel lucky.

The second paper by Jiang, Cho and Adaval provides a different perspective on how luck might have an impact on behavior. According to this research, objects and symbols can be associated with luck and this association might exist in memory around

the concept "luck". Once this concept is activated, it can influence our behavior regardless of our individual beliefs about luck. Thus, within Asian cultures, the symbolism associated with lucky and unlucky numbers can prime luck related concepts in memory. Once activated, this primed luck concept can influence a) people's subjective feeling of how lucky they are and the positive affect they experience, b) their interpretation of situations, c) motivation and performance on a cognitive task and d) product choices.

The fact that numbers can be used to prime luck related concepts suggests that beliefs about luck and events or objects associated with luck are represented in memory in some form and can be selectively retrieved. The third paper by Cowley and Farrell identifies how such luck related events might be stored and retrieved from memory. This paper identifies how people who believe in luck remember different things relative to those who don't believe in luck. A large study using data from real gamblers provides insight into the memories of these luck or chance oriented gamblers and shows that they remember different aspects of the experience. Some focus on peak wins and losses while others focus on the last experience.

Collectively, these papers provide a coherent message about how chronic and temporarily activated beliefs about luck have an impact on memory, motivation, decision making and performance.

"The Effects of Luck and Self-Esteem: Cultural Differences in Risky Decision-Making"

Ana Valenzuela, Baruch College

Peter Darke, University of British Columbia

Donnel Briley, University of Sydney

Previous literature has found that lucky experiences have a paradoxical effect on expectations of future performance (Darke and Freedman 1997). Subjects who thought luck was a personal, stable factor reacted to a lucky event with higher expectations for performance, while those who perceived luck as completely random had lower expectations following initial luck. As a consequence, beliefs in good luck may buffer people from feelings of uncertainty and enhance risk taking. These results are quite similar to findings in the self-esteem literature concerning ego-threat (e.g. Baumeister et al. 1993). In fact, self-esteem has been shown to predict risk-taking particularly in the domain of gains (Josephs, Larrick, Steele and Nisbett 1992). However, respondents' cultural identity is expected to moderate these effects. People have implicit theories about whether behavior is driven merely by an individual's ability (internal locus of control) or by situational forces (external locus of control). Individual responses to success or failure are likely to differ depending on the theory to which they subscribe (Rotter 1966). Individuals that believe in external locus of control may be more likely to shift their expectations for future performance depending on whether they are lucky or not (Hong and Chiu 1988). Research by Weisz, Rothbaum and Blackburn (1984) indicates that East Asians tend to exhibit more external locus of control than North Americans. Additionally, Heine and Lehman (1997) also identified cultural differences in self-esteem maintenance for Japanese vs. North Americans. They found that many self-esteem related effects such as post-decisional dissonance occur with North Americans but not with Japanese. As a consequence, we expect that individuals who subscribe to different implicit theories of behavior (North American vs. Chinese) will differ in their sensitivity to luck

and self-esteem in risky decision-making. In other words, people seem to use important dimensions of their self-concept as a buffer against different kinds of threats—in this case the risk of getting no money when taking a chance on winning a larger sum of money. Self-affirmation on the dimension of ability should be more effective in buffering the risk of the gamble in western cultures while self-affirmation on personal luck should be more effective in buffering risk in the eastern cultures. Three studies investigate this proposition.

In Study 1, we use a risky decision task (e.g. Tversky and Kahneman 1981) to analyze whether cultures differ in their sensitivity to luck and self-esteem. Subjects were asked to choose between an option with a certain outcome and another option (or prospect) with a probabilistic outcome. Despite differences in the level of risk involved, the expected outcomes were the same for both options. In addition, decisions pertained to either gains or losses, depending on the decision frame. For example, positively framed decisions gave subjects a choice between a sure gain of \$30 and an 85 percent chance to gain \$45. Whereas, subjects chose between a sure loss of \$30 and an 85 percent chance of losing \$45 when the decision was framed negatively. We ran the study using undergraduate students from both Canada and Hong Kong. Subjects completed a set of 10 decisions (5 with a gain frame and 5 with a loss frame) presented on a computer screen. The order was randomized by subject. The alternatives in each decision differed only in terms of the amount of risk involved. When subjects chose a risky option, the final outcome was determined using a lottery procedure. There was also an initial luck manipulation: Half of the subjects got \$5 from the start while half had to participate in a lottery to win it (although everyone won). We measured Beliefs in Good Luck (Darke and Freedman 1997) and self-esteem (Rosenberg 1965).

Results show that neither self-esteem nor beliefs in luck affect behavior in loss domains for either culture. People seem to be so averse to losses that individual differences are just not that important. In other words, loss aversion seems to be universally felt, though gain pursuit was not. In the gain domain, Canadian (but not Hong Kong) respondents chose the risky option more often when they rated high on self-esteem. Also in the gain domain, Hong Kong (but not Canadian) respondents chose more risky options when they had stronger beliefs in good luck. Only in Canada did the initial luck manipulation interact with self esteem: High self-esteem subjects took more risks after winning the initial lottery. In the case of Hong Kong, the initial luck manipulation did not interact with individual's beliefs in good luck. Instead, those who believed in luck tended to take more risks regardless of context induced by initial luck.

Study 2 replicated Study 1's design (without the initial luck manipulation) and added a between-subjects priming manipulation. U.S. Caucasian and Hong Kong undergraduate students were primed to think either about their good luck or their strong ability by describing a situation in which they were either lucky or skillful. The results showed that U.S. Caucasian respondents that were primed to think about their skill tended to choose more risky options than those that were primed about luck. Respondents that had to describe a skill-based situation felt that they were describing something more important about themselves than those that described a high ability situation. In the case of Hong Kong students, luck-beliefs priming did not enhance the effect of individual's beliefs in good luck, which again support the idea that beliefs in good luck are not as context-dependent as individual self-esteem.

In sum, our results support the idea that cultures differ in the way people deal with uncertainty in everyday life (Weisz, Rothbaum and Blackburn 1984). North Americans tend to believe in their own capability to control the situation. As a consequence, they are

willing to make more risky decisions when a positive event enhances their self-esteem. In contrast, Asian cultures tend to assess the favorability of the situation and take more risk when they believe their personal good luck will put the situation in their favor. In addition, the effects of self-esteem on risk taking seem to be more context-dependent than beliefs in good luck. Further study in risky domains that are skill-based instead of luck-based would bring more light to this research question.

“Priming Lucky Numbers: Effects on Attributions and Performance”

*Yuwei Jiang, Hong Kong University of Science and Technology
Angela Cho, Hong Kong University of Science and Technology
Rashmi Adaval, Hong Kong University of Science and Technology*

Social psychologists have typically considered luck as an external, unstable factor in explaining social events (Rotter, 1966; Weiner et al., 1987). Those who attribute an event to luck are asserting that they were not responsible for it and that it has no implications for similar events in the future. Nevertheless, this definition of luck is not universally agreed on (Meyer 1980; Meyer & Koelbl 1982) and people's own perception of luck differs from that of researchers. Fischhoff (1976) suggests that this disagreement arises because of the tendency to confuse luck with chance. While chance is more consistent with the notion of an external, unstable factor, luck might or might not fit into this classification. For example, when people think about luck, they might be referring either to attributions about the person (e.g., he is an unlucky person) in which case luck is seen as stable or, they might be referring to an event (an external, unstable factor caused his house to burn down).

Although chronic beliefs about how lucky one is are widely held (Darke and Freedman 1997) we suggest that in addition to these chronic beliefs, people might be influenced by transient factors that make luck salient. Our conception of luck is therefore somewhat different. While we agree that people might have chronic beliefs about luck, we also believe that luck exists as a concept in memory. Like any other concept, it is associated with luck-related objects (e.g., lucky numbers, a four-leaf clover) and events (e.g., situations in which a person was lucky) in addition to individual beliefs about how lucky one is. If luck exists as a concept in memory, it can be made more or less accessible through standard priming techniques (or situational factors). Thus, even though people may vary in the degree to which they hold chronic beliefs about how lucky they are, they might be influenced by objects and events around them that prime luck related concepts and make them more accessible.

We expected that when luck is made salient, people will expect lucky events to occur in the immediate future and will be less protective of their resources, and slower to exercise cognitive effort in tasks. Further, their interpretation of events (with positive or negative outcomes) might also reveal a bias towards luck related attributions. To examine these general hypotheses, we primed individuals with lucky or unlucky numbers. It is worth noting that there is ample anecdotal and some empirical evidence that numbers in Chinese cultures symbolize luck. (For example, numbers such as 8, 88, etc. are considered to be lucky, and are consequently believed to bring good luck whereas numbers such as 4, 44, etc. are considered unlucky and ostensibly bring misfortune. The sale of lucky license plates and use of lucky prices suggests that people acquire these goods with the belief that these objects will bring them additional luck (Vanhonacker, 2004).)

In the first study, we subliminally primed research participants with the lucky number “8”; the unlucky number “4”; the word “lucky”; the word “unlucky” or meaningless symbols “~”, and

asked them to indicate how lucky they felt and how happy they felt. Participants who were primed with a lucky number or a lucky word felt luckier and happier than those primed with unlucky numbers and words. Further, there were no differences between the priming of numbers or words and between control and unlucky prime conditions. It is important to note that perceptions of luck and positive affect that resulted as a consequence of priming were independent of each other.

In the second study, we primed research participants with lucky numbers, unlucky numbers or neutral numbers and provided them with scenarios where the protagonist of a story either succeeded or failed in a task. Participants were asked to attribute success or failure to personal effort or external factors. When the luck concept was activated (by priming either lucky numbers or unlucky ones), participants tended to attribute positive outcomes to external factors (e.g., the person was lucky) and negative outcomes to internal factors (e.g., the person did not work hard). The latter finding is intriguing because it suggests that even though luck was salient, people attributed negative outcomes to personal effort—perhaps because they felt the person did not succeed despite having luck on their side.

In a third experiment, we examined how priming luck would influence participants' actual task performance. We found that exposing participants to either lucky or unlucky numbers decreased their performance on a subsequent anagram-solving task especially when the anagrams were difficult. Thus, activating concepts about luck stimulated participants to believe that performance outcomes were out of their control and, therefore, they did not try as hard as they might have otherwise.

Studies 2 and 3 did not show a difference between lucky and unlucky numbers (i.e., both types of numbers made the luck dimension salient). However, a difference emerged when the numbers pertained to price. For example, in Hong Kong, a price of HK\$74 is considered unlucky, whereas a price of HK\$88 is considered lucky. In our fourth experiment, research participants were given two size options of the same brand of ice cream. One option had a lucky price HK\$88 (for a 600ml pack); the other had an unlucky price HK\$74 (550ml). In some conditions, we provided participants with the unit price while in other conditions this information was not provided. Further, we asked participants to make a choice either for themselves (self-relevant) or for their office (not self-relevant). We observed that when the choice is difficult to make (unit prices were not given) or the purchase is not self-relevant (i.e., participants are told to choose one option for their office) they were more likely to pick the lucky priced option. This finding is consistent with study 3 and suggests that priming luck might influence people's motivation and might lead to greater use of the lucky price as a heuristic in decision-making.

In sum, our four studies suggest that luck related concepts are stored in memory and may be activated through simple priming tasks. Their accessibility relative to other concepts can influence not only how people interpret situations but also their motivation to perform in a cognitive task and their purchasing choice in the consumer domain.

“Retrospective Evaluations: Will Chance versus Luck Oriented Individuals Select Different Moments of an Experience?”

Elizabeth Cowley, University of Sydney
Colin Farrell, University of Sydney

People's evaluations of past experiences, such as liking and disliking, guide their decisions about the future. A recollection of the pleasure or pain felt during an experience could be retrieved directly from memory if the to-be-remembered event was a precise

instant, but typically people consider affective episodes, not single moments. To remember how much we enjoyed an experience, we need to recall how we felt during the target episode, which consists of many moments, and summarize those feelings. Retrospective evaluations of an experience draw on select moments of the experience. The peak-end rule predicts that the most influential moments will be the most extreme moment and the final moment (Fredrickson and Kahneman, 1993; Redelmeier and Kahneman, 1996). People also tend to prefer an improving trend or a happy ending (Ross and Simonson, 1991).

Most of the research investigating retrospective evaluations examines the disliking of painful situations (Ariely, 1998; Kahneman *et al.*, 1993; Kahneman *et al.*, 1997; Redelmeier and Kahneman, 1996; Schreiber and Kahneman, 2000). Although many of our experiences are a mixture of pleasant and painful moments, little is known about how people summarize feelings for mixed episodes. The experience examined here is a gambling session which includes wins and losses. We look at two 'types' of gamblers; luck-oriented gamblers (LGs) and chance-oriented gamblers (CGs). Our proposition is that gamblers with different orientations will draw on different moments of the experience when constructing retrospective evaluations.

What is the difference between luck and chance? Luck is a causal category used to explain successes and failures that cannot be attributed to ability, effort, or task difficulty (Weiner *et al.*, 1987). Chance distributes events fairly and evenly, producing all possible outcomes with equal frequencies in the short and long term (Wagenaar, 1989; Wagenaar and Keren, 1988; Keren, 1994; Friedland, 1998).

Luck Orientation. LGs expect carryover from one random or independent event to another. LGs often believe they have an advantage when betting because they are lucky. Given that being lucky is an enviable quality and interrupting a lucky streak is brings bad luck (Wagenaar, 1989), we expect LGs to remember when outcomes indicate they are lucky and the moment a 'lucky streak' is interrupted.

Chance Orientation. CGs believe that outcomes will be the same regardless of the person involved. CGs also expect that chance will distribute events evenly such that all possible outcomes will occur with equal frequency (Wagenaar, 1989; Wagenaar and Keren, 1988; Keren, 1994; Friedland, 1998). CGs have also been found to believe that there is no reliable process for predicting the outcome of uncertain events (Darke and Freedman, 1997). Since CGs believe outcomes are due to chance, CGs should remember a more positive experience when there is a happy ending as most people like to save the best for last.

To investigate this issue, one hundred and two gamblers were recruited via posters displayed in a gambling establishment. Participants were given \$75 of tokens to bet 22 times. Their winnings were converted to club membership points.

Five items were used to measure a participant's retrospective evaluation. All statements about the experience (gave me pleasure, gave me a sense of excitement, brought me happiness, made me feel delighted, made me feel good) were answered with Likert scales ($r=0.79$). Four items were used to assess remembered irritation. Again, all items (made me feel angry, gave me a sense of frustration, gave me a feeling of dissatisfaction, brought me disappointment) were answered with Likert scales ($r=.81$).

After gambling and completing the dependent measures, participants assessed four chance/luck scenarios adapted from Friedland (1992; 1998) to determine their LG or CG status. Participants distributed 100 points between luck and chance to indicate the cause of each outcome. This categorization was used as an independent variable in the results described below.

Remembered Liking (Retrospective Evaluation). Remembered liking for LGs and CGs was tested with separate regressions including the value of the peak win and peak loss, the slope of moments for the session, the value of the final bet, and the final cash position. Remembered liking for LGs was determined by the peak win only ($F(1, 40)=2.55, p<0.05$): the larger the win, the more positive the retrospective evaluation. The memory of liking for CGs was determined by the slope ($F(1, 50)=3.13, p<0.01$): the more lucrative the ending, the more positive the memory. Importantly, the final cash position was not significant for either LGs or CGs. All moments are not weighted equally in the construction of a retrospective evaluation.

Remembered Disliking (Irritation). Consistent with previous research asserting that positive and negative responses to the same event are independent and distinct responses (Cacioppo and Bernston, 1994; Eagly and Chaiken, 1998; Herr and Page, 2004), liking and disliking were not significantly negatively correlated for LGs ($r=-.01, ns.$). The final bet was the only significant variable for remembered irritation ($F(1, 40)=3.43, p<0.01$): the larger the win on the final bet, the greater the reported irritation. This suggests that LGs felt irritated given that the session ended just as their luck turned. Irritation felt because they did not have a chance to benefit from the lucky streak as it just began is consistent with previous research by Wagenaar (1989). The remembered irritation for CGs was determined by the slope ($F(1, 50)=-2.49, p<0.05$). This is interesting because it suggests that liking and disliking may not be independent for this group ($r=-.31, p<.05$).

The results indicate that LGs and CGs select different moments of a mixed experience to reconstruct retrospective evaluations. LGs enjoy an experience that reinforces their *luckiness*, but become irritated by having a lucky streak interrupted. CGs remember more happiness when things get better at the end of the experience. For CGs, the outcome is due to chance, so the best case scenario is that the best is saved for last. It is also interesting that CGs use the same moments to remember liking and irritation while LGs use two very different moments in their retrospective evaluation.

Discussion

Robert S. Wyer, Hong Kong University of Science & Technology

People's perceptions of luck are certainly one of the more interesting topics in both psychology and consumer research. This interest was stimulated in part by Weiner's typology of the explanations that people give for their own and others' behavior. In particular, he classified the outcomes of performance in terms of both stability and agency, and assumed that luck was an unstable factor that was externally determined. Although this characterization of luck is intuitively reasonable, however, it does not always correspond to people's actual perceptions.

For example, many people believe that certain individuals are inherently lucky whereas others are chronically unlucky. That is, they perceive luck to be a stable dispositional determinant of behavioral outcomes. Several examples of people's illusions of control over chance events are provided by Langer (1975). The research reported in this symposium has similar implications. Cowley and Farrell, for example, also identified chronic individual differences in gamblers' belief that luck is at least temporarily stable. Thus, individuals often believe that their wins and losses over a series of trials are not independent. Rather, they perceive their outcomes to be guided by winning and losing streaks and base their bets accordingly.

In this regard, people may acquire implicit theories about the antecedents of their own and others' behavior that they apply when making judgments and decisions (cf. Ross, 1989; Dweck, Chiu, &

Hong, 1995; Wyer, 2004). Indeed, they may have several such theories, the application of which may be influenced by the theories' accessibility in memory and, therefore, the likelihood that they come to mind at the time a decision is made. For example, people may have both a skill related theory ("I am skilled, and so I will be successful") and a luck-related theory ("I am lucky, and so I will be successful"). The application of these theories may depend on both individual differences in their chronic accessibility and situational factors that make them temporarily salient.

Valenzuela et al.'s research exemplifies this possibility. Their results suggest that although skill-related and luck-related theories may exist to different degrees in Americans and Asians, they differ in their chronic accessibility. Americans are more likely to have a skill-related theory accessible in memory than a luck-related theory. Consequently, Americans with high self-esteem, who believe they are skillful, are likely to infer they will succeed on a task and are more likely to take risks than are those with low self-esteem. Although these individuals may also have a luck-related implicit theory, it is not highly accessible in memory, and so their beliefs in luck typically have little impact on their decisions.

In the case of Hong Kong Chinese, however, a luck-related theory may be more chronically accessible in memory than a skill-related theory. Thus, individual differences in these individuals' beliefs that they are lucky predict their risk-taking behavior whereas their beliefs in their skillfulness, do not.

As I've speculated, however, both types of theories may coexist in memory, and the cultural differences identified by Valenzuela et al. may only reflect differences in their chronic accessibility. If this is so, situational factors that influence the relative salience of the two theories could often override the differences they detected.

The research by Jiang, Cho and Adaval provides evidence that situational factors can, in fact, influence the extent to which implicit theories about luck are applied. Their research is particularly interesting in that it identifies motivational influences of these theories. Briefly, they show that activating concepts about luck in one situation can influence not only individuals' beliefs that others' outcomes are due to luck but also their own behavior and judgments. For example, priming luck-related concepts, which may activate an implicit theory that behavioral outcomes are not under one's control, decreases the effort that participants expend in achievement-related activity. Correspondingly, it increases the tendency to use heuristics in judgment task rather than expending the effort necessary to make a more reliable judgment.

However, the fact that these effects are influenced by situational factors emphasizes the fact that luck-related implicit theories may not be applied unless situational factors call them to people's attention. Jiang et al.'s work was done using Hong Kong subjects who are typically bicultural. As Valenzuela et al.'s findings also indicate, these individuals are more likely than Westerners to have luck-related theories chronically accessible in memory. Nevertheless, the chronic accessibility of these theories do not always guarantee their use when situational conditions make other bases for judgments and decisions more salient.

Affective Underpinnings of Decision Heuristics

Ritesh Saini, George Mason University

EXTENDED ABSTRACT

This research investigates the role of affective- versus cognitive-priming upon the decision-maker's subsequent use of choice heuristics (Attraction and Compromise Effect and Anchoring & adjustment).

While there is ample evidence which shows that most of us are fallible to such choice heuristics and biases like the representativeness bias or the availability heuristic, our understanding of why we are thus is limited. It is likely that several of these heuristics and biases have an evolutionary origin. It has been suggested that, given our limited cognitive abilities, several choice and judgment heuristics which provided us reasonably accurate solutions in most situations without having to expend a significant amount of effort were ingrained into our decision making-system, much like the anatomical and physiological adaptations which enhance an organism's inclusive fitness are adopted. This research explores the evolutionarily ingrained mechanisms responsible for the operation of simplifying heuristics, and the role that emotions play in the elicitation of these simplifying heuristics. In doing so, we not only expand on the role that internally-rooted affective reactions play on the use of such heuristics, but also show how manipulating the external environment's affective content can significantly influence our reliance on such heuristics.

Thus far, dual-process theories of cognition have proposed that the choices and judgments that we make are a result of a complex interplay of two systems—one a deliberate, reasoning-driven cognitive system and the other an automatic intuitive system. Related research has also suggested that several of the simplifying choice and judgment heuristics reside in the intuitive system, and are often brought forth with the help of “feelings”. This is because the intuitive system is a feelings- or emotions-based system. Several recent neuroscience studies suggest that humans often use affective cues in making decisions and judgments, and the momentary feelings elicited upon exposure to a choice option may be a very good determinant of its eventual probability of choice. This is indicative of the fact that over the course of our evolutionarily past we have encoded several kinds of ecologically rational simplifying heuristics in our intuitive system and whenever we are engaged in a choice task, these heuristics express themselves as an affective response which informs us about the qualitative suitability of a choice option. This mechanism is what explains our gut reactions to choice options even when we are hard pressed to rationally explain our positive or negative attitudes towards these options. Since emotions play such a crucial role in the operationalization of the intuitive system, it is likely that priming people into an emotional problem-solving mode, or perhaps just making the environment affect-rich is likely to result in the intuitive system becoming more accessible to the decision-maker at the expense of the analytical system. This line of reasoning suggests that humans would display a greater reliance on the intuitive system, and hence the use of simplifying choice and judgment heuristics in affect-rich environments.

We investigate the above hypothesis by setting up a series of between-subjects experiments. One group of participants is primed into a cognition-based problem-solving mode, while the other group is primed into an affect-based problem-solving mode. Following this they are tested for their susceptibility to two forms of common context-dependent choice biases (attraction effect and compromise effect) and a common judgment bias (anchoring &

adjustment). The results show that when people are affectively primed, they are more likely to be fallible to the attraction and the compromise effect, and anchoring & adjustment, versus when they are cognitively primed. These findings expand upon the “dual process theory” interpretation of the use of choice heuristics. Emotions seem to play a key role in our use of heuristics in decision-making situation.

This view is an alternative to the “cognitive miser” or the “adaptive-decision maker” view of heuristics and biases. That view suggests that heuristics are strategies that people often use, deliberately or automatically, to solve choice or judgment tasks that would otherwise be either too complex to solve given our limited cognitive capabilities, or too trivial to afford costly cognitive deliberation. This suggests that people would only deploy heuristic use when the need-for accuracy is low (like a low stakes decision) and/or cognitive resource availability is low (like time pressure). However, in our studies, none of these situational variables differed across the two groups and yet the affectively primed participants displayed a greater degree of heuristic use. Further investigations of this phenomenon are in progress.

Does Nostalgia Depend on Valence of Past Experience? An Empirical Analysis of the Discontinuity Hypothesis

Mousumi Bose Godbole, Louisiana State University

Omar Shehryar, Montana State University

David M. Hunt, University of Wyoming

EXTENDED ABSTRACT

Nostalgia, related to the judgment of the past relative to the future, helps individuals construct a sense of identity and social connectedness by facilitating continuity across time, especially in the face of existential disruptions. Davis (1979) captures this phenomenon in his "discontinuity hypothesis" to envisage that people who experience disruption in their lives tend to cling to the past more than those who experience continuity. Contemporary research on nostalgia has found weak support for this hypothesis (Best and Nelson 1985; Batcho 1995).

One of the issues not deliberated in earlier studies is the valence of the reservoir of past experiences invoked in nostalgic thoughts. In their evaluation of whether people connect to the past for shelter in the face of a potentially dreadful future, past studies have treated the reservoir of memories and recollections as unipolar. But not everyone has an identical experience of the past or has similar perceptions and interpretations of those experiences. That is, individuals have available both positive and negative experiences when they look to their past. According to Zimbardo and Boyd (1999), the recalled past may be positive or it may be aversive and negative. Consequently, past tests of the discontinuity hypothesis may be compromised by the assumption of homogeneity of thoughts, experiences and perceptions.

It is suggested in the present research that the valence of the accessible past experiences that are invoked in nostalgic thoughts moderates the degree to which nostalgia is used to cushion individuals from discontinuities in their lives introduced by threats of a strained future. When confronted with discontinuity, people with a predominantly positive past will tend to be nostalgic. On the other hand, people who have experienced a predominantly negative past will tend to avoid the past because a depressing past does not offer mental sustenance and is best discarded. As a result, such people would not be nostalgic.

Two aspects of the discontinuity hypothesis were tested in an experiment. First, a scenario portraying the dread of the future was compared with a situation depicting a bright future. The main stimulus consisted of a one page fictitious news editorial which was designed to provide either good or bad news about the economic outlook for college seniors seeking employment upon graduation. Thus, as the first independent variable, the nature of the future outlook pertaining to the participants was manipulated. Next, the hypothesis was extended by incorporating the individual differences in the valence of past experiences using Zimbardo and Boyd's (1999) time-perspective inventory as an individual-differences metric to measure the nature of participants' alignment to the past. Participants responded to items from the time-perspective inventory and were asked to describe how characteristic they thought each statement was in describing how they felt about their past. To introduce a second independent variable, two groups were created based on whether participants had predominantly positive or negative thoughts of the past. Holbrook's (1993) nostalgia proneness scale was used as a control variable to ensure that any differences in nostalgia could be confidently attributed to the variables of interest, namely future outlook and past experiences. Following the stimulus participants responded to an inventory of adjectives (borrowed from the Positive and Negative Affect Scales, Watson, Clark, and Tellegen 1988) measuring their affective state in re-

sponse to the manipulation. This served as the manipulation check to ensure that the "future outlook" manipulation successfully introduced "discontinuity" among participants in the condition with the negative outlook. Finally, participants responded to a twenty item nostalgia inventory designed and tested by Batcho (1995, 1998), which comprised the dependent variable.

Compared to the response of the participants assigned to the positive future outlook condition, the participants assigned to the negative future outlook condition scored higher on the set of negative adjectives. Further, participants assigned to the positive future condition scored higher than participants in the negative future outlook condition on the set of positive adjectives, showing successful manipulation check. A standardized overall score for positive and negative past experiences served as the second independent variable.

Analysis using Batcho's Nostalgia Index as the dependent variable showed significant results. A two-way interaction between future outlook and valence of past experience was significant. The main effect of future outlook was not statistically significant, thus rejecting the original form of the discontinuity hypothesis. The main effect of valence of past experience was statistically significant but it was interpreted in light of the significant two-way interaction.

Planned contrasts showed that participants with a predominantly positive past expressed more nostalgia when they faced a bleak outlook for the future than when they encountered a positive outlook for the future. This finding provides partial support for the discontinuity hypothesis which suggests that nostalgia is triggered by dread of a negative future. When faced with a negative outlook for the future those with a predominantly positive past were more nostalgic than those with a predominantly negative past. Taken together, it is suggested that a bright outlook for the future did not trigger nostalgia whereas a bleak outlook for the future triggered nostalgia. Moreover, when faced with a bleak outlook for the future, those with a predominantly positive past expressed more nostalgia than those with a predominantly negative past. Based on these findings we conclude that there is support for our proposed extension of the discontinuity hypothesis which considers valence of past experience as a moderator of the degree to which one seeks solace in nostalgia when confronted with a threatening future.

How Far Do Feelings Go? How Attachments Influence Brand Extensions

Alexander (Sasha) Fedorikhin, Indiana University
C. Whan Park, University of Southern California
Mathew Thomson, Queens University

EXTENDED ABSTRACT

Today, most new product introductions are brand extensions (Aaker, 1990). Hence, this area is of paramount importance for both marketing practitioners and academics. Academic research in marketing has looked at a number of important factors determining the success (or failure) of extensions (Broniarczyk & Alba, 1994). Research has suggested that the perceived fit or conceptual similarity between a parent and extended brand is a major factor driving the evaluation of brand extensions (Park, Milberg & Lawson, 1991).

Research also indicates that when consumers have favorable attitudes toward parent brands, they tend to evaluate extensions positively as well (Boush & Loken, 1991). That is, while brand extension researchers have previously studied the role of affect, the focus has been on affect either as a component of attitude (Boush & Loken, 1991; Broniarczyk & Alba, 1994) or as mood (Barone, Miniard, & Romeo, 2000). In these cases, affect as attitude is understood as a relatively less potent or "cold" (Cohen & Areni, 1991) form of affect, while mood is also a relatively mild affective state that is often not directly traceable to a specific reason or stimulus.

In the current paper, we introduce the attachment construct into the brand extension literature and suggest that it acts as a powerful determinant of consumers' reactions to brand extensions that could help marketers overcome a lack of fit. Unlike previous research on the effects of attitude in brand extension research, attachment is a "hot" stimulus-induced affect that describes certain emotionally-laden relationships between consumers and brands (Ball & Tasaki, 1992). We argue that attachment to the parent brand goes beyond both fit/similarity and attitude in determining brand extension success.

Attachment is a relationship-based construct that reflects the emotional bond connecting an individual with a specific target object (Bowlby, 1979). High attachment to a particular target (i.e. object, person) induces a state of emotion-laden mental readiness that influences one's allocation of emotional, cognitive, and behavioral resources towards the object of attachment (Holmes, 2000). It is evidenced, among other things, by such psychological and behavioral outcomes as proximity-seeking behaviors, separation distress, a sense that the attachment object offers a safe haven, and mourning of its loss (Bowlby, 1979).

The first study examined the attachment construct using a fictitious brand through manipulations of both the fit between a parent and extended brand (low, medium, or high) and the attachment (low or high) to the parent brand. Attachment was manipulated by invoking separation distress that accompanies high levels of attachment. As hypothesized, participants in the high attachment condition showed higher purchase intentions towards ($M=4.41$) and willingness to pay ($M=94$) for the extensions as opposed to those in the low attachment condition (3.52 and 84 respectively). The effect was pronounced at the high (sneakers and shorts) and medium (sneakers and sunglasses) levels of fit (for high fit, $PI: 5.35$ vs. 4.10, willingness to pay: 114 vs. 98; for medium fit, $PI: 4.50$ vs. 3.61, and willingness to pay: 98 vs. 78). When the fit was low, as in the case of sneakers and grills, even the strong emotional bond implied by high attachment did not help.

The second study replicated the above results in the context of real brands to which participants were strongly or weakly attached.

Different product categories were used for both the parent brand and the extension (jeans vs. casual shirts, sandals, or desk lamps). We also measured attitude strength and included it as a covariate, to make sure the attachment construct had an effect above and beyond attitude. Furthermore, the effect of attachment on evaluations of the extended brand was partially mediated by brand commitment.

In summary, this paper introduces an important variable of consumer attachment to the brand extension literature, and adds to the emotional richness of this important area of consumer research. Drawing from two studies employing real and fictitious brands, this paper shows that emotional attachment has a positive effect on consumer reactions to brand extensions, even when controlling for the effect of attitude favorability and strength.

SPECIAL SESSION SUMMARY

New Advances in Mental Accounting: Underlying Mechanisms and Resultant Biases

Gülden Ülkümen, New York University

Vicki G. Morwitz, New York University

SESSION OVERVIEW

The purpose of this session was to present recent research on mental accounting in consumer research. Together these papers demonstrate the scope and consequences of mental accounting effects and provide evidence for different processes underlying these effects. The session brought together three papers that address different aspects, and provide distinct perspectives reflecting on the biases that result from mental accounting practices in consumer behavior. The first two papers adopt a consumer's point of view, whereas the third paper takes a managerial approach.

The literature on mental accounting refers to mental accounts at different levels of generality (Kahneman and Tversky, 1984). Consumers can have transaction-specific accounts (Prelec and Loewenstein 1998) or expenditure type accounts (Heath and Soll, 1996). Transaction-specific accounts link specific acts of consumption and corresponding payments, whereas expenditure type accounts group similar expenditures together under a single budget. While all three papers examine mental accounts, the Zhang and Hsee paper considers transaction-specific accounts, the Ülkümen, Thomas and Morwitz paper and the Cheema and Soman paper look at expenditure type accounts.

Mental accounting is essentially a beneficial practice that consumers use strategically to simplify cognitive calculations (Schelling 1992; Shefrin and Thaler 1988) and to self-regulate expenses (Thaler 1999). Nevertheless, biases introduced by mental accounting practices have been widely documented (Arkes and Blumer 1985; Heath 1995; Heath and Soll 1996). The three papers add to this stream of literature by identifying further mechanisms through which mental accounts can have biasing effects on consumption decisions and subsequent utility.

Consumers' evaluation of an expense may depend on certain by-products of mental accounting in addition to the product price and benefit accrued from consuming it. The Ülkümen et al. paper shows that budget limits consumers set for their mental accounts are susceptible to temporal framing effects. The same expense, then, could be evaluated more or less favorably depending on how the budget period is framed and ensuing perceptions of account surplus. Cheema and Soman find that willingness to spend from an account depends not only on the amount of surplus in an account, but also on the transgression costs associated with the account. Zhang and Hsee demonstrate that the temporal pattern in prices, along with the current price of a product can affect contentment with the price and product evaluations. In sum, different aspects of mental accounts can systematically alter consumers' willingness to spend, and introduce biases in evaluations.

The papers in this session also shed light on a relatively under-researched but crucial aspect in the area of mental accounting: the temporal dynamics of mental accounts. Specifically, they demonstrate that when an annual frame is salient, or when an account has been newly transgressed into (consumers have spent from a hitherto protected account), or with a specific temporal pattern of prices, consumers may have more favorable evaluations of a target expense, and may be more likely to purchase, as compared to when they are provided a monthly frame, face an unopened account, or encounter an unfavorable temporal pattern of prices, respectively.

ABSTRACTS

"Biasing Effects of Temporal Framing on Budget Estimates"

Gülden Ülkümen, New York University

Manoj Thomas, New York University

Vicki G. Morwitz, New York University

In this paper, we uncover a temporal framing bias in budget estimates such that the estimates provided by participants considering their budgets for the next year were three times as high as the comparable estimates provided by those considering their budgets for the next month. We investigate this bias through a series of four studies.

Study 1

Study 1 aims to demonstrate this temporal framing bias. We had four between subjects conditions. In the Next Year/Next Month condition, participants considered their expenses during the next year/next month. In addition to these two main conditions, we had Typical Month and Month Next Year (a month, starting one year from now) conditions. We asked all participants to list different accounts they consider when they are budgeting for the next month/next year/typical month/month next year. Next, participants indicated their budget for the corresponding period.

Our primary expectation was that the budget estimates for the next year and the next month would be significantly different. We did not expect Month Next Year and Typical Month to be different from Next Month; they serve to test several explanations for the effect.

We converted all estimates to a common, monthly basis by dividing annual estimates by 12. The results suggest that the budget for the Next Year was significantly higher than that for the Next Month ($M_{\text{nextyear}} = \$1,773$, $M_{\text{nextmonth}} = \$576$). There was no difference between the Next Month and the two additional month conditions. We counted the number of expense categories listed and calculated per category budget by dividing indicated budget by number of categories. The average size of expense categories in the Next Year was higher than that in the Next Month ($M_{\text{nextyear}} = \$243$, $M_{\text{nextmonth}} = \$114$).

Study 1 was designed to test several alternative accounts of this substantial discrepancy in budget estimates. For all DV's, the three month conditions were significantly different from the Next Year condition but not from each other. These findings indicate that the observed effect cannot be qualified by expenses unique to the month following the experiment, temporal construal effects or optimism about one's financial future. Part of the reason for this discrepancy is that a greater number of expense categories are considered for the next year than for the next month. However, this alone can not account for our results, since there is a significant difference between the average size of budgets between conditions.

Study 2

Would the framing bias still manifest when the number of expense categories is held constant across conditions? To find out, we asked participants in study 2 to estimate only their food and entertainment budgets. We also wanted to see which frame lead to

more accurate estimates. The discrepancy could be due to underestimation in the Next Month condition or overestimation in the Next Year condition. In order to compare estimates to actual expenditures, we asked the participants to keep a diary.

The design was a 2 (Time frame: Next Month, Next Year) x 2 (Category: Food, Entertainment) x 2 (Order: Food first, Entertainment first) mixed design. The study consisted of three stages. In the first stage, all participants estimated their food and entertainment budgets, either for the next month, or next year. Then they kept a diary of their food and entertainment expenses for one week. One week later, they again estimated their budgets for the next month/next year. We also asked them to recall how much they actually spent during the diary period.

We replicated the temporal framing bias on total budget estimates. The combined food and entertainment estimate for the Next Year was significantly higher than that for the Next Month ($M_{\text{nextyear}} = \$612$, $M_{\text{nextmonth}} = \$441$). Participants in the Next Year condition provided accurate estimates, whereas those in the Next Month condition underestimated their actual expenditures. Even after keeping a diary of their expenses for a week, the magnitude of this underestimation did not diminish in the Next Month condition. All participants could accurately recall their expenses; however, participants in the Next Month condition did not seem to use this knowledge appropriately in their estimates.

So then what is causing the difference between estimates across frames? Debriefings from study 1 suggest that participants in the Next Year condition come up with an initial intuitive estimate, on which they add a lump sum amount. While estimating their budget for the next year, they were not confident that they included everything that they needed to, so they adjusted their estimate up by a certain amount. In studies 2 and 3, we examine this possibility.

Study 3

We asked the participants to estimate their monthly or annual budgets, and we recorded their response time. If indeed people are not confident and adjust their estimates up in the year condition, this should be reflected in their longer response latency.

We replicated the temporal framing bias; the budget estimate for the next year was higher than that for the next month ($M_{\text{nextyear}} = \$1,983$, $M_{\text{nextmonth}} = \$812$). More importantly, participants took longer to provide their estimates for the next year than for the next month ($M_{\text{nextyear}} = 20.00\text{sec}$, $M_{\text{nextmonth}} = 13.03\text{sec}$). This process evidence is consistent with an adjustment account.

Study 4

In order to better understand the role of confidence in the observed effects, in study 4, we manipulated participants' confidence in their estimates, along with the time frame. Participants were told that the majority of students who did this task before were quite accurate/inaccurate. Participants then estimated their budget for the next month/next year.

The results indicate that the discrepancy between budget estimates for the next month and next year are moderated by confidence in these estimates. In the Next Month condition, there was no difference between estimates across low and high confidence cells. However, in the Next Year condition, estimates made under low confidence were much higher than those made under high confidence.

The temporal framing bias we observe across four studies, which manifests itself as a large discrepancy between budget estimates made under month and year frames, is driven by the high estimates provided by the participants in the year condition, who do

not feel confident about their initial estimates, and feel the need to adjust them up.

“Breaking Open a Pot of Money: The Effect of Transgression Costs on Spending From Open and Closed Pots”

Amar Cheema, Washington University in Saint Louis

Dilip Soman, University of Toronto

We propose that consumers may incur a psychological transgression cost to break open a pot of money and spend from it. Thus, high transgression costs may deter spending. However, once a consumer incurs a transgression cost, subsequent spending from the pot may be easier. Bracketing one large pot of money into several smaller pots affects transgression costs and spending patterns. Consequences of transgression costs are demonstrated for purchase decisions with gift cards, for gambles with monetary implications, and for prepaid calling-card use. A transgression-related guilt measure and the moderating role of bracket artificiality provide additional support for the hypothesized process.

“Happiness Pump”

Yan Zhang, The University of Chicago Graduate School of Business

Christopher K. Hsee, The University of Chicago Graduate School of Business

Previous research on temporal trend (e.g., Hsee & Abelson, 1991; Loewenstein & Prelec, 1993; Ariely and Zauberman, 2003) suggests that consumers are happier with prices that decrease over time than with prices that remain unchanged or prices that increase over time. To attract and retain consumers, companies are adopting different marketing strategies. One frequently used strategy is to decrease price. However, in order to make a profit, a company cannot decrease the price indefinitely. At some point, the price will have to go back up. One possible solution is to introduce a product with a relatively high price, then decrease the price gradually, then suddenly increase the price, then gradually decrease it again, and so on and so forth. See Figure 1 below:

A problem with this strategy is, when the price jumps back up, consumers will be unhappy. And due to loss aversion, the unhappiness from the price increase may even outweigh the happiness from the price decrease.

In order to keep consumers happy and yet not to let prices decrease forever, we propose a marketing strategy in which the marketer first introduces a product with a relatively high price. Then he/she gradually decreases the price so as to make consumers happy. Then the marketer replaces the target product with a filler product. After that the marketer introduces the target product again with its higher price, and then decreases its price again. See Figure 2 below:

A key of this strategy is the insertion of filler products. The filler product will reduce the accessibility of the low ending price of the target product in a consumer's memory, and hence will lower the likelihood that the consumer will compare the high starting price of the target product in a new cycle to the low ending price of the target product in its previous cycle. If a consumer no longer remembers the lower ending price of the target product in the previous cycle, then the consumer will not be unhappy when the price of the target product returns to its higher initial level in the new cycle.

We tested this idea in a laboratory experiment that involved a 2 (trend of the target price: decreasing vs. flat) x 2 (accessibility of the target price in the previous cycle: high vs. low) design. Participants were asked to imagine that they bought fruits once a week from a local store, and that the local store featured only one type of fruit each month.

FIGURE 1

FIGURE 2

In each month, the price of the featured fruit could vary in each of the four weeks. In the month when strawberries appeared, the price in the four weeks was either (a) \$2.13/lb, \$1.75/lb, \$1.27/lb, or \$0.99/lb, respectively in the decreasing price condition, or (b) constantly \$1.535/lb in the flat price condition (with small random variations). Prices for the other (filler) fruits ranged from \$0.61/lb to \$2.29/lb (also with small random variations).

Accessibility referred to the extent to which the price of the target product in its previous cycle was accessible to consumers in their memory when they encounter the target product in a new cycle. In the high accessibility condition, the experiment simulated 3 months during which the store only featured strawberries. Because the price cycles are next to each other, the low ending price of strawberries in one month is highly accessible to people when they experience the high starting price in the next month. In the low accessibility condition, the experiment simulated 15 months in which filler fruits were inserted. From month 1 to month 15, the fruits featured were as follows: cherries, strawberries, peaches, grapes, apples, oranges, apples, strawberries, oranges, grapes, apples, cherries, strawberries, peaches, and grapes. Among all the featured fruits, strawberry was chosen as the target fruit and others as filler fruits. Due to the insertion of filler products, the low ending price of strawberries in the previous cycle is less accessible to consumers when the store featured strawberries again.

Participants were asked to rate their happiness with the price of the fruit each week. We were interested in consumer’s happiness ratings for the target fruits—strawberries.

We predicted price pattern x accessibility interaction and greater happiness in the decreasing-price/low-accessibility condition than any other three conditions. The results confirmed our predictions. It suggests that both a decreasing price pattern and low accessibility of memory when the price rises again are necessary to make consumers happy.

However, the presence of filler fruits may exert other effects than what we wanted. What we wanted is for the filler fruits to block respondents’ memory of the price of the target price. But filler fruits would introduce other confounding effects: for example, the type or the price of the filler fruits may enhance or lower respondents’ happiness with the target fruit. To remove the confounding effects of filler fruits, we replaced the no-filler conditions with another two conditions where the store also offered filler fruits but we provided reminders of the prices of each type of fruits in their previous cycles when the fruits come out next time. This is as if the filler fruits did not exist.

Comparing the two added condition with the two conditions where filler fruits were featured but the reminders about the prices of each type of fruits were not offered, the experiment results also showed the price pattern x accessibility interaction and greater

happiness in the decreasing-price/low-accessibility condition than any other three conditions.

As importantly, the mean happiness rating for all the fruits also followed this pattern. It suggests that our strategy increased happiness with the prices of the target fruits, and did not decrease happiness with the prices of the filler fruits.

This research yields important marketing implications. Marketers can tacitly arrange the price of a product so that consumers are happy when the price decreases but not unhappy when the price increases.

SPECIAL SESSION SUMMARY

Pushing the Frontiers of Decision Making Neuroscience to Help Consumers Adopt Healthy Lifestyle in Our Modern Society of Plenty

Laurette Dubé, McGill University
Antoine Bechara, University of Iowa

SESSION OVERVIEW

The program was anchored in an emerging body of work in decision neuroscience that recognizes that human biology, including lower and higher level brain functions, has evolved over millions of years in response to an environment that differs dramatically from those of the modern society of plenty, placing demands on self-control that individuals may be neurobiologically ill-prepared to meet. A prime example is the struggle many consumers engage into to make healthy food choices in a world that simultaneously values a slim body image and makes food cheap and ubiquitous. From this perspective, eating behavior may be influenced by neurobiologically-driven and culturally-reinforced impulses toward food, pitted against cognitively-driven efforts to restrain. There is abundant evidence from decision neuroscience that these processes are mediated by distinct neural systems: The appetitive drive toward food relies on basic limbic and reward-related circuits that specialize in well-learned affective associations, while the prefrontal cortex plays crucial roles in mechanisms of self-control. Presentations in this session all focused on the prefrontal cortex.

Jerome Busemeyer, Julie C. Stout, and Eldad Yechiam presented results from a series of studies that had examined individuals with different neuropsychological disorders using the Iowa gambling task (IGT). This task assesses decision making deficits tied to dysfunction in a neural circuitry in which the orbitofrontal/ventromedial prefrontal cortex is a critical component. This dysfunction translates into a poor ability to consider future outcomes. The authors presented a cognitive model which distills gambling performance into three different psychological components: the relative impact of rewards and punishments on evaluations; the rate that the contingent payoffs are learned; and the consistency between learning and responding. Several studies were analyzed to estimate parameters for each psychological component and analyses their relative contribution to decision making deficit in different pathologies.

Lesley, K. Fellows and Martha Farah reported results from a first study in which they used an affective shifting task (AST) to demonstrate the role played by orbitofrontal cortex in another facet of self-control, i.e., reversal of affective learning over time. The second study contrasted the role of dorsolateral and ventromedial prefrontal cortex on two distinct aspects of future thinking, namely temporal discounting, i.e., the subjective devaluation of reward as a function of delay and time perspective, i.e., the length of an individual's self-defined future. Results show that temporal discounting is not affected by frontal lobe injury, while time perspective depends on the ventromedial region of the frontal lobe.

Based on prior research on addiction that have found poor performance on both IGT and AST, Laurette Dubé, Antoine Bechara and their collaborators proposed that a poor performance on AST and IGT could be predictive of more frequent eating behavior in everyday life. Results from a multi-phase study showed that performance (for AST) and estimates of process parameters underlying the performance (AST and IGT) could account for a significant amount of the variance in a person's everyday eating. The pattern

of response supports the view that to some extent, food is an object of addiction and that it is possible to help individuals recognize how well-equipped they are at the neuropsychological level to face self-control challenges involved in preventing food over-consumption in the modern world of plenty.

The discussant, Barbara Mellers, reviewed the three papers in terms of the avenues and challenges they suggest for building bridges between neuroscience, consumer decision making and behaviors in everyday life, and novel sustainable food marketing strategies that could give healthy eating a fighting chance.

When Good Pictures Make for Good Products: Consumer Misattribution Effects in Virtual Product Presentation Environments

Hyejeung Cho, University of Michigan
Norbert Schwarz, University of Michigan

EXTENDED ABSTRACT

The *aboutness principle* (Higgins 1998) suggests that when people think about something, they usually assume that any thoughts that come to mind, or any feelings they experience, are *about* whatever is in the focus of their attention at the time of judgment. Hence, they tend to *misattribute* thoughts and feelings that are elicited by unrelated variables to whatever is in the focus of their attention. Misattribution is a pervasive phenomenon that has been examined from a variety of perspectives, including research on mood-as-information (for reviews, see Schwarz and Clore 1996, 2003), accessibility experiences (e.g., Schwarz et al. 1991), processing fluency (e.g., Nordhielm 2002; Reber et al. 1998; Whittlesea 1993) and priming effects (e.g., Niedenthal 1990; Winkielman et al. 1997). Much of this research in relation to general misattribution effects indicates that people's judgments of a neutral target can be influenced by various irrelevant sources unless the informative values of their thoughts or feelings is discredited. The purpose of our research is to extend this misattribution literature by examining misattribution processes in a virtual product presentation environment, which is a newly arising area for marketing research.

Research Context and Question

One of the differences between a traditional brick-and-mortar store and an online store is that in online stores consumers cannot try out products before they make a purchase decision. However, recently some online retailers in product categories like cosmetics and fashion accessories have started to provide customers with the opportunity to *virtually* try products using so-called virtual image technology. Consumers can upload their own digital photos and use those photos as "virtual mirrors" to try various products to determine how they would look on them. In the current research, we investigate how a consumer's preference for a product is influenced by the consumer's affective responses to the background image on which the product is being virtually tried. Given that consumers can virtually try products before making a purchase decision, it is important to understand how a misattribution process contributes to consumer choice and product evaluation in virtual product presentation environments. Our overarching research hypothesis is that the more consumers like their photos, the more they like the product presented on the photos. In other words, when consumers virtually try products on their digital image, they will respond holistically to the image, but misread their response as arising from the focal object, namely the product. This misattribution, in turn, will result in differential product preferences.

Experiments and Major Findings

We tested our hypothesis in three experiments. In the first experiment, forty-eight female participants evaluated different earrings, virtually presented on their own digital image with a neutral facial expression or with a smiling facial expression. Prior research shows that smiling faces are perceived as more attractive than non-smiling faces (e.g., O'Doherty et al. 2003; Otta et al. 1996). Therefore, we expected the product to be evaluated more favorably when it was virtually presented on participants' smiling faces than on their non-smiling faces. Empirically, this was the case. In the second experiment, thirty-two female participants were asked to evaluate earrings virtually presented on their own regular

photo image and on their mirror image (i.e., a photo equivalent to their reflection in a mirror). According to prior research, people usually prefer either their mirror image (e.g., Mita et al. 1977) or their regular photo image (e.g., Willis and Brown 1987) to the other. Given that people have their own preferred baseline image, we expected that a neutral product will be more positively evaluated when it is virtually presented on a person's preferred baseline image than on a less-preferred image. In this experiment, the experimental design was within-subjects and the various earrings evaluated by each participant were sometimes presented on her mirror image and at other times on her regular image. To measure each participant's preferred baseline image, after the main product evaluation task was finished each participant was shown her mirror image and her regular image side-by-side and asked to indicate the one she preferred. The key results revealed that participants evaluated the focal product more favorably when the product was presented on their preferred image: those who preferred their regular photo image over their mirror image also preferred jewelry shown on their regular image over jewelry shown on their mirror image, and vice versa for those who preferred their mirror image over their regular image. None of the participants reported that they had noticed that two different images were used in their product evaluation task. In the last experiment, we investigated whether a similar misattribution effect would occur when consumers evaluate products virtually presented on the digital image of someone they personally know. Fifty-seven female participants evaluated earrings virtually presented on their female instructor's digital image with her original skin texture or with an enhanced (i.e., smoothed by a computer graphic software) skin texture. As expected, 100% of the participants indicated that they liked the instructor's enhanced image better (when asked after their product evaluation task) and the enhanced photo resulted in more favorable product evaluations.

Conclusion

In combination, the results of these experiments support our overarching hypothesis that consumers respond holistically to the picture, but misread their response as being due to what they focus on: the product virtually tried on their image. This misattribution process results in differential product preferences, provided that the consumers remain unaware of the true source of their positive feelings. Our studies not only contribute to our understanding of how misattribution processes influence consumer choice and product evaluation, but also provide marketers with important insights into the potential benefits of using the virtual product presentation technology. More significantly, however, this research also adds to the current literature on the role of subjective feelings in the consumer misattribution process, by providing concrete marketing-specific examples of misattribution effects in the new context of virtual product presentation.

Why Consumers Engage in Virtual New Product Developments Initiated by Producers

Johann Füller, University of Innsbruck

ABSTRACT

In this article, I investigate why consumers engage in virtual new product developments initiated by producers. Drawing on motivation research found in related fields such as leisure, online communities, user innovation, and survey participation several intrinsic and extrinsic motives can be identified that may induce consumers' engagement. In this empirical study, 825 consumers participating in a virtual development project were asked about their motivations. Six motivational factors could be extracted. Intrinsic interest in the innovation activity and curiosity are found to be the most important motives for consumers' willingness to engage in further virtual development activities.

INTRODUCTION

From a producer's perspective the obtained benefits of virtual consumer integration such as risk reduction, identification of upcoming trends, or increased number of creative ideas seem to be obvious, but, why should consumers engage in virtual new product development (NPD) projects initiated by producers and share their ideas and know-how with them? What are their benefits? Up till now, no empirical data is available for this emerging field of research. In this article, I shall investigate why consumers engage in virtual new product developments initiated by producers and spend considerable time and effort actively contributing to a producer's new product development process. First, I shall give an overview of the concept of virtual consumer integration into NPD. Second, a theoretical review is provided on relevant motives inducing consumers to engage in virtual NPD. Following, the design and conduction of the empirical study is introduced, before I present the empirical results. Finally, the findings will be discussed and possible implications outlined. The results show, that rather the participation itself than the outcome of the virtual NPD—the new product—is considered as a rewarding experience, from which consumers derive benefit.

VIRTUAL CONSUMER INTEGRATION

These days, consumption becomes more fragmented and idiosyncratic (Holt 2002). This means that it is no longer possible to treat consumers at arm's length or as peripherally-related topics (Firat and Venkatesh 1995). More active consumers ask for more, but on the other hand offer new possibilities as they are more literate and willing to produce by themselves (Firat and Venkatesh 1995; Hemetsberger and Pieters 2001). Highly innovative and skilled consumers can be encountered in online communities (Kozinets 2002; McAlexander et al. 2002). For example, at *niketalk.com*, an online community for devoted basketball players, new basketball shoes are developed by users. The new designs are discussed, evaluated and improved within the community. Among others, Bagozzi and Dholakia (2002) point out that online communities present an aggregation of collective expertise that is difficult to match elsewhere. Researchers like consultants agree upon the enormous potential of online communities for new product development (Pralhad and Ramaswamy 2004; Urban and Hauser 2004).

In addition, the Internet offers new simplified modes to virtually integrate large numbers of former anonymous consumers into a producer's innovation process (Urban and Hauser 2004; von Hippel and Katz 2002). Recently, Dahan and Hauser (2002) introduced six web-based methods that facilitate the interaction between producers and consumers during new product development.

The novelty of virtual consumer integration, compared to traditional online market research is that consumers are not only asked about their opinions, wants and needs, but also to contribute their creativity and problem solving skills (Lilien et al. 2002). Consumers are invited to actively participate in the creation of new products by generating and evaluating new product ideas, elaborating a detailed product concept, evaluating or challenging it, discussing and improving optional solution details, selecting or individualizing the preferred virtual prototype, testing and experiencing the new product features by running simulations, getting information about the new product or just consuming it. Web-based tools enable the dialogue and allow the virtual transfer of consumers' explicit and implicit knowledge.

The Procter and Gamble Advisory Community, for example, illustrates, how consumers virtually contribute to innovation activities along the entire innovation process, even more than once. Consumers participate in designing, testing and launching new products such as shampoos, baby care, snacks, healthcare, and pet nutrition. This and several examples of other consumer goods firms such as Audi, Henkel, Lego, Ducati, Sony, or Swarovski (e.g. Füller et al. 2004; Verona and Prandelli 2002) demonstrate the potential of this new approach of co-creation.

However, virtual consumer integration only works, when qualified consumers are willing to participate. They have to be motivated to contribute their know-how, share their ideas and honestly state their preferences. In contrast to open source software and user innovation, consumers participating in virtual new product developments will hardly ever be able to benefit immediately from using "their" innovation. A producer of mass produced consumer goods like cars, mobile phones, TVs, or skies is able to consider only a few consumer ideas for modification or entirely new products. In addition, the products consumers contributed to, most of the time, will be available on the market with at least a 6-12 month delay. Due to this situation, it can be assumed that motivations for participating in virtual NPD slightly differ from open source software and lead user developments. The question arises: what motivates numerous consumers to engage in virtual new product developments initiated by producers?

MOTIVES FOR CONSUMER PARTICIPATION

According to social exchange theory, the reason why consumers virtually interact with producers and engage in virtual new product development is because they expect that doing so will be rewarding (Emerson 1981). An interaction is considered as being rewarding if the subjective derived benefit is greater than the experienced effort. While social exchange theory describes basic circumstances under which consumers virtually engage in new product development, it does not provide what Emerson calls a theory of values (Emerson 1987). However, whether or not a consumer engages in virtual new product development depends on the individual's motivational state, their need to receive and capacity to give (Hirschman 1987, 99).

Consumers may engage in virtual interaction because they show a certain interest for it. It is either the task itself—a playful, challenging experience—or the consequence linked to the engagement, such as recognition, a better available product, or receipt of offered incentive, what motivates them to participate. The reasons why consumers undergo virtual NPD may be manifold and originate from different sets of motives. According to Deci and Ryan,

engaging in activities and tasks can be considered as a function of intrinsic motivation and self-determined extrinsic motivation (Deci and Ryan 2002; Deci and Ryan 1985). Intrinsic motives in combination with extrinsic motives may play a role for consumers engaging in virtual NPD initiated by producers. In the following, the distinction between intrinsic and extrinsic motives will be used to discuss possible factors influencing consumers when engaging in virtual NPD.

Intrinsic Motivation

Hobbies like playing chess, dancing salsa, rock climbing, or gardening are considered as playful, interesting, challenging, and exciting activities often executed as a means of an end (Deci and Ryan 1985). Individuals intrinsically motivated may consider their virtual contribution to new product development as playful and enjoying and therefore perceive it as rewarding instead of pure effort. It is not the outcome but the activity itself, creative consumers may derive benefit from. Such individuals show a positive attitude towards and are interested in virtual new product development activities. Intrinsic motivation can be noticed as interest, involvement, curiosity, satisfaction, or positive challenge (Amabile 1996). Individuals who enjoy their participation may sink in a state of flow—an optimal experience where they get totally absorbed by the activity, losing any sense of time and space (Csikszentmihalyi 2002). Under conditions of deep involvement, freedom, self-control, attention, challenge, sense of mastery, competence and task enjoyment consumers may easiest experience flow (Csikszentmihalyi 2002).

The reason for intrinsic motivation is an individual's very own need for feeling competent and self-determining in dealing with his or her environment (Deci and Ryan 1985). For example, programmers report feeling competent, satisfied and fulfilled when they write code for open source software (Lakhani and Wolf 2003). Hofman and Novak (2000), as well as Mathwick and Rigdon (2004) notice that consumers experience flow on the Internet. In general, cognitively engaging oneself in creative tasks is considered as being intrinsically interesting (Amabile 1996). Hence, the process of generating new concepts, assessing new innovations, or designing new products may trigger virtual participation, rather than the outcome of NPD.

Extrinsic Motivation

Consumers are extrinsically motivated, if they focus on contingent outcomes that are separable from the activity per se (Deci and Ryan 2002). Deci and Ryan distinguish between 'informational' and 'controlling' extrinsic motivators, depending on its effect on intrinsic motivation. 'Informational' extrinsic motivators that increase someone's sense of competence, need for finding a creative solution, or prevailing task involvement are considered as additional bonus and activity encouraging, reinforcing someone's intrinsic motivation, while 'controlling' extrinsic motivators like status, or job promotion confine self-determination and are considered as counterproductive as they undermine initial intrinsic motivation (Deci and Ryan 2002; Deci and Ryan 1985).

In the case of virtual consumer integration, appropriate rewards will either animate already participating consumers to make even better contributions, or attract additional consumers interested in the topic, but with so far too low motivation levels to engage in virtual NPD. The danger hereby is first, that consumers, not interested in the topic at all, suddenly participate in virtual NPD because they are looking for the incentive, but do not make serious contributions. Second, consumers that initially considered virtual NPD as playful, rewarding activity, suddenly may start to hide their

ideas, thinking they can gain some economic benefit by selling them, or they may feel misused by producers because the offered extrinsic incentives, by far do not present a proper compensation for the contributions made. The individual's perceived locus of causality shifts from internal to external (DeCharms 1968). Free riding may be the consequence.

Motives for Virtual Consumer Engagement

Drawing on the rich body of motivation research found in related fields such as leisure (Unger and Kernan 1983), online communities mainly open source software (OSS) (Hemetsberger 2001; Hennig-Thurau et al. 2004), user innovation (Franke and Shah 2003), and survey participation (Groves et al. 2000; MacElroy and Gray 2003) various intrinsic and extrinsic motives can be found to explain why consumers may engage in virtual NPD initiated by producers.

Autotelic/ Playful Task (AT): Individuals engage in tasks because the activity itself is considered as rewarding. Consumers involved in innovation tasks (Mittal 1995) of a certain product category (Bloch 1986), or brand (Coulter et al. 2003; Mittal and Lee 1988) may engage in virtual product developments. According to Belk et al. (2000), such tasks may offer a state of 'jouissance' people try to maintain.

Curiosity–Exploration–Arousal Seeking (CU): Curiosity may be defined as the desire for knowledge because of intrinsic reasons (Berlyne 1960). People gain intrinsic satisfaction from relieving curiosity (Unger and Kernan 1983). A distinction can be made between specific and diverse curiosity motivated behavior (Berlyne 1960). The former refers to the exploration of a single stimulus while the latter represents a tendency to seek stimulation from a variety of sources. Consumers may engage in virtual new product development just because they are curious, or because they want to escape boredom.

Achievement–Challenge–Self Efficacy (SE): The opportunity to prove someone's self efficacy, drives consumers to innovate on the Internet (Kollock and Smith 1988). Consumers that are optimistic about their capabilities to solve a certain task and cope with anticipated difficulties may perceive the activity as a challenge to be mastered. Consumers, just like "Hackers" (Lakhani and Wolf 2003) may be proud of their contributions.

Skill Development–Knowledge Acquisition (SD): People are motivated to perform an activity because they are striving to improve their skills and gain additional knowledge (Amabile 1996; Csikszentmihalyi 2002). Innovative users get in contact with their friends, peer group members, and producers because they look for complimentary knowledge and professional support, needed to advance their own ideas (von Hippel 2002). Engaging in virtual new product development may enable consumers to learn more about new technologies and products.

Information Seeking (IS): Prior studies show that people participate in online communities because they are looking for information relevant to them (Galegher et al. 1998). According to Butler et al. (2002), online communities offer a possibility to gain access to otherwise obscure or inaccessible information. Consumers may engage in virtual new product development because they are seeking for innovation or product related information.

Recognition–Visibility (V): Consumers may participate in virtual new product development to become visible and get recognition from other participants as well as from the producer. Online community members share their know-how and participate in activities connected to effort for ego gratification motives, fame, and reputation (Hennig-Thurau et al. 2004). Further, consumers derive benefits from building up direct relationships with compa-

nies due to special treatment, offered self-esteem, and reduction of uncertainty (Gwinner et al. 1998). Strong brands provide additional benefits, as they are relevant for consumers' self identity creation (Fournier 1998) and serve as a means to express someone's individual lifestyle (Coulter et al. 2003). Engaging in virtual product developments may enable consumers to become visible and known as (co-) innovator beyond their local boundaries.

Altruism-Community Support (A): Altruism can be defined as "doing something for another at some cost to oneself" (Ozinga 1999 p.5). A lively debate is going on as how to define altruism (Takahashi 2000). Without going into the definitions in more detail, altruism may motivate consumer to engage in virtual NPD (Hennig-Thurau et al. 2004).

Make Friends (MF): Beneath the interest for the topic, the possibility to get in contact with like-minded people is a main reason why consumers engage in virtual communities (Kozinets 2002). Moreover, Gwinner et al. (1998, p.104) point out that consumers interacting with companies interpret their relationship with employees as being similar to friendship. This is illustrated by the customer statement "he's like a kind of friend now". Getting in touch with like-minded people-employees and consumers, may be a reason for consumers to participate in virtual NPD.

Personal Need-Dissatisfaction (D): Sports enthusiasts start to modify or develop their own products because they derive benefit from using their innovation (Franke and Shah 2003). Such lead users develop their own products because they are dissatisfied with existing products available on the market and because they expect attractive innovation-related benefits from a solution to their leading-edge needs (von Hippel 2002). Personal need may motivate consumers to virtually engage in new product developments despite limited influence on the final design.

Compensation-Monetary Reward (CO): Immediate as well as delayed payoffs may be the reason why consumers engage in innovation activities (Lerner and Tirole 2000). Consumers engaging in virtual NPD may be interested in the offered monetary incentives such as give-aways, bonus points, prize drawings or monetary compensations delivering immediate benefit. The more time and effort consumers invest, the stronger will be their need for monetary compensation (von Hippel 2002). While monetary incentives may be detrimental for creativity (Amabile 1996), no negative effects on survey response quality have been found (Singer et al. 1999).

EMPIRICAL STUDY

Research Field

The following empirical study was conducted to examine why consumers engage in virtual NPD initiated by producers. Consumers that had actually participated in at least one virtual NPD project were asked about their motivations for participating in virtual NPD projects. Table 1 summarizes 10 virtual NPD projects considered in this study.

For example, Swarovski, the Austrian based market leader for crystal products, initiated a crystal tattoo design competition, inviting consumers to create crystal tattoos, a new generation of "body jewelry" which can be directly applied on skin. An internet-based toolkit see Figure 1 enabled 'fashionistas' to design their own crystal tattoos. In total, more than 6,000 consumers engaged in these projects and made valuable contributions. Further, on average, 77 % of the participants expressed strong interest in participating in further virtual innovation activities. What motivates consumers to do so?

Study Design

An online survey was used for data collection. Based on an extensive literature review, measurement items for all above described potential motives have been identified. Those measurement items have been applied in motivation studies of related fields (Butler et al. 2002; Constant et al. 1996; Unger and Kernan 1983), and were used directly or slightly modified for this study. Interviews with consumers that already participated in virtual NPD, as well as discussions with 5 experts in the field of virtual consumer integration were carried out to complete the initial questionnaire.

In total, the questionnaire contained 24 motive items anchored by (1) "strongly disagree" and (5) "strongly agree". After an online pre-test with 25 participants and subsequent telephone interviews with the participants, data collection with the final, adjusted questionnaire was conducted within 3 weeks in October 2003. 4,714 emails with a link to the online questionnaire were sent, whereof 1,390 emails were undeliverable. The email addresses were obtained from consumers that previously participated in virtual NPD projects and agreed to be contacted in the future. In total 3,320 consumers were reached, and 825 complete questionnaires returned. This corresponds to a response rate of 24.8%. As some projects had been dated back more than one year, I provided consumers with a short visual and verbal overview of the project they were attending to refresh their memory. 727 consumers were included in the further analysis, as they stated that they were able to remember their participation in detail (value ≥ 3) questioned on a 5-point scale anchored by (1) "I can not remember at all" and (5) "I can remember in great detail". To test possible none-response effects as described by Armstrong and Overton (1977), first, early and late respondents (first 3rd vs. last 3rd) were compared and, second, age, gender, and education already measured at the conducted virtual NPD project were compared between respondents and non-respondents. No significant differences were recognized. 53% of the participants were male, 47% female. On average, participants were 35.06 years old and well educated. 30.1 % hold a college degree, 37.9% even hold a post graduate degree. Almost half of the participants (N=354; 42.9 %) reported that they already had an idea for a new product or product modification. But, only a handful of consumers (N= 46; 5.6 %) actually realized their ideas, and only 48 consumers (5.8 %) tried to sell their product ideas.

RESULTS

Table 2 gives an overview of all 24 identified motive items.

Principal component analysis with varimax rotation was performed on the 24 items. Varimax was chosen to identify uncorrelated factors that are independent from each other. Using the scree test criterion a six factor solution was extracted. The scree test criterion was used first, because low communalities (< 0.50) suggested to abolish apparently important motive items like consumers' curiosity when applying Kaisers' eigenvalue-one criteria, and second, for factor analysis with less than 20 remaining items, as was the case in this study, the latent root criterion has the tendency to extract too few factors (Hair et al. 1998). All items with low factor loadings (< 0.5) or with high cross loadings (> 0.35) (Hair et al. 1998), not displaying an important single item, were eliminated. Based on these criteria 12 of the 24 items were deleted. Using Kaiser-Meyer-Olkin (KMO) measure for sampling adequacy (KMO=.787) and Bartlett's test of sphericity ($p=0.000$) indicated appropriate application of factor analysis. Coefficient alpha and split-half testing was used to test reliability of factor scores. Table 3 presents the final factor solution and contains factor loadings, explained variance along with item-total correlations, and α 's as far as available. In

TABLE 1
Consumers Virtually Participating in Following Development Projects

Project/ Study Participants	Project Description
Running/ Basketball Shoes (N=43)	Consumers from different running and basketball communities participated in the development of a modular and adjustable running and basketball shoe concept.
Furniture (N=27)	Readers of online interior design and lifestyle magazines like www.wallpaper.com designed their own modular furniture system in classic design.
Model Railroads (N=85)	Model railroading enthusiasts encountered on communities like www.miba.de and www.dampf-plus.de helped to customize innovative model railroading products according to their needs and to get ideas how to extend the producers product portfolio.
Public City Shiners (N=23)	Citizens of Munich, Germany supported design students to come up with new innovate shiners for the city. The design students modified their concepts according to the participants input. Munich residents became aware of the project via articles in newspapers like "Süddeutsche Zeitung"
Baby Carriage (N=272)	Young parents, frequenting the www.eltern.de community participated in the individualization of a new multifunctional baby carriage.
Mobile Phones for Kids (N=14)	Parents assessed new mobile communication ideas to interact with their children.
Towels and Bedclothes (N=50)	Housewives, visiting the website of Vossen, a famous towel brand in Austria, were invited to participate in a design testing of five different towel collections and taking part in the creation of new bedclothes.
Crystal Tattoo (N=43)	'Fashionistas' visiting sites like www.fashion.net created their own CrystalTattoos. The Swarovski design team got inspired by the creative contributions.
Infotainment Systems in Cars (N=259)	Car enthusiasts and fans of Audi designed their own future infotainment systems. A link on the Audi webpage called consumers attention to participate in the development.
Snowboard Backpack (N=9)	Members of snowboard and backcountry communities like epicski.com , forum.powdermag.com , and www.telemarktalk.com made valuable contributions to develop a multifunctional backpack with integrated avalanche shovel and back protection.

addition, confirmatory factor analysis (CFA) on the hold out sample was used to validate the factor structure of the measurement sample. The overall fit measures of the CFA suggest a good fit for the data ($\chi^2=103.66$ with 39 df; CFI=0.961; GFI=0.957; AGFI=0.913; RMSEA=0.067), and help to cross-validate the model. The final factor structure was also validated for every single project showing an adequate sample size.

As the factor analysis shows, consumers may engage in virtual new product developments, for several reasons: a) curiosity, b) dissatisfaction with existing products, c) intrinsic interest in innovation, d) to gain knowledge, e) to show ideas, or f) to get monetary rewards. The results of the factor analysis are conform with the previous theoretic considerations. Regression analysis was conducted to determine the importance of the different motives. Consumers' interest in further participations and participation frequency served as dependent variables. Table 4 shows the results of multiple regression analysis. As the study consists of 10 NPD

projects, leave-one-project-out analysis, for projects with $n \geq 40$, was applied to investigate the potential bias of one particular project on the overall results (cf. Chakraborty et al. 2002). All regressions delivered basically the same pattern of results i.e. significance levels, overall explained variance, direction, as well as importance of beta-coefficients.

As the highly significant results show, 'intrinsic innovation interest', 'curiosity', and 'showing ideas' are main drivers for consumers to engage in future virtual product developments. While 'monetary rewards' have a negative impact on further participation interest, they are positively related to participation frequency. Monetary compensation becomes important for consumers willing to spend more time and effort. Virtual engagement may be considered as a kind of work. On the contrary, 'curiosity' and 'show ideas' motivate to participate, but do not create endurance. As consumers' engagement is voluntary, interest in the task is the most necessary prerequisite.

1: single item anchored by (1) "strongly disagree" and (5) "strongly agree".

2: single item (1) once a year, (2) once per quarter, (3) once per month, (4) once per week, (5) 2-3 days per week

DISCUSSION AND IMPLICATIONS

In contrast to open source communities and user innovations, where members engage in innovation tasks because they can benefit from using their innovation, consumers engage in virtual new product developments mainly because they consider the engagement as a rewarding experience. As virtual engagement of consumers is less intentional and planned, it may be considered as less 'professional' and persistent. However, considering consumers' innovation capabilities, illustrated by their previous innovation activities, and their stated willingness for further engagement, they offer a promising source of innovation. While monetary rewards are important for people to participate in surveys, or consumers that articulate their experiences on opinion platforms, as far as virtual new product developments are concerned, they only seem to attract a certain type of consumer. The main challenge of virtual consumer integration may be to create a compelling innovation experience. Only, if virtual integration is experienced as a spectacle, may it become a marketable, consumable product itself (Firat and Venkatesh 1995) attracting consumers to contribute on a continuous basis. Researchers developing new tools and methods for virtual integration, as well as innovation managers intending to integrate consumer into their innovation process may find some hints as to how they should design the virtual interaction in order to meet consumers' expectations. As this study covers different projects that were pursuing diverse goals and applying various interaction tools in different product categories, process stages, innovation activities, and levels of innovativeness, the findings should be broadly applicable for current virtual innovation projects in consumer markets. However, the study also comes up with many, so far unanswered, questions such as: How do consumer characteristics affect their motivation for participation? What is the effect of different consumer motives on the creativity, quality and quantity of their contributions? Further, it is interesting to know what the consequences of consumers' participation experience are. Does it evoke consumers' interest for the virtual new product? Those, and further questions may be addressed by future research investigating how to use the innovative potential of consumers encountered in online communities.

Extending the Self in a Virtual World

Shakeel Siddiqui, Dublin City University

Darach Turley, Dublin City University

EXTENDED ABSTRACT

It has been suggested that contemporary consumption is characterized more by an electronically conducted flow than by embedded heavy commodities. Widespread experimentation with consumption of technology has resulted in the creation of newer modes of consumption and possession. Computer Mediated Environment (CME) technologies have lately become a representative form of technological consumption. It can be argued that every moment spent in a mediated environment entails another given up in the real world; each act of consumption in a CME replaces an act of consumption in the real world; each simulated possession replaces a tangible one.

Technology is changing forms and modes of consumption; objects of possession and collection are being de-materialized. Examples of such replacements are letters by e-mail, cards by e-cards, paperbacks by e-books, newspaper by online versions, printed photographs by electronic format and real musical instruments by the virtual. While only some of these consumables in the CME may qualify as possessions on a par with our material possessions, all are nonetheless replacements of tangible possessions, and as such comport the potential and promise of self-extension. Given that a consumer's sense of self is in part predicated upon relationships with material objects, we ask how the dematerialization integral to new technologies such as CME alters this self definition process. Using Belk's original formulation of the extended self, we seek to understand if and how self-extension by means of consumption is affected by virtual possessions in a CME.

The study makes use of a slightly modified version of multi-sited multi-modal ethnography to cater for both landscape localism and flexible modes of netnographic data collection. Seven virtual replacements of tangible possessions represent the main focus of the findings. These are e-mail, e-cards, e-books and journals, pictures/photographs, newspapers, audio/video files and musical instruments.

Findings: The transition from real to virtual is neither sudden nor total; such replacements are progressive and incremental. There is a certain degree of fluidity and interchangeability in the way people make their consumption choices at different times. This context-dependant switching may result in an individual employing both tangible as well as hyperreal modes of consumption and possession for a single product at any given moment.

We found uncertainty a key component of this transition. Our informants found it difficult to replace tangible possessions like pictures with the digital versions. Even the very technologically adept informants wanted to keep a printout as well as multiple copies of digital pictures. This uncertainty was rooted in concerns about ownership and security of digital pictures, which perhaps echo the control aspect of possessions. Social visibility was another dimension of this uncertainty; conversion of self-defining possessions to a digital state reduced the social visibility. Such intangible possessions with reduced social visibility were not as 'self-defining' as their tangible counterparts; this 'taking a part out of me' effectively altered the source and sense of identity for our informants.

We also found emotional attachment as a missing attribute for many virtual versions of the tangible possessions. For example, where in case of real books the reasons of attachment were emo-

tional (pleasure, pride, aesthetics, value), they were purely functional for e-books (cost, ease of use, updates). Very similarly, our informants found it easier to delete an e-card than to tear up a Hallmark.

Collections (Pictures, letters, music, cards): Self-extension through possessions is often manifested in collections. Consistent with the argument presented earlier that consumers tend to experiment with the consumption of technology, we found many of our informants using CME as a platform for collection, parallel to or in addition to the other platforms of collection in their lives. Many self-defining collections—such as those of personal letters and cards, newspaper clippings with personal ties, music and pictures—act as reminders and mementos of the past and containers of identity. With the advent of new media technologies cyberspace has become the ultimate history-book. In the cyberspace, 'we are what we post'; however, for some of our informants such self-presentation in cyberspace had little self-defining or collectible value. However, digital music emerged as one exception of self-defining collection; many of our informants thought that CME, because of its seamless geographically unbounded interconnectivity, was a potent platform for music collection and consumption.

Collections—as tangible manifestations of identity, as a part of one's physical environment—are the sources of meanings, creating a sense of past. Intangible collections—such as pictures, letters, songs and cards on hard disk, presented a sense of past that was qualitatively different from the tangible collections for our informants.

Dilemmas of Virtual Possessions: Given their special characteristics, virtual possessions may become a source of many dilemmas for the consumer. Our informants seemed extremely wary of the fact that constant changes to the technological environment may limit continued control and access to their virtual possessions. Beliefs and assumptions that such changes in technological order may necessitate forced and untimely disposition of a virtual possession gave rise to many concerns. Further, since social exhibition is a desirable quality for many self-extending possessions, any dematerialization which alters this visibility also affects its role in self-extension. Finally, because simulations can be duplicated by electronic means, they appeared to be less authentic and our informants found this difficult to accept.

Conclusion

Digital dematerialization in terms of consumption and possession has been portrayed as an indication of gradual abdication of materialistic values in contemporary societies; however, a sizeable body of literature in consumer research views self extension through possessions as almost always materially oriented and external in nature.

Objectification of a possession assumes a central role in the whole process of creation and maintenance of the construct of 'possession'. We find that even though they might exist and interact in the disembodied domain of cyberspace, consumers are still conditioned to exist and respond to a material world where constructs like possessions, no matter how abstract, still need tangible foundations. The simulations in CME might replace some aspects of the real and tangible, but they do not completely replace them in terms of value and association.

Location, Location, Location: The Relative Roles of Virtual Location, Online Word-of-Mouth (eWOM) and Advertising in the New-Product Adoption Process

Fiona Sussan, George Mason University
Stephen Gould, Baruch College
Suri Weisfeld-Spolter, Baruch College

EXTENDED ABSTRACT

It is no secret that the emergence of *cyberspace* has changed marketing communications (Rogers and Allbritton 1995; Silk et al. 2001). More prominently, the Internet has changed from face-to-face social based interpersonal communications to one of computer-based social networking (Wellman 2001). Cyberspace allows consumers to “gather” in virtual communities and exchange opinions that lead to an “information democracy” in which the information is tilted toward the consumer instead of being manipulated by marketers (Armstrong and Hagel 1993; Bargh and McKenna 2004; Rheingold 1993; Sawhney and Kotler 2001). In other words, cyberspace allows the opportunity for the voices of consumers to possibly drown that of the marketers.

In spite of the advocacy and the reality of the proliferation of online word-of-mouth, (eWOM) with 33% of all adult Americans having participated in it in one way or another (www.pewinternet.org), researchers mainly remain silent about this phenomenon in relation to advertising within the new-product adoption process. Traditionally, marketing and interpersonal communications were separated by time and place with mass media transmission first, followed by word-of-mouth interpersonal communications through face-to-face social contacts (Two-Step Flow by Katz and Lazarsfeld 1955; New-product Diffusion Process by Rogers 1962). The quality of the Internet merging both mass media and interpersonal communications into one *changed that* (Deighton 1997). Consumers can now access both marketing and interpersonal communications at the same time and at the same space on multiple websites. The question then becomes, how does this new *combination* affect the persuasion process within new-product adoption? Are the combined advertising and word-of-mouth messages effective in all websites?

Previous persuasion research has elicited that when there is an incongruity between the source (the messenger) and the message (content) in advertising, the persuasion effect could be negative instead of positive as originally intended (Slater and Rouner 1996). In this paper, we argue further that even when the source and message are congruous, their incongruity with the *location* could lead to a lesser or even an opposite persuasion effect than intended. In other words, this paper speculates that when a firm includes positive eWOM in its own website to facilitate its marketing communication messages, similar to that of mass-media based advertising using “fellow consumers” word-of-mouth endorsement, the persuasive effectiveness may diminish. This is because consumers would most likely perceive the positive eWOM as a deliberate part of manipulated marketing communications, a phenomenon especially not welcome under the Internet-based new “information democracy” previously mentioned (Sawhney and Kotler 2001). This paper extends this argument to suggest that the inclusion of positive eWOM in a firm’s website may in fact undermine the firm’s own marketing messages.

In order to make eWOM a part of an effective persuasive communication within the new-product adoption process, we suggest allocating it within a 3rd-party independent website that has no affiliation with the advertising firm. While the independency of the source enabling a more persuasive effect is not new, in this paper we

are extending the independency requirement to the “location” which hosts both the source and the message. We hypothesize that the independency of the location will maximize the persuasive effectiveness of the message.

Further, we hypothesize that simply advertising on a 3rd-party independent website would not necessarily increase its persuasive effectiveness when compared to that of the firms’ own websites. This is due to the fact that persuasion knowledge model posits that consumers can detect advertising messages and can identify an agent trying to influence them and will activate their persuasion knowledge accordingly. In this sense, consumers do not vary their attitudes toward the advertising message in either website.

This paper aims to measure the perceived persuasiveness of the combination of advertising and word-of-mouth communications in two types of websites (firm-sponsored versus 3rd-party independent-sponsored websites) toward the new product adoption process to include consumers’ interest and likelihood to adopt a new product. A fictitious movie with its advertising and word-of-mouth information were given to four groups of subjects to measure their response on website location effect, word-of-mouth effect and quantitative information effect.

A 2 (firm-sponsored vs. 3rd-party sponsored independent website) x 2 (advertisement only vs. advertisement plus eWOM) between-subject design was used in this experiment. The product used was a new movie DVD. The independent variables consisted of website location and eWOM. Involvement and likelihood to adopt a new product were the two dependent variables. A total of ninety subjects were recruited from a participation pool at a large Northeastern university. The subjects received course credit for participation. All subjects were assigned randomly to the treatment conditions.

After conducting an ANOVA, we found empirical support for positive online word-of-mouth having an additive effect to advertising in 3rd-party sponsored websites but not in firm-sponsored websites. The results also supported the interaction effect between website location and eWOM messages, with eWOM added to advertising in a 3rd-party website having a larger additive effect on consumers involvement and likelihood to adopt a new product than in a firm-sponsored website. The results also supported the hypothesis that consumers do not differ in their involvement or likelihood to adopt a new product when exposed to only the advertisement, regardless of where it is placed.

In particular, the findings of this study bring forth new evidence that positive word-of-mouth does not have an additive effect on advertising when they are placed within the company’s own website. This new evidence adds empirical support to the body of literature that has prophesized that the new virtual space will change the landscape of marketing and interpersonal communications to become a hybrid of mass interpersonal communications that empowers the consumer (Deighton 1997; Sawhney and Kotler 2001).

Finally, this paper makes three important contributions. It adds knowledge to current literature in (1) website strategic management in deciding where not to include word-of-mouth communications, (2) word-of-mouth communications in the interaction effect of word-of-mouth and advertising in the online environment,

and (3) new-product adoption in shedding light as to why not all positive word-of-mouth communications are effective.

SPECIAL SESSION SUMMARY

An Examination of the Concept of Postmodern Home and the Role of Consumption in Home-Making Practices

Fleura Bardhi, Northeastern University
Eric Arnould, University of Arizona

OVERVIEW AND CONTRIBUTIONS

Home is a fundamental construct in social sciences that represents the emotional and meaningful relationship that consumers form with place (Altman and Werner 1985). However, consumer research on home is scarce (McCracken 1989; Sherry 2000). Home has been studied mainly as a context for decision-making and commercial exchange (e.g., Frenzen and Davis 1990; Grayson 1998). But previous work argues that home constitutes an important place for self-development and family life (Claiborne and Ozanne 1990; Hill 1991; McCracken 1989; Venkatesh, et al. 2001). These studies suggest that home is a symbolic and sacred object, and allude to consumers' use of possessions and consumption practices to transform place into home environments. However, we lack studies that focus on the role of the marketplace in home practices as well as studies on the concept of home per se. Furthermore, this session suggest that consumer researchers move beyond an outdated conceptualization of home as a fixed place, typically identified with the house or the homeland, and in which the consumers' display a strong, affective, nostalgic, and permanent connection to a place. By focusing on the concept of home, this session advances our understanding of the ways that consumers relate to place in postmodernity as well as the role that the marketplace plays in consumers' home related practices, such as indwelling and constructing a home.

Consistent with a current movement in social sciences that re-examines the ways that consumers relate to place in postmodernity, the three papers in this session investigate the ways that contemporary life conditions have transformed the notion of home and argue for an increasing role of the market in the social construction of home. The first paper by Bardhi and Arnould investigates a mobile notion of home among contemporary nomadic consumers. They find that the home in postmodernity is not necessary defined in terms of place, but in terms of relationships, possessions and spatial patterns. Mobile professionals actively engage in practices that transform public, commercial spaces into private and salient spaces of home. The second paper by Rosenbaum focuses on aged informants' consumption of a diner. This study demonstrates the social role this consumptionscape plays in the lives of aged consumers—becoming either an extension of their homes or a replacement home. The study investigates how consumers and service providers co-construct the consumption experience in this diner as a home experience through their social relationships, the regularity of consumption practices in the diner, and the domestic activities that take place there. The third paper by Venkatesh is part of an ongoing research project, "Family Portal Design." This research shows how the integrative use of technology in multiple aspects of domestic life blurs the traditional boundaries between the home as private sphere and society as public sphere. In the postmodern home, work and domestic lives are interpenetrating, while home takes on nomadic qualities and is no longer fixed to a place (see also Venkatesh et al. 2001). This study argues for a polysemous understanding of technology at home.

"Making a Home on the Road: A Mobile Concept of Home among Transnational Mobile Professionals"

Fleura Bardhi and Eric Arnould

Global geographical mobility is a normal condition of postmodernity. Seven hundred million people move daily across borders while eighty million people reside outside their native home country (Beck 2000). Many people live between and betwixt several homes and others are in a continuous state of mobility without a fixed place to call home (Featherstone 1995; Urry 2002). How do these contemporary nomads construct a sense of home on the road? What is the meaning of home for these mobile populations? How do they use possessions and commercial setting in the process of home making? These research questions are addressed in this study.

Home is one of the central social concepts that consumers orient themselves in time and space as well as a highly symbolic and often sacred object. However, consumer research on home is scarce (Sherry 2000). Mobile consumers' connections to home and the influence of this relationship in consumer behavior have been discussed in the acculturation literature. However, acculturation studies have examined mainly sojourner consumer segments—sedentary consumers for whom mobility is only a temporary condition and they sustain the connection to a place they call home. We also do not know much about the ways that mobile consumers construct a home on the road (Thompson and Tambyah 1999). The focus of existing studies has been on the ways that sojourners sustain connection with existing homes while on the road. Finally, consumer research has been informed by an implicit notion of home as fixed to a place (homeland or dwelling).

This study addresses these issues by studying the notions of home among consumers who willingly live nomadic lifestyles, such as transnational mobile professionals (TMPs) (Featherstone 1995). TMPs are members of a mobile professional class that has emerged worldwide with the development of the global economy. This global consumer segment is characterized by cosmopolitan orientation and voluntary nomadism, always on the road from one global city to the other, without a clear anchoring of identity to place or nationality (Featherstone 1995; Hannerz 1996). The data for this study is comprised of 35 semi-structured, long interviews with highly mobile global professionals. The informants were selected on the bases of sampling criteria derived from the literature on TMPs. The sample includes roving professionals, business travelers, and expatriates located in different parts of the world. The researchers traveled in the informants' places of residency or work to conduct the interviews, which lasted from 1 to 5 hours. N*Vivo was used to code the data following a preliminary list of codes and the recommended techniques of qualitative data analysis.

The study found that TMPs desire to have a home and engage continuously in practices that enable them to maintain or recreate a sense of home on the road. We find that TMPs define home in a mobile sense, in three different ways. First, TMPs define home in terms of order: home is found in places where certain spatial and temporal patterns exist or are created. Second, TMPs define home in terms of salient relationships. Findings show that TMPs experi-

ence places where certain family or kinship relationships take place as homes. Third, TMPs define home in terms of cherished possessions; homes are places that serve as “vaults” of precious memories represented and stored in cherished possessions. These three notions of home represent *mobile notions of home* that differ from traditional concepts of home in several ways. Home among TMPs is not only a place, but can be defined in terms of relationships, possessions, or spatial patterns. TMPs have multiple homes and the relationships they form with place are temporary where departure from home-places is not experienced negatively.

Since TMPs have a mobile notion of home not affixed to a place, the study found that TMPs engage in an ongoing process of making a home on the road. TMPs attempt to create a sense of home in the hotels in which they reside during travel, blurring the line between the private space of home and the public, commercial space. Informants engaged actively in several practices of appropriation of commercial spaces that transform them into home-like environments. For example, informants talked about moving hotel room furniture so that they create a similar spatial order to the one at home. They request certain furniture and appliances in their rooms that they consider “necessary” home objects. They find the room ambiance, such as color, light, and smell important in constructing the sense of home. Personalization of space through decorating with family photos, flowers, food, etc is another practice that informants used to transform commercial hotel rooms into homes. Informants also emphasized social elements of hotel service as important in making the hotel more like home.

We believe that the findings of this study make a two fold contribution. First, this study contributes to the social sciences literature on the construct of home by identifying a mobile concept. In this way, our research provides an empirical response to calls for more portable, fluid notions of home in postmodernity (Rapoport and Dawson 1998). Second, this study shows that home remains an important construct that influences consumer behavior even in the postmodern context. Facile postmodern notions of decentered subjects and fragmented identities require revision in light of TMP consumers’ active construction of home-like environments.

“From a Diner to a Home: Understanding How Customers Find Home in the Marketplace”

Mark S. Rosenbaum

The concept of place is well engrained in the marketing discipline as a marketing mix tool that refers to distributional and to organizational activities associated with making products and services available to targeted consumers. Marketers tend to conceptualize places in isolation from consumers’ personal lives and experiences. Places are mainly considered as mere points-of-exchange. Sherry (2000) posits that places have different dimensions of meaning for consumers on based of personal experiences in them. The goal of this paper is to offer a conceptual framework that explains how and why consumers experience places in the lives. As such, the paper advances our understanding of why and how customers may transform places from consumption settings to home-like settings. This article contributes to several research paradigms including commercial friendships, (Price & Arnould 1999), customer communities (McAlexander, Schouten, and Koenig 2002; Muniz & O’Guinn 2001), commercial social support (Kang & Ridgway 1996), and loneliness (Goodwin and Lockshin 1992).

The study employs Grounded Theory Methodology (Glaser & Strauss 1967) to develop a parsimonious, relevant, and modifiable framework regarding how and why consumers imbue places with different meanings. The study is based upon fifty-six interviews with customers (44), employees (8), managers (2), and owners (2) at Sammy’s, a casual dining restaurant located in a suburb of a large

Midwestern city. During the initial stage of data gathering, customers were asked to explain what Sammy’s means to them. The data revealed that customers emplace three types of meanings in the restaurant, and hence, experience it in three different manners. First, some customers view the restaurant as a place to fulfill a consumption need; hence, they experience *place-as-practical*. Second, other customers perceive the restaurant not only as a place to eat, but also, as place to socialize, or to “kibitz” with friends; therefore, they experience *place-as-gathering*. Third, other customers, referred to as the regulars, view the restaurant not only as a place to eat, or to socialize, but also, as their home-away-from-home. *Place-as-home* is conceptualized as a place that consumers experience in order to satisfy consumption, companionship, and emotional support needs.

The next stage of theoretical development concerns understanding why consumers imbue the restaurant with different meanings and experience it so differently. The data revealed that customers who experience the restaurant as place-as-gathering or as place-as-home do so in order to prevent, or to remedy, feelings of loneliness. In order to alleviate social and emotional loneliness, individuals typically turn to traditional sources of support, including family and friends (Weiss 1973). However, findings show that life events, such as retirement, chronic illness, or death, may deplete aged consumers’ traditional sources of support. In the study, aged informants turn to a kind of neo-tribe and commercial friendships to fill these voids. I found that “regular” customers who experience the restaurant as home are older-aged adults, most of whom are widows or widowers, retired, and who reside alone. These customers no longer had access to sufficient traditional sources of social support, and hence, turned to employees and other customers in the restaurant for supportive resources that were metaphorically imbued with domestic meanings. For example, customers talked about how the owner of Sammy’s was like their son, and that they were part of his family. Other customers discussed the love, the care, and feelings of belonging that they received from simply being at the restaurant. Thus, for these customers, the supportive relationships that they held with others in the restaurant resembled familial and friendship bonds, and led them to perceive the restaurant as their home-away-from-home (Hill 1991).

Similar to the customers who required social support, so too, did the employees and the managers at Sammys. Several of the waitresses discussed that they were in abusive relationships, and that working at Sammy’s was a temporary escape from reality. Gallo, a waiter, and recent émigré from Ecuador, discussed how he relies on his regulars for information about living in America, such as information about applying for credit, taxes, as well as, legal and medical issues. The restaurant is home not only to its customers, but also, for its employees.

The manner in which consumers experience a place affects their relationship with the place. The data reveals that customers who experience the restaurant as place-as-practical are satisfied, but not necessarily loyal to the restaurant. Customers who experience the place-as-gathering exhibit a “community loyal.” These customers are loyal to a group of people that happen to gather in the restaurant. However, customers who experience the place-as-home are customers who are fused together with a variety of individuals in bonds of human togetherness and care, so that customer and place become a social unit.

“Designing the Family Portal as Home Information System and Home Networking”

Alladi Venkatesh

This study is part of an ongoing project that aims at designing an interface for home use that would address the specific needs of

TABLE 1

<i>Family Activities</i>	<i>Mediating/Enabling Technologies</i>	<i>Home Information System Inputs</i>
Family get-togethers, vacations.	Digital Photography and Peripherals	Photographic records, Digitized family pictures
Family cooking, meal preparation.	Smart kitchen appliances	Family consumption of food, types of meals prepared, family member tastes and preferences, frequently or occasionally purchased items
Children's education and entertainment (music, reading, sports, etc).	PC use; Hand-held information appliances	Children's school performance, library information, other needs of children, records of children's interests.
Home financial management.	PC; Information Appliances	Family financial, tax records, credit card information
Family communication; Social contacts.	PC (e-mail), cell-phone, pager; Information Appliances	Addresses of friends and near/extended family, keep track of invitations and social occasions
Shopping.	Same as above	Store addresses, items purchased, record of monthly shopping both online and offline

families in the context of their domestic information based activities and routines. This project examines the use of technology at home attempting to design an information infrastructure that uses Internet technologies for home management and external networking, called the "Family Portal". Our recent work on home networking (Venkatesh, et. al. 2003) indicates that the focal point of the Family Portal is the home as an activity and information center. Table 1 provides some examples of the link between the activity center and the household information system.

This paper attempts to a) identify the ways that families use technology at home; and b) examine the influence of technology in family life and notions of home. The study was conducted through in-depth interviews with ten families followed by concept testing of the Family Portal. The key respondent (usually a female adult) provided information on current computer usage at home and other daily activities. After the interview, the respondent was presented a screen shot of "the Family Portal." This was used to encourage them to talk in detail about their potential usage of the internet for various applications. This was followed by the introduction of a more realistic version of the Family Portal.

Most published literature on computer use at home cites three major uses for the computer: communications, information and entertainment. The findings of this study confirm these results. However, there are other uses which point to the fact that family computer use is more complex or diverse. As the technology becomes more domesticated and integrated into the family life, other uses become more prevalent. Thus, families with children use the computers as part of their parenting responsibilities and child oriented activities including school. Findings suggest that family priorities and activities determine the varied use of technology in the home.

In a larger sense, many household activities involve several themes. For example, when families communicate with family members, friends, shops, service agencies, banks etc., one way to describe this is simply to say that the computer is used for communication—which suppresses a lot of finer details. This is because each act of communication has its own distinct quality and content which should be uncovered meticulously. For example, communication with family can mean family interactions on various matters or organization of family events. Communicating with children

implies some parenting activities or following everyday routines. Similarly, online shopping may involve communicating with stores (online or physical), community agencies or medical sources.

While this study argues for a polysemous use of technology at home, the findings also illustrate the domestication of technology to carry parental roles, social communicator and networking roles, as well as domestic consumption roles. Additionally, by examining the influence of technology on the home and family dynamics, the study finds that domestic use of technology has enhanced family's social networks, enabled formation of different levels of social bonds, and empowered the family members. For example, communication technology and the human decision to employ it expand the social network by increasing the emotional web of social contacts and by making it more feasible for new relationships to enter the network. The technology has provided individuals with different levels of bonding (e.g. high and low levels) in their social networks. Further, the breadth of communication technology provides more options for families to manage family and community events. For instance, the convenience of scheduling a family party is not more apparent than in a communication scenario where other families can be contacted through one correspondence. Finally, the data shows that family members are empowered by the negotiation process of communication technology. The tech-enabled network allows its members to choose a mode of communication that suits their experiential needs.

Finally, to conclude, the role of the Family Portal in this complex set of activities is that it permits families to plan events, contact friends, relatives and outside agencies, keep family records, follow news, and perform various activities that the computer is suitable for. The family portal has the potential to become a central unit that systematizes family computer use, collectively and individually. It is a meeting point for the family members and shared virtual space. At a very basic level, the family portal is an information or communication portal. At another level, it permits families to use it for different organizing needs.

SPECIAL SESSION SUMMARY
Dynamics of Self-Regulation
Suresh Ramanathan, University of Chicago

SESSION OVERVIEW

There has been considerable research in the social psychology and marketing literature on the topic of self-regulation and self-control (e.g., Carver and Scheier 1981; Fishbach, Friedman and Kruglanski 2003; Hoch and Loewenstein 1991; Ramanathan and Menon 2005; Shah, Friedman and Kruglanski 2002; Shiv and Fedorikhin 1999, 2002; Vohs and Schmeichel 2003). These have looked at self-regulation through a variety of lenses including goals and motivation, spontaneous and higher order affect, and mental resources. This session seeks to integrate some of these perspectives in presenting a dynamic view of self-regulation.

The broad purpose of this session was to present work that adds to this growing body of research, and to delineate the intrinsic dynamics of self-regulation and its influence on goal pursuit and goal management. In doing so, we identify several new dimensions to these phenomena. For example, we show that efforts at self-regulation may cause greater levels of intensity in subsequent emotional reactions (Vohs et al.). We also show how hedonic goals and regulatory goals come into conflict on a moment-to-moment basis and how people's pursuit of these goals and their emotional reactions are influenced over time (Ramanathan and Menon). Finally, we also show how people adaptively manage or regulate their goals over time through a variety of techniques such as goal shielding, goal switching, goal shedding and goal synthesis (Shah and Bodmann). The specific purposes of the session are: (a) to outline the theoretical processes at play, whether cognitive, affective or motivational, (b) to determine the conditions that facilitate and impede these processes and to understand the boundary conditions thereof; and (c) to explore these effects in different domains, across multiple research paradigms.

The papers in this session explore the mechanisms by which efforts at self-regulation may influence and in turn be influenced by affective and motivational processes. For instance, the paper by Vohs and co-authors shows that trying to exert self-regulation leads to more intense experience of both positive and negative emotions. In other words, people experience higher peaks and lower troughs in subsequent affective experiences. The paper by Ramanathan and Menon provides evidence of both affective and motivational processes at play in self-regulation, as it explores the moment-to-moment experience of approach/avoid reactions in response to hedonic or healthy stimuli. Shah and Bodmann argue that successful self-regulation requires an adaptive mechanism of goal pursuit to be followed, such that people could dynamically decide on whether to pursue their current goal and shield it from other goals, switch from it, or even shed it totally.

The first paper by Vohs, Mead, Schmeichel and Bruyneel shows that people who were depleted of resources via a variety of novel tasks reported more intense positive and negative emotions. For example, participants who had to suppress their thoughts (not think of a white bear) reported more intense positive emotions while watching a comedic film. In a second study, participants in a Stroop task involving words and colors that were inconsistent with each other (depletion condition) displayed more polarized evaluations of subsequently presented emotional pictures compared to those in a control condition with consistent words and colors. In another study, participants, after completing a depletion task, were asked to keep their hand in freezing water for as long as they could. Depleted

participants were less able to keep their hands in the water and reported more intense pain compared to a control condition. Viewed together with prior research on self-regulation and depletion, this paper makes a case that failures at self-control due to depletion may be driven by these intense emotional states.

The second paper by Ramanathan and Menon focuses on the dynamic experience of approach/avoidance motivation as people are faced with temptations. After establishing in a first study that there are significant differences in reward sensitivity between people classified as impulsive or prudent and in response latencies to the measures of impulsivity, the authors ran a second study in which half the participants pre-classified as impulsive or prudent were primed with a hedonic goal. They were then shown a tray filled with cookies or vegetables and asked to use a joystick continuously over three minutes to indicate how much they felt drawn towards the items on the tray or how much they felt like avoiding it. The dynamic traces of the like-dislike reactions showed interesting differences for impulsives and prudents, depending on whether they were primed with the hedonic goal or not. While both impulsive and prudent people who were primed with a hedonic goal showed an immediate spike in their evaluations of the cookies, the former showed greater ambivalence over time that resolved in favor of an increasing desire for the cookies. The latter however showed a marked decline in evaluations of the cookies over time that mapped on to a concurrent increase in evaluations of the vegetables, indicating goal switching.

The final paper by Shah and Bodmann looks at how people manage their goals in self-regulation. The authors present a series of studies that show how people prioritize and juggle their goals as they engage in self-regulation. They show that people might regulate the attention they pay to concurrent multiple goals via "goal shielding." In other words, they inhibit other goals and keep them from becoming salient while pursuing a focal goal, particularly when the goals in question fulfill the same regulatory need. Interestingly, they also show that certain emotional states, notably anxiety, are more conducive to such inhibition while depression actually hinders goal shielding. Even more interestingly, the authors show that goal shielding has important consequences for how intensely goals are pursued and how likely they are to be attained. Other studies by the authors also show evidence of other regulatory mechanisms. In particular the authors will present data that articulates how individuals shift from goal to goal and when they might consider shedding goals entirely. Together, these studies are powerful evidence of the way people manage multiple goals and goal conflict, important concepts in any discussion on self-control and self-regulation.

Two of the three papers in this session (Vohs et al.; Ramanathan and Menon) focus on failure in self-regulation, suggesting that these are due to more intense emotional states being created by demanding extrinsic situations or due to the pursuit of hedonic goals that continue to strengthen over time and override any ambivalence. A third paper (Shah and Bodmann) shows how good self-regulation involves adaptive goal management techniques that can potentially influence well-being over time. Together, the three papers look at different domains of self-regulation, thereby attesting to the generality of the findings presented.

“Self-Regulatory Resource Depletion Makes People More Extreme in Their Emotions and Judgments: A Possible Mechanism for Ego-Depletion”

Kathleen Vohs, University of Minnesota

Nicole Mead, Florida State University

Brandon Schmeichel, Texas A&M University

Sabrina Bruyneel, Katholik University Leuven

Self-regulation has been studied from a variety of perspectives (e.g., Carver and Scheier 1981; Hoch and Loewenstein, 1991) but virtually all of this research finds that people have a difficult time (at best) controlling impulses and overriding desires in order to reach goals. Reviews of the literature have suggested that self-regulation can be viewed as operating off a limited resource (e.g., Baumeister, Bratslavsky, Muraven and Tice 1998; Vohs and Schmeichel 2003). It is not yet known, however, why people who have fewer self-regulatory resources fail at subsequent attempts at self-regulation, except to say that they have fewer resources to put to the task. The current research examined changes in the subjective feeling-state of participants who were depleted versus those who were not depleted, as a possible explanation for decrements in self-regulation after earlier self-control. Results from five experiments support this assertion.

In Study 1, participants first engaged in a thought-listing task—those in the depletion condition were given thought suppression instructions (do not to think of a white bear), whereas participants in the control group were told they could think of whatever they wished, including thoughts about a white bear. Later, all participants watched a comedic film. Results of mood after the film indicated that participants in the thought suppression condition subsequently felt more positive emotions and less negative emotions as compared to participants in the control condition. Also, participants in the depletion condition reported deeper emotions while watching the film compared to participants in the control group.

Study 2 provided further support for the hypothesis that depleting self-regulatory resources leads people to become more polarized emotionally. The Stroop color-listing task was used to manipulate self-control. Participants in the depletion condition were asked to read the color of ink that the word was printed in, with ink colors and names of color being inconsistent (the word “red” written in blue ink), whereas participants in the no depletion condition were asked to name the color of ink that four XXXXs were printed in. Results showed that participants in the depletion condition had more extreme ratings of highly-emotional pictures than did participants in the no depletion condition.

In Study 3, participants in the depletion condition were asked to read aloud boring, technical text but to do so with exaggerated gestures and high enthusiasm, whereas participants in the no depletion condition read aloud the same passage without further instructions. Next, participants rated 20 Chinese characters on their attractiveness. As predicted, participants in the depletion condition rated the Chinese characters more extremely than did participants in the no depletion condition.

Study 4 tested whether multiple types of judgments were affected by self-regulatory resource depletion or whether only those relating to emotions were affected. We employed two different dependent measures (within-subjects; counterbalanced): ratings of Arabic letters as to their likeability (emotionally-laden judgments) versus sensory-based judgments of products, such as “How heavy is this glass?” To manipulate self-regulatory resources, participants were randomly assigned to complete either an easy or difficult version of a proofreading task. As expected, only judgments of likeability were affected by depletion, whereas ratings of sensory aspects of products were unaffected. Participants in

the difficult proofreading group showed significantly more variability in their ratings of likeability of Arabic characters (i.e., they were more extreme) than participants who completed the easier version of the proofreading task. No differences were found in variance of ratings for sensory perceptions between groups.

In Study 5, participants in the depletion condition read aloud boring text in an animated fashion (as in Study 3), whereas no-depletion participants read aloud without instructions. All participants then submersed their arms in freezing water for as long as they could. This cold pressor task allowed for measurements of pain sensations and self-control. Results revealed that participants in the depletion group were less able to keep their arms in frigid water as compared to no-depletion participants and reported more intense pain. Mediation analyses suggest reduced self-regulation is due in part to reports of increased pain.

In sum, the current research suggests that being in a state of resource depletion from earlier expenditures of self-control changes people’s subjective feelings states. They experience highs as higher and lows as lower. This change in emotionality likely makes it significantly more difficult to regulate, with the result being less control over oneself.

“Moment-to-Moment Pursuit of Hedonic Goals”

Suresh Ramanathan, University of Chicago

Geeta Menon, New York University

There is considerable research on self-control and failures thereof, examining these occurrences from a variety of different perspectives, such as spontaneous hedonic or low-road affect (Giner-Sorolla 1999; Shiv and Fedorikhin 1999, 2002), ego-depletion (Baumeister, Bratslavsky, Muraven and Tice 1998; Vohs and Schmeichel 2003), and goal conflict (Fishbach, Friedman and Kruglanski 2003; Ramanathan and Menon 2005). One area that has not been studied is the dynamic nature of the process of exerting self-control or giving in to temptations. Specifically, what happens to us on a moment-to-moment basis as we see a tempting stimulus?

Our first goal was to show that there are differences between impulsive and prudent people in terms of reward sensitivity and chronicity of such reward-seeking. We used a task called the CARROT (Card Arranging Reward Responsiveness Objective Task, Powell et al. 1996) to show these differences. This task requires participants to sort a stack of 100 cards, each of which has a five digit number printed on it, into three piles. Each five digit number has one of the numbers 1, 2 or 3 occurring in it at any position, and the participant is required to sort the stack into piles that contain the digit 1, the digit 2 or the digit 3. This task is performed over three trials, with the middle trial being rewarded (20 cents for every five cards). People classified as impulsive on a standard impulsivity scale sorted significantly more cards on the rewarded trial compared to the average of the non-rewarded trials. Response latencies to measures of impulsiveness were significantly smaller for those classified as impulsive, suggesting that these self-ratings were chronically accessible.

Study 2 focused on how differences in these chronic hedonic goals might manifest in moment-to-moment reactions to hedonic or healthy stimuli. Participants completed a scrambled sentence task that either primed a hedonic goal or was neutral in content. Following this, they were presented with a tray filled with cookies or cut vegetables and were asked to look at the items while using the joystick continuously to indicate exactly how they felt at the precise moment towards the items on the tray (by pulling it towards themselves if they felt drawn towards the items at the moment and pushing it away if they felt like avoiding it). Movements of the joystick were captured every 0.1 seconds over three minutes by the program, and averaged to 1 sec. The stream of data showed four

interesting results. First, impulsive people primed with the hedonic goal showed an immediate spike in their approach reactions to cookies that lasted 40–50 seconds. This was reflected in a high positive velocity and acceleration in evaluations. This then gave way to an intensely ambivalent state characterized by sharp ups and downs. This period showed the highest variance in feelings. Around 100 seconds, this state of ambivalence was replaced by a steadily increasing approach reaction indicating that an unsatiated hedonic goal was still at play. Second, in line with the findings of Fishbach, Friedman and Kruglanski (2003), prudent people who were not primed with the hedonic goal showed an immediate spike downwards (as reflected in a high negative velocity/acceleration) after seeing the cookies that lasted about 30 seconds and then gave way to a stable, unconflicted, low variance reaction over time. On the other hand, prudent people primed with the hedonic goal and presented with cookies showed a sharp increase in the approach reactions that lasted approximately 60 seconds and then decreased sharply to below baseline levels as obtained in the non-primed condition. Correspondingly, prudents primed with a hedonic goal, but presented with vegetables showed a sharp increase in their evaluations of the vegetables around the same time as the decrease observed in the cookie group.

These data suggest that there are differences between impulsive and prudent people in terms of how they dynamically handle the fight between willpower and desire. Hedonic goals, whether chronic or primed, lead to spontaneous approach reactions towards tempting stimuli among both impulsive and prudent people in the immediate term. However, the time course of these reactions is markedly different over a longer window. A key characteristic of goal conflict is ambivalence—this was clearly seen among impulsive people soon after they got over their immediate affective reaction. They managed this ambivalence by choosing the unsatiated hedonic goal that continued to gather strength. In contrast, prudent people who were primed with the hedonic goal managed their goal conflict by switching to a health goal, as seen in the sharp decrease in evaluations of the cookies and the corresponding increase in evaluations of vegetables.

“Attention Mechanisms in Goal Management”

James Shah, Duke University

Shawn Bodmann, University of Wisconsin-Madison

Goal pursuit is rarely done in isolation. We are almost always pursuing multiple goals at once, often with only limited time and resources. Given such limitations, an important, although perhaps under-examined, component of effective self-regulation is the manner in which we prioritize and “juggle” our various pursuits and resolve goal conflict in order to best ensure the successful attainment of as many goals as possible. This paper focuses on the mechanisms involved in such goal management and the degree to which they may unfold automatically.

One challenge of pursuing multiple goals is how easily one pursuit can pull one away from another (see Shah & Kruglanski, 2002). Indeed, there may often be significant benefit to inhibiting alternative goals in that such inhibition may better allow one to direct one’s full attention to the goal at hand. We explore the role of goal inhibition in self-regulation by examining how the activation of goals may inhibit the salience of one’s other important intentions. Study 1 examined how goal shielding (as evident in fewer listing of alternative goals) was positive related to focal goal commitment, need for closure and general differences in goal-related tenacity. Study 2 replicated the general goal commitment results of Study 1 using a lexical-decision technique that assessed goal shielding in terms of the latency of responding to an alternative after being

primed with a focal goal. In Study 3 the same technique was used to examine the same effects for participants’ short-term goals. Study 4 again used this technique to examine whether goal shielding varied as a function of the relation between the goals involved. Whereas commitment to a goal was found to more strongly inhibit redundant (substitutive) alternatives, this commitment was less likely to inhibit facilitative alternatives since pursuing such alternatives would presumably help one attain the focal goal in question. Thus, for some individuals the goal of playing tennis may readily inhibit the goal of jogging since both fulfill a higher-order need to get in shape. Alternatively, goal activation less readily inhibits alternatives whose attainment is viewed as facilitating the salient focal goal. Thus, for other individuals the goal of playing tennis may not inhibit the goal of jogging because the latter may be perceived as helping one attain the former. Study 5 examined how the regulatory purpose of goals in question may influence goal shielding. Whereas a promotion focus and promotion-related emotions (dejection) was found to lessen goal shielding, since individuals with a promotion focus have an orientation toward change, a prevention focus and prevention-related emotions (agitation) was found to enhance goal shielding as prevention focus is oriented toward issues of security. Finally, Study 6 found evidence that, independent of goal commitment, goal shielding may serve important self-regulatory functions in that it has distinct consequences for how intensely goals are pursued and how likely they are to be attained (as evident in individuals’ persistence and performance in pursuing specific task goals).

Effective goal management thus involves not only goal shielding but also three other mechanisms—goal shifting, goal synthesis and goal shedding. Goal management may be aided by the consideration of how goals relate to each other. Does the attainment of one goal, for instance, aid the attainment of another? Does goal attainment render another goal less important? Understanding the ways in which different goals may be synthesized could prove to be an invaluable tool for effectively juggling one’s various pursuits.

Giving and Receiving Humanity: Gifts Among Prisoners in Nazi Concentration Camps

Jill G. Klein, INSEAD

Tina M. Lowrey, University of Texas at San Antonio

EXTENDED ABSTRACT

Gift-giving research in the field of consumer behavior has expanded our understanding of what a gift can be and of what it means to give. However, this research has been conducted in fairly normal contexts such as romantic dyads and family holiday exchanges. But what happens when the context becomes much more extreme and gift-giving embodies life and death decisions? The purpose of this paper is to explore instances of gift-giving in Nazi concentration camps. In spite of intense pressures toward selfishness, prisoners gave gifts to one another, demonstrating the basic personal need to express humanity through generosity.

A careful textual analysis of personal memoirs as case studies (Stake, 1995) and historical accounts was conducted. All of the memoirs were written by Jews, who are widely acknowledged to have suffered the greatest deprivation and mistreatment of all prisoners in the camps. Thus, their gift-giving was done under the most difficult of circumstances. The historical accounts (Cohen 1953; Des Pres, 1976; Todorov, 1996) were used as a way to include the perspectives of authors who have carefully studied life in concentration camps, as well as to verify our interpretation of the memoirs used in our study.

The structure of the concentration camp system and the dismal conditions endured by prisoners were not conducive to concern for others. All forces pushed one to focus on survival. As Cohen (1953) writes of his initial days at Auschwitz, "I had only one thought left: How can I survive (p. 123)?" This drive for survival necessarily put prisoners at odds with one another as they fought for extremely scarce resources: "Will you survive, or shall I? As soon as one sensed that this was at stake everyone turned egoist (Lingens-Reiner, 1948, p. 23)." As Louis de Wijze (1997) writes of Auschwitz, "Everyone lives for himself. Our one and all-encompassing credo is: Survive! Between the outer limits of life and death, previous values and norms lose their meaning, and our spiritual baggage gradually erodes. The only norm that counts is "I". All our senses, thoughts, and deeds are used only for our own benefit (p. 67)."

Yet, we found many instances of helping and gift-giving in the camps. Further, we found that the act of giving was in part a defiance of the dehumanizing forces. Along with other attempts to re-establish humanity such as engaging in intellectual activities (Levi, 1989), religious observances (Cohen, 1953), and the modification of uniforms to express individuality (Klein, 2003), giving to others helped both the giver and the receiver feel more human. Some gift-giving was more directly instrumental, and thus we present instances of gift-giving along a continuum from the very instrumental (i.e., bribes) to giving that is motivated by the simple desire to demonstrate humanity. Giving on this end of the continuum was motivated not by expectations of return but simply by the notion that helping is the correct and human thing to do. Sometimes this helping was very reflexive and natural in nature.

Gift-giving was most likely to take place within dyads or small groups (i.e., cliques). Dyads were sometimes governed by a norm of true balance (i.e., circular reciprocity), while other giving relationships were notably skewed in a particular direction because one member of the pair had greater access to resources (Belk, 1976). In some cliques, the norm of equipollence (Lowrey, Otnes, and Robbins 1996) seemed to play a major role, in that every member tended to expect equivalent treatment and violation of this norm caused distress to all concerned. In other cliques, it was recognized

that dyads within the group—such as sisters—would give primary support to one another.

Although the concentration camp setting is certainly extreme, we believe that our findings are relevant to consumer behavior researchers in a variety of other contexts as well. The recent tsunami disaster points to one area ripe for future study. Do inhabitants of relief camps exhibit similar acts of giving, perhaps establishing normative guidelines and pressuring those who fail to comply? Similarly, refugee camps, often more long-term in nature than temporary disaster relief situations, may offer further evidence of a widespread "need" to give. These contexts can still be classified as somewhat extreme, but we would argue there are situational factors inherent in these settings that are not that different from living in a totalitarian regime, or living in dire poverty. Past gift-giving literature has stayed mainly in the realm of middle-class respondents (or higher income levels), but those at lower levels, and in more restricted life circumstances, give nevertheless. Despite pressures toward selfishness, we argue that both giving and receiving helps us to feel more human, which is a strong behavioral motivator regardless of circumstance.

The Transition to a Special Needs Consumer: My Ethnographic Journey Caused by Celiac Disease and Diabetes

Lawrence Lepisto, Central Michigan University

ABSTRACT

About two years ago I was diagnosed with celiac disease for which the only treatment is a strict gluten-free diet which eliminate all foods with wheat, rye, or barley. Then, nine months ago I was found to have developed diabetes which added further dietary restrictions, blood sugar monitoring, and medications. This paper describes, in ethnographic fashion, the multitude of changes in my consumer behavior and offers insights into the behavior of many other consumers who face dramatic restrictions in their diets.

INTRODUCTION

About two years ago I was diagnosed with celiac disease. Celiac disease (or celiac sprue or sprue) is caused by the intake of gluten which limits the ability of the small intestine to absorb food. There is no cure other than a strict diet which eliminates all gluten from the food being consumed. The challenge with this diet is that gluten is found in wheat, rye, and barley which means that I cannot eat traditional bakery items (e.g., breads, rolls, pizza crust, cake, cookies), crackers, most canned soups, many sauces, beer, and breaded items. Then about nine months ago I was diagnosed with diabetes which necessitated reducing carbohydrates, timing meals, and instituting new medications, including insulin.

As a marketing professor who teaches consumer behavior, I observed myself over the past two and a half years as I drastically changed my purchasing, food preparation, self perception, and other aspects of consumer behavior. While I am a sample of one, it raises issues that millions of consumers face as they attempt to adjust to new lifestyles and priorities when confronted by diseases or other limitations introduced into their lives. There are many consumers who find that they must live on newly restrictive diets. People with allergies, especially food allergies, find themselves avoiding certain foods or additives. Diabetes forces multitudes of consumers to monitor their intake of carbohydrates. Lactose intolerance limits the intake of dairy products. Therefore, my experience presented in this paper would, in varying degrees, likely parallel the experience of millions of these consumers. Hopefully, this ethnographic experience can identify areas of research that lead to better understanding of consumers who face similar situations. To describe my journey, I will discuss these personal and consumer-based changes when I first faced celiac disease and then diabetes.

FIRST, CELIAC DISEASE

I had been losing weight and I lacked energy. The ordeal of diagnosing celiac disease is often a challenge because the symptoms can vary from person to person (American Family Physician, 2003). Celiac disease is an autoimmune disease in which the body attacks gluten which in turn attacks the villi, the microscopic hairs in the small intestine which absorb nutrition. These villi atrophy resulting in nutrition not being absorbed which can affect those organs nourished by that part of the intestinal track (Jahar and Jahar 2001). The only treatment is a strict lifelong gluten-free diet (Green et al., 2001). Another symptom, which I had the pleasure of experiencing, was months of diarrhea. Finally, my gastroenterologist did a scope into the stomach and the opening of the small intestine which produced biopsies which found blunted villi. A new blood test finally confirmed celiac disease. He gave me a few brochures, told me that I cannot eat anything with flour, barley, and rye and sent me on my way. I remember walking out to my car

wondering how on earth am I supposed to eat. It was very much a life changing day for me.

Celiac disease affects about 1 in 133 people although a significant percentage are not aware they have the disease (Fasano et al., 2003). They (referred to as "celiacs") may be asymptomatic or may have symptoms which physicians may not associate with the disease (Lohimmiemi, 2001). It is becoming more recognized but physicians continue to have difficulty diagnosing the disease because it can manifest itself in so many ways.

As I was struggling to adjust to my new diet and my new life, I certainly didn't approach this struggle as a consumer researcher. However, over time I began to notice how different my consumer behavior was becoming. Two and a half years have added greater perspective to these changes and this paper will identify the dimensions of consumer behavior that have changed. I will present these consumer behavior dimensions roughly as I became aware of them over time.

Evaluative Criteria

An average consumer looks at the array of food products and evaluates them on the basis of taste, price, calories, etc. Glanz, Basil and Mailbach (1998) noted that taste is the most important attribute of food for most people. For those with celiac disease, foods must first be evaluated to determine if it is gluten-free. Everything else is secondary. The problem is that so many foods contain gluten, it is estimated that gluten is the second most prevalent food substance in Western civilization (Harder, 2003). As a result I needed to become very focused on ingredients to which I previously paid little attention. Gluten can come in different forms: flour, rye, barley, and for some people, oats. However, they are often not listed on the ingredients in that form. They are often camouflaged as "modified food starch" or "malt" which contains barley. There are literally hundreds of forbidden foods and ingredients ranging from brewer's yeast to some soy saucez to some vegetable gums (Celiac Sprue Association, 2001). Gluten might also be found in aspirin, preservatives, dental fillings, toothpaste, and colorings. To add further confusion, "wheat-free" does not mean "gluten-free" because malt, rye, etc. could be in the product. As a result, in a grocery store and in our kitchen, the assessment of ingredients became an obsession for me and my wife.

This task of deciphering ingredients should improve with the Food Allergen Labeling and Consumer Protection Act (FALCPA) that will go into effect on January 1, 2006. In plain English food labels must indicate if the food has one of eight major food allergens responsible for over 90% of food allergies: milk, eggs, fish, crustacean shellfish, peanuts, tree nuts, wheat, and soybeans. The intent of this law is to allow consumers to more easily note if these problem ingredients are present in the food.

Perceived Risk

Before my diagnosis food was something to be sampled and savored but after my diagnosis food was a potential danger. I had to completely eliminate gluten from my diet to recover because any gluten would exacerbate my symptoms. I avoided restaurants for many weeks and my first visit required a phone call to the cook to reassure me that it was indeed safe to eat in that restaurant. In an incident a few weeks later, a salad dressing at a luncheon that a well-meaning waiter assured me was fine, set me back for three weeks.

I now realize that cooks in many restaurants don't even mix ingredients, they merely assemble pre-made foods and they are not even aware of what might be in a sauce. French fries that used the same oil as breaded items would pick up gluten. Potato salad at a family get together could have gluten. Some instant rice contains gluten but how do you know if it is instant or regular rice?

Gradually the risk was reduced as I learned what was safe (e.g., most fast food restaurants use separate fryers for french fries while sit down restaurants do not), I took more food with me (e.g., gluten free power bars, packets of gluten-free salad dressings), and adopted other options (e.g., bunless burgers, no sauces). It got to the point where I traveled to France knowing little French but, equipped with a sheet describing my problem written in French that I gave to waiters, I managed quite well.

Social support

My primary care physician and even my gastroenterologist give me little guidance in just how I should change my diet. Lee and Newman (2003) found that only 17% of newly diagnosed celiacs received information from physicians and 13% found dietitians helpful. I had a useless appointment with a dietitian who gave me information printed off of web sites, some of which my wife and I had already found. The only real assistance my gastroenterologist offered was the phone number of the local celiac support group. They provided innumerable and invaluable suggestions and support in terms of how to shop and how to cook-gluten free. Lee and Newman found that 71% found the most assistance from the Internet and support groups. My wife bought gluten-free cook-books, reminded me at restaurants to watch out when I became a little too casual about checking ingredients, and was a real partner in helping develop my new diet.

Store choice

Mass marketers essentially do nothing for celiacs. However, there are niche marketers in the health food market that provide gluten-free options and also insights and advice. The day after my diagnosis I went to a new health food store in my community. After I outlined my problem, the assistant manager walked me through sections of the store that offer gluten-free products. I remember feeling so grateful that I really do have some options that I was misty-eyed walking out with food that I could actually eat. Food co-ops generally offer more options of gluten-free foods. I also found numerous web sites that specialize in gluten-free foods, and while they vary considerably in quality, I began to realize there was hope.

Impulsive purchases/consumption behavior

Nothing can be done on impulse. One mistake, especially in the early months, exacerbates and prolongs symptoms. I had to look at the ingredients first. No more sampling in the copy room at work when someone brings in snacks, restraint is needed at buffets or luncheons, and those Saturday samples at the grocery store are now generally ignored.

Self reliance

When a person is on a restricted diet you cannot assume that you can just pick up something to eat when you get hungry. I am used to bringing my lunch to work but now I bring my own snacks. I have a refrigerator in my office and my car always has food in the glove compartment. Going to a party means taking something in case there is nothing "legal" to eat. A fellow celiac developed a strategy of ordering frozen gluten-free sub rolls on-line and bringing one to luncheons to make his own sandwich.

Vacations and traveling bring self reliance to another level. Hotel breakfast buffets usually mean bagels, rolls, and cereals

which are off limits so I pack my own cereals. I now have several coolers of different sizes to accommodate trips of varying lengths.

Stages of transition and self image

When I went from "normal" to a celiac, my self image seemed to evolve, not unlike Kubler-Ross' (1969) stages of dying. In retrospect, there were four stages of transition of my self image. First, the diagnosis was not unexpected after months of assorted tests and researching my symptoms, but there was an initial period of shock, disbelief, and "why me." I loved whole grain breads and savored bakery items which I could never again eat. I felt no control of my life. I had to give up seemingly most foods and I was very unsure of how I was to manage. Second, my mental state evolved to acceptance that I could probably get a handle on this as I began to understand that there were alternatives. I began to gain confidence that I might be able to get control over my life again. Third, a sense of mastery evolved where I developed strategies to manage travel, we bought a bread machine to make my own gluten-free bread, my wife began to gather and use excellent gluten-free recipes, and I my symptoms gradually faded away after a year. Fourth, after gaining back control over my life and my health, I must admit to feeling a bit of superiority compared to people who complained about their ability to stay on their diets, their difficulty of staying away from sweets, etc. They can't stay on a simple diet when half the grocery store is off limits for me? Maybe it was the draconian changes that I endured to make that made me feel I could do anything, maybe it was a way for me to reduce the dissonance of having to restrict my diet, but it was like going through boot camp and now I can handle anything.

Rituals and symbolic representation of food

There are some rituals in which we participate that are dramatically changed for celiacs. For example, Thanksgiving dinner now means no stuffing, bread (unless I bring my own rice-based bread), or pumpkin pie. I cannot have a hot dog in a bun at a ball game. I cannot have a beer and pizza watching a game on TV with friends or just a beer after a long day. I grew up in northern Michigan where pasties (meat and vegetables baked in a crust) are enjoyed at family gatherings but, unless one is made without crust for me, I must eat something else. In these types of situations, food serves as a common binding focus that the group can share. The result is these rituals lose some of their affective appeal for celiacs. This kind of exclusion also leads to a sense of alienation because I cannot enjoy things like everyone else.

There are other comfort foods that I enjoyed as a child, such as cinnamon rolls and real home made bread that are no longer an option. There is no chicken noodle soup when I am sick. If someone has a birthday, unless they really plan ahead and make a gluten-free cake (there are such things), I must pass on the cake.

Life satisfaction

Food is integral to providing satisfaction in everyday life. When the previously described comfort foods (e.g., breads, pastries, pies, pasta, or even beer) are removed from a diet, it would be expected that life satisfaction would be reduced. The research on life satisfaction with celiacs is conflicting. Some have found lower quality of life satisfaction (e.g., Hallert et al., 2003, 2004) while others found that celiacs had similar quality of life scores as the general population (e.g., Greco, Mayer and Ciccarelli, 1997; Lohiniemi et al., 1998). In my situation, I have gradually accepted the elimination of gluten and those old foods are barely a memory. Pies and pastries were an occasional treat and whole wheat bread was a staple. Now, I haven't had a sandwich in a year because gluten-free bread quickly dries out and makes sandwiches a crum-

bly mess, but that is something that seems in the past. However, there are times such as at parties or during the Christmas holidays when I do miss sampling the special dishes and treats.

NEXT, DIABETES

About two years after being diagnosed with celiac disease (about nine months ago) and several months after my celiac symptoms finally disappeared, I gradually began to notice that I was again fatigued, had groggy thinking, and was losing weight. My doctor told me that I had diabetes even though I was an active, physically fit person, not at all overweight, obviously had a controlled diet, did not smoke, and did not have a family history of diabetes. Here we go again.

Diabetes occurs when the pancreas does not produce enough insulin. The body digests carbohydrates and converts it to sugar. Insulin is used by the cells to take in the sugar for nutrition and energy. Insufficient insulin means that the sugar is not being absorbed by the cells and the sugar levels in the blood increases. My diabetes is something between Type 1 and Type 2 meaning that my pancreas still works but produces insufficient insulin. After months of experimentation I found a combination of oral medication and insulin injections brought down my sugar level. This added another layer of food issues revolving around closely monitoring my carbohydrate intake, monitoring my blood sugar level, and regulating my meds.

My progression through the process of treating diabetes is remarkably similar to that experienced with celiac disease. I went through parallel stages of disbelief to acceptance, I started a new learning curve of monitoring foods, and I am now counting carbs along with eliminating gluten. That learning curve is not quite complete since, while I have brought down my blood sugar levels to normal, low sugar levels occur with some frequency since my pancreas is not completely predictable. Of course the two diseases cannot be separated; the diabetes issues were just added to the celiac issues. The addition of diabetes exacerbated many of the consumer behavior changes experienced with celiac disease.

Evaluative criteria

Carbohydrates are the second determinant attribute added to my evaluative criteria on foods. Too many carbs relative to insulin leads to high blood sugar so monitoring carb intake is critical. This is also important even if one takes insulin injections because the volume of insulin for each injection is dependent on the blood sugar level and the amount of carbs in the upcoming meal so lower carbs allow for better prediction of the appropriate level of insulin to inject. Fortunately low carb foods are now much more common and give me far more alternatives than diabetics had in the past. After I was diagnosed with celiac disease, I felt that I could at least have orange juice and a big bowl of fruit for breakfast. That big jolt of sugar was the last thing a diabetic needs in the morning and had to be drastically reduce and the new low-carb orange juice helps.

Perceived risk

The risks associated with celiac disease gradually retreated as I was able to get my diet under control. The perceived risk related to diabetes is more immediate and is constantly present. If my blood sugar is too high, that is temporary and I usually feel no symptoms but still needs to be minimized. However, if I use too much insulin, if I work out in late morning or afternoon (exercise sharply drops my blood sugar level), if my meal has fewer carbs than I realized, or if my pancreas decides to produce a little extra insulin for a few hours, my blood sugar can quickly drop. The symptoms can be a shaky feeling, fuzzy thinking, or with very low blood sugar levels, coma

(which I have thus far avoided). I find myself making sure I have food with me if a meeting might extend over the lunch hour, keeping sugar packets in my brief case in case I start to feel wobbly in class, and planning meals and snacks to head off the potential low blood sugar. My level of risk has declined as I have gained a better grasp of anticipating potential blood sugar levels and my confidence correspondingly has increased.

The combination of celiac disease and diabetes exacerbates risk. If I am at a meeting where lunch is provided and there are no gluten-free options, I cannot just eat the salad because I need enough carbs to keep my blood sugar up. Another risky situation is being stuck on an airplane for longer than anticipated with no gluten-free options (which is common) but needing carbs. Hence, I keep gluten-free power bars in my brief case just in case and an even bigger stash of these bars when I am traveling.

Symbolic representation of food

To most people, food is often presented in attractive ways and can be an adventure in new tastes, textures, and flavors. Restaurant menus and new recipes are offer tantalizing options. Food can be a treat, an indulgence, a pleasant reward. That is the also the goal for celiacs and diabetics but there is a layer of restrictions that first must be satisfied. In most settings the threats that foods present must first be avoided and, since that cannot often be determined (no one really is sure what is in that sauce), it is best to pass on that item. The result is the food is usually viewed warily and has lost some of its excitement. However, when my wife or friends make a new gluten-free meal with reasonable carbs, it is just as tantalizing and is probably more exciting because it happens less frequently. (My wife and I share cooking duties but I tend toward the predictable. Fortunately, my wife enjoys the challenge of new recipes.)

Situational perceptions of food

The same foods can be viewed differently depending on the situation. I have found that my perception of certain foods changes depending on my: blood sugar level (impending low blood sugar suggests eating some fruit but high blood sugar levels means fruit is off-limits); the other foods in the upcoming meal (I need to add some carbs if the rest of the meal is low carb, such as meat and vegetables, but I will minimize carbs if the rest of my meal is higher in carbs such as potatoes and bread); or time of day (having an apple as dessert after lunch is not usually a good idea because it will increase my blood sugar level too much but having an apple handy in the late afternoon gives me the assurance that I can eat the apple to pop my blood sugar back up). Even a candy bar, usually problematic because of its high carbs, becomes a comfort in my coat pocket to be used if low blood sugar hits. Of course it is gluten-free.

Self reliance

Self reliance is now even more pronounced. I have to plan and anticipate meals and snacks even more and, in the end, only I am responsible. I have blood testing kits at home, in my car, and at the office. In this situation, being a slightly obsessive person is helpful and probably contributes some self reliance.

Self image

Even though I am well along on my diabetes learning curve and generally have my diet and blood sugar levels under control, I have occasional low blood sugar levels. It takes a considerable commitment to check my blood sugar levels and plan my meals and my meds. I haven't reached the level of perceived mastery that I felt dealing with celiac disease. My unpredictable pancreas, and therefore my unpredictable blood sugar levels, put me in the category of

a “brittle” diabetic, meaning quick changes in blood sugar levels can result from my insulin or from my diet. The feeling of control that I experienced with celiac disease is not yet there.

There is also the feeling of being alienated or “being different” from others at a buffet or in a restaurant as they ponder their options or when discussions turn to the merits of various foods. It doesn’t seem to be my conversation; I am more of an observer. There are other situations when I am the center of concern. If my family is evaluating restaurants, some are excluded because “there is nothing there for Dad.” Everyone is being very considerate but that too is sometimes uncomfortable because there is the feeling that others are working around my limitations.

During the last days of writing this paper I received a call from my endocrinologist’s office with the news that my A1C score (a three month cumulative blood sugar level) is back to normal. Finally. In retrospect, I don’t think I have been “normal” for many years. My blood sugar levels had increased dramatically only in the past year but I suspect that my celiac disease has been problematic, but at a sub-clinical level, for a number of years. I could not think as crisply and often felt rather blank. Lately I am beginning to be more productive and felt more clear-headed than I can remember. My life, any my self image, have probably been suboptimal for many years. I got things done because I forced myself to do them, not from an internal spirit. I now realize that I did not have the energy and drive that I am again beginning to feel. For many years I did not realize that I was just sick, but only sick enough to cast a cloud over me, and in a way, over my family.

Family and social impact

As a celiac/diabetic, who is being careful with his diet, I find that I affect my wife and family and others in a social setting. They select restaurants based on my diet, I am checking my blood sugar levels, giving myself shots, checking ingredients, making sure we eat early enough before my blood sugar drops, coming home from running errands with low blood sugar, or thinking out loud about my day’s dietary plans. It can be consuming, especially when a celiac/diabetic is learning the ropes. This can be a bit much for my wife although she is very supportive and understanding. In fact, she has been a true partner in helping figure out these dietary problems over the past few years. Hopefully in the future many of these activities and concerns will become unstated and be less of an annoyance to everyone around me.

Another dimension of social impact is how others make adjustments to accommodate my diet. If we are visiting friends or relatives, some are not sure if I can eat something, some are bewildered about what is gluten-free, or some just don’t think about it and then feel embarrassed that I can’t eat the wonderful meal they’ve prepared.

An interesting phenomenon occurs with spouses of someone who has my kinds of problems where it seems the spouse takes on the disease with his or her partner and it becomes “their disease.” Fortunately my wife is supportive and we work well as a team. However, we are aware of some couples where the spouse becomes frustrated and even suggests cheating by suggesting “oh go ahead, a little won’t hurt you” or by clearly communicating how irritated he or she has become. This seems to be more common with diabetes because the effects of high blood sugar are not obvious.

Perceived age

My cognitive or perceived age used to be well under my chronological age. Since I work out virtually everyday, I was in excellent physical shape and my blood pressure and cholesterol were to be admired. In retrospect, celiac disease started to close this age gap and diabetes hastened the process. In part it may be the

physical impact on my body but it is also the physical and mental energy of planning meals and checking blood sugar levels that takes some toll. Physical challenges (e.g., blowing the snow from the driveway, starting a project in my shop) and intellectual challenges (e.g., starting a new paper, revamping a course) now seem a little more daunting and gives me pause. It is irritating and even feels a little embarrassing but, maybe as a sign of true aging, I am beginning to accept it.

Then there is the previously described restaurant example where my family eliminates restaurant options based on me and my diet. Could this be the first whiff of what my parents used to worry about of “becoming a burden. . .?”

Quality of life

Considerable research has been conducted on diabetics and their life satisfaction and quality of life. Generally, these findings suggest a decrease in quality of life for diabetics (e.g., Ahlgren et al., 2004; Naess et al., 2005). However, as diabetics gain control of their diet and medications, their quality of life approaches that of the rest of the population (e.g., Rubin and Pegrot, 1999; Senecal, Nouwen and White, 2000). As previous discussion suggests, I am still adjusting to diabetes but am making progress. It seems that as the extraordinary (restrictive diets, injections, packing food, etc.) becomes just another part of my life, it then approaches ordinary. Hopefully, I will continue to evolve to that stage in the near future.

CONCLUSION

My experience is obviously not representative because I have several advantages. First, I have a Ph.D., as does my wife, so I understand my issues, ingredients, and what is necessary to deal with my problems. There are other segments of the population who sometimes don’t have the capabilities to deal with all of these issues. Second, my wife is bright, resourceful and dogged in assisting me while many others either do not have a supportive spouse or have no one to provide support. Third, we are comfortable enough financially which allows me to buy any gluten-free food that is of interest to me. Gluten-free foods are more expensive which can be a significant financial burden for many people. Fourth, I am 59 years old, which in this case is probably an advantage. I feel sympathy for teenage celiac/diabetics who cannot eat most foods in a school lunch line or have a pizza or burger with their friends. I was able to drink beer in college but college age celiacs will not have that experience. My limited feeling of alienation as an adult, because I cannot enjoy the same foods as others, must be magnified for a child or teenager. Lastly, I am fortunate to be disciplined and fitness-oriented. Now I just have to be more extreme about that so, in some ways, the adjustment was not terribly dramatic. People who have an unhealthy diet and have little willpower may just not be able to make the significant changes necessary to become healthy.

It is surprising how little consumer research has focused on what consumers experience as health problems force changes in their lives. I could find no consumer-based research articles on diabetics or celiacs. While less than one percent of the population have celiac disease, 18 million people have diabetes (Elder, 2004). Millions of others develop food allergies or allergies to additives, become lactose intolerant, are on chemotherapy, or contract other diseases that force radical changes in their diets. Not only are these consumers compelled to alter their diets and experience the accompanying challenges and adjustments, but their families also are affected by these changes.

There are other changes that are creating more special needs consumers. Childhood and adult obesity has increased two to three times the rates of previous generations are causing dramatic increases in diabetes (Ebbeling, Pawlak and Ludwig, 2002). Increas-

ing awareness and improved diagnostic techniques will likely result in more people being diagnosed with celiac disease (Harder 2003). As aging baby boomers approach 60 years of age, health issues are certain to increase.

Clearly consumer researchers could contribute to these consumers by helping to understand the myriad challenges faced by these consumers and their families. I hope that this paper facilitates this process by highlighting the issues that I faced and increases the sensitivity toward these special needs consumers.

A Transformative Look at Food Security and Surrogate Consumption Behavior

Terrance G. Gabel, University of Arkansas, Fort Smith

ABSTRACT

The primary objective of this paper is to draw consumer researcher attention toward the issue of food security. We also seek to encourage consumer researchers to view the concept of surrogate consumption more broadly. Toward this dual end, we profile food-insecure persons, a growing segment of disadvantaged consumers in the United States, as a type of surrogate consumer user. By drawing attention toward the issue of food security we hope that consumer researchers might be better equipped to make positive differences in the lives of the growing number of food-insecure consumers in the United States.

INTRODUCTION

According to the United States Department of Agriculture (USDA), in 2003, nearly 36.3 million persons—12.7 percent of the U.S. population—lived in households that, at some time during the year, “were uncertain of having, or unable to acquire, enough food for all their members because they had insufficient money or other resources” (Nord, Andrews, and Carlson 2004, p. iv). Of these more than 36 million people living in “food-insecure” households, approximately 9.6 million lived in households experiencing hunger by virtue of being food insecure to the extent that one or more household members could not afford enough food at some time during the year (Nord, Andrews, and Carlson 2004). USDA research indicates that the number of persons living in both food-insecure and “food-insecure with hunger” households has risen steadily since 1999 (Nord, Andrews, and Carlson 2004).

These and other data suggest that food insecurity is a large and growing consumption-related social problem in the United States. Understanding consumption issues related to food insecurity has not, to date, been a major priority for all but a select few consumer researchers. Given the Transformative Consumer Research theme of the 2005 ACR conference, we feel that this is an opportune time for disciplinary scholars to consider paying greater attention to this important social problem. Accordingly, the primary purpose of this exploratory, conceptual inquiry is to draw consumer researcher attention toward the issue of food security. We pursue this goal via conceptualization of the food insecure as surrogate consumer users—as disadvantaged consumers that (often must) rely on the intervention of others in the consumption process in order to meet (often basic) needs. We begin, below, by examining the concept of food security.

FOOD SECURITY (AND INSECURITY) IN THE UNITED STATES

Understanding food security in the United States is predicated on understanding at least three issues related to the concept: 1) the historical development of definitions of food security (and its relationship to hunger), 2) measurements of food security (and insecurity), and 3) the incidence of food insecurity. Each issue is discussed below.

History of “Food Security”

Hunger has been researched in the social sciences and has been of interest to public policy makers in the United States for many years. The notion of food security, however, is of relatively recent vintage. The origins of current conceptualizations of food security—and the concept’s relationship to hunger—can be traced most directly to 1984 when the President’s Task Force on Food Assis-

tance “... recognized the distinction between the concept of hunger in the traditional medical usage and a more socially oriented, common-sense meaning” (Andrews, Bickel, and Carlson 1998, paragraph 3).

The work of hunger analysts, driven by the findings of the 1984 Presidential Task Force, culminated in the formulation of definitions of food security, food insecurity, and hunger which remain in common use today. These definitions were reported by the Life Sciences Research Office (LSRO) of the Federation of American Societies for Experimental Biology in 1990. The seminal LSRO definitions are as follows.

Food security—Access by all people at all times to enough food for an active, healthy life. Food security includes at a minimum: (1) the ready availability of nutritionally adequate and safe food, and (2) an assured ability to acquire acceptable foods in acceptable ways (e.g., without resorting to emergency food supplies, scavenging, stealing, or other coping strategies).

Food insecurity—Limited or uncertain availability of nutritionally adequate and safe food or limited or uncertain ability to acquire acceptable foods in acceptable ways.

Hunger—The uneasy or painful sensation caused by a lack of food. The recurrent and involuntary lack of access to food. Hunger may produce malnutrition over time... Hunger... is a potential, although not necessary, consequence of food insecurity (Nord and Brent 2002, p. 20).

Using the LSRO definitions, households and, to a less precise extent, household occupants¹ can be categorized into one of three segments based on degree of food-related deprivation: food secure, food insecure without hunger, and food insecure with hunger.

The LSRO’s definition of food insecurity warrants brief elaboration. There are two main types of food insecurity contained in this definition (Hamilton et al. 1997). The first—hereafter referred to as food insecurity “type A”—concerns the household’s inability to acquire a sufficient amount of food to meet basic needs. The second form of food insecurity included in the definition—“type B”—occurs as a result of having “to resort to socially unacceptable ways of obtaining food” (Hamilton et al. 1997, p. 62). A household can also be classified as food insecure for both reasons simultaneously. Food insecurity type A is generally considered the more severe form of insecurity due to a greater probability of it leading to a state of hunger (Hamilton et al. 1997).

Food Security Measurement

Arguably the most significant use of the 1990 LSRO definitions has been by the USDA. In 1994, the USDA, working jointly

¹USDA measurements of food security are done at the household level. If any member of the household has experienced food insecurity in the time period of interest, then the household is classified as food insecure. It is thus: a) possible for a food-secure person to be living in a food-insecure household, and b) not appropriate to assume that all members of food-insecure households are themselves food insecure. For further discussion on this issue see: Nord, Andrews, and Carlson 2004; Nord and Brent 2002.

with the U.S. Department of Health and Human Services, hosted an inaugural conference on food security measurement and research (Wilde 1994). The main outcome of this conference was the formulation of food security measurements that continue to be utilized by the USDA (in the Food Security Supplement to the U.S. Census Bureau's annual Current Population Survey). Food security is measured by asking respondents a series of 18 questions—10 questions addressing food conditions at the household level and among adults in the household and, if the household contains children, eight additional questions examining their food conditions (Nord, Andrews, and Carlson 2004; Nord and Brent 2002). See the Appendix for a complete listing of questions included in the USDA's food security measure.

Since its development in 1994, the USDA's 18-item scale has been used by governmental agencies, the media, and advocacy groups to: 1) report on the extent of food insecurity and hunger in the United States, 2) monitor progress toward national food-security and hunger goals, and 3) evaluate the impact of particular hunger and food-security policies and programs (Wilde 1994). The USDA's food security measures have, however, been criticized (e.g., on grounds that the statistical model used is inappropriate and that measures are "crude" [Wilde 1994, p. 6]). The USDA has admitted inadequacy with regard to the ability of its scale to measure "type B" food insecurity—the form present when a household finds it necessary to resort to socially unacceptable means of acquiring food. In 1997, the USDA tested the possibility of adding a "resource augmentation index" to the scale to remedy this deficiency but chose not to do so (see Hamilton et al. 1997). This decision was based on the USDA's conclusion that adding these items does not significantly improve the overall measurement capabilities of the scale. According to USDA analysts:

A resource augmentation index... and estimates of "type B" food insecurity derived from the index, provide a potential means of broadening the basic categorical measure of food insecurity prevalence to include the dimension of food insecurity involving reliance on non-normal, "emergency," or "socially unacceptable" forms of food acquisition. The practical effect of broadening the reach of the categorical food security measure in this way, however, turns out to be slight. This is because a very large proportion of the households that would be classified as food insecure on the basis of the resource augmentation index are already classified as food insecure by the underlying measurement scale and the classification criteria for the food security status indicator (Hamilton et al. 1997, p. 66).

These same USDA analysts do, however, note that "resource augmentation or coping behaviors... constitute an important area for future research" (Hamilton et al. 1997, p. 68). Since 1997, several teams of researchers have attempted, with at best moderate success, to, among other things, better measure the social aspect of food insecurity inherent in its "type B" form (see Kennedy 2003). Official USDA measurements of food insecurity remain focused on "type A" insecurity (capturing mainly the "sufficiency" or "economic access to enough food" dimension of the concept).

Overall, there is generally strong consensus that the USDA measures of food security have been, at the very least, a large step in the right direction with regard to understanding U.S. food security. Arguably the most significant achievement of the measures has been their ability to help inform the national debate over the incidence and nature of hunger in the United States. Prior to 1995, for example, hunger was typically viewed as a monomor-

phic—"yes" or "no"—malady experienced by as many as 30 million U.S. residents per year (Wilde 2004). Today, thanks in large part to the USDA's food-security measures: 1) hunger is seen as existing on a continuum—with various degrees of relevant deprivation, and 2) assessments of the incidence of hunger in the U.S. are generally more accurate (and considerably lower than previously thought) (Wilde 2004).

Incidence of Food Insecurity in the United States

As previously alluded to, the number of food-insecure households in the United States is large and growing. Table 1 contains selected USDA data documenting the incidence of food insecurity between 1999 and 2003.

Most notable in Table 1 is the steady upward trend in the number (and proportion) of "food-insecure" and "food-insecure-with-hunger" households (and persons living in these households). Another way to comprehend the magnitude of this growing problem, given that being food insecure entails having "...an assured ability to acquire acceptable foods in acceptable ways (e.g., without resorting to emergency food supplies, scavenging, stealing, or other coping strategies)" (Nord and Brent 2002, p. 20), is to track recent increases in demand for the services of privately run emergency food relief (EFR) organizations (i.e., food banks, food pantries, and soup kitchens). It is now estimated, for example, that tens of thousands of EFR organizations in the United States provide assistance to "nearly a tenth of the population during some point in a given year" (Martin, Cook, Rogers, and Joseph 2003, paragraph 3). America's Second Harvest (A2H), a rapidly growing network of more than 200 food banks and food-rescue organizations² serving every county in the U.S., provided EFR services to 23.3 million persons in 2001—a nine percent increase over 1997 (America's Second Harvest 2004a). Demand for A2H's services has risen fastest in the nation's largest cities. In New York, for example, demand at soup kitchens and food pantries was up 45 percent between 2000 and 2002 (America's Second Harvest 2004a). In Boston, the Greater Boston Food Bank recently saw demand for emergency food rise from the normal level of 350,000 pounds a week to between 500,000-600,000 pounds (America's Second Harvest 2004a). The operator of a state-level food bank system sums the situation up as follows.

Food is flying off the shelves and not keeping up with demand... Once again, we had an increase in the number of working poor, folks who kind of fall through the cracks. They don't qualify for public programs... Rents are not going down, utility costs are going up, gas prices are going up, and people are having to stretch a dollar farther (Graves 2004, paragraph 2).

EFR organizations, which have existed in the United States for more than 200 years, were, until very recently, predominantly temporary in nature. Today, however, driven by the escalating number of food-insecure persons (coupled with what many analysts view as inadequate governmental assistance programs for the food

²Food banks "serve people in need by securing and storing surplus food and distributing it through their own network of local service agencies" (America's Second Harvest 2004c, paragraph 3). Food-rescue organizations "often operate within a shorter time-frame, picking up and delivering perishable foods on a single run" (America's Second Harvest 2004c, paragraph 3). Some A2H affiliates combine the two types of operations.

TABLE 1
Selected USDA Data on the Prevalence of Food Insecurity 1999-2003

Unit	Total		Without Hunger		With Hunger	
	# (1000s)	% (of all U.S.)	#	%	#	%
Households						
1999	10,529	10.1	7,420	7.1	3,109	3.0
2000	11,101	10.5	7,786	7.3	3,315	3.1
2001	11,521	10.7	8,010	7.4	3,511	3.3
2002	12,058	11.1	8,259	7.6	3,799	3.5
2003	12,583	11.2	8,663	7.7	3,920	3.5
Household Members						
1999	31,015	11.5	23,237	8.6	7,779	2.9
2000	33,231	12.1	24,708	9.0	8,523	3.1
2001	33,642	12.2	24,648	8.9	9,014	3.3
2002	34,902	12.5	25,517	9.1	9,385	3.4
2003	36,255	12.7	26,622	9.3	9,633	3.4

insecure [see: America's Second Harvest 2004d; Biggerstaff, et al. 2002; Graves 2004; Martin, et al. 2003³], these organizations appear to have become permanent fixtures on the U.S. social landscape (Biggerstaff et al. 2002).

THE FOOD-INSECURE CONSUMER

Although it is difficult to calculate the exact number of food-insecure consumers in the United States, there appears to be strong consensus among EFR service providers and food-security analysts as to who the food-insecure consumer is. Biggerstaff, Morris, and Nichols-Casebolt (2002), for example, in a study of approximately 1,500 food pantry and soup kitchen users, find that: 1) 24.9 percent of respondents were employed, 2) 25.7 percent stated that the main reason for EFR use was that they are "working poor and cannot make ends meet," 3) 15 percent of informants were homeless at some time during the previous six months, 4) 16 percent had lost Food Stamp Program (FSP) benefits in the previous six months, 5) 13 percent had recently lost Medicaid or other health insurance benefits, 6) more than 67 percent of respondents had completed high school or above, and 7) primary risk factors for food insecurity include recent job loss, low earnings (even if employed), and recent retirement. Graves (2004), reporting on a state-level survey of 3,761 households seeking EFR assistance, finds that: 1) 43 percent of informant households include at least one working adult, 2) 80 percent lived below the 2004 federal poverty level (of \$18,850 for a family of four), 3) more than 50 percent turned to EFR assistance

"because their food stamps ran out," 4) 45 percent of households included adults without health insurance, 5) many EFR clients have high levels of debt, and 6) 10 percent are homeless. Finally, America's Second Harvest (2001), in a study of more than 32,000 clients, finds that: 1) 39 percent of households include at least one employed adult, 2) 6.7 percent of households are dual-income households, 3) 1.1 percent of client households contain three working adults, 4) 19.7 percent of clients who have worked or are currently working have or had managerial or professional jobs, 5) 64 percent of households have incomes at or below the poverty level, 6) 45 percent of clients had to choose between paying for food and paying for utilities or heating oil, 7) 36 percent had to choose between paying for food and paying their rent or mortgage bill, 8) 30 percent had to choose between paying for food and paying for medicine or medical care, 9) 30 percent of clients are receiving (federal) food stamps, and 10) 10 percent are homeless.

At least two notable segments of food-insecure consumers emerge from these (and other similar) studies: 1) the working poor, and 2) the newly poor. Each type of food-insecure consumer is discussed below.

The Working Poor

Not surprisingly, low levels of income and wealth increase one's chances of being food insecure. Arguably not so predictable is the number of households with one or more employed adults who have, in recent years, found it necessary to seek EFR assistance. The working poor are not only typically the largest client segment for EFR service providers, they are also among the fastest growing group of EFR users (America's Second Harvest 2004b). A2H estimates that: 1) 70 percent of poor families with children include a person who works, 2) the poverty rate among working families has risen by nearly 50 percent in the past two decades, and 3) nearly half of all parents in working poor families lack health insurance (2004b). A2H sums up the predicament faced by the food-insecure working poor as follows.

³While many EFR clients utilize these services due to being ineligible for or having recently lost governmental benefits just as many appear to be driven to seek private EFR assistance by the complexity of governmental assistance programs, being poorly informed about these programs, and/or the stigma associated with utilization of governmental benefits (see: Biggerstaff, et al. 2002; Martin et al. 2003).

In the last decade, hunger-relief agencies have found that the greatest increase in hungry Americans has been among the working poor. Despite the strong economy and their own hard work, they cannot always make ends meet (2004b, paragraph 1).

As many poor families continue to make the difficult transition from welfare to work, as their benefits are cut or reduced, they are finding that their meager wages are not sufficient to meet their basic needs... Too often, a family finds that it must cut their food budget or turn to a local charity for aid (2004d, paragraph 2).

The Newly Poor: Food Insecurity Among the White-Collar Unemployed

As alluded to above, Biggerstaff et al. (2002) find that recent job loss is one of the primary risk factors associated with seeking EFR assistance. As suggested by America's Second Harvest's (2001) finding that nearly 20 percent of their clients who have worked before or are currently working had or have managerial or professional jobs, a considerable portion of food-insecure persons seeking EFR assistance may be motivated to do so as a result of losing well-paying jobs (and facing resultant financial hardship).

Other research supports this contention. USDA researchers Nord and Brent, for example, note that: "During the 3-year period from 1995 to 1997... middle- and high-income households accounted for 20 percent of all food-insecure households and 17 percent of all households with hunger" (2002, p. ii). According to Nord and Brent: "This apparent anomaly raises questions about the measurement process" (2002, p. ii). The researchers then set out to determine whether these middle- and high-income households truly are food-insecure or if their identification as food-insecure is the result of measurement error. Nord and Brent (2002) find that measurement error is not a significant factor and that "food security as measured is the same phenomenon" (p. ii) as experienced by low-income households. They conclude that "determinants of, and responses to, food insecurity are similar across the income range" (p.iii).

Berner and Zellner (2003) also support the notion that once financially secure persons facing recent hardship constitute a significant and growing proportion of the food-insecure. Berner and Zellner tell the story of Michael Smith, a senior project manager at Nortel Networks, Ltd. in Richardson, Texas. Mr. Smith often donated money to a local food charity (where his wife was a volunteer worker). In January of 2001, Smith lost his job. He quickly found another job but shortly thereafter lost it as well. After being unemployed for nearly a year, Michael and his wife "found themselves back at the food pantry... but this time as supplicants" (Berner and Zellner 2003, paragraph 1). According to Berner and Zellner, this case is exemplary of a startling trend in food insecurity among the newly poor. Berner and Zellner report, for example, that, in 2002, the number of white-collar clients was up 190 percent at the Center for Food Action in Mahwah, New Jersey. At the food pantry where Michael Smith and his wife reluctantly became clients, the number of white-collar clients has recently quadrupled.

Berner and Zellner (2003) cite several factors (beyond mere job loss) that create this growing segment of food-insecure consumers. These include: 1) unemployment among college graduates rising faster than for those with high school degrees, 2) white-collar job hunters taking longer to find new work—9.6 weeks presently vs. 5.8 weeks in the economic downturn of the early 1990s, and 3) the white-collar unemployed having high levels of debt as a result of having "...locked themselves into high-dollar lifestyles during the boom and are now strapped with hefty mortgages, college

tuition, car payments, and credit-card debt" (paragraph 4). Finally, Berner and Zellner speculate that the newly poor may become an even more important customer segment for EFR service providers. According to Berner and Zellner (2003): "Often, the wealthy have fewer coping skills than the poor, who may better understand how to take advantage of the resources available to those down on their luck" (paragraph 6). As increasing numbers of the white-collar unemployed learn how to cope with their newfound food-insecurity—and seeking EFR assistance begins to lose its negative connotations, as Berner and Zellner suggest it might—we may see more and more newly poor persons frequenting food pantries and other EFR service organizations.

Food Insecurity and Surrogate Consumption

Surrogate consumption exists as an area of consumer research offering a wealth of opportunities to disciplinary scholars interested in advancing knowledge with regard to food security and, most particularly, the consumption behavior of food-insecure persons. Below, we first briefly review seminal surrogate consumption literature and then conceptualize the food-insecure as surrogate consumer users.

SURROGATE CONSUMPTION: THEORETICAL BACKGROUND

Solomon (1986) defines a surrogate consumer as "an agent retained by a consumer to guide, direct, and/or transact market activities" (p. 208). The two main theoretical treatments of surrogate consumption—Hollander (1971) and Solomon (1986)—both focus on exchange-based surrogate consumption activities involving professional surrogate consumers (e.g., wardrobe consultants and interior decorators) and the relatively wealthy persons choosing to employ them. Hollander (1971) focuses on describing various functional motivations for surrogate usage (e.g., lacking product knowledge and limited access to goods). Solomon (1986), while also addressing functional motivations, expands upon Hollander's perspective by: 1) discussing psychic and expressive motivations driving the employment of surrogates (e.g., the desire to make the most socially advantageous purchase possible or to move up in the social hierarchy), and 2) suggesting that surrogate consumption activity is most likely to occur when consumers are in role transition.

Overall, what emerges from a preponderance of the surrogate consumption literature in marketing and consumer research is: 1) the notion that surrogate users tend to be relatively wealthy and relatively young, and 2) that role transition and/or a desire to move up in the social hierarchy are situational factors that significantly increase the likelihood of surrogate consumer utilization. Another important—albeit seldom explicitly discussed—issue involves the notion that surrogate usage is a matter of choice and that it involves an economic exchange. Specifically, for either aesthetic and/or functional reasons, surrogate consumer users choose to formally assign the right to perform acquisition and other consumption activities to an expert, professional agent.

The practicality of our disciplinary focus on the relatively privileged persons most likely to choose to employ the services of a surrogate consumer is not questioned from a strategic/practitioner perspective. However, a problem that potentially arises from a theoretical perspective is whether or not these privileged consumers are the only surrogate users worthy of researcher attention. Related problems concern: 1) whether or not surrogate users necessarily choose to formally employ the surrogate consumer, and 2) whether or not an economic exchange necessarily takes place between the surrogate consumer and the person benefiting from their involvement in the consumption process.

It is our opinion that there exists a sizable segment of consumers, including but not limited to food-insecure persons (see Gabel 2005), who: 1) frequently need and use surrogates, 2) do not and/or cannot formally employ the surrogates that perform services for them, 3) often have little if any choice but to rely on surrogate intervention for fulfillment of consumption needs, and 4) go unaccounted for in existing surrogate consumption theory. Below, we view the food-insecure as surrogate consumer users worthy of consumer researcher attention.

The Food-Insecure as Surrogate Consumer Users

Food-insecure persons often lack the financial resources to function within the “normal” exchange-based marketplace in which surrogate consumption studies are typically conducted. The food insecure are, however, highly likely to utilize the services of surrogate consumers (e.g., persons employed by EFR organizations) based on strong functional need. Although the food insecure typically do not compensate or formally employ the persons or organizations providing EFR services, these service providers do function as surrogates in that they perform consumption activities (e.g., food acquisition and preparation) on behalf of the food insecure.

The newly poor food-insecure warrant special consideration as surrogate consumers. This is due to the fact that these persons, who may account for as many as 20 percent of food-insecure consumers in the U.S. (America’s Second Harvest 2001; Nord and Brent 2002), differ from their working-poor counterparts in at least two important ways central to the concept of surrogate consumption. First, the newly poor are in role transition—they, often due to recent job loss, unemployment, and/or underemployment are learning their new role as lesser-affluent consumers. This transitional condition, according to Solomon (1986), is likely to motivate the persons experiencing it to seek the help of others—EFR surrogate consumers—in an effort to adjust to their new living conditions. Second, the newly poor may be far more likely than their working poor counterparts to exhibit “type B” food insecurity—food insecurity resulting from resorting to socially unacceptable means of food acquisition. Thus, the social implications of surrogate consumption here differ significantly from those generally discussed. Whereas the privileged surrogate users discussed by Solomon (1986) often employ surrogates in an effort to either make the most socially advantageous purchase or to move up in the social hierarchy, newly poor food-insecure surrogate users may experience negative social consequences (e.g., stigmatization) as a result of surrogate use. Accordingly, the newly poor may be hesitant to use EFR services or may not use them to the extent that they perhaps should. It is possible, however, that this may change over time as the newly poor learn to cope with their new roles and “do what they have to do” to make ends meet.

DISCUSSION

Food insecurity is a large and growing social problem in the United States. With but few notable exceptions (e.g., Hill’s [Hill 1991; 1992; Hill and Stamey 1990] work on the food acquisition behaviors of the homeless), consumer researchers have had little to say about food security. We feel that consumer researchers are well qualified to both advance knowledge on food security and to make positive differences in the lives of the food insecure. Further, we believe that viewing the food insecure as surrogate consumer users is a potentially fruitful perspective for scholars interested in food security.

One area where consumer researchers, particularly those experienced in ethnography, have much to offer involves better

measuring and understanding “type-B” food insecurity—the dimension of food insecurity most in need of additional study (Hamilton et al. 1997). For example, in the context of surrogate consumption activity engaged in by the newly poor, disciplinary scholars are well equipped to investigate the under-researched issue of what does and what does not constitute a socially unacceptable means of food acquisition (at the level of the lived human experience of the food-insecure surrogate user). In extant research on “type B” food insecurity, researchers have used questions that they assume serve as indicators of socially unacceptable means of food acquisition only to then cite as a limitation to their findings their (post-hoc) observation that the questions used “could be interpreted by some respondents as not indicating behaviors that are socially unacceptable” (Hamilton et al., 1997, p. 65). Social unacceptability is, in short, a highly subjective matter: 1) that at times has not been viewed as being highly subjective in attempts to measure “type B” food insecurity, and 2) that consumer researchers are in an excellent position to better conceptualize.

Additional examination of the interface between the food-insecure surrogate user and the surrogate service provider also provides consumer researchers with an opportunity to advance knowledge of food security in heretofore non-considered ways. Better profiling the food-insecure surrogate user, perhaps in an attempt to better segment the food-insecure surrogate user market or to understand the consumption-related expectations of food-insecure surrogate users, is one possible avenue for research. Another goal for consumer researchers to pursue might be better understanding what motivates food-insecure persons to seek (or not seek) interactions with EFR surrogate service providers. Whatever the specific objective, we hope that this exploratory inquiry will encourage consumer researchers to at least consider better understanding food security and, perhaps, try to make positive differences in the lives of the growing number of food-insecure consumers in the United States.

APPENDIX

Questions Used to Measure Household Food Security in the Current Population Survey Food Security Supplement¹

1. We worried whether our food would run out before we got money to buy more.
Was that often, sometimes, or never true for you in the last 12 months?
2. The food that we bought just didn't last and we didn't have money to get more.
Was that often, sometimes, or never true for you in the last 12 months?
3. We couldn't afford to eat balanced meals.
Was that often, sometimes, or never true for you in the last 12 months?
4. In the last 12 months, did you or other adults in the household ever cut the size of your meals or skip meals because there wasn't enough money for food? (Yes/No)
5. (If Yes to Question 4) How often did this happen—almost every month, some months but not every month, or in only 1 or 2 months?
6. In the last 12 months, did you ever eat less than you felt you should because there wasn't enough money for food? (Yes/No)
7. In the last 12 months, were you ever hungry, but didn't eat, because you couldn't afford enough food (Yes/No)
8. In the last 12 months, did you lose weight because you didn't have enough money for food? (Yes/No)
9. In the last 12 months, did you or other adults in your household ever not eat for a whole day because there wasn't enough money for food? (Yes/No)
10. (If Yes to Question 9) How often did this happen—almost every month, some months but not every month, or in only 1 or 2 months?

(Questions 11-18 are asked only if the household includes children under 18 years of age.)

11. We relied on only a few kinds of low-cost food to feed our children because we were running out of money to buy food.
Was that often, sometimes, or never true for you in the last 12 months?
12. We couldn't feed our children a balanced meal because we couldn't afford that.
Was that often, sometimes, or never true for you in the last 12 months?
13. The children were not eating enough because we just couldn't afford enough food.
14. In the last 12 months, did you ever cut the size of any of the children's meals because there wasn't enough money for food? (Yes/No)
15. In the last 12 months, were the children ever hungry but you just couldn't afford more food? (Yes/No)
16. In the last 12 months, did any of the children ever skip a meal because there wasn't enough money for food? (Yes/No)
17. (If Yes to Question 16) How often did this happen—almost every month, some months but not every month, or in only 1 or 2 months?
18. In the last 12 months, did any of the children ever not eat for a whole day because there wasn't enough money for food? (Yes/No)

A Sheep in Wolf's Clothing: Exploring Researcher Vulnerability

Kathy Hamilton, Queen's University Belfast

Hilary Downey, Queen's University Belfast

Miriam Catterall, Queen's University Belfast

ABSTRACT

Methodological concerns surrounding the research of vulnerable consumers tend to focus on respondents' welfare, that they are not harmed or further disadvantaged by the research process (Reinharz 1992; Finch 1984). Consequently, researcher vulnerability has been largely neglected within the consumer research literature. This paper aims to identify the ways that research with vulnerable consumers can impact on consumer researchers. Reflecting on our doctoral research experiences with vulnerable consumers, namely low income families and consumers confined to the home due to disability, we identify areas where the physical and psychological vulnerability of the researcher was exposed and the resulting strategies employed.

INTRODUCTION

Despite the heightened awareness of diversity within society during the last decade, consumers who are not deemed part of the dominant social system have traditionally been "underresearched and underserved" (Henderson 1998). Transformatory consumer research is likely to be accompanied by increased interest in vulnerable and disadvantaged consumer groups such as consumers with disabilities and those on low incomes. Vulnerable consumers are "those who are at a disadvantage in exchange relationships where that disadvantage is attributable to characteristics that are largely not controllable by them at the time of the transaction" (Andreasen and Manning 1990). Researching such diverse consumer populations can result in insights into human behavior that have the potential to enhance quality of life (Henderson 1998; Moore and Miller 1999). A less ambitious but still important aim is to provide such consumers with 'a voice.' Reinharz (1992) cited demystification as one of a number of transformatory research strategies where the aim is to investigate and challenge common myths and stereotypes that persist about such groups. Vulnerable consumers are not often the subject of interest within marketing and consumer research and it has been acknowledged that further research aimed at dispelling myths and overcoming stereotypical misconceptions is needed (Murphy 1990; Philips 1990).

Methodological concerns surrounding the research of vulnerable consumers tend to focus on respondents' welfare, that they are not harmed or further disadvantaged by the research process (Reinharz 1992; Finch 1984). The re-institutionalization of ethical review is evident by the expanding role of Research Ethics Committees across the UK and North America in recent years (Truman 2003). Hill (1995) identified a number of issues and ethical dilemmas that consumer researchers face when researching vulnerable consumers. Whilst the protection of vulnerable research subjects has attracted much debate across all disciplines, little attention is given to the impact of such research on the researchers. Researcher vulnerability has been largely neglected within the consumer research literature. As the following definition implies, sensitive research can impact on both the researcher and the researched: "a sensitive topic is one that potentially poses for those involved a substantial threat, the emergence of which renders problematic for the researcher and/or the researched the collection, holding, and/or dissemination of research data" (Lee and Renzetti 1993).

The assumption of researcher power is questionable, rather, the relationship between researcher and respondent is one of

"shifting boundaries" (Davison 2004, 338). As the title of this paper implies, the researcher is not always in the dominant position but is open to vulnerability. The aim of this paper is to identify and highlight the ways that research with vulnerable consumers can impact on consumer researchers leaving them vulnerable. Following a brief review of the limited literature in this area, we go on to reflect on our own experiences of undertaking doctoral research interviews with vulnerable consumers, namely low income families and consumers confined to the home due to disability or long term illness. We identify a number of areas where the physical and psychological vulnerability of the researcher was exposed and the strategies employed as a result. Finally, the paper argues for more recognition of this issue and how it might be incorporated into the researcher training and supervision processes.

LITERATURE REVIEW

Due to the paucity of material dealing with researcher vulnerability within consumer research, it was necessary to consult other disciplines to provide the background for this paper. The sociological arena provided some initial ideas on this subject.

Berger and Kellner (1981, 11) suggested that a defining feature of sociology is precisely what they call "a certain debunking angle of vision." In other words, it is a frame of reference which looks beyond the visible and the obvious to what is latent, hidden or obscured. Drawing on this definition, it should be a natural progression to move from the obvious potential vulnerability of the researched to the masked vulnerabilities of the researcher. De Laine (2000, 3) stated that during the fieldwork "researchers experience ethical dilemmas with an immediacy and personal involvement that draws on intuition and empathy, feelings and emotion." Davison (2004) concluded that the potential to feel isolated, vulnerable and distressed does not magically disappear because we assume the role of researcher.

Marshall (1994) went a step further than this and suggested that doing research can seriously damage health. For example, Goode (2000) carried out a research project on drug and alcohol-using mothers, a group who remain a hidden and hard to access population. Using a feminist perspective Goode (2000) found that there were no strict guidelines on how such research should be conducted and stated that "I had to find my own way through these dilemmas." Researching this group placed "emotional demands" on the researcher and the fieldwork was described as "difficult and demanding." Indeed, from a feminist perspective, Reinharz (1992, 36) discussed stress as an inherent variable that the researcher encounters in addressing topics of a sensitive nature: "The interview process gives the researcher an intimate view of this pain and the shock of discovery may eventually force her to confront her own vulnerability."

Similarly, Scott's (1998) research on ritual abuse illuminated such vulnerability on the part of the researcher. In this study, the effects acknowledged were both emotional and physical. Scott (1998, 5.14) stated that "the sheer quantity of stories in the research process created a high level of stress. I had dreams about dying, and dreams in which I learned that none of my interviewees had told me the truth. Staying in an unfamiliar house after one interview I walked in my sleep for the first time in my life, and during the weeks of transcription I endured stomach cramps and nausea on a regular

basis." She concluded that doing research can not only damage your health but also "make a nasty dent in your ontological security."

Nursing literature identified such effects experienced by the researcher. James and Platzer (1999) suggested that hearing stories from vulnerable populations (in this case, lesbians and gay men) can be "upsetting and stressful." Consequently, "it is rare to find honest accounts of the difficulties and dilemmas encountered when conducting sensitive research with vulnerable research populations" (James and Platzer 1999, 1).

Although there has been some interest raised in this direction it is generally secondary to the main thrust of the investigation. Historically, many researchers have tended to disguise the problems arising in the research process so as not to elicit negative feedback in terms of result validity (Brewer 1993). Furthermore, the admission of vulnerability may be interpreted by others as a sign of weakness or even researcher incompetence and thus such vulnerabilities are usually experienced in isolation (Davidson 2004).

The paucity of research accounts on disadvantaged consumers means that conducting research on such populations may appear a daunting task for the researcher and, in practice, can expose unthought-of ethical and methodological problems. More consumer researchers need to override these problems and acknowledge the presence of invisible, under-researched disadvantaged groups. In consideration of these thoughts, we now go on to reflect on some of the problems and issues that emerged during fieldwork with such groups and their impact on the researchers.

METHODOLOGY

Although many consumer and qualitative research accounts provide advice on interviewing techniques (e.g. Thompson, Locander and Pollio, 1989; Carson et al. 2001), there has been little advice about strategies to use in the case of sensitive topics with vulnerable consumers. Findings in this paper are drawn from a reflection on the research process incorporating two studies on vulnerable populations, namely the home-confined consumer and the low-income consumer. The study on home-confined consumers, which is still ongoing, investigates the consumption practices in this population through multiple depth interviews with a small number of case study respondents over a period of two years. The low-income families study examined the coping strategies employed by families to deal with disadvantage in the marketplace and the ways in which these could be interpreted as acts of consumer agency. Single in-depth interviews were undertaken with all family members. In total, 30 families were included in the study. Interviews were held in respondents' homes in both studies.

The methodological approaches adopted, namely, radical constructivism and social constructionism, were considered effective in capturing the consumer lived experience without compounding the vulnerabilities of respondents. Given the limited opportunities for social interaction, radical constructivism offers an appropriate channel for exploring the transition from ableism to non-ableism in the experiential reality of the home-confined consumer. In contrast, the "ableism" of the low-income consumer dictates that social constructionism provides the means to explore the subjective consumer experience within a social context.

Additional supporting material was deemed necessary to complement interviewing procedures in order to obtain a more holistic picture of realities under exploration. In both studies, living diaries consisting of the reflective thoughts of the researcher were compiled immediately after each interview when the experience was still "fresh." These diaries provided the basis for the discussion pertaining to researcher vulnerability presented in this paper.

Researchers in the qualitative tradition see the disclosure of sensitive information as dependent upon the ability to manage

privacy and confidentiality with a non-condemnatory attitude. The creation of a relaxed environment can aid researchers to confront issues which are deep, personally threatening and potentially painful (Lee 1993). The implications for understanding those groups marginalized within the context of consumption rely on the researchers adopting an empathic stance to ease exploration and knowing. Given that the two studies were of a very personal and confidential nature, it is naturally assumed that the interview is typically a stressful experience for all parties concerned (Brannen 1988) and to alleviate this stress, every effort was made to minimize potential discomfort.

Researching vulnerable populations can make the researcher more sensitive to the demands of those we study. This shows itself in data collection methods that emphasize and support the informants' empowerment when the presence of the researcher (i.e. an outsider) may enhance and exaggerate vulnerability. We now go on to reflect on some of the problems and issues that emerged during fieldwork with such groups and their impact on the researchers.

REFLECTIVE FINDINGS

This section discusses the transformative measures that were required by the researchers throughout these studies to counterbalance both the researcher and researched vulnerability, and as such demonstrates the inextricable linkage between both these vulnerabilities.

Interview Issues

In both studies interview topics could be considered as sensitive in nature and interviews involved the discussion of private and personal issues. Despite this, in most cases the researchers found that respondents were keen to share their personal experiences. Participants in the home-confined consumer study were obviously limited in opportunities for social interaction and this was also found to be a problem for low-income consumers, especially lone mothers, because of employment status and an inability to participate in the leisure lifestyle. As such, many respondents suffered feelings of isolation and consequently welcomed the opportunity to talk to someone. Given this isolation and the researchers' empathetic response, the danger of raising respondents' expectations of ongoing contact and friendship was evident. In the low-income consumer study, the researcher had to make it clear that contact would be over a short time scale.

Even with informed consent, qualitative interview routes can never be fully predicted and from the researchers' perspective this created the dilemma that respondents may reveal too much information. In relation to the disclosure of intimate details, Finch (1984, 80) noted that "I have emerged from interviews with the feeling that my interviewees need to know how to protect themselves from people like me." Particular emotional (e.g. depression) and behavioral (e.g. obtaining of illicit income) aspects of respondents' lives indeed caused upset for the researchers and emphasized the two way vulnerability between researcher and the researched. Despite hearing stories of hardship, researchers had to ensure that they did not don the counselors' robes and heighten the consumers' expectations of receiving personal advice. Rather, researchers prepared in advance of interviews a list of potential organizations where consumers could seek advice and support (e.g. debt counseling).

With reference to the interview process, it should be acknowledged that when conducting research in private homes the risk of intrusion is high (Stalker 1998), given the unequal exchange between researcher and respondent in the research process. A study by Swain, Heyman and Gillman (1998) involving people with learning difficulties acknowledged the danger of unwanted disclosure or disclosures later regretted, and the need to balance respon-

dents' right to "a voice" and respondents' right to privacy. This highlights the necessity for transformative consumer research especially when it is unclear what the benefits to respondents will be. The overriding challenge then for researchers has to be the ability to balance unwanted intrusion with over-immersion in 'the cause' (Stalker 1998).

Language

Within research carried out on the home-confined consumer, particular cases called for increased attention in terms of the mode of language utilized. To illustrate this point we will consider the example of Jay, a quadriplegic as a result of an accident.

Both the researcher and the researched conversed using language associated with movement and the ableist perspective. This was employed to accentuate feelings of "normalism." For example, Jay did not adopt discourse related to immobility and rather made comments like, "I was up since 4 o'clock this morning" or "Imagine I had to go to bed at 10.30pm on a Friday night!" The significance of this style of language, given the extreme situational confinement to bed, is apparent. For the researcher this involved careful consideration of using strong ableist adjectives by adopting a style dictated by respondent's own experiential reality in his special space.

As well as oral communication the researcher also had to consider the issue of body language in this particular case. During interviews with Jay, the researcher attempted to suppress their own body movements in favor of a more animated form of speech. In a situation of this nature, the researcher felt awkward and guilty with respect to their own "ableism" and in order to downplay this imbalance and prevent feelings of disempowerment, the emphasis was shifted to oral communication.

Language is not only a consideration for groups "in extremis," rather it is a compulsory tool that all researchers of vulnerable populations should be aware of in terms of its extended implications. Take the case of the low-income consumer, whose presence is more prevalent as regards population figures than the former home-confined consumer. While not all respondents complied with the stereotypical view that low-income consumers are essentially those of a low level of education, it was an issue for the majority of the respondents involved in this study. This placed a strain on the researcher to employ an appropriate style of language that minimized educational differences in order to make respondents feel comfortable.

These studies were carried out in a community in conflict where political unrest and cultural divisions resulted in additional problems for the researchers. Many of these issues arising could also be pertinent and applicable to other communities in conflict or post-conflict situations. The researchers had to access and interact with respondents coming from different religious and cultural backgrounds. While this aspect was not a major player in the mechanics of the data interpretation process, it nevertheless played a significant role in terms of researchers' language during in-depth interviewing. As a result, researchers' language had to adopt a more neutralized form to avoid offence and misunderstandings, which is inherent in different cultural settings within the same community. This placed a considerable strain on the researchers and demanded a constancy of thought that inevitably placed constraints on the free flow of communication.

Security

As stated previously, the study of low-income consumers involved interviews in respondents' own homes. Although this was advantageous to informants in that the natural setting offered both sanctuary and empowerment, it however, created problems for the researcher. In the main, security was an overriding concern. The

majority of interviews in this study were conducted in zones considered as high criminality. To avoid respondents encountering feelings of relative deprivation, the researcher chose not to arrive at respondents' homes in a car, even in cases where access via public transport was particularly problematic. From the researcher's perspective this created feelings of pre-interview anxiety in relation to the journey to and from respondents' homes.

The primary concern of research on sensitive topics has been the protection of vulnerable subjects (Lee, 1993), and as such, this resulted in the researcher placing her own personal security at risk. Reliance on public transport necessitated the meticulous planning of routes to ensure that personal safety was maximized. Part of these journeys entailed some measure of walking and at these times personal risk was heightened due to the overriding sectarian climate evidenced in these areas. Interviews were scheduled to facilitate respondents and as such did not always fit with times that took into account the welfare of the researcher. This resulted in the researcher being forced to "kill time" in areas that rendered the researcher "vulnerable."

Similar problems were encountered within the home-confined consumer study. For example, the researcher felt that her own possessions (an accepted extension of the self, Belk 1988) appeared alien to the research landscape. The registration plate on the researcher's car identified it as being different to the accepted norm within the respondent's community and therefore a potential target for sectarian crime. This became a particular worry of the researcher during periods of civil unrest and led to the systematic checking of the vehicle upon departure.

Researcher Identity

It has been acknowledged that ethnography is "*a means of self-discovery and creative self-authorship*" and through the ethnographic process, the ethnographer's identity is indirectly and creatively managed (Humphries, Brown and Hatch 2003). However, it is not only in the domain of ethnography that issues concerning the researchers' identity arise. Identity concerns highlighted within ethnography will also be apparent in the utilization of depth-interviewing involving vulnerable consumers. In consideration of our studies, the disclosure of sensitive information caused the researchers to be more reflective and as such, the discovery of the other also led to the discovering of the self (Humphries, Brown and Hatch 2003).

Taking a contextual viewpoint, the peculiarities of the research arena have already been identified. Such an environment has had an impact on the researchers' self-identities. To illustrate, the researchers have had to enter social spaces where they are confronted with and have to interact with ideologies that conflict with their own perspectives. The desire to adapt and adopt rules of social behavior exhibited by respondents led to the suppression of the researchers' own identities.

This problem was evidenced in both studies to varying degrees. The different zones where research was conducted required the researchers to present differing aspects of the self in order to establish an interactive equilibrium. As a result, other aspects of the self were diminished to avoid disconnection from respondents and sustain an interactive forum.

The home-confined consumer study extends this aspect of suppression to a heightened degree due to the longitudinal nature of the study. Understandably, increased involvement and contact with respondents resulted in the internalization and regularization of the codes of conduct particular to respondents' settings. As a consequence of this, the researcher's own sense of self had to be altered during the data collection period.

As literatures suggests, the maintenance of the outer body is a reflection of self-identity (Thompson and Haytko 1997; Featherstone 1991). The importance of this upon entering the field becomes heightened when interacting in vulnerable spheres. In relation to the low-income consumer study, the concerns of outer body image were of particular significance given the research environment. Within the contrasting cultural communities, differing styles of “uniform” were evident. As such, failure to comply with the common mode of dress could have had a detrimental effect given that apparel is perceived as an indicator of one’s political and religious stance as well as socio-economic grouping. These concerns were incorporated into the research design, meaning that the researcher had to fit with the prerequisites of each community resulting in the shedding of one identity in favor of another. The donning of multiple identities, other than the researcher’s own, accentuated feelings of displacement and suppression of the researcher’s known and desired self-image.

In absence of “knowing” the rules of respondents’ social worlds, researchers encountered obstacles and embarrassment in accessing respondents’ experiential reality. In one case of home-confinement, the non-realization that all manner of perfumes, deodorants, soaps and fumes of smoking instantly created barriers to entry and consequential inclusion to respondent’s social network. This showed the importance of immersing oneself in the socio-historical perspective. This is made compulsory by the respondent’s stringent testing to judge if the researcher could be allowed entry into the respondent’s special space. The washing ritual employed by the researcher in this particular case to eliminate all artificial odors led to continual self-examination and testing for levels of smell before carrying out the explorative study.

These rules were not relaxed and all subjects interacting in this social world had to adopt such measures to gain access. The respondents in this case, two sisters, are gatekeepers and it is only through their high standards of acceptability that their social world is constructed. Obviously such measures fall heavily with the researcher to keep in an outer body condition that matches respondents’ level of suitability.

Multiple Vulnerabilities

Respondents addressed within these studies can be considered to be doubly vulnerable. This highlights the danger of defining respondents in terms of one characteristic such as poverty or disability. As Henderson (1998) acknowledged, diversity exists not only across groups but within generalized groups and as such the exploration of the human situation demands an individualized gaze. Moore and Miller (1999) noted that the inclusion of doubly vulnerable individuals in the research design may present special challenges. With respect to the home-confined consumer, a particular case scenario presented the researcher with not only home confinement but also “interiorized” confinement in terms of “ableism” in the home. Having two sources of confinement to negotiate adds to the difficulties presented to the researcher. The extremely restrictive special space of this respondent accentuated the problems that access to such a social world entails. The significance of this extreme confinement, emotionally and physically caused the researcher to maintain a constant focus on the minutiae of interaction. It can be extremely tiring to keep a constancy of behavior suitable for the respondent without overpowering and dominating the situation. In the respondent’s world, the rules that are constructed subjectively should be adhered to at all times and the researcher must acknowledge that their position within this context is not perceived as “abuse” of the respondent. This reflexive introspection coupled with the intensity of said situation together maximizes both the respondents’ and researcher’s vulnerability.

Many of the low-income consumers studied in this research are considered as doubly vulnerable. They are not only relatively deprived in monetary terms, but the added “ghettoization” ostracizes and stereotypes them as a direct result of their geographical landscape. These respondents are also stigmatized for their reliance on welfare state benefits and have to deal with the negativity projected towards them by other members of the consumer society. The researcher not only had to address the respondents’ feelings of isolation, low self-esteem and social exclusion but the added pressures of dealing with the cultural implications in conjunction with “ghettoization,” played a major role in how the ambience of social exchange was established.

When dealing with consumers who are faced with multiple sources of vulnerability, the researcher is presented with the problem of determining the most appropriate way to respond to informants. Davison (2004) discussed this aspect in relation to social work researchers suggesting that feelings of powerlessness arise due to the conflict between the role of researcher and the role of social worker. In these studies, the disclosure of personal stories regarding the difficulties encountered by vulnerable consumers aroused feelings of empathy in the researchers. For example, one respondent involved in the low-income consumer study discussed the recent suicide of her sister and the imprisonment of her son. Hearing stories of this nature created feelings of sympathy and compassion and increased the researcher’s awareness of the real need to help such vulnerable individuals. Personal circumstances like these, presented the researchers with an added dilemma in relation to power asymmetries. Careful management of the researcher-respondent relationship was required to ensure that respondents were not further “victimized” or “romanticized” (Edwards 1990) in terms of their poverty and disability.

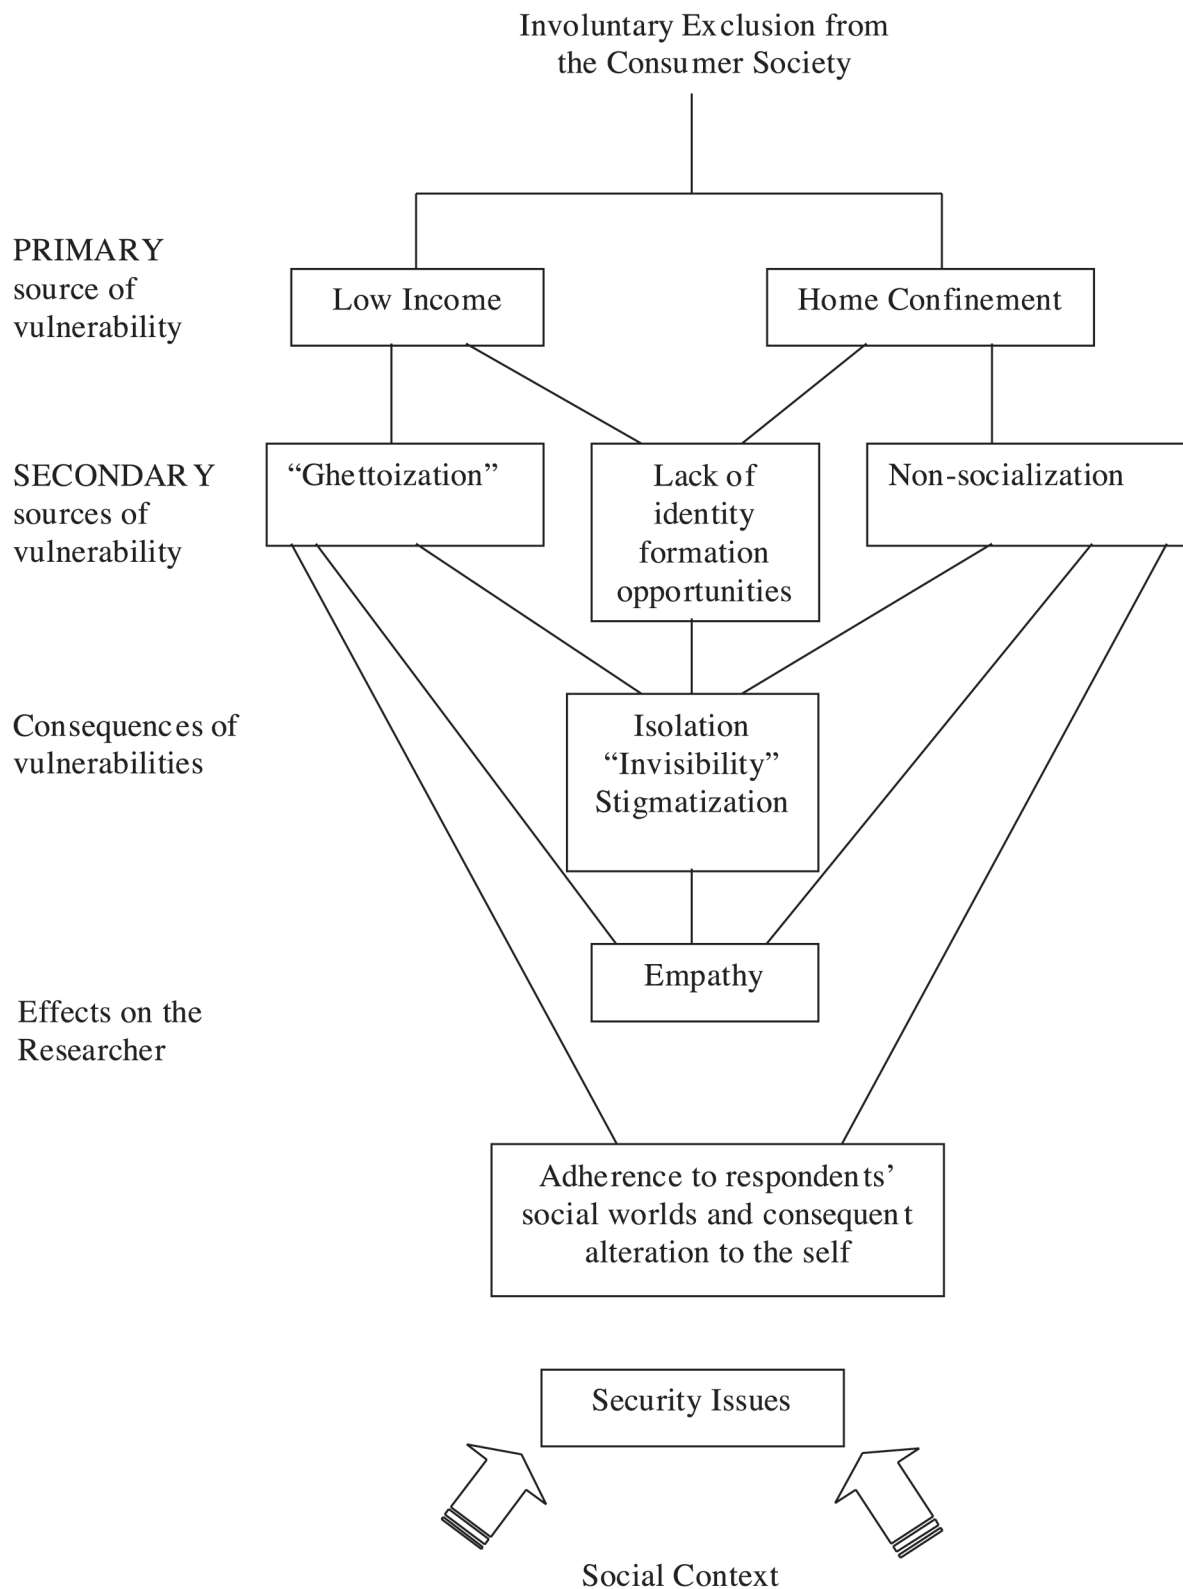

Figure 1 illustrates the multiple vulnerabilities facing both the low-income and home-confined populations and the consequent effects on the researcher. The primary source of vulnerability can stem from various factors such as divorce or the death of a breadwinner for low-income consumers and an accident or illness for home-confined consumers. In both populations the primary source of vulnerability results in additional difficulties that also render respondents vulnerable. These factors, as well as the social context in which the research was carried out, presented a number of obstacles for the researchers. However, it is important for the researcher to enter into the consumer vulnerability experience with openness in attempting to experience it and embrace vulnerability as a reflection of the diversity of humanity.

CONCLUSIONS

Researchers working in the domain of vulnerable consumers need to be aware that feelings of vulnerability may be reflected back to the researcher. As a consequence, research involving vulnerable populations calls for careful consideration of the holistic research environment in order to minimize potential risks for both parties. Although it is possible to anticipate certain aspects of risk associated with researcher vulnerability, it is only during the process of fieldwork that hidden risks emerge and, as a result, every eventuality cannot be addressed in the context of formal training. Topics not considered sensitive at the research design stage may become so as fieldwork progresses. Similarly, it is difficult to predict in advance exactly how the research will impact on the researcher and what vulnerabilities will be exposed.

Consequently this strengthens the case for open dialogue between supervisors and doctoral students to ensure that doctoral students obtain the relevant guidance and support (Davison 2004). In other words, researcher vulnerability needs to be on the supervisory agenda so that uncomfortable issues can be explored. This is

FIGURE 1
Sources and Consequences of Vulnerability

especially important as fieldwork begins and researchers are at their most vulnerable. It is also important to devote attention to issues of researcher vulnerability at the outset of a research study. Davidson (2004) suggested that when conducting research with vulnerable groups, supervisors may find it helpful to explore the motivations and assumptions that research students bring to the research topic.

Some of the issues highlighted in this paper should be considered during any research study, regardless of whether it involves vulnerable or non-vulnerable consumers. There is always going to be a researcher/participant(s) interaction that cannot be avoided in that each party is affected by the research experience.

Product Attribute Evaluations: Understanding the Role of Consumer Experience and Halo Effects

Sylvia Long-Tolbert, Drexel University
Brian D. Till, Saint Louis University
Srinivasan Swaminathan, Drexel University

EXTENDED ABSTRACT

Product trial is an important marketing activity in highly competitive markets where true product differentiation is lacking (Bloom and Pailin 1995). As a personal introduction to a brand, product trials are frequently used to gain consumer acceptance of innovative offerings (Smith and Swinyard 1982). The self-generated knowledge produced from product trials serves as an important input to consumer brand knowledge—the experiential information subsequently becomes the *basis* for product-related brand associations. According to Keller (1993) brand associations are the foundation of a brand's image and the primary mechanism for imparting brand meaning to consumers. However, most brands are an amalgamation of attributes that vary in kind and whose relative importance in brand building is unclear.

We explore the influence of experience and non-experience based attributes on brand evaluations by drawing on previous findings from consumer behavior research. The extant literature reveals that direct experience compared to indirect experience disproportionately affects consumer beliefs (Fazio and Zanna 1978, Smith and Swinyard 1988). Additionally, brand beliefs derived from direct experience are stronger and held with greater confidence than those constructed from marketer-controlled sources of information such as advertising (Fazio and Zanna 1978). Moreover, the influence of direct experience on consumer brand beliefs tends to vary depending on an attribute's specific properties (Wright and Lynch 1995). Based on the seeming power of self-generated knowledge and direct experience, the major premise guiding this research is that consumers anchor their beliefs on experience rather than non-experience attributes when trying products.

Research on halo effects, a cognitive process in which the global evaluation of a brand influences one's response to other attributes or the impression of one attribute shapes the impression of another independent attribute (Nisbett and Wilson 1977), permits us to make a priori predictions about the influence of experience-based attributes on brand evaluations. For example, co-variation in attribute relationships appears to be driven by experience attributes. Wirtz and Bateson (1995) also proclaim that experience attributes have a potential to induce 'halo effects'. Beckwith and Lehmann (1975) and James and Carter (1978) further suggest that attributes lacking a physical dimension or well-defined properties tend to be affected by halo effect. Hence, it is possible that the nexus of brand evaluations resides in consumers' evaluation of experience attributes.

The purpose of this research is to identify the source of co-variation, if any, in product trials. Our investigation of consumers' evaluation of the different types of attributes (i.e., search, experience and credence) builds on theories of 'halo effects' and 'information diagnosticity'. We make two predictions: (1) attribute evaluations for search, experience and credence attributes are dependent on one another and (2) consumers' post-trial evaluation of credence attributes are affected by their post-trial evaluation of experience attributes.

We conducted two experiments using everyday grocery items (fruit cocktail and trash bags) to test our hypotheses with student subjects. In Study 1, subjects evaluated search, experience and

credence attributes for a nationally-branded product both before and after trying the product. The primary measures included attribute evaluations for each of the three types of attributes both before and after trying the product. We analyzed the data to understand how post-trial ratings of search, experience and credence attributes vary when compared to their pre-trial ratings. Study 2 replicated the first study using a different national brand as the target product. The key findings from both studies support our hypotheses. First, we found evaluations of search, experience and credence attributes are not independent. Subjects displayed a systematic pattern of bias in their post-trial attribute evaluations. Second, subjects' post-trial evaluation of experience attributes compared to their pre-trial evaluation significantly affected their post-trial credence attribute evaluation. The observed halo effect applied to both positive and negative brand evaluations. However, evaluations of search attributes were not affected by the halo effect.

In sum, product trial experiences appear to alter consumer evaluations of credence attributes but they show no significant influence on evaluations of search attributes. The halo effects we observed in attribute-level evaluations stem from the anchoring of brand evaluations around experience attributes. Consequently, the presence of halo effects in brand evaluations can potentially enhance or erode brand building efforts for nationally-branded products by overshadowing the true merits or masking the inadequacies in search and credence attributes. Marketing academicians and managers should increase their efforts to understand and harness the power of experience attributes to create unique brand associations.

The Effect of Target Familiarity on Prediction Accuracy

Davy Lerouge, Tilburg University
Luk Warlop, Katholieke Universiteit Leuven

EXTENDED ABSTRACT

A couple leaves the furniture store quarreling because she cannot understand why he likes the black leather upholstery for the recliner seat they had agreed to buy. A man buys one of his friends a T-shirt of his favorite football team that he will never wear. A girl gets an expensive Gwen Stefani haircut because her fiancé loves No Doubt, only to find out that he likes the music but not the looks of the singer. Why are we so inaccurate in predicting the product attitudes of familiar others, like family members, friends and colleagues?

Although it could intuitively be expected that target familiarity results in more accurate predictions due to the extensive amount of pre-stored target information, previous research already provided some evidence that people are indeed not very good in predicting a familiar target's product attitudes. Davis, Hoch, and Ragsdale (1986), for instance, found that only 53 percent of the partners were able to outperform a hypothetical forecaster who simply used the average gender-specific preference. A lack of diagnostic information about the familiar other's specific product attitudes has typically been identified as the main reason for these low levels of accuracy (e.g., Kenny and Acitelli 2001; Swann and Gill 1997). This implies that it would be easy to overcome prediction accuracy, once diagnostic information is available. In this study, we argue that predicting product attitudes of familiar others induces prediction problems far beyond a simple lack of diagnostic information. In fact, we hypothesize that familiarity will even have a negative effect on prediction accuracy in the presence of product-specific target feedback. A first explanation is that people, at least initially, assume high levels of attitude similarity with familiar others (e.g., Moreland and Zajonc 1982). This initial similarity assumption likely colors new but ambiguous attitude information and motivates predictors to ignore attitudinal discrepancies (e.g., Davis and Rusbult 2001; Stapel and Schwarz 1998). Therefore, high levels of projection may persist, despite the availability of veridical attitude feedback. Second, people have an elaborate amount of information about familiar others. This diverse knowledge base probably makes them highly confident and, in turn, less sensitive to new, product-specific attitude feedback (Alba and Hutchinson 2000).

Taken together, we predict that target familiarity will have a negative effect on prediction accuracy if product-specific attitude feedback is available because people will put heavy weight on their own attitudes and their pre-stored target information at the cost of more diagnostic attitude feedback. To test the specific effects of familiarity on prediction accuracy, we asked participants to predict their relationship partner's attitudes towards a series of product alternatives. Instead of manipulating the prediction target, we manipulated the awareness that one is predicting the partner's attitudes. More specifically, for some participants we disguised the true identity of the target by telling them they had to predict the product attitudes of a stranger. For the others, we revealed the true identity of the target and asked the participants to predict their partner's product attitudes. By keeping the target (i.e., the partner) constant in all conditions, we avoided confounds (like differences in attitude similarity).

Applying this manipulation in three experiments, we provide the first evidence that target familiarity hurts prediction accuracy in the presence of product-specific attitude feedback. This negative

effect is especially strong when attitude similarity was low. This could indicate that participants continue to rely heavily on their own product attitudes when predicting those of a familiar, but dissimilar other. Yet, our findings provide evidence that familiarity does not hinder participants in adapting their projection level to the actual level of attitude similarity. Instead, our results suggest that target familiarity causes predictors to put an overly heavy weight on pre-stored target information relative to the new and diagnostic feedback about their partner's product attitudes. More specifically, we find that people attend to product-specific attitude feedback and they also learn from it. Yet, when predicting their partner's product attitudes in a subsequent task, people do not fully rely on this newly encoded and diagnostic information. Instead, they continue to retrieve other, pre-stored partner information. Given that most of this pre-stored partner information is not diagnostic for specific attitude predictions, the elaborate partner information turns out to be a cause of prediction inaccuracy rather than a prediction advantage.

Preference Exploration and Learning: The Role of Intensiveness and Extensiveness of Experience

Steve Hoeffler, University of North Carolina
Dan Ariely, Massachusetts Institute of Technology
Pat West, Ohio State University
Rod Duclos, University of North Carolina

EXTENDED ABSTRACT

“Not alone *age* matures one, but *breadth of experience* and *depth of reflection*.”
—Ross (1948, p. 214)

Thinking back to their first sip of wine or their first visit to a modern art museum, people are often surprised at how much their tastes and preferences have evolved. Though too slow to draw attention, these changes can become quite striking over time. In this research, we attempt to shed new light on how and why preferences evolve.

We reviewed the extent literature and identified two broad classes of factors exerting influence on preference learning. One class of factors (e.g., biology and exposure) has a direct influence, whereby preferences respond to lower-order forces such as biological adaptation and sensory feedback (Beauchamp, Bertino, and Engelman 1983; Birch & Marlin 1982; Janiszewski 1993; Lawless 1985; Pliner 1982; Rozin & Schiller 1980; Torrance 1958). The second class of factors (e.g., informational goals and social learning) has an indirect influence, whereby preferences are subject to higher-order forces such as cognitive representations of desirable end states (Bandura 1977; Belk 1988; Bourdieu 1984; Brewer 1991; Heilman, Bowman, and Wright 2000). Despite the wide range of literature covered, however, we found a dearth of research on the role of breadth of experience in the preference formation process. We attempt to remedy this shortcoming by refining the “experience” construct, thereby introducing two new subconstructs: intensiveness and extensiveness of experience.

We define intensiveness of experience as the amount or the frequency with which a person has been exposed to a product category. For example, a consumer who has been drinking Chardonnay for 20 years has accumulated a high intensiveness of experience with wine. Alternatively, we define extensiveness of experience as the breadth or the variety of exposure a person has accumulated in a product environment throughout her consumption history. For example, a consumer who completes a two-week tour of California’s vineyards for her twenty-first birthday may have limited intensiveness of experience with wine, yet her extensiveness may be well developed. Indeed, during these two weeks, the consumer benefited from a wider spectrum of experiences than many regular wine drinkers whose exposure to wine has been more frequent but more limited in breadth.

In essence, our conceptual effort focuses on refining the experience construct, whereby we try to disentangle the impacts of intensiveness and extensiveness of experience on the preference learning process. Note that, though these two constructs are not mutually exclusive, we believe that they need not accrue simultaneously. Indeed, it is possible to develop one aspect of experience (e.g., intensiveness) without necessarily enriching the other (e.g., extensiveness). In light of this argument, we contend that one’s preference formation will be influenced by the nature of one’s past experience. More specifically, we predict that, as consumers gain familiarity in a product category, they also experience a preference

shift, whereby more experienced consumers become able to identify and appreciate higher quality products, and predict their own preferences. Furthermore, we argue that such enhanced capabilities are afforded more readily by extensiveness than by intensiveness of experience. Stated formally:

H1: Extensiveness (intensiveness) of experience leads consumers to more (less) preference learning as identified by their greater (a) semantic knowledge of the category, (b) ability to identify high quality products, and (c) ability to predict their own preferences.

Note that our measures of preference learning also follow Alba & Hutchinson’s definition of expertise, i.e., “the ability to complete product-related tasks successfully” (1987). Therefore, this paper also contributes to the expertise literature by shedding light on the expertise building process.

Empirical Approach

We selected beer as the product environment to test our predictions because the category allows for large contrasts among individual experiences and because it is rich in normative knowledge.

To disentangle the respective impacts of intensiveness and extensiveness of experience on preference learning, we created two indices. We captured intensiveness through two questions: number of years drinking beer and number of beers consumed in a typical week. We standardized responses to both questions and added them to create an overall “intensiveness index.” We followed the same procedure for the three questions (e.g., number of brands regularly consumed, number of beer types experienced, and number of specific brands experienced) that formed the “extensiveness index.” We then retained the resulting two indices and their interaction as independent variables in our regression analyses.

Study 1

To test participants’ knowledge of the product category, we set up three tasks. The first task consisted of ranking ten target brands in terms of quality. We then correlated each participant’s ranking with an “objective” ranking formed by using price and experts’ testimonials as surrogates for quality. The second task consisted of naming countries famous for producing high-quality beer. We retained the number of countries cited as our second dependent variable. However, to avoid crediting participants for citing countries whose ties with beer remain questionable, we devised an accuracy scale with the help of five beer experts. Depending on the relevance of the countries cited, each participant received an accuracy score. The third task consisted of ranking five target beers in terms of alcohol content. Again, we correlated each participant’s ranking with an objective ranking of alcohol content.

As expected, intensiveness of experience did not predict preference learning. In contrast, we found that extensiveness of experience was an accurate predictor. Indeed, participants with greater breadth were better able to discriminate quality, knew a

greater number of countries legitimately famous for producing high-quality beer, and were better able to estimate the alcohol content of beers. These results support H1A.

Study 2

Study 2 included two tasks. First, we asked participants to visually inspect and then rank a set of eight target beers according to their preferences. Next, participants went to an adjacent room where we asked them to blindly taste and then rank a subset of five unidentifiable beers according to their preferences. To devise our dependent variables, we used three rankings: (1) a quality ranking, formed by using price as surrogate for quality; (2) a semantic ranking of preference, collected when participants ranked the eight brands; and (3) a sensory ranking of preference, collected when participants tasted and ranked the five unidentifiable beers. Our dependent measures were the pairwise correlations between these rankings.

As predicted, greater intensiveness of experience conferred no significant benefit whether in terms of semantic knowledge about the category, ability to identify quality, or ability to predict idiosyncratic preferences. Extensiveness of experience, on the other hand, yielded significant coefficients on all three measures. These results support H1A, H1B, and H1C.

Discussion

Using semantic and sensory tasks, we showed that preferences shift as one gains experience in a product category. Over time consumers become able to identify and appreciate higher quality products, and predict their own preferences. Furthermore, we established that such enhanced capabilities are afforded more readily by extensiveness than by intensiveness of experience.

Decoy Effects and Brands

Jungkeun Kim, University of Minnesota
Jongwon Park, Korea University
Gangseog Ryu, Korea University

ABSTRACT

The relative preference for a target product over a competitor can be increased by providing a third alternative (a decoy) that is clearly inferior to the target but is not necessarily inferior to the competitor. We investigated how these “decoy” effects are influenced by the presence or absence of brand name information and the level of consumer brand knowledge. A field experiment was conducted with three hundred and twenty married females. Results indicated that overall, inclusion of a decoy in the choice set significantly increased the relative preference for the target (i.e., a decoy effect). However, identifying alternatives with real brand names eliminated this effect when participants possessed an extensive amount of knowledge about the brands, but it did not when participants had relatively limited knowledge. These results were generally consistent with implications of the category-based processing view about brand name information.

INTRODUCTION

The decoy effect (or attraction effect) refers to a possibility that adding a new alternative in the choice set increases the choice for one of the existing alternatives that dominates the new one. This effect, which was first identified by Huber, Payne, and Puto (1982), has been replicated in a wide variety of choice situations involving not only commercial products (Ariely & Wallsten, 1995; Dhar & Simonson, 2003; Pettibone & Wedell, 2000; Sen, 1998; Simonson, 1989), but also gambling (Wedell, 1991), jobs (Highhouse, 1996) and political candidates (Pan, O’Curry, & Pitts, 1995). The cognitive processes that potentially underlie these effects have also been extensively investigated (i.e., Dhar & Glazer, 1996; Park and Kim 2005; Pettibone & Wedell, 2000; Shafir, Simonson, & Tversky, 1993; Wedell & Pettibone, 1996).

Most of the past research, however, has investigated the decoy effect in situations under which no real brand names were given. That is, participants typically received attribute information about a target, a competitor, and a decoy that were denoted only by hypothetical brand names or simple letters (e.g., Brand A, B, C). Presumably, these participants had to choose among them, or evaluate each alternative only based on the externally available product information. The decoy effect was then claimed to be evidenced if the preference for the target (relative to the competitor) increased when the decoy was present compared to than when it was not. In the real world, however, there are only rare situations in which consumers compare alternatives without knowing their brand names. Moreover, the literature has shown that brand names can exert distinct influences on cognitive processes underlying consumer judgments and choices. Thus, the effects of a decoy might turn out quite differently in terms of magnitude and/or direction if brand names are provided along with specific product information. The present research intended to provide insights into this matter.

THEORETICAL BACKGROUND

Suppose there are two competing brands in the market: a target (T) and a competitor (C) as in Table 1. The attribute configurations indicate a trade-off: the target is superior to the competitor on dimension 1 but inferior on dimension 2. Consider that a third alternative (D) is also available, one that is clearly inferior to the target but not to the competitor. Adding D (a decoy) in the

consideration set is likely to increase preferences for T (i.e., decoy effects). Now suppose that the three products are not only described using the attributes but also explicitly identified by real brand names such that T and C are competing brands but T and D are of a same brand (see Table 1). How then would the brand names influence participants’ decisions regarding the alternatives? According to the literature on brand name effects, there seem to be at least two distinct possibilities. First, a brand name can serve simply as another piece of attribute information about the alternative. In this case, the evaluative implication of the brand name might be incorporated with implications of the other information into overall evaluations of the product in an averaging fashion (hereafter, “averaging process view”). Second, a brand name can be more than just an attribute. That is, it can serve as a distinctive cue activating a brand schema or category from memory, thus inducing category-based processes during judgment formation. In this case, providing a brand name might systematically influence the amount or direction of cognitive processes of the other information (hereafter, “category-based process view”). Both views predict a general decrease in the magnitude of the decoy effects when real brand names are available. However, they make different predictions regarding how the level of consumer brand knowledge would interact with the brand names. These are elaborated in turn below.

Averaging Process View

The way in which individual informational items are integrated into an overall judgment of the target is well articulated by the information integration theory (Anderson 1971, 1981). It assumes the evaluation of alternatives as a function of individual informational items about the target object. Further, it posits the “averaging model” which assumes that each attribute’s importance is adjusted according to the weight of the other attributes being considered (e.g., Anderson 1971; Birnbaum & Mellers 1983). If so, adding new information is likely to reduce the impact of the existing information on overall judgments about the target. It follows that providing real brand names along with attribute information about alternatives is likely to decrease the impact of the latter information on overall evaluations. Since the decoy effect occurs due to specific attribute configurations of the existing and new alternatives (e.g., Wedell and Pettibone 1996; Pettibone and Wedell 2000), adding brand names is likely to reduce the magnitude of the decoy effects. Further, this should occur regardless of the level of knowledge that participants have accumulated about the brands. People certainly differ in terms of extensiveness of product knowledge. Thus, upon exposure to a same brand, different people will activate different memory associations that might have different evaluative implications about the brand. However, the activated brand knowledge would still weaken the impact of the attribute information on judgments of the alternatives, regardless of the specific nature of the implications of it. This can be formally stated in the hypothesis below.

Hypothesis (averaging process view): The effect of a decoy will be reduced or eliminated when real brand names are provided along with attribute information about choice alternatives. Moreover, this will occur regardless of the level of consumer brand knowledge.

Category-based Process View

Consumer researchers have also identified an alternative way of forming product judgments, i.e., category-based processing (e.g., Meyers-Levy and Tybout 1989; Rao and Monroe 1988; Sujan 1985; Sujan and Dekleva 1987). Further, it has been shown that a brand name can serve as a category label and thus lead to a category-based evaluation (e.g., Aaker and Keller 1990; Maheswaran, Mackie and Chaiken 1992; Sujan and Bettman 1989). The category-based product judgments have been typically conceptualized with reference to dual processing formulations of impression formation (see Fiske, Lin and Neuberg 1999; Fiske and Neuberg 1990). According to the formulations, perceivers first attempt to categorize an object on the basis of available cues that might signal a particular social category to which it belongs. The affect or the evaluations associated with the category are then transferred to the object and serve as a basis for evaluating it without engaging in a detailed analysis of additional features or individuating information. Further, perceivers may engage in relatively elaborative processing of individuating information. However, this additional process is usually confirmatory in nature, i.e., to preserve the initial categorization, and also largely dependent upon the level of personal relevance of the evaluation object for the perceivers and their ability to process the additional information.

One obvious implication of the categorization literature for decoy effects is that providing brand names would induce a category-based processing, thus reducing the impact of individuating information of alternatives on preference construction. Therefore, the effect of a decoy on preference for the target is likely to be reduced or eliminated when brand names are available. On the other hand, the existing literature on consumer knowledge suggests that consumers with high knowledge usually have previously-formed evaluations of various brands, hold strong confidence with their evaluations, as well as possess detailed information about the brands. Furthermore, it has been shown that category-based processing tends to be even more pronounced when stereotypes or category schema in memory are strong rather than weak (e.g., Fiske 1982). Therefore, decisions by high knowledge consumers might be quite independent of the specific information that is externally available on the spot. Consequently, the negative influence that providing real brand names might have on the magnitude of decoy effects is likely to be the case, particularly for participants with extensive brand knowledge. In contrast, consumers with limited knowledge usually do not have a strongly-held prior evaluation about products. Therefore, their decisions might have to be constructed on the spot, mainly based on the externally provided information. Thus, attribute configurations of a decoy can come easily into play.

The categorization literature also suggests a possibility that attribute information about alternatives can be actively processed even if brand information is available. In this case, however, the attribute information is typically processed in accordance with implications of the existing schema in memory. It is particularly so when the schema or category stereotype is strongly held (e.g., Maheswaran 1994; for more theoretical processes see Fisk and Neuberg 1991). If so, we can expect that providing real brand names is likely to reduce decoy effects, particularly for the high knowledge consumers. This prediction also seems to be in line with the previous finding that decoy effects may not be observed when the information about alternatives is rich and meaningful to consumers (Ratneshwar, Shocker, and Stewart 1987), when we consider another previous finding that attribute information is more meaningfully encoded when brand information is available (e.g., Maheswaran 1994; c.f., Hong and Wyer 1990). In sum, the above

considerations suggest that providing real brand names is likely to reduce decoy effects, particularly for high knowledge consumers. This can be summarized into the hypothesis below:

Hypothesis (Category-based process view): The effect of a decoy will be reduced or eliminated when real brand names are provided along with attribute information about choice alternatives. However, this is more likely to occur for participants with a high level of brand knowledge than for those with limited knowledge.

EXPERIMENT

A field experiment with married females was conducted to test the implications of the averaging process view vs. the category-based process view. To do so, we provided participants with information about a target (T) and a competitor (C), which was either accompanied by information about a decoy (D) or not. In addition, in some cases, real brand names were used to identify the alternatives: T and C were two competing brands in the market, whereas T and D were the same brand. In other cases, simple letters (e.g., A and B) denoted alternatives instead. Then, attractiveness ratings of each alternative and the preference were measured.

Participants and Design

Three hundred and twenty married females in a metropolitan city participated in the study. They were randomly assigned to each cell of a 2 (decoy conditions: no-decoy vs. decoy) x 2 (brand name conditions: no-brand vs. real-brand). Later, these participants were divided into two groups of brand knowledge (high vs. low). A median split was used for this division based on the measured knowledge scores regarding the target product category in the market. Therefore, the study involved a 2 x 2 x 2 between the subject factorial design.

Stimulus Material

The stimulus materials we presented are summarized in Table 1. That is, the target product (T) was a refrigerator that had fast freezing time but moderately high operating cost, whereas the competitor (C) was a refrigerator that had slow freezing time but low operating cost. The decoy (D) had virtually the same (fast) freezing time as the target but much higher operating cost than either the target or the competitor. Therefore, the decoy was dominated by the target but not by the competitor. In addition, simple letters (A and B) were used to identify the alternatives for no-brand name conditions, whereas the real (famous) brand names were used for real-brand name conditions.

Procedure

The survey was administered by a professional survey organization. The data were collected through face-to-face interviews with individual respondents, assisted by a structured questionnaire. All interviewers were highly experienced and well trained regarding the purpose of the survey and the contents of the questionnaire.

The participants were told that we were concerned with how consumers make judgments on the basis of limited information. They were told that they would be asked to consider several alternative refrigerators, each of which would be described along two dimensions. They were also told to assume that they were actually going to visit an electric appliance shop. They were then presented with product information about choice alternatives.

Participants first reported their preferences. They then evaluated each refrigerator along a scale from 1 (unattractive) to 10 (attractive). In addition, they evaluated the desirability of the

TABLE 1
Attribute Values of Choice Alternatives, Stimulus Materials

	Refrigerator alternatives		
	Competitor (C)	Target (T)	Decoy (D)
<u>Relative attractiveness</u>			
Dimension 1	2	4	4.1
Dimension 2	4	2	1
<u>Stimulus Material</u>			
Freezing time (min)	25	10	9
Running Cost	\$49	\$56	\$69
Brand	Brand A	Brand B	Brand B

alternatives along each dimension individually along scales from 1 (not good) to 7 (good). Finally, they indicated their subjective knowledge about refrigerator types and characteristics along a scale from 1 (I do not know about it better than the others) to 7 (I know about it better than the others).

Results

To reiterate, it was expected that overall, the effect of a decoy would be reduced or eliminated when real brand names are provided along with attribute information about choice alternatives. Further, the averaging process view predicted that such reduction is likely to occur regardless of the brand knowledge levels, whereas the category-based process view predicted that it is more likely to be the case for participants with extensive rather than limited brand knowledge.

In order to examine these predictions, we analyzed the overall attractiveness ratings data (for each alternative) and the choice data. Mean attractiveness ratings and percentages of participants who chose the target are summarized in Table 2 as a function of *decoy* (no-decoy vs. decoy) and *brand name* (no-brand vs. real-brand) and *brand knowledge* (high vs. low). We now present results from the two types of data separately.

Attractiveness ratings. Separate ANOVAs with decoy, brand name, and brand knowledge as between-subject factors were conducted on evaluations of T and evaluations of C. As apparent in Table 2, evaluations about the competitor did not vary significantly across experimental conditions, all p 's > .10. However, the evaluations of the target systematically varied over the conditions.

First, the ANOVA on evaluations of T yielded a significant interaction effect of *brand name* and *decoy*, $F(1, 316)=9.80, p<.01$. As expected, the evaluation of T in no-brand name conditions increased significantly when the decoy was available (6.38) as compared to when it was not (5.31), $F(1, 158)=22.58, p<.01$. By contrast, this was not the case in the real-brand name conditions (6.81 vs. 6.69), $F(1, 158)=0.07, p>.10$.

Second, the two-way interaction effect between *decoy* and *brand name* was qualified by *brand knowledge*, $F(1, 312)=4.77, p<.05$. Subsequent analyses indicated that for the low-knowledge group, there was a significant main effect of a decoy on evaluations, $F(1, 118)=13.11, p<.01$, which was not contingent upon the brand name conditions (no-brand name vs. real-brand name), $F(1, 118)<1$. For the high-knowledge group, however, the interaction between *brand name* and *decoy* was significant, $F(1, 194)=13.55, p<.01$.

The target was evaluated more favorably in the decoy conditions than in the no-decoy conditions (6.36 vs. 5.37) when no real brand names were used, but the pattern was reversed when real brand names were available (7.22 vs. 6.52). This pattern of results was more consistent with the implications of the category-based processing view.

Choices

Results from the choice data were quite similar to those from the attractiveness ratings data. Since the choice data was categorical in nature, we used a binary logistic regression to analyze it as a function of consumer knowledge, decoy condition, and brand name condition.

First, there was a significant interaction of *brand name* and *decoy* ($B=-.980, Wald=3.98, p<.05$). Specifically, proportions of participants who chose the target were higher in the decoy conditions (.388) than in the no-decoy conditions (.175), $z=3.10, p<.01$ when no real brand names were available. However, this difference was negligible (.500 vs. .525), $p>.10$, when real brand names were provided.

Different patterns of results, however, emerged when the level of brand knowledge was considered. In the low-knowledge group, the decoy significantly increased the choice of the target (.208 vs. .536), ($B=-1.46, Wald=6.03, p<.05$), which was not contingent upon the no-brand name vs. real-brand name conditions ($B=-0.02, Wald=0.01, p>.10$). In the high-knowledge group, by contrast, there was a significant two-way interaction of *brand name* and *decoy* ($B=-1.31, Wald=4.26, p<.05$). Further analyses indicated that the decoy effect was significant only in the no-brand name conditions (.333 vs. .184), $z=1.80, p=.07$, whereas in the real-brand name conditions, the decoy had no effect on choices (.457 vs. .586), $z=1.09, p>.10$. In sum, these results were generally consistent with the implications of the category-based processing view.

DISCUSSION

In this paper, we investigated the role of brand names in the effect of a decoy on preference construction. The averaging view and category-based processing view were considered to make predictions. Both views predict a general reduction in the decoy effect if the real brand names are provided along with attribute information about choice alternatives. On the other hand, the two views make different predictions regarding the moderating role of

TABLE 2

Relative Attractiveness Ratings and Choice of Target as a Function of Decoy Type, Brand Name, and Brand Knowledge

	No brand name		Brand name	
	No-decoy	Decoy	No-decoy	Decoy
<i>Attractiveness ratings of each alternative</i>				
Target (T)				
Low knowledge group	5.23	6.40	5.73	6.91
High knowledge group	5.37	6.36	7.22	6.52
Total	5.31	6.38	6.81	6.69
Competitor (C)				
Low knowledge group	6.55	6.34	6.82	6.50
High knowledge group	6.37	6.76	6.52	6.91
Total	6.44	6.58	6.60	6.74
<i>Proportions participants choosing target</i>				
Low knowledge group	.161	.457	.273	.618
High knowledge group	.184	.333	.586	.457
Total	.175	.388	.500	.525

consumer brand knowledge. That is, the category-based processing view predicts a significant moderating role of brand knowledge (i.e., a significant reduction of decoy effects by presenting real brand names only for high brand knowledge conditions), but the averaging view predicts no such role.

Results from a field experiment supported the category-based processing view. Specifically, both attractiveness ratings and choices data revealed that providing real brand names eliminated the decoy effects only when participants possessed extensive knowledge of various brands in the market.

In addition, in the brand and decoy condition and for high-knowledge consumers, we actually found that the target share or evaluation was reduced in the decoy condition. This surprising opposite pattern for a decoy effect could be explained by the role of "persuasion knowledge" in a context effect (Friestad and Wright 1994). That is, consumers who are knowledgeable about a product category are also likely to be equipped with a substantial amount of persuasion knowledge. When an inferior decoy product has the same brand as the target product, these consumers would activate their persuasion knowledge and infer a negative motive about that brand. This will lead to no effect or even a negative effect of the decoy.

This study has several limitations that suggest the direction for future studies. First, in this study we did not include any measures or methods to further explore the underlying mechanisms (such as "averaging view" and "category-based processing view"). Second, we need more concrete evidence for explaining the unexpected decoy effect for high-knowledge consumers in the brand and decoy condition. Finally, our study focused only on the presence or

absence of brand name information, and used the same brand for the target and decoy product. In future research, we can systematically vary the strength of, as well as location of, brands in the set to further enhance our understanding about the role of brands in the decoy effects.

SPECIAL SESSION SUMMARY

Time and Decisions: Attention Based Perspective on Temporal Effects in Judgment and Choice

Selin Malkoc, The University of North Carolina- Chapel Hill

SESSION OVERVIEW

Consumers are constantly faced with decisions about the timing of their consumption. These decisions involve tradeoffs between costs and benefits that are distributed over time, and are prevalent in almost every consumption context. How consumers make such decisions has been of interest to researchers from several disciplines. Prior research has consistently shown that people have a bias toward the present (e.g., Thaler 1981). That is, individuals overweight the near outcomes compared to the later outcomes. This pattern of behavior has been attributed to impulsivity (Loewenstein 1996), to differences in cognitive representations between near and future events (e.g., Trope and Liberman 2003; Zauberman and Lynch 2005) or to an individual difference in time orientation (e.g., Zimbardo and Boyd 1999). The three papers in this special session propose a different mechanism that leads to present-biased and time inconsistent preferences. Specifically, these papers offer a novel attention-based process to account for consumer preferences over time and demonstrate that drawing attention to the “time” component of the decisions moderates intertemporal preferences.

First paper, by Urminsky and Kivetz show that preferences favoring smaller-sooner outcomes over larger-later ones can be altered if the options are coupled with an immediate, but common outcome. Their results indicate that when an immediate outcome is added to both options, consumers are more willing to wait for a larger reward. Importantly, segregating the common immediate reward from the options eliminates this effect, indicating that drawing attention to the timing of common reward helps facilitate a reduction in tradeoff conflict, reducing present bias.

Second paper, by Ebert and Prelec, examines the role of attention to future time in time inconsistent preferences. They show that making mental resources available during decision making increases attention to future time, attenuating the hyperbolic pattern in consumers’ preferences. Their results consistently show that with greater mental resources and greater attention to future, individuals show relatively less discounting of near outcomes and relatively more discounting of far outcomes, leading to increased time consistency in preferences.

Third paper, by Zauberman, Bettman and Malkoc, shows that consumers do not naturally consider the duration over which decisions take place, unless it is made accessible. Authors demonstrate that consumers use succession cues (i.e., number of transactions) and are insensitive to duration cues. However they display heightened sensitivity to the time horizon when duration is made accessible. Authors further demonstrate that present-biased preferences can also be attributable to time horizon neglect, by showing that making duration accessible decreases this tendency.

Collectively, the papers in this session provide new insights about the cognitive psychological mechanisms underlying consumers’ time-inconsistent preferences and offer an attention based process as a novel explanation. This perspective is distinct from the previous explanations, which focused on affective or cognitive differences regarding time, but assumed no changes in attention to time.

Following presentations, Drazen Prelec, the session discussant, provided an overview of how these papers inform and qualify the findings of previous research, as well as noting some of the ways

in which the session offers diverging perspectives on intertemporal preferences.

EXTENDED ABSTRACTS

“The Effect of Common Rewards on Tradeoff Conflict: The Case of Inter-temporal and Risky Choice”

Oleg Urminsky and Ran Kivetz

Consumers often face timing decisions involving tradeoffs between smaller-valued outcomes that would be acquired sooner and higher-valued outcomes that would require waiting a longer time. Such choices represent an interpersonal conflict between the opposing goals of immediacy and magnitude of gain. The literature on intertemporal choice models this tradeoff using systematic discounting functions to account for the effect of time delay on utility. As an alternative to the normative exponential discounting model, Strotz (1956; see also Ainsle 1975) proposed the hyperbolic discount function to account for intertemporal preference reversals. The hyperbolic discounting model was extended to account for the magnitude effect (Thaler 1981, Loewenstein and Prelec 1992) and for the asymmetry between speed-up and delay of gains (Loewenstein 1988). These models generally assume that utility is a monotonically increasing function of amount and immediacy (but see Loewenstein and Prelec 1993; Kivetz and Simonson 2002).

In this paper, we demonstrate a systematic bias in intertemporal choices that violates prior models of consumer time discounting. We consider a fundamental choice between two outcomes involving a tradeoff between the timing and magnitude of gains, such as choosing between: (a) \$400 in one week, (b) \$1000 in one year.

We show that in such choices between a sooner-smaller reward and a later-larger reward, the addition of a common reward to both options (shown below) systematically alters consumer preference. (a) \$100 in 3 days *and* \$400 in one week, (b) \$100 in 3 days *and* \$1000 in one year.

In a series of studies we had subjects make a single choice, either with or without a common reward (manipulated between subjects), and we demonstrate that the addition of the common reward to both options significantly increases choices of the later-larger reward. We argue that this effect occurs because the common reward disrupts the tendency to adapt to the more psychologically proximal option (Hoch and Loewenstein 1991), in this case the sooner-smaller reward. When adaptation is disrupted, the absence of experienced loss aversion favors the more psychologically distant later-larger option. This common reward effect represents a violation of the principle of separable additivity in discounting, which underlies both exponential and hyperbolic discounting.

In the first study, conducted in the lab with a student sample, we demonstrate the effect of a common reward on intertemporal trade-offs across a range of sooner-smaller and later-larger amounts. We find a significant increase in choices of the later-larger reward when both options are bundled with an early common reward. This finding was then successfully replicated in a second study and extended to a wider range of reward sizes, using a large sample of over 3000 consumers. In this second study, we also confirmed that common reward effect is robust, holding across a variety of demographic groups.

In a third study among consumers, we employed a series of tests designed to rule out alternative explanations for the observed bridge effect. First, we demonstrate that the results cannot be attributed to the magnitude effect in hyperbolic discounting. Second, we show that segregating the common reward in the text of the question eliminates the effect. Specifically, when we inform consumers that they will receive the common reward regardless of their choice and then have them make a choice between sooner-smaller and later-larger rewards, consumer preferences are unaffected by the common reward. This is a violation of the invariance axiom and suggests that the common reward reduces the experienced conflict between the options (rather than relaxes a liquidity constraint.)

In a fourth study, we demonstrate that the common reward effect can be induced in a way that holds constant the net present value of the proffered rewards. Specifically, we show that, for a reasonable empirical range of interest rates, a common reward can be introduced while proportionately reducing the amounts of the sooner-smaller and later-larger rewards, enhancing preference for the later-larger reward. Therefore, an institution providing a choice between two payoffs (e.g. two bonds) can restructure the payoffs and shift preference for the later-larger payoff without changing (or even reducing) the net present value of its expenditures.

In a series of additional studies, we provide further evidence that the common reward effect operates by disrupting a process of adaptation to the sooner-smaller reward and loss aversion relative to that reference point. We show that increasing psychological distance of both options (by making rewards uncertain) debiases the common reward effect. Further, we show that endowing participants with the sooner-smaller option enhances the common-reward effect, while endowing participants with the larger-later reward debiases the effect. Finally, we show that a trait measure of delay aversion predicts the common reward effect, with only delay averse participants exhibiting the common reward effect.

Lastly, we note that a body of literature has demonstrated the underlying commonalities between uncertainty and delay (e.g. Prelec and Loewenstein 1991; Rachlin et al 1991). Accordingly, in a series of studies, we extend the common reward effect to the domain of risky choice. Consumers made choices between a smaller lottery reward with a higher probability of winning and larger lottery reward with a lower probability of winning. Consumers who made a choice between the two options bundled with a small certain common reward were more likely to choose the larger-riskier lottery than those whose choice options did not include the common reward. This effect was debiased when the common reward was segregated in the text of the question. We argue that this effect is due to a similar process, in which the common reward disrupts the process of adaptation to the smaller-more certain option. In three studies, we provide evidence that the common reward effect for risky choice is moderated by temporal distance, endowment and the loss aversion trait.

“Time Insensitivity: The Impact of Time Pressure and Attention on Discounting of Near and Far Future”

Jane E. J. Ebert and Drazen Prelec

It is a basic finding in economics and psychology that people heavily discount future events relative to the present (Gately 1980; Loewenstein and Thaler 1989), and we can see evidence of it in many areas of our lives. In financial decisions, people fail to save adequately in the present for the distant prospect of their retirement (Laibson 1998). They fail to take proper care of their health—putting off exercise, eating unhealthy snacks, avoiding vaccinations or the dentist, smoking a cigarette or having unprotected sex. An influential explanation of high temporal discounting is that people would

discount less if only they applied more mental effort and resources.

In this paper, we suggest an alternative hypothesis: that people are naturally somewhat insensitive to time and discount “casually”. This means they discount heavily for the near future, but show relatively little discrimination between times in the more distant future. We predict that both mental effort and resources and attention to future time will have a similar effect, increasing time-sensitivity with reduced discounting for the near future and increased discrimination of more distant future times. One potentially surprising consequence of this hypothesis is that, while mental effort and attention to future time should reduce discounting for the near future, they may actually increase discounting for the more distant future. Overall, the result is increased time-consistency, i.e., a discount function that is less hyperbolic, moving closer to the exponential discounting norm.

In this paper we test this hypothesis that mental effort and resources and attention to future time result in increased time-sensitivity and hence a more time-consistent, i.e., less hyperbolic and more exponential discounting function. Under conditions of restricted mental resources or with less attention to future time people are likely to be time-insensitive: overdiscounting near future events and underdiscounting distant future events.

We use three types of experimental manipulation to test our hypothesis. The first restricts the time available for judgment. (Time pressure has frequently been used in judgment research as a mental resources manipulation (Gilbert 2002)). In experiment 1, participants valued a set of hypothetical restaurant certificates that vary on several attributes including future time. Some participants completed this task while under time pressure, while others had extended time. We applied conjoint analysis to analyze the influence of the future time and other attributes in participants’ valuations of the restaurant certificates. (Sultan and Winer (1993) is, to our knowledge, the only previous application of conjoint analysis to discounting.) Consistent with our hypothesis, our analyses revealed a Future time X Valuation time interaction where participants with restricted time for evaluating the certificates showed relatively more discounting in the near future and relatively less discounting in the far future compared to those with extended time for evaluating the certificates. Furthermore, while participants in both conditions showed hyperbolic temporal discounting, the discounting for those with extended time was more time-consistent or “rational” (i.e., it was more exponential). Thus, we also identified a moderator of hyperbolic temporal discounting, a fundamental tendency shown by people and other animals, while also confirming the robustness of this tendency.

The second type of manipulation, employed in experiments 2 and 3, compared between-subjects and within-subject judgments of present value. The premise here is that a within-subject design highlights the time dimension, drawing attention to it. (Griffin, Dunning and Ross (1990) and Abele and Petzwold (1998) use a similar presentation mode method to manipulate the salience of a dimension.) Finally, in experiment 4, we manipulated subjects’ attention to the future time dimension directly using explicit instructions.

The results of these 3 experiments (Experiments 2-4) were consistent with those of Experiment 1. In each experiment there was a significant interaction between the primary experimental manipulation (effort or attention) and future time. Compared to those subjects in the lower mental resources or attention conditions, subjects in the higher mental resource or attention conditions showed relatively lower discounting of near future rewards and higher discounting of far future rewards. Put another way, those subjects with greater mental resources and attention to future time

showed greater sensitivity to future time. Also, as in Experiment 1, while participants in both conditions showed hyperbolic temporal discounting, those participants in the higher mental resource or attention conditions were more time-consistent or exponential in their discounting.

The difference in time-sensitivity was also tested more formally in experiments 1 and 4, where the constant-proportion hyperbolic function fitted to the data gave a significantly higher time-sensitivity constant for the data of the higher resource or attention subjects than for the lower resource or attention subjects. The time-sensitivity constants obtained for the two attention conditions in experiments 2 and 3 showed a corresponding directional difference, i.e., a higher time-sensitivity constant for the higher attention subjects than for lower attention subjects, but it was not possible to test this difference statistically in these experiments.

It comes as no great surprise that people become more sensitive to a dimension when it is made more salient for them. What is more surprising is the effect of their attention to the dimension of future time on their valuations. We might expect that people would show less discounting for all future times, consistent with previous explanations of heavy discounting, or that they might simply weigh the time dimension more heavily in their valuations of the future resulting in greater discounting for all future times. However, the increase in sensitivity resulted instead in less discounting for some times (the near future) and greater discounting for others (the far future). Furthermore, these experiments demonstrated the moderating effect of mental resources and attention on hyperbolic temporal discounting. To our knowledge this research and that by Zauberman and his colleagues (also presented in this Special Session proposal) provide the first demonstrations of moderation of this fundamental and important human tendency.

“Time Horizon Neglect: Prospective Duration Insensitivity in Consumer Preference”

Gal Zauberman, James R. Bettman and Selin A. Malkoc

Consumers often make decisions about events that occur over time. For instance, in choosing between two online pharmacies, consumers may consider setup costs, how long they intend to use the service, and their expected frequency of future transactions. A consideration of prospective duration is necessary in these instances. However, attempts to understand how consumers’ perceptions of duration itself (i.e., the time horizon over which a decision takes place) affect their intertemporal preferences have been limited. The focal issue for our research is to understand the degree to which consumers are sensitive to the time duration relevant to their decisions and what factors influence such sensitivity.

Building upon ideas from philosophy and psychology of time (Heidegger [1924] 1992), we hypothesize that in forming their preferences, consumers make use of the cues that represent succession (i.e., number of transactions within a period) and are not sensitive to the duration over which events take place. That is, consumers display time horizon neglect. Such insensitivity to time horizon can be attenuated, however. Prior research has demonstrated making duration more salient increases participants’ judgments of elapsed time (Block and Zakay 1997, 2001). We expect the same attention-based mechanism to affect the way that prospective duration is incorporated into preferences and hypothesize that making duration more accessible not only increases attention given to time horizon in making decisions, but also helps consumers to display more consistent preferences over time.

We test these ideas in two contexts: decisions about selecting between providers with different types of costs over time and consumption timing decisions. In a set of three experiments, we

show that consumers neglect time horizon unless they are primed to think about prospective duration, and that this tendency has implications for intertemporal preferences. In experiments 1 and 2, participants had to select between two online retailers that differ in their relative cost structure. Each provider was defined by two temporally distinct time cost categories: a one-time initial setup cost and ongoing usage costs that apply every time a transaction takes place (Zauberman 2003). Assuming no delay discounting, in our experimental setup, a short time horizon or a small frequency of favors the low setup and high usage cost retailer. But in the long term or with high frequency, the reverse is true.

Experiment 1 (N=112) tested the question of consumer sensitivity to time horizon when frequency cues are present in the decision context. Time horizon (3 vs. 12 mos.) and purchase frequency (3 vs. 12 purchases) were manipulated orthogonally. Participants choose between two retailers described above and responded to a subtle manipulation check of time processing by answering “how likely is it that a new superior on-line retailer would enter the marketplace in that time frame?”. The analysis produced a main effect of time horizon manipulation on the manipulation check ($F(1, 108)=16.78, p<.0001$), indicating that participants indeed understood the manipulation. The results also showed that time horizon over which multiple transactions were expected to occur had no effect on choice ($\chi^2(1)=0.04, p=.85$) and attractiveness of the high setup option ($F(1, 108)=.03, p=.87$). Instead, frequency of purchase influenced the preferences ($F(1, 108)=24.31, p<.0001$) and choice ($\chi^2(1)=19.05, p<.0001$). Thus, the data support the idea that consumers select the low initial cost option because they attend more to frequency cues than to time horizon.

Experiment 2 used a similar task but added a supraliminal priming manipulation of duration accessibility, holding purchase frequency constant. Time horizon (3 and 12 mos.) and priming (control vs. duration) were manipulated between subjects. Priming was implemented by having participants estimate either the duration of seven activities (duration-prime) or the number of calories contained in seven food items (control-prime). We find the expected 2-way interaction ($F(1, 103)=.47, p=.50$), indicating that in the control condition, time horizon had no effect on preferences for the high-setup option ($t(1, 51)=-.62, p=.54$) (replicating experiment 1), but had an increased effect on preferences when duration is primed ($t(1, 52)=2.38, p=.02$). Our results suggest that it is not that individuals lack the ability to take duration into account, but that people normally do not attend to it.

Experiment 3 was aimed at extending our findings to situations where duration is the only available cue (i.e., timing decisions) and tests the moderating role of duration accessibility in stability of preferences over time. Specifically, we examine whether priming duration would moderate one of the most robust effects in research on intertemporal choice, hyperbolic discounting. We employed the supraliminal priming task used in the previous experiment, but used a common intertemporal preference task in which participants indicate their preference for the timing the usage of a \$75 gift certificate as a function of time delay. Both priming (duration vs. control) and time horizon (1 vs. 3 mos.) was manipulated between-subjects. The analysis provided the expected 2-way interaction, demonstrating that the degree of hyperbolic discounting is diminished when duration is primed ($F(1, 188)=3.96, p<.05$). This experiment shows that even in the absence of succession cues, consumers neglect time horizon but making duration accessible attenuates this tendency.

In sum, we show that participants reacted to the number of events (experiment 1) and were insensitive to the time horizon in

many circumstances (experiments 1, 2 and 3). Experiment 1 shows that participants were aware of the differences in time horizon (manipulation check), but did not incorporate duration into their decisions. Experiments 2 and 3 confirmed that when time horizon is not accessible (the control-prime), participants are insensitive to time horizon; however, when duration is primed, they display heightened sensitivity to future time horizon. Thus, it appears that people do not naturally consider prospective duration unless it is made more accessible. We suggest that the recent trend in incorporating psychologically accurate individual behavior into economic models of intertemporal choice would benefit from considering individuals' insensitivity to prospective time horizon.

SPECIAL SESSION SUMMARY

Investigating Neural Correlates of Consumer Judgments

Jim Bettman, Duke University
Carolyn Yoon, University of Michigan

SESSION OVERVIEW

The past decade has seen a virtual explosion of research in the cognitive and social neurosciences that is transforming our understanding of mental functioning and human behavior. Imaging technology allows us to directly observe and report the brain activity of individuals engaged in a variety of experimental tasks, and to study psychological constructs and processes at the neural level. This offers the potential to move us closer to a coherent understanding of everyday thoughts, emotions, decisions, and behavior.

In particular, functional magnetic resonance imaging (fMRI) has become increasingly accessible to investigators, and offers a powerful platform for answering research questions across a wide range of academic disciplines, to complement more traditional methods of inquiry (see, for example, Smidts (2002) and Zaltman (2003) in marketing; Camerer, Loewenstein & Prelec (2005) in economics). Despite the potential benefits associated with fMRI, few consumer research studies have as yet adopted it. The main goals of this session are to bring together three fMRI papers that demonstrate the usefulness of neuroimaging to study consumer behavior and decision making, and to encourage the use of fMRI to inform and complement findings from behavioral studies.

The papers in this session focused on different task domains and, consequently, separate (albeit interrelated) neural regions. The first paper, "Relative vs. Absolute Rewards: Evidence from Experimental Tasks and Neuroimaging," by Dan Ariely, Gregory Berns, Rosa Chávez-Eakle, and Nina Mazar, dealt with an important issue in behavioral decision theory. Prior work raised the hypotheses that the nucleus accumbens, subthalamic extended amygdala, amygdala, and hypothalamus may produce responses related to reward (Aharon et al., 2001). In the current paper, the authors examined the activity in these neural regions in order to better understand the way reward is encoded in the brain. In particular, they tested how relative versus absolute reward values produce differential behavioral responses and activate the limbic areas of the brain. They manipulated the mixture of positive and negative stimuli using a "keypressing" paradigm in a set of behavioral and fMRI studies, and found converging evidence that individuals have high sensitivity to relative, but not absolute, rewards.

In the second paper, "Why Celebrities are Effective: Brain Mechanisms of Effective Advertising," Vasily Klucharev, Guillen Fernandez, and Ale Smidts tackled the issue of whether neural regions are differentially activated during judgments of products that are featured with celebrities either with or without expertise relevant to the product. Recent behavioral research on celebrity presenters has suggested that their effectiveness critically depends on celebrities having a readily perceivable 'expertise hook' with respect to the product they are endorsing. In line with behavioral results, they found better memory and higher purchase intentions for products paired with the expert celebrity than non-expert celebrity. This 'expertise hook' effect on brain activity was examined in an event-related fMRI study. Whereas activity in a distributed network of prefrontal and cingulate cortex was associated with buying intention for everyday products, differential activation in dorsal posterior cingulate cortex reflected negative subjective evaluation of the product. They further found that the effect of 'expertise

hook' on buying intention was mediated by an evolutionarily old emotional neuronal network (i.e., orbitofrontal cortex).

The third paper, "A fMRI Study of Neural Dissociations between Brand and Person Judgments," by Carolyn Yoon, Angela Gutches, Fred Feinberg, and Thad Polk, investigated whether a common presumption in the field—that descriptors for human and for brand 'personality' are essentially interchangeable—is supported at the neural level. Individuals are readily able, when asked, to indicate the degree to which various trait adjectives are descriptive of a target object or brand. The authors suggested that because assessments of products' qualities and attributes have thus far been universally carried out using this sort of protocol, it is of fundamental importance to determine whether qualities ascribed to brands (and more generally, everyday objects) are processed as they are in their typical, human-related usages. In an event-related fMRI study, they compared personality judgments of self relevant and non-self relevant brands and persons and obtained neural dissociations. Specifically, greater activation in the medial prefrontal cortex region obtained for person judgments; for brand judgments, activation was greater in the left inferior prefrontal cortex, an area known to be involved in object processing. Based on these findings, they cautioned against the tendency to view the processing of products and brands as being akin to that of humans.

Finally, Richard Gonzalez led a discussion on how each of the three papers provided insights about processes underlying consumer judgment that would be difficult or impossible to obtain using standard behavioral research methods (e.g., experiments, participant observations, surveys). He discussed how neuroimaging is expected to play an increasingly larger role in understanding psychological and social processes. The next decade will undoubtedly see rapid growth in the adoption of neuroimaging methods by consumer researchers.

“Ethically Concerned, yet Unethically Behaved”: Towards an Updated Understanding of Consumer’s (Un)ethical Decision Making

Andreas Chatzidakis, University of Nottingham
Sally Hibbert, University of Nottingham
Andrew Smith, University of Nottingham

ABSTRACT

The paper complements existing research on ethical consumer behavior by examining how people cope with the psychological tensions that arise when they behave in ways that are in apparent contradiction to their expressed ethical concerns. It advances the concept of neutralization – justifications that soften or eliminate the impact that norm-violating behavior might have upon self-concept and social relationships – and presents hypotheses on the role of neutralization in ethical consumer decision making processes.

INTRODUCTION

Research into ethical consumer behavior has grown substantially since the 1990s (Vitell 2003) and has provided valuable insights, yet it remains a relatively small body of literature and we still lack a unified understanding of the role of ethics in consumer behavior. One of the key challenges identified by researchers in this field relates to the fact that people’s ethical concerns are often not manifest in their behavior (e.g. Carrigan and Atalla 2001; Strong 1996). Here we address the attitude-behavior discrepancy in ethical consumer behavior, advancing the concept of neutralization – a process through which people justify or rationalize their behavior as a means of coping with decision conflict and insulating themselves from blame and guilt. We start with a review of extant literature on ethical consumer behavior; then introduce the concept of neutralization and consider its application to consumption contexts. Subsequently the paper examines the theoretical tenets of neutralization with a view to integrating the concept with existing models of ethical consumer behavior.

ETHICS AND CONSUMER BEHAVIOR

Ethical consumer behavior can be broadly defined as the “decision making, purchases and other consumption experiences that are affected by the consumer’s ethical concerns” (Cooper-Martin and Holbrook 1993, 113). Earlier research on ethical consumer behavior was prompted by the consumerism movement of the 1970s, and investigated specific topics in the context of “environmentally concerned/conscious consumption” (e.g. Anderson and Cunningham 1972; Webster 1975; Brooker 1976; Antil 1984; Haldeman, Peters, and Tripple 1987; Alwitt and Berger 1993; Jackson et al. 1993). Similarly, studies emerged for issues such as self-restraint (Horowitz 1985), voluntary simplicity (e.g. Leonard-Barton 1981; Shaw and Newholm 2002), ethical investing (e.g. Irvine 1987; Lewis 1999), consumer boycotts (e.g. Smith 1990; Burke, Milberg, and Smith 1993) and shoplifting (e.g. Kallis, Freeman, and Zelditch 1986; Moschis and Powell 1986; Cox, Cox, and Moschis 1990).

More general treatments of ethical consumer behavior can be grouped under two headings: “ethical consumerism” and “consumer ethics”. “Ethical consumerism” (e.g. Shaw and Clarke 1999; Creyer and Ross 1997; Carrigan and Attalla 2001; Roberts 1996; Straughan and Roberts 1999) can be seen as an evolution of green consumerism. In contrast, “consumer ethics” (e.g. Vitell and Muncy 1992; Vitell et al. 1991; Fullerton et al. 1996; Albers-Miller 1999; Singhapakdi et al. 1999) refers to misconduct, mainly in retail settings (e.g. failing to declare undercharging).

Central amongst this research have been attempts to develop theoretical models of consumers’ ethical decision making either in particular contexts (e.g. Fullerton and Punj 1993; Jackson et al. 1993; Tan 2002; Thong and Yap 1998; Whalen et al. 1991; Nebenzahl et al. 2001) or the broader domains of ethical consumerism (Shaw and Clarke 1999; Shaw et al. 2000; Shaw and Shiu 2002a, 2002b, 2003) and consumer ethics (Marks and Mayo 1991; Vitell et al. 2001; Fukukawa 2002). In this endeavour, the two most prominent theoretical approaches have been Hunt and Vitell’s (1986) general theory of marketing ethics and Ajzen’s attitude models (Ajzen 1985, 1991). Hunt and Vitell’s model (1986, 1992) was applied to ethical consumer contexts by Marks and Mayo (1991) and Vitell et al. (2001) (see also Thong and Yap 1998). They propose that the ethical decision process begins with the consumer perceiving an ethical problem (exogenous variables include the consumer’s cultural environment, reference groups and past personal experiences; Marks and Mayo 1991). Subsequently, s/he combines a deontological and a teleological evaluation to arrive at a judgment, i.e. attitude about the ethical problem¹ which, in turn, influences the consumer’s behavioral intentions. It is suggested that teleological evaluations affect intentions indirectly through ethical judgments but also directly. That is, an individual may not choose the most ethical alternative due to desirable consequences of a less ethical one. Furthermore, intention may differ from actual behavior due to situational conditions enabling consumers to engage in unethical behavior (e.g. the opportunity to adopt an alternative). Finally, the consequences of the consumer’s behavior become part of the consumer’s learning experiences. In the case of choosing an unethical alternative, the consumer might have guilt feelings that will affect future behavior.

The theory of planned behavior (TPB; Ajzen, 1985, 1991) applied in ethical consumer contexts by Fukukawa (2002) and Shaw and colleagues (Shaw and Clarke 1999; Shaw et al. 2000; Shaw and Shiu 2002a, 2002b, 2003), suggests that behavior in a specified situation, is a direct function of behavioral intention, which in turn is a function of attitude and subjective norm. Perceived behavioral control refers to the individual’s control beliefs and is suggested to impact both behavioral intentions and behavior. Both of the above models are established on the fundamental premise that an individual’s intentions are consistent with ethical judgments in most cases (Fukukawa 2002). However, as in other consumption contexts, there is clear evidence of attitude-behavior discrepancies: consumers’ ethical concerns and attitudes are not always manifest in actual behavior (e.g. Carrigan and Atalla 2001). For example, consumers have been found to buy environmentally hazardous products regardless of their expression of concern for greener alternatives (Strong 1996) and to shoplift regardless of their adherence to societal and economic norms of behavior that guide

¹Teleological ethical theories hold that the moral worth of actions is determined solely by their consequences. Deontological theories hold that one or more fundamental principles of ethics differ from the principle of utility; they are based on principles of duty such as “never treat another merely as a means to your own goals” (Beauchamp and Bowie 1988, 37)

marketplace behavior (Strutton, Vitell, and Pelton 1994; Strutton, Pelton, and Ferrell 1997). Generally, attitude-behavior discrepancies have been accounted for by sampling, operationalization and behavior-specific issues (see e.g. Ogden 2003; Luzar and Cosse 1998) or by the addition of further constructs. For example, in the context of consumer ethics, Fukukawa (2002) has proposed the addition of a fourth construct affecting intentions, namely "perceived unfairness"; while in the ethical consumerism field, Shaw and colleagues (Shaw and Clarke 1999; Shaw et al. 2000; Shaw and Shiu 2002a, 2002b, 2003) have proposed the addition of two constructs, namely "ethical obligation" and "self identity". The additional influences that are apparent in the context of ethical consumer behavior point towards the internal tensions that consumers feel when balancing their own desires with moral behavior that favors societal well being. However, both models inevitably fail to account for the psychological realities of consumers who consistently behave in ways that are in apparent contradiction to their expressed ethical concerns.

Theories of cognitive or attitude-behavior consistency within social psychology, in general, have left the diverse modes of restoring equilibrium without attitude change unexplored (Hazani 1991). Even within the cognitive dissonance literature, where attitudes after performing a counter-attitudinal behavior have been found to remain in striking opposition to that behavior, the focus has largely been on the arousal of dissonance, as opposed to the subsequent processes that lead to attitude change; hence generating little evidence regarding the nature of those processes (Kunda 1990; Holland et al. 2002). Accordingly, Holland et al. (2002) observe that there is surprising little research on the different ways in which people justify their attitudinally-incongruent behavior: "Although many different examples of self-justification have been documented in the psychological literature, this has not produced a comprehensive taxonomy of self-justification strategies" (Holland et al. 2002, 1714). The concept of neutralization and the associated taxonomy of neutralization techniques is one theoretical contribution that promises to fill this gap.

INTRODUCING TECHNIQUES OF NEUTRALIZATION

Social norms play a crucial role in guiding ethical behavior (e.g. Davies et al. 2002). When social norms are not internalized to the degree that they guide behavior under all circumstances, consumers may develop coping strategies to deal with the dissonance that they experience. Neutralization theory represents a conceptual approach that has been applied to understand how individuals soften or eliminate the impact that their norm violating behavior might have upon their self-concept and social relationships (Grove et al. 1989).

In 1957, Sykes and Matza published their seminal article on juvenile delinquency criticising the predominant theoretical viewpoint that delinquency is a form of behavior based on the values and norms of a deviant sub-culture in the same way as law-abiding behavior is based on the norms and values of the larger society. These authors suggested that rather than learning moral imperatives, values or attitudes standing in a complete opposition to those of his/her society, the delinquent learns a set of justifications or rationalizations, i.e. the techniques, which can insulate him/her from self-blame and the blame of others. This perspective can be attributed to the flexibility of the normative systems in contemporary societies: rather than being categorical imperatives, social norms or values are "qualified guides for action, limited in their applicability in terms of time, place, persons, and social circumstances" (Sykes and Matza 1957, 666). For example, the

moral injunction against killing does not apply in time of war and so on. Thus, the delinquent learns patterns of thought that help him/her to remain committed to the normative system and qualify his/her actions as "acceptable" if not "right". While neutralization techniques may be viewed as following unethical behavior, ultimately they can precede it, and make unethical behavior possible. That is, once successfully internalized, they can truly become neutralizing devices (Grove et al. 1989). The five techniques, as adapted by Strutton *et al.* (1994, 254) in a consumer context, are listed below:

- 1) Denial of responsibility (DoR): A circumstance in which one argues that s/he is not personally accountable for the norm-violating behavior because factors beyond one's control were operating; e.g. "It's not my fault I don't recycle, the government should make it easier".
- 2) Denial of Injury (DoI): A circumstance in which one contends that personal misconduct is not really serious because no party directly suffered as a result of it; e.g. "What's the big deal, nobody's gonna miss one towel!"
- 3) Denial of Victim (DoV): A circumstance in which one counters the blame for personal actions by arguing the violated party deserved whatever happened; e.g. "It's their fault; if the salesman had been straight with me I would have told him he undercharged me".
- 4) Condemning the condemners (CiC): A circumstance in which one deflects accusations of misconduct by pointing out that those who would condemn engage in similarly disapproved activities; e.g. "It's a joke they should find fault with me after the rip-offs they have engineered".
- 5) Appeal to higher loyalties (AtHL): A circumstance in which one argues that norm-violating behavior is the result of an attempt to actualize some higher order ideal or value; e.g. "I'd like to buy more environmentally friendly products but the choice is limited and I like trying out different stuff".

Since its original formulation by Sykes and Matza, neutralization theory has been one of the most widely known and frequently cited theories in sociology of deviance, either incorporated into or rebutted by most subsequent theories of crime and norm-violating behavior (Minor 1981; Copes 2003). Examples of its application include a variety of juvenile (e.g. Ball 1966; Minor 1981; Costello 2000) as well as adult deviance contexts (e.g. Levi 1981; Eliason and Dodder 1999; Fox 1999). Further, neutralization theory has been the subject of more intuitive applications, both within and beyond the boundaries of what is typically labelled as deviant behavior. Examples include the role of neutralization techniques in the victimization of battered wives (Ferraro and Johnson 1983), genocide and the Holocaust (Alvarez 1997), organizational rule enforcing (Fershing 2003), abortion (Brennan 1974), religious dissonance (Dunford and Kunz 1973) and the management of the "temporary deviant" label of pageant mothers in the United States during the peak of negative press in 1997 (Heltsley and Calhoun 2003).

Neutralization has been applied to consumption contexts, but research in this domain remains very limited. Grove et al. (1989) advanced the concept as a basis for understanding non-normative behavior, mainly in retail settings while empirically, neutralization has only been applied to investigate quite extreme 'criminal' behavior (Strutton et al. 1994, 1997) or more obliquely, as an explanation for reported unethical behavior (Mitchell and Chan 2002) and in relation to anomie and subsequent fraudulent behavior

(Rosenbaum and Kuntze 2003). More recently, an exploratory study has illustrated the theory's applicability in a wider array of consumer ethical choices (Chatzidakis et al. 2004). Thus, the usefulness of the concept is recognized but, to date, no attempt has been made to carefully examine and relate neutralization's theoretical tenets with existing theories of ethical consumer behavior.

COPING WITH UNETHICAL CONSUMPTION: A PLACE FOR NEUTRALIZATION?

The need for neutralization assumes that behavior violates social norms. Yet, in many instances, the contemporary ethical dilemmas facing consumers do not involve the violation of conventional or universal social norms (Reiss 1951; Sartorius 1972) to which neutralization theory was originally applied. For example, there is not an absolute norm that "one ought to buy fair trade products". Nevertheless, as an arena of behavior, consumer activities offer the opportunity for the expression of a wide range of norm types (Grove et al. 1989).² Failure to behave ethically may involve the violation of different group norms (Bettenhausen and Murnighan 1985; March 1954) or subcultural norms (Yinger 1960) or, what Jackson et al. (1993) describe as "felt" norms. It is these felt norms that affect activities such as recycling and buying fair trade products. People may also make individual ethical judgments (e.g. Beauchamp and Bowie 1988; Sartorius 1972), as neither all non-normative behaviors are unethical nor all unethical behaviors normative (e.g. Beauchamp and Bowie 1988; Strutton et al. 1997). Individuals may view certain consumer choices as wrong for themselves, but not necessarily wrong for others (Baron 1999). Nonetheless, even these individual judgments may be violated in some circumstances. In sum, it is important to recognise the nature of the norms relevant to particular consumption contexts, but neutralization can nevertheless be used in any circumstance in which a consumer has a desire to commit (or has committed) a questionable activity but has an ethical concern that requires neutralization (Minor 1981, 300-301).

The relative negligence of neutralization theory to account for how people cope with dissonance in ethical decision contexts is not surprising given that its origins are sociological (see Eagly and Chaiken 1993). Nonetheless, the potential usefulness of neutralization theory in this domain (Minor 1984; Hazani 1991) stems from the fact that it is a well-established and relatively comprehensive conceptual framework, which describes and predicts which self-justification strategies may be employed as a defense against dissonance and feelings of guilt consumers might otherwise experience when violating their internalized norms and values. Therefore, it represents a psychological process capable of restoring equilibrium without attitude change.

Despite its sociological origins, neutralization shares similar theoretical tenets with recent advances in psychology. For example, in opposition to the more traditional social cognition models, which assume a rational and unbiased consumer, proponents of motivated cognition argue that an individual's motives on a particular occasion bias reasoning processes and the resultant judgments. A number of studies (e.g. Kunda 1990; Ditto et al. 1998; Baumeister 1996) have made a strong case to suggest that directional goals, as opposed to accuracy goals, "may affect reasoning through reliance on a biased set of cognitive processes: strategies for accessing, constructing and evaluating beliefs" (Kunda 1990, 480). Similarly, one of the dominant models within persuasion and attitude change, i.e. the heuristic-systematic model (Chaiken 1980, 1987; Chaiken,

Liberman, and Eagly 1989), assumes that three different types of motivation – accuracy, impression and defence – may affect the type (heuristic versus systematic) and final outcome of a certain information processing task. Indeed, even the mainstream attitude models themselves (e.g. Ajzen 1991; Eagly & Chaiken 1993; Fazio 1990), have been recently criticized for not incorporating explicit or at least adequate, motivational content (see Perugini and Bagozzi 2004).

The theoretical developments outlined above share similar ground with neutralization theory in that a range of enduring and situational motives affect the final behavioral outcome, but also the cognitive strategies deployed before and afterwards. Of course, neutralization is specifically concerned with ethical reasoning processes, where motives such as self-esteem maintenance and self-worth are of dominant importance. Moreover, although neutralization is likely to co-occur with other modes of reasoning and effortful cognitive processing, it should be particularly pertinent in cases where the motive is to maintain self-esteem as opposed to arriving at a valid ethical judgment (see e.g. Eagly and Chaiken 1993). The lack of effort devoted to many ethical decisions was highlighted by Irwin (1999, 212) who claimed that most individuals are unlikely to "incorporate a complex hedonic calculation of the greatest utility for society into (their) weekly supermarket trip". However, involvement can fluctuate as ethical concerns are continuously influenced by contingencies such as peer pressure and availability of information (Clarke 2004). Nevertheless, neutralization represents a very specific theoretical proposition, which is most easily applied to less deliberative decision making and describes and predicts which cognitive "heuristics" or strategies may be employed when there are motives to maintain self-worth and at the same time violate personal ethical beliefs and values. This relatively effortless mode of cognitive processing is most likely to occur in everyday, low-involvement contexts, where consumers downplay ethical considerations.

TOWARDS A MODEL OF "UNETHICAL" CONSUMER DECISION MAKING

The foregoing discussion proposes that the cognitive process of neutralization can help consumers to cope with feelings of guilt or dissonance when their behavior in ethical contexts is not consistent with their beliefs and attitudes. The ensuing model and discussion elaborate on how neutralization complements existing models of ethical decision making, thus moving towards a model of unethical consumer decision making.

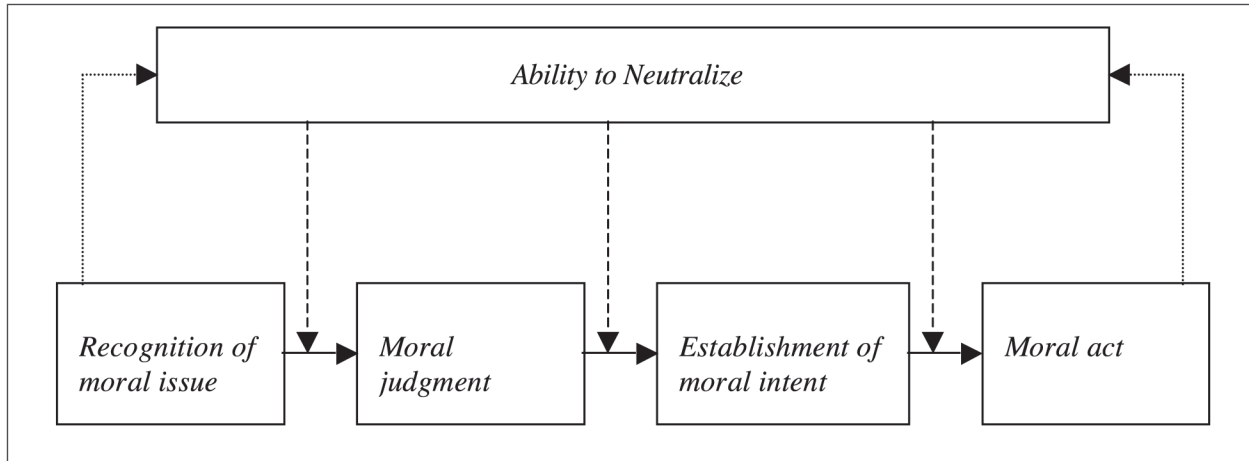

Figure 1 depicts the basic four-stage model of ethical decision making advanced by Rest (1979). This model is consistent with the core elements of many subsequent models on ethical decision-making (e.g. Hunt and Vitell 1986; Ferrell and Gresham 1985; Tan 2002), which focus on one or more of the stages outlined (for an overview, see Jones 1991). Thus, we adopt this model here for the sake of simplicity and comparability.

Rest's model proposes that in the ethical decision process an individual must a) recognize the moral issue, b) make a moral judgment, c) resolve to place moral concerns ahead of other concerns, and d) act on the moral concerns. Each of these stages is conceptually distinct and success at one stage does not imply success in subsequent stages. We propose that individuals can bring to bear neutralization techniques between each and/or every stage of the ethical decision process to mitigate potential dissonance and feelings of guilt. The hypotheses presented below detail the proposed moderating effect of a person's ability to neutralize between each stage of the process.

At the beginning of the process, an individual recognises that there is a moral dimension to the decision. In the process of making

²Grove et al. (1989, 132), refer to three different norm types, i.e. "folkways", mores and laws.

FIGURE 1
The Influence of Ability to Neutralize on the Ethical Decision Process

a moral judgment on the issue, the degree to which a person considers it acceptable, if not right, to deviate from the relevant norm or value will be influenced by his or her ability to apply neutralization techniques to the situation. For example, within the domain of consumer ethics (e.g. acknowledging being given the wrong change), it has been widely documented that beliefs about whether the consumer or the seller is at fault underlie consumer moral judgments (Fukukawa 2002). Vitell and Muncy (1992) have linked this type of rationalisation to the neutralization techniques of "condemning the condemners" and "denial of victim".

H1: Where an individual recognises that there is a moral dimension to a decision, the ability to neutralize will have a negative effect on moral judgments (attitudes) and will make unethical alternatives more acceptable

When a moral judgment or attitude towards the ethical issue has been formed, a consumer does not necessarily establish an intention to pursue what s/he perceives to be a morally superior course of action because other competing concerns/desired consequences sometimes take priority (e.g. Hunt and Vitell 1986). In such cases, neutralization techniques can serve as self-defence mechanisms that mitigate the virtues of ethically superior choices. For example, a consumer may have shaped an ethical judgment in favour of recycling. At the same time however, s/he may not be willing to undergo the inconvenience of keeping separate bins, driving to the recycling station and so on. By employing neutralization techniques such as "no one else is doing it in the neighbourhood" or "it is the council's responsibility for not having a better infrastructure in place", s/he can avoid dissonance or feelings of guilt that might otherwise arise due to the inconsistency between his/her moral judgments and intended behavior.

H2: When a moral judgment is in favor of ethically superior choices, the ability to neutralize will a) increase the likelihood that a consumer will form inconsistent moral intentions and b) reduce the likelihood that an individual will experience dissonance or guilty feelings.

Even if the consumer has established an intention to pursue an ethically superior course of action, situational constraints or the existence of an opportunity might affect actual behavior (Ferrell and

Gresham 1985; Hunt and Vitell 1992). Again, the techniques can guard against any feelings of guilt or dissonance that might arise due to the inconsistency. For example, a consumer may be willing to pay a higher price for fairly traded goods but when s/he goes to the supermarket the fair trade brand is out of stock. Similarly, an individual may have no intention to engage in any sort of consumer "transgressions", but when s/he is undercharged in a large chain retail store, s/he may "overlook" the incident. In both cases, techniques such as attributing responsibility to the retailer and claiming that "no one else would do it" can effectively guard against the anticipation of feelings such as remorse or shame, and thus smooth the process of not acting on previously established moral intentions.

H3: When moral intentions are in favour of more ethical choices the ability to neutralize will a) increase the likelihood that a consumer will submit to situational constraints or opportunities that inhibit him or her from acting upon those positive intentions and b) reduce the likelihood that an individual will experience dissonance or feelings of guilt.

Actual (unethical) behavior might lead to the employment of neutralization techniques on a *post hoc* basis, indicating the consumer's sensitivity to its unethical nature and becoming part of his/her experience. If successful, the techniques might be internalized and thus they will affect the recognition of an ethical issue in subsequent decisions on an *ad hoc* basis. That is, if they have become genuine neutralizing devices, on similar occasions in the future an individual will not consider there to be a moral dimension to the problem (Vitell and Grove 1987; Grove et al. 1989). Indeed, by making the unexpected expected, the untoward either justified or inconsequential, neutralization techniques essentially make things "right" (Massey, Freeman, and Zelditch 1997, 238).

H4: The use of neutralization techniques following behavior (if successfully internalized) will reduce the likelihood that a consumer will recognize a moral dimension to a similar problem in the future.

Following Vitell and Grove's (1987) related endeavor in the business ethics field, it is further proposed that both the type of

ethical problem and various background characteristics of the consumer act as moderating variables upon the proposed relationships between the “ability to neutralize” and (un)ethical behavior. While some indications of possible interrelationships already exist in the literature (for type of ethical problem see e.g. Strutton et al. 1994; Chatzidakis et al. 2004; for individual characteristics see e.g. Strutton et al. 1997; Holland et al. 2002), a further elaboration on those issues would move beyond the purpose of this paper, which is to illustrate how the techniques may affect any of the basic steps in the consumer’s ethical decision-making process.

The proposed construct can be readily added in the context of Hunt and Vitell’s (1986, 1992) general theory in marketing ethics since it is based in all steps of Rest’s ethical decision-making process and also accounts for moderating or exogenous factors. Furthermore, it can also be adjusted in the context of theory of planned behavior. It can represent a new construct, in the same way that Fukukawa (2002) argued for “perceived unfairness”, and Shaw and Shiu (2002a, 2002b) for “ethical obligation” and “self identity”; thus affecting attitude, behavioral intention as well as behavior. Clearly however, those conceptualization issues await future investigation.

CONCLUSIONS

Neutralization theory offers to significantly complement existing knowledge of ethical consumer behavior by outlining ways in which consumers can mitigate the negative impact of their ethically questionable activities. In addition to the theoretical contribution of neutralization theory to understanding unethical consumer behavior, the arguments and hypotheses advanced in this paper, if empirically verified, have implications for both public policy and marketing practice. Most notably, given an understanding of how consumers use neutralization techniques to justify pursuing their more selfish goals in particular contexts, marketing communications and persuasion activities can be designed to counter the arguments that consumers use to justify unethical choices. Investigations into which neutralization techniques are mostly employed to justify, for example, shoplifting, drink driving or declining to give to charity, could provide the basis for initiatives that seek to manipulate, negate and pre-empt the deployment of those techniques in particular (e.g. Strutton et al. 1994, 1997). In relation to shoplifting, statements such as “everybody loses from shoplifting” and “shoplifting does make a difference because at the end it increases the final cost for the consumer” may work against the “denial of injury” neutralization technique. Yet, more research is needed to empirically validate all of the hypotheses advanced and to identify the more effective approaches to communication. For example, while it is possible that communication attempts that target at disrupting a cognitive adaptation (via neutralization techniques) will ultimately lead to behavioral adaptation (via more ethical behavior; Peretti-Wattel 2003), it is also possible that consumers may counterbalance it by inventing a series of new neutralizing beliefs (Minor 1981).

Furthermore this research can have important implications for the lives of consumers. Awareness and understanding of how individuals use neutralization techniques could provide valuable insights for consumers on their own everyday behavior. A more critical stance on the ethical rationalizations that consumers intuitively employ in so many daily consumer contexts could perhaps be powerful enough to uplift change. For example, being aware of the widespread employment of certain neutralization techniques, a consumer would probably think twice about whether his own internal dialogues concern real expressions of situational or utilitarian ethics or somewhat self-deceptive “excuses” (see Bersoff 2001, 1999). Is it sensible and valid to argue that “I do not recycle paper

because the council does not provide a collection service”, or is it the case that we have a responsibility to recycle the waste produced through our consumption, even if doing so is not as convenient as we would like? It has been suggested that relatively small, non-duress driven social breaches are likely to be the most strongly influenced by self-presentation and self-esteem needs, and indeed, these are the types of questionable behaviors that are the most common (Bersoff 2001). Recognising and readdressing some of these minor violations may have positive consequences for consumers in terms of their freedom from guilt and peace of mind as well as broader societal benefits.

Explicit and Implicit Determinants of Fair-Trade Buying Behavior

Delphine Vantomme, Ghent University

Maggie Geuens, Ghent University

Jan DeHouwer, Ghent University

Patrick DePelsmacker, University of Antwerp

INTRODUCTION

Although the consumers' commitment to environmental issues, animal testing, working conditions, fair trade, and other ethical issues has gained more attention in recent years (Nicholls 2002), ethical consumer behavior remains a relatively under-researched consumer domain (Folkes and Kamins 1999; Uusitalo and Oksanen 2004). Evidence of a growing market for ethical products is often inferred from the results of opinion polls indicating increasing concern with the ethical features of products (Tallontire, Rentsendorj and Blowfield 2001). However, this raising concern does not seem to translate into actual purchase behavior. More specifically, several authors have reported an attitude-behavior gap (Bird and Hughes 1997; Boulstridge and Carrigans' 2000; Carrigan and Attalla 2001; Folkes and Kamin 1999) and pointed out that most of the ethical labeling initiatives with respect to, for instance, organic food, products free from child labor, legally logged wood, and fair-trade products, have market shares of less than 1% (MacGillivray 2000).

The purpose of this study is to propose and test a measurement technique of implicit attitudes that can partly account for the attitude-behavior gap in ethical consumer behavior, to investigate to what extent implicit attitudes determine ethical buying behavior, and to discuss the marketing implications of the findings.

THE ATTITUDE-BEHAVIOR GAP AND IMPLICIT ATTITUDES

There are two plausible explanations for the reoccurring discrepancy between attitudes towards ethical issues and buying behavior as measured in survey research and actual buying behavior. The first relates to characteristics of ethical products, while the second is related to measurement problems. Primarily, the low attitude-behavior consistency in ethical consumer behavior may be ascribed to the fact that ethical products may well be desirable because they are environmentally friendly or serve a social cause, but still a premium price has to be paid or extra effort has to be exerted to find the products (Hurtado 1998). Previous research indicates that higher prices and efforts are the main reasons that ethically-oriented consumers mention when their attitude-behavior inconsistency is pointed out to them (De Pelsmacker, Driesen, and Rayp 2005). Moreover, the majority of people evaluate product attributes jointly in making purchase decisions. Price, quality, convenience, availability in regular supermarkets, and brand familiarity are often still the most important factors affecting the buying decision (e.g. Boulstridge and Carrigan 2000; Carrigan and Attalla 2001; De Pelsmacker et al. 2005a; Tallontire, Rentsendorj and Blowfield 2001). Thirdly, consumers may still need to be convinced that their purchase behavior can make a difference in ethical terms in order to be persuaded to buy them (Bird and Hughes 1997).

With respect to the measurement problems in ethical consumer research, there is the heavy reliance on self-report measures that assume that people are *aware* of their attitudes and that they are *able* and *willing* to reveal them if asked appropriately. However, these assumptions are not always valid (Greenwald and Banaji 1995). Ulrich and Sarasin (1995) somewhat cynically claimed not to do any research and not to ask the public any question on ethical buying behavior, because the answers are never reliable, and often

useless if not misleading. Especially in situations in which respondents want to make a good impression on the researcher or want to conform social norms, attitudes tend to be more positive than actual behavior (King and Bruner 2000). Typically in questionnaires on sensitive topics such as ethical issues this could be the case. (La Troobe, Helen, and Acott 2000).

Furthermore, self-report attitude measures operate on the assumption that people have a-priori attitudes towards all attitude-objects or that they are able to form them on the spot (Schwarz and Bohner 2001). Consequently, even when respondents are unfamiliar with the attitude-object (and do not have a-priori attitudes), they will still answer the question in order not to seem *ignorant*. Especially, the presence of an interviewer, monetary and physical inducements or the expectation of knowledge may motivate respondents to provide uninformed responses or "guessing" at answers (Hawkins and Coney 1981). In other cases, previously formed attitudes may not be easily accessible to the individual (Fazio et al. 1986). Thus, even when individuals have a previously formed attitude, they may report a newly created one.

Finally, substantial research on social cognition suggests that a large portion of our daily activities is the result of cognitive processes that occur outside conscious awareness and control (Bargh 2002; Greenwald and Banaji 1995). As a result, traditional self-report measures are not well suited to capture these implicit processes. Related to the latter point is the renewed interest in the "unconscious" (Weinberger 2000) and the distinction between explicit and implicit attitudes. Explicit attitudes are attitudes that operate in a controlled conscious mode and are typically measured by self-report tasks. Implicit attitudes can be defined as "introspectively unidentified (or inaccurately identified) traces of past experience that mediate favorable or unfavorable feeling, thought, or action towards social objects" (Greenwald and Banaji 1995, p. 8). Given these insights, several authors have argued that automatic processes should also be considered in order to fully understand consumer attitudes and decisions (e.g. Brunel, Tietje, and Greenwald 2004; Maison, Greenwald, and Bruin 2004).

The arguments discussed above suggest that the discrepancy between ethical consumer behavior and self-reported attitudes could partially be due to problems with self-report tasks. Recently, researchers have developed a number of alternative measures that do not rely on self-report. These measures are assumed to register implicit attitudes and to be less sensitive to social desirability effects. One of these measures, the Implicit Association Test (IAT), is perhaps the most promising upcoming solution to these measurement problems.

IMPLICIT ATTITUDE MEASUREMENT

The Implicit Association Test

The IAT, developed by Greenwald et al. (1998), is presumably the most well-known implicit measurement technique in psychology (Fazio and Olson 2003). The IAT is a computerized task that measures the strength of association between two contrasted target concepts (e.g. flower and insects) on the one hand and an attribute dimension (e.g. positive and negative words) on the other hand. The idea behind the IAT is that it should be easier to map two concepts

onto a single response when those concepts are similar or associated in memory than when the concepts are unrelated or dissimilar. The difference in reaction times between these two tasks is taken as an indication of the degree of association between concepts (Greenwald et al. 1998). A substantial number of studies have demonstrated the reliability and validity of the IAT in psychological research (Greenwald and Nosek 2001). For example, IAT-effects were shown to be indicative of in-group preference with respect to ethnic groups (e.g. Japanese-American and Korean-American, Greenwald et al. 1998), spider and snake phobics (Teachman et al. 2001), homosexuals (Banse et al. 2001), vegetarians, cigarette smokers (Swanson et al. 2001), etc. Further, convergence has been reported between IAT measures on the one hand and semantic priming measures (e.g. Cunningham et al. 2001) and physiological measures such as the fMRI (Phelps et al. 2000) on the other hand. Although less work has been conducted concerning the prediction of behavior from IAT scores, different studies demonstrated the IATs' ability to predict behavioral leakage. For instance, Asendorp et al. (2002) showed that the IAT significantly increased the prediction of spontaneous (but not deliberative) shy behavior in a realistic situation.

IAT in Consumer Research

According to Bargh (2002) "the realm of consumer research would seem to be the ideal playing field on which to establish whether the new models of automatic goal pursuit and automatic evaluation processes do, indeed, apply to the real world, [...]". However, only a few researchers have accepted this challenge by introducing the IAT into consumer research. Maison, Greenwald and Bruin (2004) examined implicit attitudes towards different types of products (juices and sodas; low and high calorie products) and brands (brands of yoghurt, fast food restaurants and cola). The results showed positive correlations between implicit attitudes and both explicit attitudes and behavior (self-reported and observed). Generally, heavy users of a particular product or brand demonstrated more positive implicit attitudes towards that product or brand than light users. Further, there are some indications that implicit attitude measures may reveal evidence of unique contribution to the prediction of behavior (i.e. consistently positive beta coefficients, Maison, Greenwald, and Bruin 2004).

Brunel, Tietje, and Greenwald (2004) obtained similar results. On the basis of the results of their first study, they concluded that in situations where implicit and explicit attitudes were expected to converge (attitudes towards Macintosh versus PC Windows based machines), IAT measures of brand attitude and brand relationship showed strong, positive correlations with explicit measures of brand attitude, ownership, and usage. Moreover, they found that the IAT effectively discriminated between consumers with more favorable explicit attitudes, ownership, and usage of one brand versus those with unfavorable explicit attitudes, ownership and usage of the same brand. In a second study on the race of advertising spokespersons, they demonstrated that under some conditions the IAT could uncover consumers' attitudes that traditional measures did not detect. In this second study, explicit and implicit attitudes towards ads for sportswear advertisements portraying African-American (Black) and European-American (White) athlete-spokespersons were measured. The results showed that at the explicit level there was no difference between attitudes towards the ads with White spokespersons compared to ads with Black spokespersons. However, the IAT revealed a strong preference for ads containing White spokespersons. When analyzing White and Black participants' subgroups, divergent results arose. White participants showed an in-group (=pro-White) IAT preference, but no significant ex-

PLICIT preference. Opposite results were found for the Black group: Black respondents showed a pro-Black preference at the explicit level, but no significant implicit preference. However, in consumer research, it has until now not yet been examined whether the use of the IAT in combination with explicit measures predicts behaviour more accurately than self-report measures alone in situations where consistently weak explicit attitude-behavior relationships have been found. This is the main purpose of this study.

METHOD OF ANALYSIS AND DATA COLLECTION

In an experiment we measured explicit and implicit attitudes towards Fair Trade and traditional (non-Fair Trade) products in participants who did (buyers) or did not (non-buyers) regularly buy Fair Trade products. The purpose of Fair trade products is to establish trading partnerships that aim for sustainable development of excluded and/or disadvantaged producers in the Third World. In a narrow sense, Fair Trade products can be defined by their best-known component: fair prices for the products of producers in developing countries (Krier 2001). Explicit attitudes toward the two assortments ('assortment with traditional products' vs 'assortments with Fair Trade products') were measured using semantic differential scales whereas implicit attitudes were measured using the IAT. The specific attitude-objects were coffee and rice, two commonly used fast moving consumer goods. This allowed us to examine whether implicit measures can differentiate between buyers and non-buyers. More specifically, we expected that IAT scores would reveal less positive implicit attitudes towards Fair Trade products (as compared to traditional products) in non-buyers than in buyers. Because we also included explicit measures, we could examine whether implicit measures are related to actual purchase behavior even when explicit attitudes are taken into account.

Method of analysis

Participants and procedure. Eighty-six people (52 women, 34 men) participated in the experiment in exchange for a coupon with a monetary value of approximately 6 euro (a coupon for purchases in Fair Trade shops for the 'buyers' of fair trade and a movie ticket for the 'non-buyers' of fair trade). Thirty-seven participants were recruited at the time of fair-trade purchase and conducted the experiment in a room next to a Fair Trade shop. The other participants (N=49) were selected by means of street interviews and completed the experiment in a meeting room of the University. All participants questioned at the Fair Trade shop and 11 participants questioned at the University reported to buy Fair Trade products at least a few times a year, whereas the remaining participants indicated never to buy Fair Trade products. As a result, we labelled the former participants 'Buyers of Fair Trade products' (N=48), while the latter participants were considered 'Non-buyers of Fair Trade products' (N=38). All respondents were between 18 and 64 years old ($M_{buyers}=29.79$, $SD=11.84$; $M_{non-buyers}=30.66$, $SD=13.10$, $F(1, 85)=0.103$, $p=0.749$).

The experiment consisted of three phases: (1) a learning phase, (2) an IAT and (3) a paper-and-pencil questionnaire. The IAT preceded the explicit measure to minimize potential, if any, carry-over effects (Egloff and Schmukle 2002). The entire study was conducted individually and each individual session took about 20 minutes.

Learning phase. The purpose of the learning phase was to ensure that every respondent knew the products in the experiment as well as the category that a product was meant to represent ('Fair Trade' versus 'traditional, open market'). During the learning phase, the assortment labels 'Fair Trade' and 'traditional' were

paired together with their (1) specific characteristics (fair price for the producer and control of production and trade, price premium due to the fair price and restricted number of outlets [Fair Trade], or striving for maximum profit, normal price and large number of outlets [traditional]) and (2) four illustrative (pictures of) Oxfam products (the best known fair-trade brand in Belgium): coffee 'dessert', coffee 'mocha', 'white' rice, and 'basmati' rice; and the two leading coffee and rice brands in Belgium respectively). Respondents were instructed to memorize the assortment labels, characteristics and products. In the memory test following the learning phase, respondents had to indicate to which assortment the product presented on the computer screen belonged by pressing the appropriate key. When the memory test was error free (which was the case for all respondents), the IAT was initiated. The order of learning the concepts and/or products was counterbalanced.

IAT. The IAT was designed to measure implicit attitudes towards the Fair Trade and traditional products in the experiment. The target stimuli were the individual pictures of the Fair Trade and traditional products shown during the learning phase. The attribute stimuli were positive (e.g. smile, paradise) and negative (e.g. pain, murder). Stimuli were presented in the centre of the computer screen and the respondents' task was to assign each stimulus to one of four categories. The IAT procedure comprised five blocks. In the first block, respondents discriminated between positive and negative words on 20 trials. Block 2 consisted of a target discrimination task (20 trials) in which respondents had to classify the pictures of the products in 'Fair Trade' and 'traditional' categories. In Block 3 (24 practice and 48 data collection trials) respondents were asked to categorize items by pressing one of the two keys (pictures of Fair Trade products and positive words assigned to one key versus pictures of traditional products and negative words assigned to the other key). Block 4 included once again a target discrimination task, but now with a reversal of the side of the screen on which the two category labels appeared (20 trials, the reverse of task 2). Block 5 (24 practice and 48 data collection trials) consisted of the reversed combined categorization task of block three (pictures of Fair Trade products and negative words assigned to one key versus pictures of traditional products and positive words assigned to the other key). The order of performing block 3 and 5 was counterbalanced between subjects. Before and during each phase, category labels were displayed on the left and right sides of the screen. Respondents were asked to respond as quickly but also as accurately as possible.

Explicit measures. A four-item seven-category semantic differential scale measured explicit attitudes towards the Fair Trade and traditional products ($\text{Alpha}=0.66$).

RESULTS

Explicit attitudes

Overall, explicit attitudes towards Fair Trade products ($M_{\text{Fair Trade}} = 5.43$, $SD = 1.08$) were significantly more positive than towards traditional products ($M_{\text{traditional}} = 4.79$, $SD = 1.07$, $t(85) = 3.96$, $p < 0.001$). An ANOVA with type of consumer (buyers or non-buyers) as a between subjects variable and type of product (Fair Trade products or traditional products) as a within-subjects variable revealed a main effect of type of product, $F(1, 84) = 14.85$, $p < 0.001$, and a significant interaction effect between type of consumer and type of product $F(1, 84) = 40.80$, $p < 0.001$. Moreover, t -tests indicated that buyers of Fair Trade products showed explicit attitudes towards these products ($M_{\text{Fair Trade buyers}} = 5.93$, $SD = 0.93$) that were significantly more positive than towards traditional products ($M_{\text{traditional buyers}} = 4.55$, $SD = 1.18$, $t(47) = 6.83$, $p < 0.001$), while non-buyers ($M_{\text{Fair Trade non-buyers}} =$

4.79 , $SD = 0.90$, $M_{\text{traditional non-buyers}} = 5.09$, $SD = 0.93$, $t(37) = -1.82$, $p = 0.08$) only showed a trend in the opposite direction.

Implicit attitudes

Prior to analysis, IAT data were treated following the procedure outlined by Greenwald and colleagues. (1998). The average error rate was 2.28% (0%- 12%) and all respondents were included in the analysis. We conducted an ANOVA with type of consumer (buyers or non-buyers) as a between subjects variable and IAT task (fair trade-positive or fair trade-negative) as a within-subjects variable. The ANOVA revealed a main effect of IAT task, $F(1, 82) = 5.43$, $p = .022$, and a significant interaction between type of consumer and IAT task $F(1, 82) = 45.64$, $p < 0.001$. Further t -tests showed that buyers performed significantly better in the fair trade-positive block ($M = 841$, $SD = 165$) than in the fair trade-negative block ($M = 1012$, $SD = 210$), $t(47) = 7.20$, $p < .001$, whereas non-buyers were faster in the fair trade-negative block ($M = 850$, $SD = 174$) than in the fair trade-positive block ($M = 935$, $SD = 214$), $t(35) = -2.80$, $p = .008$. These results indicate that buyers had a more positive implicit attitude toward fair trade products than toward traditional products whereas the reverse was true for non-buyers.

Logistic Regression Analysis

In order to assess the explanatory power of implicit and explicit attitude measures, a logistic regression analysis was carried out. The criterion for the logistic regression analysis was the dichotomous behavioural variable 'buying or not buying Fair Trade products', which is identical to the earlier split up of respondents into 'Buyers' vs 'Non-buyers' of Fair Trade products. For the explicit and implicit predictors (attitude measures) we calculated two difference variables that were scored in such a way that higher values indicated preference for Fair Trade products. The explicit attitude difference score (EDS) was computed by subtracting the standardized score of 'attitude towards traditional products' from the standardized score of 'attitude towards Fair Trade products'. We used an analogue procedure for the implicit attitude difference score: standardized values of the mean response time for performing the 'Fair Trade-positive' (same key for fair trade products and positive words; Combination 1) were subtracted from the 'Fair Trade-negative task (same key for fair trade products and negative words; Combination 2). The correlation between the explicit and implicit predictors was 0.43 ($p < 0.001$). In the stepwise logistic regression, the explicit difference score was entered in the first step and the IAT in the second step. This enabled us to estimate the additional predictive value of the implicit attitude measure beyond the influence of the explicit measure.

Buyer $\approx Z = B_0 + B_1$ Explicit attitudes + B_2 Implicit attitudes

The analysis yielded a significant positive relationship between the dependent variable on the one hand and the explicit ($\text{Exp}(B) = 3.89$; $B = 1.36$; Wald's statistic = 10.96; $p = 0.001$) and implicit difference score ($\text{Exp}(B) = 3.72$; $B = 1.32$; Wald's statistic = 11.45, $p = 0.001$) on the other hand. The overall $-2 \log$ likelihood difference for the fitted logistic model indicated a significant fit ($\chi^2 = 54.18$; $df = 2$; $p < 0.001$; Nagelkerke $R^2 = .63$). Moreover, we found a significant decrease of the $-2 \log$ likelihood in the transition from the first model (including only the explicit difference score; $-2LL = 78.43$, $\chi^2 = 37.98$; $df = 1$; $p < 0.001$; Nagelkerke $R^2 = .48$)¹ to the full model (including both difference scores; $-2LL = 62.23$, $\chi^2 = 16.20$;

¹When including only the implicit difference score in the regression analysis a Nagelkerke R^2 of .45 is obtained with $-2LL = 81.53$, $\chi^2 = 34.88$; $df = 1$ and $p < 0.001$

$df=1; p<0.001, \Delta Nagelkerke R^2=0.15$). This result implies that the IAT accounts for 15% unique contribution to the prediction of behaviour. In fact, the full model was able to classify 83.5 % of the respondents correctly, while the model based on the explicit measure alone assigned only 76.5 % of the respondents to the right category.

CONCLUSIONS, IMPLICATIONS AND SUGGESTIONS FOR FURTHER RESEARCH

The purpose of this research was to examine the usefulness of implicit attitude measurement with respect to ethical consumer behavior and to better investigate its relevance for the prediction and establishment of ethical buying behavior in society. Our results support the relevance of implicit measures such as the IAT as a useful tool in this context. First, we found that the IAT effects for buyers and non-buyers of Fair Trade products were significantly different, showing that the IAT can be used to differentiate between buyers and non-buyers. Moreover, it is suggested that to incite non-users to consume in a socially responsible way, not only explicit, but also implicit attitudes need to be changed. Thirdly, the logistic regression analysis demonstrated that IAT effects partially predicted ethical consumer behavior even when the influence of the explicit measure was controlled for. In other words, the IAT provided an independent contribution to the prediction of behavior. This conclusion is consistent with previous research that suggested independence in predictions of behavior by IAT and explicit measures (e.g. Egloff and Smukle 2002; Maison, Greenwald, and Bruin 2004). Although Maison, Greenwald and Bruin's (2004) study 3 already indicated significant positive beta-coefficients for the IAT in multiple regression analysis, so far no formal statistical test was used to validate a predictive pattern of behavior (e.g. Nosek 2004). The present study is the first demonstration of the usefulness of implicit attitude measurement for the prediction of consumer behavior in general, and ethical buying behavior in particular. More specific, the data suggest that in ethical consumer behavior research the combined use of explicit and implicit attitude measures could lead to a better prediction of behavior as compared to when only explicit attitude measures would be used. This finding is in line with the dual attitude model of Jarvis² et al. (2001) suggesting that, in certain situations, old and new attitudes can be jointly activated and influence subsequent thought and action. However, we also need to point to the fact that in the regression analysis the explicit attitude measure had larger β values and accounted for the largest part of the variance explained in the behavioral intention variable. This means that the explicit measure predicted behavior better than the IAT. A possible explanation for the importance of the explicit measure in current experiment is that social desirability distortion did not form such a big problem as could be expected on the basis of previous research. That is, it is suggested that not measurement problems, but rather the discordant character of ethical consumer products account for the attitude-behavior gap found in our experiment. This interpretation is further confirmed by the moderate and significant correlation that was found between the two types of measures ($r=.43$). Furthermore, the correlation indicates that although there

is an overlap between the two types of measures, they may still measure different constructs.

The findings have a number of practical implications. First, to make non-users of ethical products behave more ethically, not only explicit, but also implicit attitudes need to be enhanced. As a consequence we recommend practitioners to not only attune their product strategy to the influence of explicit, but also implicit attitudes. Because especially positive affective experiences with products form the basis of implicit attitudes (e.g. Rudman, 2004) and positive affective reactions and familiarity are shown to be closely related (Janiszewski, 1990), we believe that exposure to and thus familiarity with the products should be increased. To that end, we advise an improved and extended distribution network next to a greater visibility of the products in all kind of food shops. That is, ethical products should become part of daily life by placing them next to A-brands of the same product category in supermarkets as well as bars and restaurants. Further, negative or less positive affective reactions can be altered by giving consumers positive experiential contact with the products. Free samples of ethical products in the supermarket or within the framework of a direct marketing campaign could serve this goal. In the context of fair trade, the authors found in a previous study that the indifference towards these products was substantial and that they were not particularly liked. Furthermore, in a follow-up study, an explanatory model of fair-trade buying behavior showed that these factors had a substantial effect on buying behavior. Stimulating product experiences may therefore be very important. Fair-trade organizations and other non-profit organizations promoting ethical consumer behavior should therefore develop strategies that lead to maximum trial and product experience.

As a limitation, we should point to the fact that this study was conducted in a relatively small exploratory group of Belgian consumers. Moreover, the study focused on only two product categories in one specific ethical buying situation (fair trade). Further research in different cultures and for different ethical products and issues should be conducted to corroborate our findings. Indeed, implicit attitude measurement in general and the IAT in particular could also be useful to study reactions to environmentally friendly products and initiatives and to other social marketing issues, such as smoking, drinking alcohol, speeding, not wearing a seatbelt... Secondly, although the purpose of the learning phase was to make sure that all respondents (and especially the non-buyers) knew the difference between the traditional and Fair Trade products, it remains questionable whether the distinction between buyers versus non-buyers would itself translate to differences in implicit attitudes, without the learning phase. Further research could also try to clarify what kind of variance it is exactly that is uniquely predicted by the IAT or focus on the potential moderating effects of, for instance, the amount of experience with the product and the intensity of product use, and perceived consumer effectiveness. Maybe the most interesting suggestion for further study is to try to identify the relative importance of factors such as the type of information and product experience to diminish negative implicit attitudes.

²According to the dual attitude model of Jarvis et al. (2003) persuasion does not necessary lead to attitude change, but rather to changes in confidence with respect to prior held attitudes. That is, people may lose confidence in their prior attitude and have enhanced confidence in a new attitude. Consequently, if an individual comes to have less confidence in an attitude, even if it has not changed in valence, it should be less directive of behavior, less stable and more susceptible to subsequent persuasion.

The Impact of Aging on Consumer Attributions of Blame for a Product Harm Crisis

Daniel Laufer, University of Cincinnati

David H. Silvera, The University of Tromsø

Tracy Meyer, University of North Carolina at Wilmington

EXTENDED ABSTRACT

Recently, a number of articles suggest that consumer segments assess blame differently for a product harm crisis. For example, Laufer & Gillespie (2004) found in two separate experiments that women blame a company more than men for a product harm crisis in which it is unclear whether the company, consumers, or situational factors were responsible for the crisis. Studies in psychology also suggest that blame attributions can differ across consumers in different countries. In a review of studies comparing North American and East Asian perceivers, researchers concluded that the sharpest differences in attributions for the cause of an individual's behavior lie in the weight accorded to contextual constraints and to pressures imposed by social groups (Choi, Nisbett & Norenzayan 1999). In a consumer context, Laufer (2002) suggests that based on these findings, consumers in individualistic societies may be more likely to attribute product failures to a company whereas consumers in collectivistic societies may be more likely to consider situational factors external to the company.

This paper reviews the literature in marketing, gerontology and psychology to examine whether another segmentation variable, age, impacts attributions of blame for product harm crises. In the paper we explore possible differences between older and younger consumers in the relation to antecedents of attributions, as well as to the attributional dimensions associated with consumer blame attributions. Based on our review of the literature, it appears that age is likely to impact the interpretation of product harm crises in a variety of ways. The net effect of these influences on blame attributions to companies is likely to depend on the circumstances surrounding the judgment context.

Despite widespread perceptions regarding the vulnerability of elderly consumers to harm, no evidence was found in the literature to support this. In fact, studies of psychological responses to fear-based appeals show no differences based on age (Benet, Pitts and LaTour 1993). Therefore, we cannot assume that older consumers will generally be more likely to make defensive attributions and blame a company for a product harm crisis as Laufer & Gillespie (2004) found for women. However, it is possible that elderly consumers will make defensive attributions for product harm crises involving products that focus on the elderly market due to increased similarity between them and the victims of the crisis.

The role of limitations in the cognitive ability of the elderly in assessing blame for product harm crises is also likely to be context dependent. The finding that 80% of older consumers read the newspaper in the morning (Yoon 1997) suggests that when older consumers are exposed to information about a product harm crisis, they will often have the opportunity and cognitive resources to perform detailed processing of information that does not differ from younger consumers. However, when they are exposed to a product harm crisis through other media, or perhaps when they are personally affected by the crisis, older consumers are more likely to rely on prior schemas (rather than information specific to the current crisis) when making blame attributions.

Prior beliefs might play a role in differences between older and younger groups in the assessment of blame in a product harm crisis, however in the direction of reduced blame to the company. Hart, Evans, Wissler, Feehan and Saks (1997) found for example that

older consumers have better developed schemas for injury-causing situations due to their greater life experience. It is possible that this results in an accumulated understanding of the power of situational forces, and thus a tendency for older consumers to place less blame on companies than younger consumers. However, this reliance on prior knowledge also implies a lack of attention to the specifics of the immediate situation. As such, older consumers might be less responsive in unambiguous product harm crises where the evidence clearly suggests that one of the parties is to blame. Thus, when available evidence points toward company blame, older consumers might be less likely to blame the company than younger consumers, and vice versa when evidence points toward consumer or situational blame.

Finally, findings from studies examining differences between younger and older consumers in their perceptions of Weiner's attributional dimensions may suggest less blame to the company in product harm crises in certain situations. Evidence suggests that older consumers are less impacted by the fundamental attribution error in certain situations and are also less likely to infer controllability. Since the dimensions of locus and controllability impact overall assessments of blame (Weiner, 1980; Klein & Dawar, 2004), elderly consumers might be less likely to exhibit negative consequences associated with blaming the company, such as reduced purchase intentions and negative word of mouth.

Collectively, existing research comparing attributions and cognitive abilities between the elderly and younger adults suggests that studying age differences in blame attributions for product harm crises is a potentially fruitful domain for future research. Examining how the net effect of these influences impact differences between older and younger consumer segments in judgments of culpability for product harm crises could potentially enrich our understanding of the impact of aging on attributions and its implications in the domain of consumer behavior.

Fairness in Relational Marketing Exchange

Dixon Ho, University of Arizona

EXTENDED ABSTRACT

The relationship marketing literature shows that marketing exchange is socially embedded in various exchange contexts (Price and Arnould 1999). Most research in this domain has focused on the beneficial consequences of building and maintaining long-term customer relationships for both firms and customers. Much less research has examined the roles and functions of pre-existing (i.e., prior to the occurrence of a transaction) social relations in marketing exchange. The purpose of this research, therefore, is to examine the implications of pre-existing social ties for consumers' outcome evaluations in a unique form of relational exchange—network marketing. In particular, this research investigates how interpersonal trust, social obligations, and relational norms affect consumers' post-purchase fairness perceptions when buying goods from friends.

Drawing on literature on social embeddedness (Frenzen and Davis 1990; Granovetter 1985; Halpern 1997), social justice (Lind and Tyler 1988), interpersonal trust (Geyskens, Steenkamp, and Kumar 1998; Robinson 1996), and relational contracting (Kaufmann and Stern 1988; Macneil 1980), this research hypothesizes that customers' sense of social indebtedness and trust in the seller mitigates the negative effect of an unfavorable transaction outcome on their perceived fairness. In addition, it is hypothesized that when customers firmly believe that their friends should uphold the implicit relational norms in the transaction, the negative effect of an unfavorable transaction outcome on perceived fairness is attenuated. However, when the transaction outcome is favorable, all the relational variables would have no effect on customers' perceived fairness.

To test these hypotheses, a scenario experiment was conducted in a laboratory setting. One hundred ninety-five MBA students participated in the experiment. Subjects were randomly assigned to one of the eight conditions in a 2 (transaction outcome: favorable and unfavorable) \times 2 (interpersonal trust: low and high) \times 2 (social obligations: low and high) between-subjects factorial design. Beliefs of relational norms were measured as an individual characteristic. In the experiment, subjects read a scenario about a purchase they had just made from a friend, who was a sales agent of a direct selling firm. The scenario described a situation in which the subject bought a water filter from his or her friend without knowing the exact quality of the product. However, subsequent to the purchase, the subject had a chance to read a water filter rating in *Consumer Report*. The product rating indicated the value of the brand the subject bought relative to other reference brands. In the favorable (unfavorable) outcome condition, the focal brand had a higher (lower) value than the reference brands. In the high (low) trust condition, the sales agent was described as a more (less) trustworthy person. In the high (low) social obligations condition, the subject owed a big (small) favor from the sales agent in previous social interactions. After reading the scenario, the subjects completed a questionnaire that included the dependent measures and manipulation checks.

The empirical findings show that customers' fairness perceptions in a relational exchange are determined not only by the favorability of the transaction outcome but also by their unfulfilled social obligations and trust in the seller. The ANOVA result indicates that social obligations and interpersonal trust mitigates the negative effect of an unfavorable transaction outcome on customers' perceived fairness. When the transaction outcome is favorable, the above relational factors have no effect on customers'

perceived fairness. This implies that social obligations and interpersonal trust act as buffers against the influences of negative outcomes on customers' evaluations. On the other hand, contradictory to our predictions, the ANOVA result shows that beliefs of relational norms boost customers' fairness perception when the transaction outcome is favorable. A plausible explanation is that when the outcome is favorable, customers confirm their normative expectations of benevolent acts on the part of the sales agent, which in turn increases their perceived fairness.

In this research, an explicit and unambiguous transaction outcome (i.e., a product rating in *Consumer Report*) was used as the manipulation. The empirical findings, however, provide convincing evidence that relational variables can alleviate the negative effect of unfavorable outcomes on customers' perceived fairness. In daily purchases, quality and value of some products (e.g., credence goods like dietary supplements) is more difficult to evaluate. In such cases, it is anticipated that customers would be more reluctant to blame the sales agent for any outcome that seems unfavorable. As a result, sales agents in relational exchange could act opportunistically and capitalize on customers' biased judgment for their own benefits.

In conclusion, this research provides insights into the adverse consequences of relational exchange for consumer welfare. Previous research in relationship marketing predominately addresses the positive effects of social embeddedness and considers social relations as the by-product of successful exchanges over time. On the contrary, this research conceives social relations as an exogenous variable and tests their effects on consumers' post-purchase perceptions. This research therefore reveals the potential dark side of relational exchange in consumer market.
