Endowment Effect as Inertia Equity in Brand Switching

Gewei Ye, Towson University
Curtis Haugtvedt, Ohio State University
W. Fred Van Raaij, Tilburg University

Abstract

Little research has investigated the behavioral aspect of brand inertia in brand switching based on behavioral decision theory. The present research employs endowment effect to conceptualize the inertia element of brand switching (e.g., from brand A to B). Past research normally separately assesses consumers' willingness to accept (WTA) to give up brand A and the willingness to pay (WTP) to acquire brand B. The effect postulates that the WTA is normally larger than the WTP. The present research proposes a joint assessment of the endowment effect in brand switching. It uses the price reduction (i.e., inertia equity) that just overcomes brand inertia to measure the difference between WTA and WTP. Empirical evidence demonstrates and strengthens the conceptualization of endowment effect as inertia equity in brand switching.

Relationship Proneness—The Concept, Its Dimensions and Indicators

Alberto Marcati, LUISS Guido Carli University, Italy
Claudio Barbaranelli, University of Rome La Sapienza, Italy
Michele Vecchione, University of Rome La Sapienza, Italy

Introduction

In the last decades, research has highlighted the existence of a wide spectrum of approaches to buyer-seller exchanges, ranging from transactional to relational (for instance, Dwyer, Schurr and Oh 1987). In search for explanations of such a wide spectrum, reference is sometimes made to the individual attributes of both buyers and sellers, pointing towards their inclinations to engage into or to shy away from relationships. As far as buyers are concerned, researchers have evoked the existence of "relational", "long-term oriented" or "transactional", "short-term oriented" customers (Garbarino and Johnson 1999)—meaning that some of the customers are eager to engage in stable relationships and interactions with their suppliers, while others are more prone to establish arm's length transactions.

Nevertheless, very little research has been devoted to the analysis of this orientation, and of its antecedents and consequences, if it isn't for some pioneering efforts and a few noteworthy exceptions (De Wulf, Odekerken-Schroeder and Iacobucci 2001; Odekerken-Schroeder, De Wulf and Schumacher 2003).

Such an orientation is meant to be a stable trait of individuals and has been termed "relationship proneness", defined as a conscious tendency to engage in relationships.

"Relationship proneness" has been associated with an interest for stable exchanges, and has been measured in terms of willingness "to be a regular customer" and "a steady customer", and for "going the extra mile" to buy at the same shop (De Wulf et al., 2001). But, occasionally, a different approach has crept into and different items have been used, without much discussion, related to the existence of personal contact and special treatment ("looking for personal contact with the personnel" and "making efforts in order to be treated in a special way") (as in De Wulf and Odekerken-Schroeder 2000). This is an important undertaking, since relations are multidimensional, and it is therefore very important to work out their different facets and to better understand how those facets relate to each other.

Researchers have also dealt with a whole host of constructs related to the antecedents and consequences of relationships. On the one hand, in keeping with evidence from social psychology, showing that relationships are influenced by stable traits of personality of the partners involved (Robins, Caspi and Moffitt 2000), they are suggesting that also buyers-sellers relationships are influenced by those traits (Aaker, Fournier and Brasel 2004). On the other hand, they have addressed the complex web of links between the propensity to engage in relations (relationship proneness) and behavioral intentions or relationship outcomes (De Wulf and Odekerken-Schroeder 2000; De Wulf, Odekerken-Schroeder and Iacobucci 2001; Odekerken-Schroeder, De Wulf and Schumacher 2003).

Research objectives

Our research objectives are threefold.

First of all, we want to analyze the 3+2 items that have been associated originally to relationship proneness (De Wulf et al., 2000; 2001), and that have been referred to above, to uncover their links.

Secondly, we want to explore the many aspects of relations, that add to the ones which have already been focused upon and that have been associated to interpersonal relations in the literature in socio-psychology (Fiske, 2000). Finally, we relate relationship proneness to personality traits, and in particular to basic traits (Big Five) and narrower dimensions (sociability and approval motivation).

Methodology

We develop a scale of relationship proneness, trying to capture the many-sided facets of relations; we end up with a compact and parsimonious 14-items scale, referring to the relationship to hairdressers. We measured the Big Five with a short version of the Big Five Questionnaire (Caprara, Barbaranelli, Borgogni & Perugini, 1993). Sociability is measured as in Cheek and Buss (1981); approval motivation as in Martin (1984). We run the traditional correlation and factor analysis. The sample is a convenience sample of 220 subjects, with diverse socio-demographic characteristics.

Results

When the 3+2 original items are pooled together and factor analyzed, 2 factors emerge, accounting for 68% of variance, with the 3 initial items loading on the first factor and the other 2 on the second.

When factor analyzing our 14-items scale, 3 factors emerge—social/interpersonal dimension, preferential treatment and reassurance, explaining 51% of variance. Correlations among factors ranged from .26 (social/interpersonal and preferential treatment) to .46 (social/interpersonal and reassurance).

When the 3+2 original items are pooled together with our 14 items, 4 different factors emerge, with the 3 items loading on a factor by themselves, and the other 2 splitting on 2 different factors (social/interpersonal and preferential treatment).

The social/interpersonal dimension was significantly correlated with traits of extraversion ($r=.21$), friendliness ($r=.18$) and sociability ($r=.30$). Preferential treatment and reassurance were respectively correlated with extraversion ($r=.20$) and approval motivation ($r=.34$). Relationship proneness and social/interpersonal dimension were significantly correlated ($r=.30$). These two dimensions showed the only relevant associations with satisfaction, respectively $r=.27$ for social/interpersonal and $r=.35$ for relationship proneness. An alpha level of .01 was used in all significance test.

Managerial implications:

We suggest that managers need to analyze the multi-dimensional nature of buyer-supplier relationships and to identify their different facets, and the relations among them.

We have established clearly that the orientation towards repeated and stable relationships is different, and can be treated differently, from the willingness to establish personalized relations; but also that they are related to a certain extent. This same orientation is not linked to the willingness to receive a special treatment and reassurance from one's own supplier.

We have also established that there is a significant relation between personality traits and orientation towards relations, implying that buyers will establish the same kind of relation across categories and across suppliers.

Limitations and extension for further research:

Although it has been widely used in research, we are aware that results may not be directly generalizable, because of the idiosyncratic nature of the service setting. Therefore a wider research approach is required, in order to feature in differences across categories (in the service sector and otherwise) and different approaches towards categories by consumers.

U.S. Consumer's Cultural Choices: The Interplay of Ethnocentrism and Global Openness

Dale Russell, INSEAD, France

Extended Abstract

This paper focuses on the factors affecting U.S. consumers' cultural choices, especially their consumption of domestic versus foreign movies. The U.S. movie market is the world's most profitable and has been dominated by domestic productions for nearly a century (Vogel 2004), with foreign movies rarely exhibited in American theaters and often only at smaller independent theaters (Kaufman 2006). Although this market situation is often explained by corporate or government tactics (Puttnam 1997), it may also be attributed to the American consumer, the focus of this inquiry.

The constructs of ethnocentrism and global-openness can be especially useful in explaining their behavior. The propensity of American consumers to primarily view domestic movies may reflect the citizenry's ethnocentric tendencies and lack of global-openness. Global-openness, also referred to as cultural-openness, reflects a willingness to interact with foreign people and cultures, including cultural products (Suh and Kwon 2002, Sharma, Shimp and Shin 1995). It connotes both cognition and emotion, whereby the human will is engaged in learning about global differences and similarities, and is characterized by three essential components: (a) a desire for cross-cultural understanding, (b) cultural self-awareness, and (c) the development of cross-cultural skills, such as languages (Wenger 1998). Ethnocentrism is a psychosocial construct depicting the proclivity for individuals to view their own group as superior and to reject people who are culturally dissimilar (LeVine and Campbell 1972). This concept was first adapted into consumer research by Shimp and Sharma (1987) who developed an instrument to capture consumer ethnocentrism. Research found it to be an important predictor of domestic versus foreign purchases, and more consistently of the former than of the latter (Balabanis and Diamantopoulos 2004). The extant research suggests that these constructs should apply to cultural choices, with ethnocentrism being positively related to consumption of domestic movies and global-openness positively related to consumption of and desire for watching foreign movies.

These propositions were tested with survey data collected from American moviegoers. Movie consumption was addressed by having respondents list the last five movies they had watched at a theater and at home in the past month. This actual consumption measure ensured the validity of the answers. All reported movies were subsequently coded by country-of-origin to compute ratios of U.S. and foreign movie consumption. Respondents were asked a series of questions regarding the factors contributing to their movie choices and preferences. They indicated their level of agreement with a series of statements, including measures of the two key constructs, on 5-point Likert scales. Control measures about movie consumption and preferences as well as demographic data were collected last.

The dataset included 405 complete responses from U.S. consumers (151 males; mean age 22.5). The age group represents an important segment for movie consumption. In 2003, consumers aged 12-24 comprised 39% of all U.S. moviegoers (USCB 2005; MPAA 2004). Respondents had watched an average of 10.15 movies in the past month. In general, ethnocentrism levels ($\alpha=.72$) were low, with a mean of 1.95 ($SD=.64$), echoing recent research reporting that America's Generation-Y expresses little ethnocentric tendencies (Werder and Roberts 2005). Global-openness ($\alpha=.74$) was skewed to the high end of the scale with a mean of 4.15 ($SD=.70$). The two constructs were negatively correlated ($r = -.41, p < .01$).

Consumption ratios were computed based on the reported movies watched at the theater. Movie consumption was strongly skewed toward U.S. films, with 95.86% being American movies. Global-openness and ethnocentrism scores were compared between those consumers had seen 100% American movies at the theater and those who had seen at least one foreign movie. As the literature suggested, consumers in the first group were more ethnocentric and less globally open than consumers in the second group (1.99 vs. 1.54 $t(292)=3.42, p < .01$ and 4.08 vs. 4.56 $t(292)=3.43, p < .01$ respectively); but regression analyses indicated that global openness (or lack thereof) was the only factor ultimately affecting movie consumption.

To provide additional insights, the ratings of movie decision factors were also compared. Interestingly, for foreign movie consumers, only the language of the movie was rated as a less important factor, suggesting that language may be a strong barrier to American movie consumers. A close investigation of the open-ended responses provides further insights into the resistance to foreign movie consumption amongst U.S. consumers. Respondents were asked if they preferred movies from any specific country, and why. Even though few respondents had reported seeing foreign movies, the majority of the comments (67%) reflected openness to them. 11.7% brought up, without being prompted, the lack of access or limited exposure they have to foreign movies. Few indicated they disliked foreign movies (2.9%); that they would never watch one (4.3%); or that foreign films are difficult to relate to (3.2%); still, 14.3% indicated that domestic movies were easier to relate to and understand.

A truer test of participants' openness to foreign films is their choice for the movie tickets offered as an incentive for participation. Chi-square analyses comparing choices between respondents who expressed global-openness and those who did not showed that, of the latter group, only 1.2% selected the foreign movie tickets whereas amongst the former, 13.8% did ($\chi^2(1)=19.2, p < .01$). Those selecting foreign movie tickets were more globally open (4.7 vs. 4.10; $t(398)=5.37, p < .01$) and less ethnocentric than those selecting domestic films (1.41 vs. 2.00; $t(398)=4.98, p < .01$). Logistic regression analyses on the choice variable further indicate that global openness is the only predictor of foreign movie choices, through a main effect and an interactive effect when ethnocentrism is low.

This research provides initial evidence of discriminant and predictive validity for the constructs of global-openness and ethnocentrism. U.S. consumers' cultural choices were mainly affected by their level of global-openness, both in terms of actual movie consumption and in a hypothetical choice situation giving consumers an unequivocal option to consume foreign films.

Self-Monitoring and Status Motivation: An Implicit Cognition Perspective

Sandor Czellar, HEC Paris, France

Extended Abstract

People differ in the way they regulate themselves in social situations (Snyder 1974). Some care little about the appropriateness of their behavior in the eyes of others. These are the *low self-monitors*, who project towards others a stable self in diverse settings of social interaction. *High self-monitors* exert more expressive control over their social behavior and tend to adapt their appearance and acts to specific people and situations.

In an extensive review, Gangestad and Snyder (2000) concluded that we know little about the motivational factors in self-monitoring. They called on researchers to study the possible role of status as a motivation associated with self-monitoring. They claim that high self-monitors wish to progress upward in social hierarchy by trying to win others' favor. Therefore, they adapt their behavior to the specificities of the context. Indeed, "high self-monitors may well attempt to cultivate public images that create appearances that connote social status and may strive to construct social worlds that function as effective instruments of status enhancement" (Gangestad and Snyder 2000, p. 547). Status motivation could therefore be the driving force behind the high self-monitor's social behavior, whereas low self-monitors should be motivated less by status. If self-monitoring indeed proves to be motivated by status seeking, this should explain why it is an important moderator of consumer behavior. In particular, why low self-monitors are more receptive than high self-monitors to functional quality cues; whereas high self-monitors are more receptive than low self-monitors to symbolic cues serving a social-adjustive function (DeBono 1987, 2000; DeBono and Harnish 1988; DeBono and Rubin 1995; Shavitt, Lowrey, and Han 1992; Snyder and DeBono 1985).

Our approach is based on advances in implicit cognition and builds heavily on Fazio and Olson (2003). Fazio et al. (1986) conceptualized attitudes as object-evaluation associations in memory. According to the MODE model of attitude-behavior processes, there are two ways in which attitudes may exert an influence on consumer behavior (Fazio and Towles-Schwen 1999). Depending on motivation and opportunity, attitudes play a role in behavior either through spontaneous processes or deliberative processes. In spontaneous processing, "attitudes may have an impact on eventual behavior, even without the individual's reflecting upon the attitudes" (Fazio and Towles-Schwen 1999, p. 98). That is, some attitudes can be activated spontaneously, on the mere presentation of the attitude object. In such cases, a behavior is acted upon on the basis of the automatic attitudes that become spontaneously accessible in memory (Fazio, Powell, and Williams 1989). Spontaneous processing contrasts with deliberative processing, whereby the consumer engages in extensive retrieval of any data available about the attitude object. In deliberative processing, automatic attitudes may also be activated; however, they will be used less to form explicit judgments and to choose a response vis-à-vis the attitude object.

The motivation component of the MODE model is our central interest. If the attitude object does not induce sufficient motivation, subsequent explicit judgment and behavior toward it will be guided by spontaneous processing, through automatically activated attitudes. In this case, we can expect a high correspondence between automatic attitudes about an object and explicit judgments about it (Fazio and Olson 2003). On the other hand, if motivation is high, the consumer engages in a processing of the attributes of the object, situational factors etc. In these circumstances, the consumer would rely less on automatic attitudes to form explicit judgments. Therefore, a weak match is expected between automatic attitudes about the object and explicit judgments about the same object (Fazio and Olson 2003).

We expect high self-monitors to be highly motivated by status. When probed explicitly about their attitude toward status with no time constraints, we expect elaborated answers from them in agreement with deliberative processing, leading to a low correspondence between automatic attitudes and explicit attitude measures about the concept of status. If motivation is low, as Gangestad and Snyder (2000) theorize it should be for low self-monitors, then the explicit evaluation of an attitude object should correspond to automatically activated attitudes (Fazio and Olson 2003; Karpinski and Hilton 2001), leading to a high correspondence between automatic attitudes and explicit attitude measures with respect to status. The following hypothesis is therefore to be tested:

For low self-monitors, there will be a high correspondence between automatic attitudes about status and explicit attitude measures about status; for high self-monitors, there will be a low correspondence between automatic attitudes about status and explicit attitude measures about status.

Eighty-one undergraduate students participated in the study in individual sessions. The traditional Implicit Association Test (IAT) was used to measure automatic attitudes about status (Greenwald, McGhee, and Schwartz 1998). Word stimuli to represent the attitude objects of interest (high status vs. low status) were selected on the basis of a pretest. For “high status”, *upper class*, *high status*, *high class*, *high society*, *noble*, and *royalty* were used. For “low status”, *lower class*, *employee*, *worker*, *low status*, *blue collar*, and *working class* were used. For the “pleasant” and “unpleasant” attributes, stimuli were randomly selected from Greenwald et al. (1998). Explicit attitude measures were elicited through six-item, seven-point semantic differentials: “unpleasant-pleasant”, “bad-good”, “dislike-like”, “ugly-beautiful”, “unfavorable-favorable” and “awful-nice” (Swanson, Rudman, and Greenwald 2001). The order of IAT and explicit attitude measures was counterbalanced. Finally, participants completed Snyder and Gangestad’s 18-item self-monitoring scale (Snyder and Gangestad 1986).

To calculate IAT effects, we used Greenwald, Nosek and Banaji’s (2003) scoring algorithm. For explicit attitude measures, difference scores (e.g. summed item score for “prestige brands” minus summed item score for “common brands”) were calculated. Groups of high- vs. low self-monitors were constituted using conventional median split.

Implicit attitude measures were positive for low and high self-monitors. Traditional IAT measures correspond to automatic association strength between status-related concepts and valence attributes. They may be interpreted as the sum of environmental stereotypes and personal experience with attitude objects in a specific cultural environment (Dasgupta and Greenwald 2001; Karpinski and Hilton 2001; Olson and Fazio 2004). The dominance of positive automatic associations suggests the presence of shared stereotypical associations about status.

Explicit attitude measures were also positive for low and high self-monitors. Following Aiken and West (1991), explicit attitude measure was regressed on IAT measure ($t=3.26, p<.01$), self-monitoring ($t=-.32, p<.01$) and the IAT X self-monitoring interaction ($t=-2.27, p<.05$). As expected, the correlation between IAT and explicit measures was significant for low self-monitors ($r=.45, p<.01$) but not for high self-monitors ($r=.01, ns$). These results suggest that consumers have positive automatic associations about status, but only low self-monitors seem to rely on those associations to form explicit status judgments, confirming our hypothesis. However, this preliminary result calls for more empirical evidence about the processes at play.

Replications with other consumer segments are warranted. Within the same cultural environment, people with different income levels may share the same stereotypes about status and status symbols. However, personal experience with status symbols could vary, with affluent people having easier access to these brands than people with lower incomes. The effects we observed could actually be stronger with high-income consumers, since they might have more and more diverse experience with status and status symbols than undergraduates. Relatedly, it would be interesting to introduce variation in the level of cultural capital (Holt 1998). We may expect consumers with a high cultural capital either to be less sensitive to stereotypes or to have different stereotypes than people with lower levels of cultural capital. Additionally, high self-monitors may reveal different types of status evaluations depending on situational cues. For example, if they are in a party with people who all look down on prestige brands, the high self-monitor may adapt to the circumstances and reveal a very negative evaluation of these brands, just to please others. Therefore, future research may benefit from the manipulation of situational cues, too.

A Construal Level Theory Approach to Understanding Self-Control Strategies

Kelly Haws, University of South Carolina

EXTENDED ABSTRACT

Failures to exercise self-control over one's behavior contribute to a variety of maladies that affect modern society. Virtually constant media attention, on such issues as increased health care problems due to obesity, rising bankruptcies caused by overextension of credit, lack of savings by Americans, and a variety of addictions to both legal and illegal substances, suggests a common link to under-regulated behavior. As such, understanding strategies that can be used to increase consumer self-control is crucial. Many strategies have been discussed in the marketing and psychology literature, but a thorough integration of the different strategies is lacking. In extant research, Hoch and Loewenstein (1991) distinguish between desire reducing and willpower enhancing strategies. Similarly, Dholakia et al. (2006) categorize self-control strategies either as "approaching the desire-resistance goal" or "avoiding the temptation".

The present research seeks to enlighten various strategies that consumers use to exercise control over their own behavior by organizing these strategies using construal level theory (CLT) principles of psychological distance (Trope and Liberman 2003). Recent research by Fujita et al. (2005) discussed the integration of CLT and self-control in order to better understand consumer decisions. The basic proposition is that consumers' high-level construals are more highly correlated with their actual values and attitudes than are their low-level construals.

Although the primary focus of their CLT research is temporal construal, Trope and Liberman (2003) suggest that the same principles apply to other dimensions involving psychological distance, and therefore propose level of construal as a basis for a unified theory. The specific construal level mechanisms are known as the four W's of CLT: 1) When (temporal distance), 2) Where (spatial distance), 3) Who (social distance), and 4) Whether (hypotheticality or probabilistic distance). Across the various construal level mechanisms, a concerted focus on higher-level construals enhances the likelihood that an individual will successfully exercise self-control. The present research uses the four construal level mechanisms to organize and understand specific a total of 30 distinct consumer self-control strategies.

Construal Level Self-Control Strategies

Many temporally-based self-control strategies are likely to be fairly common for consumers. Because two of the three primary components of self-control (i.e., both standards and the monitoring of progress) (Baumeister 2002) are represented in the temporal distance category, this set of strategies is foundational to overcoming potential consumer self-control failures. Spatial strategies primarily involve contextual changes to one's environment, such as avoidance or removal. Social distancing strategies use distance between oneself and others, as well as one's actual and ideal selves. Probabilistic strategies cover a broad spectrum of approaches to regulating self-control through careful assessment of one's potential actions and the impact of these actions on the likelihood of accomplishing higher-level goals.

The present research specifies strategies as representing one or more CLT mechanism. Many interesting issues arise from this organization of self-control strategies. It is simply not possible for all of the various strategies to be equally effective or for the same strategies to be equally effective for all individuals. Identifying the circumstances and individual difference variables that most impact self-control represents an important next step in understanding the effective use of self-control strategies.

Factors Affecting Self-Control Strategy Use

The first individual difference factor for examining the differential effectiveness of self-control strategies is one's inherent level of self-control. Generally, consumers with high levels of trait self-control will be more likely to successfully use self-control strategies than those with low levels of self-control. Identifying which strategies or category of strategies work most effectively for those with low levels of self-control would be an important contribution. Individuals with low self-control are likely to try fewer strategies in their efforts to self-regulate. Self-efficacy suggests that past failures in exercising self-control will be taken into account in dealing with current temptations (Bandura 1977). Similarly, those with high levels of self-control simply need fewer strategies to obtain the desired results because they are confident in the success of a few core strategies based on past experiences. However, consumers with moderate levels of self-control are more likely to draw from a larger assortment of strategies when attempting self-regulation because of the greater ambiguity associated with their own ability to exercise self-control.

Method. Two studies involving various individual difference measures and open-ended response data regarding use of self-control strategies were conducted to enlighten the use of such strategies by consumers. Study 1 used a student sample (n=80), while study 2 consisted of adult consumers (n=157). Select study 1 results are reported below. The data collected in the two studies provide a rich data source that can be analyzed in a variety of ways useful to understanding consumers' use of self-control strategies.

Results. A total of 238 self-control strategies (i.e., an average of 3.0 per participant) emerged from the open-ended responses obtained in study 1. Two coders independently coded responses into predetermined categories, based on extant literature and the CLT framework.

Temporal strategies were the most common (127), followed by probabilistic (85), spatial (21), and social/self (3). These results indicate that temporal and probabilistic strategies are the most commonly used strategies. Specifically, budgeting was by far the most common self-control strategy used by consumers.

The data collected in study 1 also allowed for a test regarding the number of self-control strategies used by individuals differing in their level of self-control. Responses to Tangney et al.'s (2004) 13-item self-control measure were averaged to form an index ($\alpha=0.83$). The sample was then split three ways to represent low, medium, and high self-control groups. A one-way ANOVA revealed the predicted curvilinear relationship among the three groups, with the greatest number of different strategies being used by those in the moderate self-control group ($M_{\text{LowSC}}=2.77$, $M_{\text{MediumSC}}=3.44$, $M_{\text{HighSC}}=2.69$, $F=2.82$, $p=.066$).

Summary

Although previous research has investigated the ability of various self-control theories to explain a variety of consumer behaviors, only limited research has focused on understanding the strategies used to combat self-control failure. The present CLT based approach for organizing and understanding self-control strategies serves to enlighten previous research on self-control and provides a foundation for future related work. Increasing understanding of how, when, and why particular self-control strategies are used provides an important avenue for enlightening the problems associated with self-control failure.

Collins's Interaction Ritual Theory: Using Interaction Rituals to Conceptualize How Objects Become Sacred Symbols

Kyle A. Huggins, University of Arkansas - Fayetteville, USA

Jeff B. Murray, University of Arkansas - Fayetteville, USA

Jeremy Kees, University of Arkansas - Fayetteville, USA

Elizabeth H. Creyer, University of Arkansas - Fayetteville, USA

Abstract

Numerous marketing articles have been published on special possessions emphasizing the roles that objects play in constructing identity or self. While these articles emphasize the importance of special possessions, there has been a dearth of theory and understanding as to how these objects are commissioned as "special" by the consumer. Currently unbeknownst to marketers, Collins's Interaction Ritual Theory provides a new conceptual tool by which marketers can investigate this consumer selection process. By examining consumer's interaction rituals, marketers can gain a better understanding of the process by which objects become sacred, that is to say how material objects become special possessions symbolically representing previous positive interactions.

Summary

It was not until the late 1970s that sociologists like Heise (1979), Hochschild (1979), Kemper (1978), and Shott (1979) undertook the systematic study of emotions. In retrospect, this late date is remarkable in spite of the fact that emotions permeate virtually every aspect of human experience. How could a majority of sociologists have turned a blind eye to emotions all this time? Not all of them did, but with relatively few exceptions, sociologists had studied just about every aspect of human behavior and somehow given comparatively little attention to the dynamics of emotion (Turner & Stets 2005). Historically, it seems that Western thought has juxtaposed emotion or affect and cognition. Cognition is often associated with rational thinking, such as information processing models. However, research on the neurology of emotions now demonstrates that this is simply incorrect. Data clearly indicate that when areas of the cerebral cortex, particularly the prefrontal lobe, are disconnected from subcortical emotion centers of the brain, individuals have difficulty making decisions of any kind and almost always make what appear to be irrational or at least suboptimal decisions (Damasio 1994, 2003). Thus, human rationality and, more generally, decision making are dependent on emotions, and without them, individuals cannot attach valences or utilities (Turner & Stets 2005).

Therefore, emotions make individual decisions, social structures, and systems of cultural symbols viable. Conversely, emotions are also what can drive people apart and push them to tear down social structures and challenge cultural traditions (i.e. Berlin wall). Thus, experience, behavior, interaction, and organization are connected to the mobilization and expression of emotions and greatly need to be

more understood at the individual level of consumption. Randall Collins (2004) argues that emotions are the common denominator of rationality because rationality depends on assessing the utility (or capacity to bestow positive affect) of alternative lines of conduct. Hence, in general, sociological theories of emotion assume that people pursue lines of conduct that bring about positive emotional outcomes and try at all costs to avoid experiences that lead to negative emotional consequences. Using this assumption of emotional behavior, it is the purpose of this paper to bring to light Collins's Interaction Ritual Theory and its possible impact on marketing literature in understanding how emotions transform symbols (objects) into sacred artifacts for groups and individuals.

Collins explains that the interaction ritual is an emotional transformer, turning some transient emotions (e.g. joy, happiness, fear) into other enduring emotions (privilege, power, status acceptance or rejection) as outcomes representing emotional energy that is carried across situations. Collins gives us a model by which this emotional transformation process occurs. For a ritualistic situation to produce emotional energy, there are some necessary ingredients required of the situation. First, there must be a co-presence of bodies or a group assembly (more than one). According to Collins, an interaction ritual cannot occur by one's self. Next, barriers to outsiders must be established. These can be physical barriers like house walls or a group of girls standing in a tight circle, or these barriers can be psychological. Either way, a person commonly knows whether they are on the inside or outside of the interaction circle. Thirdly, there must be mutual focus of attention by all persons in the ritual. People focus their attention upon a common object or activity, and by communicating this focus to each other become mutually aware of each other's focus of attention. Finally, there must be shared common mood or emotional experience among the individuals. Ingredients three and four become a feedback loop that intensifies through rhythmic entrainment, meaning that as the persons become more tightly focused on their common activity, more aware of what each other is doing and feeling, and more aware of each other's awareness, they experience their shared emotion more intensely, as it comes to dominate their awareness.

This feedback intensification then produces collective effervescence, or what Durkheim called collective consciousness, which is the collective situation engrossment or participation in the moment that results in shared common excitement. This process then produces very specific ritualistic outcomes that become important only to the group who experienced the collective effervescence. The first outcome is group solidarity or group identity, which is a feeling of membership to each person. Secondly, each member receives emotional energy, or a feeling of confidence, elation, strength, enthusiasm, and initiative in taking action, which is able to be transferred beyond just this interaction ritual. Thirdly, emblems or other representations (object, visual icons, words, gestures even) become sacred symbols of social relationship. These artifacts are representative of the group interaction and only the interaction. These objects are not sacred to those who did not experience the interaction ritual, but only to the participants. And finally, the group develops standards of morality or the sense of rightness in adhering to group norms, especially concerning the sacred symbols. Participants respect these symbols and will even defend them against group transgressors or outsider's violations of the symbols. Therefore, it is clear to see how Collins's IR Theory describes the process by which symbols or objects become sacred to a group or individual, and how these objects become symbolic representations of positive emotional rituals.

Within a marketing context, numerous articles have been published on special possessions and the roles that these objects play in constructing identity or a sense of self (Csikszentmihalyi & Rochberg-Halton 1981; Belk 1988; Curasi, Price, & Arnould 2004; Ahuvia 2004). While these articles emphasize the importance of special possessions, there has been a dearth of theory and understanding as to how these objects are commissioned as "special" by the consumer. Currently unbeknownst to marketers, Collins's Interaction Ritual Theory provides a new innovative conceptual tool by which marketers can investigate this arena of the consumer selection process. By examining consumer's interaction rituals, marketers will be able to gain a better understanding of the process by which objects become sacred, that is to say how material objects become special possessions symbolically representing previous positive interactions.

Increasing Persuasion, Reducing Resistance: Maximizing the Efficacy of Persuasive Appeals for Esthetic Product Consumption

Elyria Kemp, University of Arkansas, USA
Elizabeth H. Creyer, University of Arkansas, USA

EXTENDED ABSTRACT

Consumers are inundated with messages via print, television, Websites and interpersonal conversations—all with the purpose of inducing a certain behavior or eliciting attitude change. The choice decision process has increased in complexity as consumers are presented with more and more options in today's marketplace. In some cases, the consumer may have difficulty in arriving at a decision.

Knowles and Linn (2004) propose that there are two different ways to persuade people to accept alternatives. Using Dollard and Miller's (1959; Miller 1944, 1959) approach-avoidance conflict model as a conceptual framework, Knowles and Linn (2004) introduce two different strategies for promoting movement toward a goal: Alpha and Omega strategies. Alpha strategies activate the approach forces, thereby increasing motivation to move toward the goal. Alpha strategies have a long tradition in the marketing literature. Offerings are made more attractive by adding incentives, creating more convincing reasons, and finding more credible sources (Knowles and Linn 2004).

Conversely, Omega strategies promote change by minimizing the avoidance forces, reducing the motivation or resistance to move away from the goal. Omega strategies have appeared less frequently in the influence literature. Examples of Omega strategies, as codified by Knowles and Linn (2004), include sidestepping resistance, addressing resistance directly, addressing resistance indirectly, distracting resistance, disrupting resistance, consuming resistance and using resistance to promote change.

The purpose of this study is to examine the effectiveness of using both Alpha and Omega persuasive message appeals in a consumption domain where consumers express or exhibit some resistance—attending the symphony orchestra.

Attendance at Symphony Orchestras

The symphony orchestra, one of the oldest artistic institutions in America, is facing declining audiences (Wang 2003). Nationwide, the average age of consumers who attend orchestra performances is 57; sadly, audiences of many local and regional orchestras are dying off (NEA 2002; Winzenreid 2004; Page 2005). Critics admonish that as the segment that appreciates this art form dwindles, the local orchestra may cease to be a beacon of civic pride. (Brooke 2005).

Symphony orchestras face a challenge in finding convincing ways to communicate to younger consumers the affordability and enjoyment of attending the symphony. In order to ensure survival, marketing managers should look to develop innovative marketing practices to attract new and younger audiences. Subsequently, this involves tailoring elements of the marketing mix to meet the needs of younger audiences. One way marketing managers can go about targeting younger audiences is by developing marketing communications with the goal of reaching this segment. In addition to emphasizing the benefits of attending a symphony orchestra performance, the resistance that younger consumers might have to such an experience should be addressed.

Two studies in this paper assess the efficacy of various persuasive appeals directed toward younger adults in encouraging them to attend the symphony orchestra. In Study 1, Alpha and Omega influence strategies as well as self and other-referencing techniques were examined for their efficacy in engendering favorable attitudes and strong behavioral intentions towards attending the symphony orchestra. The moderating role of affect intensity (Larsen 1984) was also examined to ascertain whether individuals that have more favorable attitudes toward attending a symphony orchestra performance possess this trait in greater magnitudes.

Study 2 complemented Study 1 by further examining the effectiveness of Alpha and Omega influence strategies, but in the context of temporal framing. Additionally, ego-control (Block 1980, 2002), or the inhibition/expression of impulse, was examined for moderating effects on temporal frame.

Study 1

Study 1 was a between-subjects experiment that included manipulations of advertisements using both Alpha and Omega influence strategies as well as self-and other-referencing. The experiment was a 3 (Alpha/Alpha-Add Incentive/Omega- Acknowledge-Validate Resistance) x 2 (Self/Other Referencing) x (High/Low Affect Intensity) between subjects design. A total of 119 students from a southern university participated in the study.

The Alpha condition was a "traditional" advertisement that made the symphony orchestra experience appear "enjoyable, exciting and dramatic;" the benefits of attending the symphony orchestra were emphasized. The Alpha-Add incentive condition included the same enticing appeal but also offered a free T-shirt with each ticket purchase. The Omega-Acknowledgement/Validation condition confronted resistance by acknowledging that one "might think that the symphony is dull and boring". All three conditions referenced the self by use of first person (i.e., "you want to be sure to experience this enjoyable evening") or referencing others, by use of third person (i.e., "everyone should be sure to be a part of this enjoyable evening"). All ads indicated that student tickets were available.

In study 1, it was found that individuals that possessed greater magnitudes of the emotional component of affect intensity expressed more favorable attitudes ($M=4.48$ and $M=4.01$, $p<.05$) and behavioral intentions ($M= 3.96$ and $M=3.52$, $p.05$) toward attending the symphony orchestra. Additionally, in the Alpha: Add Incentive and Omega: Acknowledge/Validate conditions, individuals that exhibited high levels of affect intensity expressed stronger intentions toward attending the symphony orchestra than those in the traditional Alpha condition. Furthermore, self-referencing played an important role in increasing the persuasive impact of the advertising appeals, particularly for those that exhibited high levels of the intensity component of affect intensity.

Study 2

A total of 110 students from a southern university participated in Study 2. The experiment was a 2 (Alpha-Discount/Omega-Guarantee) x 2 (Proximal/Distal Temporal Frame) x 2 (High/Low Ego-control) between subjects design.

The Alpha-Discount condition consisted of an advertisement that again presented the symphony experience as “enjoyable, exciting and dramatic” but also offered a second subscription to the symphony for half-price with the purchase of one subscription at full price. The Omega-Guarantee condition promised a money-back guarantee if the performance was not enjoyed. Both conditions were framed in a proximal (in the present) and distal (several months from the present) temporal frame. Ego-control (Block 1980, 2002) was a measured variable.

Results from Study 2 indicated that the Omega-Guarantee condition elicited stronger behavioral intentions than the Alpha-Discount condition ($M=3.53$ and $M=3.07$, $p<.05$). There was no significant moderating effect between temporal frame (proximal/distal) and ego control; however, those individuals that exhibited higher levels of ego-control expressed more favorable attitudes towards attending the symphony orchestra than those low in ego-control ($M=4.27$ and $M=3.75$, $p<.01$).

These findings could have implications for marketing managers at symphony orchestras as well as those responsible for developing marketing communications for products that are emotionally provocative, hedonic and experiential in nature. Specifically, targeting consumers that exhibit higher levels of affect intensity might be prudent. These high affect intensity individuals might include more socially active consumers that belong to various clubs and organizations, as well as enjoy activities that are emotionally stimulating. In developing marketing communications targeted at these consumers, employing self-referencing techniques might be an effective strategy for increasing the persuasive impact of the message.

Also, either providing incentives for attendance or addressing some form of resistance that these individuals might have could yield better results than just emphasizing the features and benefits of a product or experience.

Are Good Intentions Enough? Encouraging Regular Savings Through Implementation Intentions

Căzilia Loibl, The Ohio State University, USA
Robert Scharff, The Ohio State University, USA

Introduction and Hypotheses

This study concerns the implications of Gollwitzer’s (1993) concept of implementation intentions. Intention, attitude, subjective norm, perceived behavioral control and past behavior from for Ajzen’s (1985) Theory of Planned Behavior were used to measure the motivation of participants’ of an “America Saves” campaign to save regularly prior to an intervention in which participants made implementation intentions concerning when, how, how much, and from what source of income they will deposit money into their savings accounts in the next month. The study suggests the following testable hypotheses:

Participants who form implementation intentions concerning when, how, how much, and from what source of income they will deposit money into their America Saves account will be more likely to deposit money into their America Saves account than participants who do not form such intentions.

Participants who form implementation intentions will save in a manner consistent with their intentions.

Procedures

We are collecting data of three points in time: one baseline and two follow-up surveys. For the present paper, we present the results of the first two data collections. The third data collection is currently ongoing. One hundred and fifty-six participants completed the questionnaire at Time 1, $N=68$ completed the questionnaire at Time 2. The data collections for Time 2 and Time 3 are not yet completed but will be available for the conference presentation.

Measures

The standard “Theory of Planned Behavior” measures followed closely the description in Ajzen (2002). The implementation intention intervention was designed following the procedure described by Gollwitzer (1993) and Orbell, Hodgkins, and Sheeran (1997). Participants in the treatment group were asked to make implementation intentions specifying first, when they would deposit into their savings accounts in the next month, second, the dollar amount they would deposit, third, how they would deposit the amount, and fourth, from what income source the deposited amount would come from.

Results

Sixty-nine per cent of this sample were women ($N=47$) and 31 per cent were men ($N=21$). Participants’ mean age was 40.06 years ($SD=12.66$), most were white (66%), had a college degree (66.2%), were married (42.6%), employed full time (80.9%). The mean family size was 2.71 people ($SD=1.39$), the mean household income was \$42,000 ($SD=\$2,760$). The primary savings goals are saving for emergencies (30.3%) and for retirement (15.2%). The 47 responses are divided into 57.4 per cent treatment group ($N=39$) and 42.6 per cent control group responses ($N=29$).

All scale reliabilities were satisfactory, ranging from .689 (Past behavior) to .937 (Intention).

A MANOVA showed no significant differences between the two groups on preintervention measures of intention, attitude, subjective norm, perceived behavioral control, or previous behavior, $F(5, 64)=0.562$, *ns*. These findings indicate that prior to the intervention, the two groups held similar beliefs concerning regular savings.

Univariate *F*-tests confirmed that there were no differences between the groups on preintervention measures of intention, attitude, subjective norm, perceived behavioral control, or past behavior. Similarly, there were no significant differences in age, family size, household income, employment status, education (*t*-test not significant) between the groups and there were equivalent proportions of men

and women, races, marital status in the control and treatment group. We also inspected the correlations between past behavior and intention for the two groups. Past behavior is significantly associated with intentions for both the treatment group ($r=.578$, $p=.000$) and the control group ($r=.766$, $p=.000$).

In sum, both groups had positive intentions, attitudes, subjective norms, and perceived behavioral control. Behavioral intentions were strong in both conditions, with mean scores greater than 14 on a 3 to 21 scale. We can conclude that both groups base their intentions to save regularly upon their previous savings behavior and that both groups are motivated to save regularly.

Overall, the effect of the implementation intervention is not yet obvious from the data currently available. At the 1-month follow-up, 83 per cent of the respondents reported that they had deposited money into their savings account compared to 86 per cent of the control group (Chi-square=27.499, ns.). Thus, our first hypothesis cannot be supported. The effect of implementation intention manipulation may emerge on the second follow-up only as described in Sheeran and Orbell (1999).

At follow-up, participants were also asked to report when, how, and from what source they have deposited money into their savings accounts, and these responses were compared with their implementation intentions. At both time-points, most participants intended to and actually deposited on payday (baseline: 74.4%, follow-up: 71.4%) or on a specific day during the month (baseline: 23.1%, follow-up: 21.4%). At follow-up, all respondents in the treatment group reported to take the savings from their paycheck (100%), compared to 92.3 per cent in the implementation intentions. The responses differed for the mode of deposit. While about half of the respondents (54.1%) intended to use direct deposit, only 14.8 per cent did so, responding to an increase in payroll deduction, electronically/internet deposit, and mailing. About one-third of the respondents intended and actually deposited the funds in person (baseline: 29.7%, follow-up: 29.6%).

In conclusion, the ongoing data collection will provide further evidence of the usefulness of implementation intentions to increase the likelihood of action among people motivated to save.

Consumers' Appreciation of Product Personalization

Ruth Mugge, Delft University of Technology, the Netherlands

Jan P. L. Schoormans, Delft University of Technology, the Netherlands

Addie de Lange, Delft University of Technology, the Netherlands

Extended Abstract

Due to consumers' individual preferences, many consumers are unfulfilled with standard goods (Piller and Müller 2004). A promising strategy for companies is to offer consumers the opportunity to personalize their products (Franke and Piller 2003). Based on the definition of Blom (2000), product personalization is defined as a process that defines or changes the appearance or functionality of a product to increase its personal relevance to an individual. By implementing product personalization, consumers are offered a certain degree of design authority (Fox 2001). An example of product personalization is mass customization. Mass customization allows consumers to create a personalized product by choosing different options (e.g., colors) from lists that are predefined by the manufacturer. For example, Nike enables consumers to design their own personalized shoes (<http://nikeid.nike.com>). This study investigates consumers' attitude to and purchase intention for personalized products. Specifically, we focus on personalizing a product's appearance.

Consumers may want to personalize a product's appearance in such a way that the product becomes expressive of their identity (Blom and Monk 2003; Mugge, Schifferstein, and Schoormans 2004). If consumers are only offered a relatively low degree of design authority, the options to create a product that fits one's unique identity are limited, resulting in a suboptimal solution. In contrast, personalizing a product with unlimited options enables consumers to create a product with a supreme fit to their identity. It is likely that consumers have a more positive attitude and a higher purchase intention for personalized products if they are offered a higher degree of design authority.

Offering consumers a higher degree of design authority in product personalization also has a downside: Personalizing a product requires consumers' time and effort. Therefore, the outcome of the personalization process has to provide enough additional value for the owner. Otherwise, the required time and effort will negatively affect consumers' attitude to and purchase intention for the product. Expressing one's identity may have both a personal and a social goal. People have a need to define their identity to themselves (personal goal), but also to others (social goal). The social goal of self-expression is reduced if the personalization is only visible to the owner. Therefore, we hypothesize that the visibility of the personalization moderates the effect of design authority on attitude and purchase intention.

Our study had a 2 (design authority: low vs. high) x 2 (visibility: low vs. high) between-subjects full factorial design. In each condition, subjects read about a company that sells wireless home phones with an opportunity to personalize the phone's appearance. The personalization process was illustrated by a written description and several color pictures of examples of personalized phones. To

operationalize design authority, the number of personalization options was varied. In the low design authority condition, subjects were presented with 4 color options. In the high design authority condition, subjects could personalize the home phone by choosing a color out of a palette of 99 options. In addition, they could select one of the 24 possible patterns, resulting in a total of 2376 personalization options for the high design authority condition. Visibility was operationalized by varying the component of the home phone that was personalized (display vs. cover). Subsequently, subjects filled out a questionnaire in which measures were obtained for attitude, purchase intention, design authority, and visibility of the personalization. All variables were measured using multiple items on seven-point Likert scales.

The questionnaire was sent to 100 members of a consumer household panel. Sixty-one subjects (51% males, $M_{\text{age}}=41$) returned the questionnaire, resulting in 14 to 17 subjects per condition. Both manipulations were satisfactory and no confounding effects were found. The results revealed a significant design authority \times visibility interaction effect for attitude ($F(1, 57)=4.52, p<.05$) and purchase intention ($F(1, 55)=4.32, p<.05$). If the personalization concerned a highly visible product component, subjects in the high design authority condition had a more positive attitude towards the product ($M_{\text{low DA}}=4.60$ vs. $M_{\text{high DA}}=5.56$) and a stronger purchase intention ($M_{\text{low DA}}=4.21$ vs. $M_{\text{high DA}}=5.11$) compared to the subjects in the low design authority condition. However, if the personalization concerned a hardly visible product component, the opposite pattern was found: Subjects in the high design authority condition had a more negative attitude towards the product ($M_{\text{low DA}}=4.78$ vs. $M_{\text{high DA}}=4.24$) and a weaker purchase intention ($M_{\text{low DA}}=4.23$ vs. $M_{\text{high DA}}=3.43$) compared to the subjects in the low design authority condition.

Our findings suggest that although offering consumers a higher degree of design authority in product personalization enables them to create products that better fit their identity, consumers may in some cases actually prefer to have less freedom. Personalizing products only provides value for consumers if the personalization concerns a highly visible product component. Personalizing a visible aspect enables them to create a more self-expressive product to define their identity to themselves and to others. If the personalization is only visible to the owner, the social goal of self-expression is reduced, and consumers refuse to invest their time and effort in the personalization process.

Consideration of Future Consequences as a Moderator of Temporal Framing and Regulatory Focus in a Risk Domain

Jeremy Kees, Villanova University
 Scot Burton, University of Arkansas
 Elizabeth Creyer, University of Arkansas
 Eric Knowles, University of Arkansas
 Kyle Huggins, University of Arkansas

Introduction

In this working paper, we examine Consideration of Future Consequences (CFC; Strathman et al. 1994) as an important moderator of temporal frame and regulatory focus. CFC is an individual difference variable that captures the extent to which people consider distant versus immediate consequences of potential behaviors. Drawing from construal level theory (Liberman and Trope 2003), recent literature on temporal framing effects (Chandran and Menon 2004), and regulatory focus theory (Higgins 1997), we demonstrate how this time orientation variable can moderate framing effects observed in the literature.

Study 1

Study 1 examines the moderating effect of CFC on temporal frame. Hypotheses were tested using a 2 (temporal frame: proximal versus distal) X 2 (CFC: low versus high) between-subjects experiment.¹ During freshman orientation, 90 first-semester college freshmen were presented with a mock public service advertisement that discussed the risk for weight gain while in college. Temporal frame was manipulated by altering the time in which the typical college student experiences weight gain (i.e., one month versus 48 months). After stimulus ad exposure, participants responded to questions related to their perceived levels of risk for weight gain. The 12-item CFC scale was administered at the end of the questionnaire.

As predicted, the more proximal temporal framing of the risk message resulted in (marginally) higher probability estimates of gaining weight ($F=2.32, p<.10$) than the more distal temporal framing. However, this temporal framing main effect was qualified by an interaction effect between temporal frame and CFC. Pairwise contrasts show that the probability estimate for low-CFCs was much higher for the proximal temporal frame than for the distal frame ($t=1.70, p<.05$). However, high-CFC subjects reported similar probability estimates across temporal frame conditions ($t=0.64, p>.30$). Similar results were found for the risk likelihood variable.

Consistent with previous research (e.g., Chandran and Menon 2004), Study 1 findings suggest that framing the health risk in more proximal terms may be more effective than framing the risk in more distal terms. Study 1 also uncovered a moderating effect of CFC on temporal framing effects for consumer risk perceptions. For both the consumer's probability estimates and risk likelihood estimates, low-CFC individuals were more strongly affected by the more proximal framing of the health risk than were high-CFC individuals. As predicted, high-CFC individuals reported relatively high risk perceptions for gaining weight (a risk typically construed as long-term in nature) regardless of the temporal frame of the message. Low-CFCs reported low risk perceptions when the health risk was framed in distal (distant future) terms. However, when the health risk was framed in more proximal (near future) terms, low-CFC's reported much higher risk perceptions consistent with, and even exceeding that of high-CFC's.

Study 2

The purpose of Study 2 was to replicate findings from Experiment 1 and examine an important third factor, regulatory focus. Although there has been some studies that have examined the relationship between regulatory focus and temporal distance (e.g., Pennington and

¹A median split was performed to represent low versus high CFC subjects. This procedure for segmenting subjects based on an individual difference factor is consistent with past research (e.g., Strathman et al. 1994; Joireman, Sprott, and Spangenberg forthcoming; Boninger, Gleicher, and Strathman 1994).

Roese 2003), no study to date has examined the moderating influence of individual differences in time orientation on regulatory focus. Hypotheses were tested using a 2 (regulatory focus: promotion versus prevention) x 2 (temporal frame: proximal versus distal) x 2 (CFC: low versus high) between-subjects experiment. Temporal frame was manipulated by altering the time period in which consumers of high-fat fast food meals may suffer adverse health effects as a result of consuming the food. Regulatory focus was manipulated through evoking a promotion or prevention focus through framing of the message.² After exposure to the mock public service ad, 119 participants responded to dependent measures and the CFC measure.

Findings show a significant univariate temporal framing effect on the probability estimate ($F=2.90, p<.05$). Consistent with Study 1 findings, the more proximal temporal framing of the risk message resulted in higher probability estimates than the distal temporal framing. Also consistent with Study 1, CFC was found to moderate the temporal framing effects. Contrasts indicate that low-CFC individuals reported somewhat higher probability estimates ($M=58.48$ versus $49.37; t=1.40, p<.10$) when the risk was framed in proximal rather than distal terms. High-CFC individuals reported similar probability estimates for the proximal and distal frame conditions ($p>.30$). As in Study 1, similar results were found for the risk likelihood variable.

A regulatory focus by CFC interaction was found for perceived effectiveness of the message and attitude toward the message ($F's=2.94$ and 11.07 respectively; $p's<.05$). Consistent with predictions, low-CFC individuals evaluated the promotion framed message more positively ($M's=5.26$ versus 4.71) and perceived it as more effective ($M's=4.87$ versus 4.35) than prevention-framed message. In contrast, high-CFCs evaluated the prevention framed message more favorably ($M's=5.54$ versus 4.75) and more effective ($M's=4.54$ versus 4.22) than promotion framed message.

Findings from Study 2 show consistent effects of temporal framing in this health-risk domain and demonstrate that CFC can moderate these effects for risk-related variables. Findings also show that CFC can moderate regulatory focus for attitude and perceived effectiveness variables. High-CFC individuals evaluated prevention-framed messages more positively and as more effective; low-CFCs evaluated promotion-framed messages more positively and as more effective.

Brief Discussion

Consideration of future consequences has not yet been directly studied in a marketing context, nor has the potential interaction of this variable with temporal framing on risk variables been addressed. Findings from our preliminary studies offer evidence that CFC may be an important moderator of both temporal frame and regulatory focus. While Chandran and Menon's (2004) ground-breaking work addresses important moderators of temporal framing, our results extend their findings by demonstrating another important variable (CFC) can moderate temporal framing effects. This research also contributes to the small amount of literature examining the relationship between time and regulatory focus. The findings also have potential practical implications the important areas of public policy and health marketing (Aaker and Lee 2006).

Managing Experiential Marketing: Insight from a Prototypical Experience

Elyria Kemp, University of Arkansas, USA

Jeff Murray, University of Arkansas, USA

Extended Abstract

One of the greatest assets that a company or individual can have is a strong brand identity. The leading brands of the world all enjoy one thing—a strong emotional connection with consumers. Recently, experiential marketing has gained momentum among marketers as a means of communicating a brand's personality and values (Live Brand Experience Association 2005). Conceptually, experiential marketing attempts to engage consumers in memorable ways by "staging experiences" around products and services, in hopes of invoking positive emotional energy around a brand.

²This manipulation is consistent with past studies that manipulate regulatory focus by framing outcome contingencies in terms of gains or losses (e.g., Higgins 2002; Lee and Aaker 2004, Pennington, Aaker, and Mogilner).

Experiential marketing can encompass everything from “live” product sampling to product demos. In 2004, companies spent 17.6 billion on in-store advertising and this number is expected to continue to rise (Nelson and Ellison 2005).

Limited research has explored and explained what actually occurs when experimental marketing is successful. The purpose of this paper is to provide theoretical explanation for the phenomena using Randall Collins’ Interaction Ritual Theory (1975, 1981, 1990, 2004). The paper will also present an ethnographic analysis of a prototypical interaction ritual—a live music performance. The specific purpose of this approach is to glean information from an ideal experiential context that can be applied to the management of experiential marketing phenomena.

Interaction Ritual Theory

An interaction ritual, according to Collins, is an emotional transformer, taking some emotions as ingredients, and turning them into other emotions as outcomes. There are four elements or ingredients that go into producing an Interaction Ritual: (1) co-presence of individuals (2) ecological barriers (3) common focus of attention (4) and common emotional mood among present individuals.

The outcomes of the Interaction Ritual are (1) symbols marking the social relationship, which can include objects, persons, gestures, words, and ideas (2) a sense of moral righteousness about symbols marking group membership (3) group solidarity (4) and enhanced emotional energy. Interaction Ritual Theory is a useful tool in explaining a live music performance since all the ingredients of an Interaction Ritual are present.

Enhancing the Experiential Marketing Experience

Ethnographic fieldwork was conducted in a local dueling piano bar, called Charley’s, in a medium-sized city in the southern part of the United States during the course of two months. Participatory observation and ethnographic interviews were conducted. Findings from field notes are discussed in terms of four major themes extrapolated from Collins’ Interaction Ritual Theory: (1) ecological barriers (2) emotional transformers (3) symbols and (4) emotional energy.

Ecological Barriers

According to Collins, a primary component of an Interaction Ritual is the creation of physical barriers to outsiders. The more effective boundaries are in separating people from external stimuli, the greater the likelihood that an emotionally rousing, successful interaction will occur. Charley’s was a quaint, charming venue. Every element of the club set its patrons up for an experience. Its décor, including the abstract paintings and the pencil sketching of musicians all helped to create and welcome an atmosphere for music and fun. Companies are aware that creating an environment that appeals to the senses is paramount in creating an experience for the consumer. Examples of retailers that successfully stimulate the senses by creating effective ecological barriers include Apple computers, Victoria Secrets Auntie Anne’s, and Bath and Body Works.

Transforming the Emotions: Focusing Attention and Creating Shared Mood

Interaction Rituals have the ability to transform negative emotions into positive emotions (Collins 2004). When individuals are gathered together and separated from the surrounding environment, a mutual focus of attention and common awareness can set the stage for a shared mood among the group. Moods are transitory and may ebb and flow, but creating shared mood can be facilitated by rhythmically synchronizing the group. The musicians at Charley’s were able to skillfully manage the emotions of the audience by allowing interaction among individuals at tables, but then periodically calling their attention back to the stage by getting the group to engage in an activity, whether it be clapping in unison or singing along.

Based on the values and interests of the target group for an experiential marketing endeavor, activities can be planned which stimulate interaction among consumers and get them to share in carrying out the same activities. This can include involving them in a recreational activity, enjoying a live music performance or eating and drinking.

Symbols

In Collins’ Interaction Ritual Theory, symbols become the focus of attention of emotionally entrained crowds. These symbols can be objects, ideas and theme, or people and are imbued with emotional overtones. Audience members at Charley’s engaged in a chant that had become the Charley’s rallying cry and theme. Even though there were expletives and offensive language in the chant, both men and women, young and old heartily participated in shouting out the chant at their top of their lungs along with the musicians on stage.

Collins’ symbols are not unlike brands. The most popular brands of the world have a strong emotional connection with consumers. Experiential marketing endeavors should be designed in such a way that the brand’s image (ie. logo) is always visible or present. At Charley’s an important artifact that became a symbol were the red mugs that patrons brought to the club on Thursday nights. Although very utilitarian, these mugs were imbued with meaning.

Placing the brand on other objects (in the form of promotional giveaways) that may be of both utilitarian and hedonic benefit for the consumer might help to create additional symbolic representations of the brand. Having the brand on these objects (although not necessary the actually product itself) can help to keep the brand at the “top of the mind” of consumers.

Emotional Energy: Becoming a Link in the Consumption Chain

Transient emotions such as joy help to fuel Interaction Rituals. In interaction Ritual Theory, these emotions intensify into shared excitement and culminate into a collective effervescence. The high, positive emotional energy generated from each encounter at Charley’s helped to facilitate and fuel subsequent visits. Patrons became “regulars” and Charley’s became part of their consumption chain.

Applying Collins’ theory in an experiential marketing context, if a marketing event is successful, the identity of the brand has been enhanced in the minds of consumers. This positive affect toward the brand, product, or even company should help to spawn future consumption of the brand or product.

As future consumption begins to take place and consumers develop strong emotional ties to a brand or product, they may start to feel a sense of belonging to the community of consumers that also share strong loyalty for the product. Consumers may become so enamored with the product that they are encouraged to participate in brand communities. Subsequently, by focusing on the ingredients that go into an interaction ritual, marketers can create successful experiential marketing experiences.

Immediacy Bias in Consumer Attitudes and Choices over Time

Katherine White, University of Calgary, Canada
Leaf Van Boven, University of Colorado at Boulder, USA

Extended Abstract

Many consumer decisions involve comparing the emotional intensity of alternatives that occur at different points in time. Is a currently sampled movie preview more or less enjoyable than the last movie previewed? Is the present culinary sample more or less delicious than the last sample? Is the song just sampled in iTunes more or less enjoyable than the last song sampled? Such judgments of emotions over time have the potential to influence consumer attitudes, involvement, and choices.

Our past research finds that people tend to exhibit an “immediacy bias,” judging immediate emotions as more intense, all else equal, than temporally or socially distant emotions (Van Boven, White, and Huber 2006; Van Boven, White, Johnson-Graham, and Kruger 2006). For example, people perceive a recently viewed (i.e., more immediate) movie clip as creating more intense emotions than a movie clip that was viewed in the past (regardless of the order in which the two clips are shown). This immediacy bias appears to be quite robust and can emerge across various emotions such as fear, amusement, and sadness. In the current research, we suggest that the immediacy bias should have important implications for consumer attitudes, involvement, and choices when consumers sequentially sample different alternatives. In particular, we propose that a positive consumption experience that is immediately experienced is more likely to lead to positive attitudes, greater consumer involvement, and product choice than a consumption experience that is not immediately experienced.

In study 1 we provide a preliminary test of the predictions that consumers will experience more positive emotions, have more positive attitudes, and report greater involvement towards an immediately experienced alternative rather than an alternative that was experienced in the past. Fifty-nine participants were asked to watch and evaluate a short film by BMW (Ticker, 2002). One half of participants evaluated the film immediately after viewing it (immediate condition) and one half of participants evaluated the movie after a half hour delay (past condition). Participants were asked to report the intensity of their emotions, their attitudes towards the film, their involvement with the film, and whether they would be inclined to repeat the consumption experience. As predicted, participants rated their feelings while watching the film as more intense ($t(56)=2.05, p<.05$), indicated their attitudes were more positive ($t(56)=2.10, p<.05$), and reported a greater degree of involvement ($t(56)=3.48, p<.01$) when the consumption experience was immediate rather than in the past. Finally, those in the immediate condition reported being somewhat more interested in repeating the consumption experience again than did those in the past condition ($t(56)=1.93, p<.06$).

In study 2 we tested the same predictions as in study 1, but also wanted more explicitly to test our prediction regarding consumer choice—that consumers would be more likely to choose an immediate option as opposed to a past option. Sixty-nine participants viewed two video clips of stand up comedians (i.e., Tim Allen and Robin Williams), each approximately four minutes long. The order in which the two film clips were shown was counterbalanced and the viewing of the film clips was separated by a 50 minute time delay. Thus, half of the time the Tim Allen clip was the immediate option (and Robin Williams the past option), whereas half of the time Robin Williams was the immediate option (and Tim Allen the past option). After participants viewed the first film they were asked to report their attitudes towards the first film. Immediately after viewing the second film, participants were asked to report the intensity of emotions in response to each film, their attitudes towards each film, their involvement with each film, and which comedy routine they would like to view in its entirety (i.e., our measure of consumer choice). Repeated measures ANOVAs, including film 1 and film 2 ratings as the repeated measure and order as a factor, revealed that participants reported more intense emotional reactions ($F(1, 67)=4.85, p<.03$), more positive attitudes ($F(1, 67)=4.10, p<.05$), higher involvement ($F(1, 67)=4.08, p<.05$), and a greater inclination to actually watch the entire comedy routine ($F(1, 67)=7.73, p<.01$), when the film was immediate rather than distant. Participants also misremembered their emotional reactions to the first film as less intensely positive after viewing the second film. Finally, the immediacy bias meant that participants were more likely to “mischoose”—that is, choosing to view the film they actually enjoyed less—when they chose the second rather than the first film.

The results of the current studies demonstrate that the immediacy bias does indeed have implications for consumer attitudes and choices. That is, compared to the distant option, the more immediate option led to greater perceptions of emotional intensity, more positive attitudes, higher involvement, and consumer choice. The results of our research have implications for both consumers and marketers. For consumers, it is valuable to be aware of this bias and to be cautious regarding choosing immediate options (i.e., Do I really want a cheeseburger more than chicken teriyaki, or is just because I can currently smell the cheeseburger?). In addition, because consumers show a preference for more immediate alternatives, marketers should invite consumers to make choices while they are currently experiencing or sampling the key product option.

The Second Wind Phenomenon: Recovery from Cognitive Fatigue with Sensory Arousal

Adam Craig, University of South Carolina, USA
Roland Leak, University of South Carolina, USA
Cait Poynor, University of South Carolina, USA

Extended Abstract

Historically, researchers studying cognitive overload have examined the effects of decision making such as suboptimal choice and choice deferral. However, research is just beginning to focus on how consumers recover from overload in order to try to maintain optimal decision making ability (Brice & Smith, 2001 and van Duinen, Lorst, & Zijdwind, 2005). Brice and Smith (2001) administered caffeine to participants in a one-hour simulated driving task and found that steering accuracy was improved. Van Duinen et al. (2005) explored

the effectiveness of caffeine in improving cognitive performance when faced with motor fatigue. Researchers found that caffeine improved cognitive performance resulting in fewer errors during a motor task. However, these studies did not examine decision making in cognitively demanding scenarios that consumers often face over prolonged cognitive effort resulting in cognitive overload. There may also be more effective means for improvement than chemical arousal (which may have decreased effectiveness over longer periods of time).

Here, we explore the effectiveness of other strategies: decreasing arousal (relaxation or sleep), increasing mental arousal (listening to music, playing an involved video game), increasing arousal through physical activity, distracting oneself from the task, interacting with people (talking on the phone or to someone), or as a control merely continuing the task until completion or failure. The perceived and actual effectiveness of cognitive overload cures has important implications for how and when consumers will use different strategies to cope with difficulty in decision-making situations.

One hundred and twenty participants participated in a preliminary study focused on gaining initial insight into the ways that consumers experience and attempt to remedy cognitive overload. Participants were first asked to describe a situation in which they felt “mentally tired,” and subsequently, provided a description of the measures they took to relieve their tiredness. After describing their remedy strategies, consumers reported the degree to which they felt their strategy was effective, and how cognitively tired they remember feeling after undertaking this measure.

Overload cures were coded as either:

1. Decreasing Arousal
2. Increasing Arousal—mental
3. Increasing Arousal—physical
4. Distraction from the task
5. Social Interaction
6. No cure used, attempted to keep working.

The most common cognitive relief strategy reported by participants involved the use of artificially induced physical arousal—caffeine—in order to recover from their cognitive overload. Interestingly, although such strategy was most widely used, it was not reported to be the most effective: A significant effect for cure type ($F=3.478, p<.006$) revealed that instead, “Social Interaction” ($M=7.286, SD=.745$) and “Distraction” ($M=6.769, SD=0.547$) were perceived as significantly more efficacious as compared to the control of “No change” ($M=4.091, SD=.594$), ($M=3.195, p<.001$ and $M=2.678, p<.001$ respectively). The most common reported strategy, physical arousal through the use of caffeine or other chemical stimulants, did not differ significantly from the reported effectiveness of doing nothing to alleviate cognitive fatigue.

These preliminary results indicate that consumers may be misguided in their choice of recovery strategies. Although they routinely choose increased physical arousal (especially through using chemical stimulants such as caffeine and nicotine) as a means to get a cognitive “boost”, this strategy seems to be less effective than mere social interaction. As a result, consumers may make poor judgments and actually decrease their cognitive ability in the long run, even if they experience a short enhancement (van Duinen, 2005).

Based on these results, Study 1 will be conducted in order to further explore the efficacy of strategies cited by consumers as means of recovery from cognitive overload. We will increase cognitive load by asking participants to conduct a series of ordinary cognitive tasks, such as price-related calculations. These tasks will include objective timing and performance measures, so that pre-remedy performance can be measured. Participants will then either increase cognitive arousal by listening to fast-paced music, decrease cognitive arousal by listening to slow music, send an email on an unrelated subject (social interaction), eat a piece of chocolate candy (to increase physiological arousal), or simply continue working on calculations. After their remedy activity, participants will resume another objectively measured cognitive task. Finally, they will rate their own feelings of cognitive tiredness and subjective sense of the efficacy of their remedy activity. Analysis will focus on performance patterns subsequent to the remedy activity, particularly as compared to participants’ subjective sense of cognitive repair. Results from this study will be available for discussion at ACR 2006.

The French Paradox Redux: Internal and External Cues of Meal Cessation

Brian Wansink, Cornell University, USA
 Collin R. Payne, Cornell University, USA
 Pierre Chandon, University of Pennsylvania, USA
 Paul Rozin, University of Pennsylvania, USA

Extended Abstract

A person who uses internal cues (such as hunger, satiation, or taste) to determine when to stop eating may be more effective in ultimately eating less than one who relies on external cues (such as portion sizes, social norms, or when an accompanying beverage or activity is over).

A demographically-matched sample of 134 Parisian and 148 Chicagoan students completed a brief survey on meal cessation, which asked the extent to which they agreed with three statements associated with internal cessation cues and three statements with external cessation cues. Their answers to these were compared across countries, genders, and BMI-levels.

While the French indicated they were more likely to be influenced by internal cues of meal cessation than Americans ($P < .001$), Americans indicated they were more likely to be influenced by external cues of meal cessation ($P < .001$). In summary, compared to their counterparts, French people ($P < .001$), females ($P < .05$), and normal weight individuals ($P < .01$) were more influenced by internal cues of meal cessation than external cues.

This study shows that one correlate with obesity may be the extent to which people rely on external cues to determine when they will stop eating a meal. While there are a number of possibilities of why those in some countries have less of an obesity problem than the United States, these results suggest one contributing explanation would be they are more likely to use internal cues, versus external cues to know when to stop eating.

Exercise Behavior in Loyalty Program: The Influence of Regulatory Focus

Ahmad Daryanto, Maastricht University, the Netherlands

Ko de Ruyter, Maastricht University, the Netherlands

Martin Wetzels, Maastricht University, the Netherlands

Paul G. Patterson, University of New South Wales, Sidney, Australia

Abstract

Our study examines the influence of regulatory focus (RF) on reward preferences in a customer loyalty program. Specifically, we aim to contribute to the emerging literature on RF by addressing five issues. First, we simultaneously investigate RF as a state and a customer trait. Second, we address the interaction between type of rewards and message framing. Third, we test whether the influence of the RF trait on consumer loyalty is mediated by exercise motivation. Fourth, we examine whether the transfer of regulatory fit effect is embedded in multiple interrelated constructs that make up a customer's evaluative judgment. Finally, we investigate the impact of simultaneously presenting promotion and prevention rewards on customer loyalty.

Overview of the Research

In many retail contexts, loyalty programs are employed to attract new and retain existing customers. This form of customer relationship management is also enjoying widespread popularity in health club services (e.g. <http://www.fitrewardsclub.com>). Many gyms have adopted loyalty programs (similar to frequent flyer programs in the airline industry). We investigate the influence of regulatory focus (RF) on reward preferences in a health club member loyalty program.

RF posits that there are two types of foci; (1) a promotion focus which aims at achieving positive outcomes and guides an individual to use an eagerness strategy and (2) a prevention focus aimed at avoiding negative outcomes, instigating individuals to use a vigilant strategy (Higgins, 1997). In prior research on RF, these foci are either framed as situational states or personal traits (e.g., Lee & Aaker, 2004). However, as reward preferences of health club members may be determined by both situational and individual differences, it is both theoretically and managerially relevant to understand the relative contributions of situational and dispositional foci by analyzing them simultaneously rather than independently (Kammrath et.al, 2005).

In addition, regulatory focus fit has recently been advanced to explain the match between a person's goals and the way to pursue these goals (Avnet & Higgins, 2006). The fit between regulatory focus and the manner in which goals are pursued influences customer beliefs about the appropriateness of their (re)actions. It has been argued that the 'feel right' factor, in turn, enhances motivational intensity in goal pursuit (Avnet & Higgins, 2006).

We address the interaction between types of reward and message framing, advocating an action to pursue loyalty program credit points. The type of reward is presented to health club members as a means to induce their state RF. Two types of goal exercise-related rewards are used: *approach reward* (which aims at *improving* their health) and *avoidance reward* (which aims at helping them to *maintain* good health). Thus, the messages are framed as either eagerness (using a gain frame) or vigilance (using a loss frame). In the gain frame, respondents are informed about the benefits of recommended future exercise. In contrast, in the loss frame, health club members are informed about the consequences of not exercising frequently enough. Consistent with RF theory, we expect that a fit effect occurs between the approach reward and gain frame as well as the avoidance reward and loss frame. Furthermore, this fit effect is predicted to be embedded in multiple interrelated constructs that form a customer's evaluative judgment of loyalty.

Our research also aims at contributing to goal framing research in relation to the mixed results that have been reported with respect to message framing (Lee & Aaker, 2004). In our study, we assess the interaction effect between type of rewards and message framing in support of the regulatory focus fit effect. In addition, we hypothesize a main effect of frame in that a loss frame is expected to be more effective to promote exercise. This is suggested by Levin, Schneider, & Gaeth (1998), who report that a loss frame is more effective for goal framing. In addition to a main effect of message framing, we predict that avoidance type of reward will be most preferred by health club members, because, in general, exercise is predominantly construed as a preventive behaviour (Rothman & Salovey, 1997).

In addition to the direct impact of RF on consumer preference in loyalty programs, we investigate whether this impact is mediated by other, more domain-specific variables. We introduce exercise motivation as a mediating variable as it has been demonstrated that this is a powerful predictor of exercise behavior (Markland & Ingledew, 1997). In our experiment, we expect promotion (prevention) RF will be more enhanced if an approach (avoidance) reward is presented to a promotion (prevention)-focused individual than to prevention (promotion)-focused individual, and this strengthened-RF orientation is predicted to influence exercise motivations, which in turn, will have an effect on customer exercise behavior.

Another important concept in RF theory is regulatory relevance, which refers to the match between customer's goals and his/her outcome decisions (Avnet & Higgins, 2006). This theoretical refinement of RF theory posits that customers with different regulatory focus value a reward as a function of its relevance to their regulatory orientation namely, promotion (prevention)-focused individuals prefer promotion (prevention)-related stimulus. However, it has not been assessed how customers with a different regulatory focus orientation react to promotion and prevention focus stimuli when these are simultaneously presented. Wang & Lee (2006) argue that in this case, RF serves as a selective filter to process the information, such that people pay attention to information that fits their RF, but only when they use heuristic information processing. The argument for this finding is that regulatory fit occurs due to the use of heuristic rather than systematic information processing (i.e., customers paid attention to perceptual salience of the product that fit their regulatory focus). In this research, we test the robustness of the fit effect in the setting of loyalty program (a high involvement situation). We predict that promotion-focused health club members are more likely to adopt approach rewards than avoidance rewards and vice versa.

To test these predictions, two studies were conducted. The first study aimed testing regulatory focus fit theory in the context of exercise, whereas the second study aimed at regulatory fit relevance. For the first study we used an experimental design in which different participants were assigned to each scenario in 2 (type of rewards: approach, avoidance) X 2 (advocated message: gain, loss) between subject design, whereas in the second study, survey with questionnaire was used. Data analyses of both studies were conducted using structural equation modeling with partial least squares.

Significance and Implication of the Research

In general, our study aims at to contribute to the emerging RF and regulatory fit literature. Specifically, we investigate whether the regulatory focus fit effect is an important explanatory mechanism that accounts for the customer preferences in relation to loyalty programs.

Hey, What Gives?

The Effects of Altruistic Versus Egoistic Charity Appeals on Donation Intentions

John Peloza, Simon Fraser University, Canada
Katherine White, University of Calgary, Canada

Extended Abstract

In the face of unprecedented competition, charities have adopted many sophisticated marketing techniques—relationship marketing, branding, and the measurement of marketing return on investment—previously considered to be the domain on their for-profit counterparts.

One of the more notable techniques used by charities is a move away from traditional charitable marketing strategies that are characterized by altruistic appeals to initiatives that focus more on the egoistic (i.e., selfish) benefits received by the donor (Hassay and Peloza 2005).

The long-running debate between those who argue that charitable donations are based in altruism (e.g., Batson 1990) and those who argue charitable donations are merely an exchange relationship (e.g., Cialdini et al. 1987) highlights the primary distinction between the majority of charitable appeals. When charities are seeking donor support they typically position the appeal either as an opportunity to help others (i.e., an altruistic appeal) or an opportunity for the donor to receive something in return (i.e., an egoistic appeal). Whether altruistic or egoistic appeals lead to more positive responses to requests for charitable donations remains equivocal and research has produced mixed evidence supporting the effectiveness of both altruistic and egoistic appeals (e.g., Pessemier, Bemmaor, and Hanssens 1977; Holmes, Miller, and Lerner 2002). The current paper seeks to address this contradiction by exploring moderators of the influence of appeal type (i.e., altruistic versus egoistic) on donation intentions.

A series of three experiments was conducted in order to test for the effects of potential moderators of the influence of egoistic versus altruistic appeals on consumers' willingness to donate. We predicted that consumers would respond more positively to egoistic rather than altruistic appeals under conditions that make egoistic motives salient. In particular, we examined the type of donation (volunteerism versus money), the donation setting (private versus public), and self-construal (independence and/or interdependence) as moderators of the effectiveness of egoistic and altruistic appeals. Across all three experiments, participants were shown an advertisement requesting donation in which the appeals were either egoistic (i.e., promoting donation as a self-serving behavior) or altruistic (i.e., promoting donation as a selfless behavior). One local charity that provides shelter and food to the homeless was chosen because in pretests it was generally well regarded and was equally likely to receive donations of time and money.

First, we hypothesized that people would respond more positively to egoistic appeals when the donation request was for time rather than money because donations of time mean higher costs which tend to lead to exchange valuations (i.e., more egoistic motives) by potential donors (e.g., Snyder, Omoto, and Crain 1999; Wilson 2000). In study 1, participants responded to either altruistic or egoistic appeals and indicated on a three-item scale how willing they would be to donate time and how willing they would be to donate money. As expected, a 3 (Appeal Type: egoistic vs. altruistic vs. combination) X 2 (Donation Type: volunteer vs. monetary donation) mixed model ANOVA revealed a significant interaction ($F(2,57)=10.39, p<.01$). Intentions to donate time were significantly higher than when participants viewed the egoistic versus the altruistic appeal ($M_s=5.2$ and 3.6 respectively, $t(57)=4.33, p<.001$). Intentions to donate money revealed the opposite effect, with intentions to donate time significantly higher intentions to donate time in response to altruistic appeals ($M_s=4.3$ and 3.4 respectively, $t(57)=2.38, p<.025$).

Next, we hypothesized that the donation setting would impact the effectiveness of charity appeals on donation intentions since individuals alter consumption patterns in private versus public (Ratner and Kahn 2002). Because society generally expects individuals to donate to charity as a selfless act, we expected egoistic appeals to be more successful than altruistic appeals when donation intentions are private. A 2 (Appeal Type: egoistic vs. altruistic) X 2 (Donation Setting: public versus private) ANOVA revealed a significant interaction ($F(1,140)=14.68, p<.001$). When donation intentions were private, people were more willing to donate in response to the egoistic than the altruistic appeal ($M_s=4.45$ and 3.77 respectively, $t(140)=2.13, p<.04$). When the donation intentions were public people demonstrated a trend towards being more likely to donate in response to altruistic than egoistic appeals ($M_s=4.22$ and 3.14 respectively, $t(140)=3.27, p<.002$).

The third study expands on the results from study 2 by examining the interactive impact of self construal (Singelis 1994) and donation setting on responses to egoistic and altruistic charity appeals. Previous research has shown that those high in independence are less likely to have negative reactions to the misfortunes of others (White, Lehman, and Cohen, in press). The private donation setting should reveal respondents' "true" intentions and those who are independent should exhibit the most positive donation intentions in response to egoistic appeals. A 2 (Appeal Type: egoistic vs. altruistic) X 2 (Donation Setting: public vs. private) X 2 (High vs. low independence) ANOVA revealed a significant 3-way interaction ($F(1,137)=14.95, p<.001$). In the private condition, consumers high in independence were reported significantly higher donation intentions in response to the egoistic than the altruistic appeal ($M=5.03$ and 4.05 respectively, $t(137)=2.23, p<.03$). In addition, among those low in independence in the private condition, donation intentions were stronger in response to the altruistic appeal ($M=4.81$) than the egoistic appeal ($M=3.73$; $t(137)=2.08, p<.04$).

Despite the fact that the execution style of an advertisement has been shown to affect consumer response in a variety of settings (e.g., Shiv, Edell, and Payne 1997), the debate over the efficacy of egoistic and altruistic appeals in motivating charitable giving has, until now, remained relatively unexamined. Although it has been argued that both egoistic and altruistic appeals can be successful, our research provides evidence that the efficacy of each appeal is dependent upon the task, contextual characteristics, and individual differences.

Consumer Goal Orientation in Different Service Contexts: The Different Impacts of Affect on Perceived Quality and Satisfaction

Cheng Lu Wang, University of New Haven, U.S.A.

Ying Jiang, University of Connecticut, U.S.A.

Extended Abstract

The role of affect in consumption experience has attracted substantial research interests in the last two decades (e.g., Erevells 1998; Mano and Oliver 1993). A general finding from the literature is that affective responses are important consumption outcomes that relate to satisfaction/dissatisfaction. However, in addition to being just a consumption outcome, affect can also serve as a primitive motive for consumption as consumers purchase products (e.g., video games) and participate in leisure activities (e.g., theme parks) in order to experience desired affect (e.g., Hirschman and Holbrook 1982; Holbrook and Hirschman 1982). When the consumption is driven by affect, consumers usually anticipate that they will experience higher levels of some specific affect (e.g., pleasure, arousal) during the consumption process. Such goal orientations often play very important roles in consumer behavior. For example, Garbarino and Johnson (2001) have demonstrated that customers' goal orientation can determine what information is used in satisfaction evaluation of a live theatre company. Yet, little is known about how consumers' goal orientation and affect derived from the service consumption experience together influence quality and satisfaction evaluations in different service contexts.

Therefore, the objective of this research is to investigate the different impacts of affect (pleasure and arousal) on perceived service quality and satisfaction in different service contexts in which consumers' major goal orientation is either task-fulfillment, pleasure-seeking, or arousal-seeking.

Hedonic services refer to those services that are consumed primarily for affective and sensory experiences (e.g., Hirschman and Holbrook 1982). Hence, consumers' major goal orientation in hedonic services is to experience desired affect. Such an affect-seeking goal orientation can be further classified as primarily pleasure-seeking (e.g., fine dining), primarily arousal-seeking (e.g., nightclub), or both (e.g., theme park). On the other hand, utilitarian services are those services that are consumed primarily for instrumental and functional values, e.g., banking. Therefore, consumers' major goal orientation in utilitarian service contexts is task-fulfillment.

Consumers' perceived service quality usually results from the comparison of subjective standards with service performance (Parasuraman, Zaiethaml and Berry 1988). However, satisfaction differs from perceived quality in that it is relative to situational expectations and involves affective dimensions. As consumers' major goal orientation in different service contexts determines their expectation of different levels of affect, affect may have different impacts on perceived quality and satisfaction.

In utilitarian service contexts, quality evaluations are mainly based on the judgment of the functional utilities. Such judgment often results in pleasant or unpleasant feelings. The valence of affect may influence perceived service quality through the usage of "how-do-I-feel-it" heuristic (Pham 1998) and/or mood transfer (Bagozzi, Gopinath and Nyer 1999). Given that consumers do not anticipate pleasure in utilitarian service contexts, pleasure may not impact satisfaction directly. Instead, such unanticipated pleasure is likely to influence satisfaction through the mediation of perceived service quality. Similarly, consumers do not particularly pursue arousal in pleasure-seeking hedonic services or pleasure in arousal-seeking hedonic services, such secondary affect may enhance the primary affect and influence consumers' service quality perception. Therefore, the effect of such secondary affect on satisfaction is expected to be mediated by perceived service quality.

On the other hand, when consumers specifically anticipate strong feelings of pleasure in pleasure-seeking hedonic services and arousal in arousal-seeking hedonic services, such primary affect will have a strong effect on satisfaction even after the effect of perceived service quality is controlled. In other words, primary affect will have a direct effect on satisfaction.

We have conducted two empirical studies to test our hypotheses. In study 1, we examine the different impacts of affect on service quality and satisfaction in a hedonic service context in which consumers' major goal orientation is pleasure-seeking, and a utilitarian service context in which the major goal orientation is task-fulfillment. In study 2, we examine such relationships in two different hedonic service contexts in which the goal orientation is primarily arousal-seeking or pleasure-seeking.

In study 1, a pretest was conducted to identify the prototype pleasure-seeking hedonic service and utilitarian service. Participants from a university in Hong Kong rated that karaoke and banking services were such services that they often patronized. Questionnaires with a screening question asking participants whether they had patronized karaoke or banking (excluding online banking and ATM) services in the last one month were given to undergraduate students in Hong Kong. Consistent with our hypotheses, results show that the effect of pleasure on satisfaction was mediated by perceived service quality in the utilitarian service context in which the major goal orientation is not pleasure-seeking. As expected, pleasure had a direct effect on satisfaction in the pleasure-seeking hedonic service context; the effect of arousal on satisfaction was mediated by perceived service quality as arousal-seeking was not the major goal orientation.

Study 2 was designed to test our hypotheses in two different hedonic service contexts in which the major goal orientation is either arousal-seeking or pleasure-seeking. Two pretests were conducted to identify and confirm such service contexts. In the first pretest, participants from a U.S. university agreed that nightclubs and fine restaurants represented such service contexts. In the second pretest,

participants who didn't participate in the first pretest were asked to rate the extent of different feelings they wanted to experience the last time they went to a nightclub or a fine restaurant. Results show that participants wanted to experience more arousal than pleasure at nightclubs, whereas they wanted to experience more pleasure than arousal at fine restaurants. Questionnaires with a screening question asking whether they had been to a nightclub or a fine restaurant in the last one month were given to undergraduate students in two U.S. universities. Consistent with the findings of Study 1, the results showed that pleasure had a direct effect on satisfaction in the pleasure-seeking hedonic service context. As hypothesized, arousal also had a direct effect on satisfaction in the arousal-seeking hedonic service context.

This research adds to the literature of consumer goal orientation and service consumption experience. It further examines consumers' pleasure-seeking and arousal-seeking goal orientation in different hedonic service contexts. This research also shows how goal orientation determines the direct and indirect impact of affect (pleasure and arousal) on satisfaction. Based on the results of the two empirical studies, we can conclude that the affect that consumers pursue most will have a strong and direct impact on satisfaction; whereas, the impact of other desirable secondary affect on satisfaction will be mediated by perceived service quality.

Multidimensional Price Comparison: The Moderating Role of Across Consumers and Across Firms Price Comparison on Perceived Fairness, Regret, and Satisfaction

Felix Tang, The Chinese University of Hong Kong, China
 Jianmin Jia, The Chinese University of Hong Kong, China

Extended Abstract

This study is part of a research project that examines the interaction of dimensions in a transaction space of reference price. Research on reference price can be aligned into a congruent perspective by using Bolton, Warlop, and Alba's (2003) four dimensional transaction space, which postulates that consumers may consider the price of any point along the *consumers* (i.e., comparing between consumers), *products* (i.e., comparing cost and profit), *firms* (i.e., comparing between competitors), and/or *time* (comparing across time) dimensions in a four dimensional transaction space as a reference point. The results of such realignment exercise enlighten an insight, that sparse effort has been expended to investigate, and clearly separate, both independent and joint influence of multidimensional price comparison on consumer behavioral variables.

Of the four dimensions, the *consumers* and *firms* dimensions are particularly important because comparison across consumers is related to the concept of fairness and comparison across firms is related to the concept of regret. While both concepts influence consumer satisfaction, no study has investigated the joint influence of reference price across consumers and across firms on fairness and justice. This investigation not only contributes to both research on reference price and satisfaction but also links the two streams of research together. The relative importance of the two concepts on consumer satisfaction in different price comparison situations may be examined. An equally interesting issue is whether the amount of influence on fairness and regret depends on the direction of price discrepancy; that is, whether the impact is symmetry or asymmetric.

The purposes of this study are 1) to investigate the independent and joint effects of across consumers and across firms price comparison on perceived fairness, regret, and consumer satisfaction, and 2) to examine the presence/absence of asymmetric effect of price inequality on perceived fairness and regret in an experimental setting.

When consumers engage in price comparison, discrepancy in prices across *consumers* may lead to the issue of fairness (Feinberg, Krishna, and Zhang 2002). Larger price discrepancy across consumers decreases perception of fairness, leading to lower satisfaction (Bolton and Lemon 1999). Similarly, when consumers engage in price comparison, discrepancy in prices across *firms* may lead to the issue of regret (Inman, Dyer, and Jia 1997). Larger price discrepancy across firms increases perception of regret, leading to lower satisfaction (Taylor 1997). However, the joint impact of discrepancy in prices across consumers and across firms may not simply be additive for two reasons.

First, Kahneman, Knetsch, and Thaler's (1986) principle of dual entitlement suggests that a price increase is perceived to be fair if the firm's existing level of profit is the same. When discrepancy occurs across consumers, consumers may attribute the extra income the

company generates as extra profit, this attribution is more applicable when comparing within firm than across firms because the cost of offering the same product/service to different consumers should be very similar. Second, Tsiros and Mittal (2000) identified counterfactual thinking as the underlying cognitive mechanism that stimulates regret. Possibility of counterfactual thinking is reduced when price discrepancy is within firm than across firms.

Regarding asymmetric effect, the property of loss aversion in Kahneman and Tversky's (1979) prospect theory implies that the impact of a loss is larger than the impact of a gain of equal magnitude. The influence of disadvantageous price discrepancy, which is coded as a "loss", on consumer perception of fairness and regret is expected to be larger than advantageous price discrepancy, which is coded as a "gain".

Previous studies have examined the impact of perceived fairness (Bolton and Lemon 1999) and regret (Tsiros and Mittal 2000) on satisfaction independently. This study examined their joint impact on satisfaction. It follows that:

- H1: The impact of price inequality across consumers on fairness is diminished when such price comparison is also across firms.
- H2: The impact of price inequality across consumers on regret is magnified when such price comparison is also across firms.
- H3: The effect of disadvantageous price inequality on perceived fairness is larger than the effect of corresponding advantageous price inequality.
- H4: The effect of disadvantageous price inequality on regret is larger than the effect of corresponding advantageous price inequality.
- H5: Perceived fairness has a positive influence on satisfaction, and regret has a negative influence on satisfaction.

One hundred and thirty-six undergraduate students in Hong Kong participated in the experiment. The manipulation was scenario-based, in the context of choosing an internet service provider. Price equality (advantageous vs. disadvantageous vs. control) was manipulated to be across consumers and/or across firms. Existing scales for perceived fairness, regret, and satisfaction were adopted and measured. Manipulation checks and suspicion probe were measured. The manipulations were successful and all scale reliability was satisfactory with alphas above 0.80. Data analysis with ANOVA, regression, and SEM yielded converging results supporting all five hypotheses.

This study contributes to the reference price literature in four ways. Firstly, it extends Bolton and Lemon's (1999) antecedents of payment equity by proposing that consumers not only use their own normative expectation but also another consumer's outcome as reference points in judging fairness and satisfaction. Secondly, in response to Bolton et al.'s (2003) suggestion, this study investigated the influence of prices paid by other consumers on fairness perception. Thirdly, the findings of asymmetric price effect add support to the property of loss aversion in perceived fairness and regret. Fourthly, this study demonstrates that different dimensions of the transaction space can interact with each other. The significant interaction effect between across consumers and across firms price comparison suggests that simply looking at one dimension of the transaction space at a time may oversimplified the complexity of reference price research. Future reference price research is encouraged to examine other multidimensional interactions.

Impact on Online-store Loyalty from Store Image under Influences from Consumption Values

Yiping Song, Fudan University, China
Baijun Zhu, Fudan University, China

Extended Abstract

Fast development of electronic technology and low entry barrier precipitated a heated competition in the online business (Auger and Gallaughier 1997; Klein 1998). More and more online shops are seeking new ways to stand out the competition to win over customers, loyal ones in particular.

Extant researches focusing on off-line business found *store image* a key contributor to business performance (Nevin and Houston 1980; Samli 1989; etc.). Online store also bears image which is able to create a competitive advantage that is not easily duplicated by other

retailers (Rosenbloom 1983). Store image is the complex of a consumer's perceptions of the different attributes of the store, namely, general attribute, appearance and service (Manolis et al. 1994). Good store image may lead to *store loyalty* (Lessig 1973; Sirgy and Samli 1989).

People buy out of various incentives, thus paying attention to different aspects of the store image, which is universal in everyday life. Researches on *consumption values* suggest that the reason why consumers pay attention to different aspects of the product and make different choices is the seeking of different consumption values (Sheth et al. 1991). The five values identified by Sheth et al. (1991) are *functional value*, which derives from the perceived utility of the object in the choice situation; *social value*, attached to a product from its association with social groups; *emotional value*, which relates to the affective or emotional response to the product; *epistemic value*, obtaining to a product through curiosity, novelty or knowledge seeking; and *conditional value*, ascribed to an object through circumstance of use.

818 eligible finished questionnaires were collected online by a professional research company. Demographic indicators of these respondents are consistent with former studies of online-shoppers in China (Dong 2005; Cui 2004).

According to Sheth et al. (1991), although the basic five-dimension framework of consumption values is given, the items for the values should be designed based on specific condition, and each dimension may consist of more than one factor. The multi-dimensional value structure is proved in previous research (c.f., Long and Schiffman 2000; Pope 1998).

Following the guidelines suggested by Churchill (1979), we developed scales of consumption values on online-shopping. Each consumption value scale was independently factor analyzed using SPSS. Seven factors for the consumption values were identified, the uni-dimensional social value, epistemic value, and conditional value, along with two-dimensional functional value (functional and costs advantages) and emotional value (gratification and safety). Tests indicate a good reliability of all the seven values (Cronbach $\alpha > 0.80$).

Hierarchical cluster analysis using Ward's method with Squared Euclidean distance, based on the seven factors, grouped the respondents into three, comprising of 230, 297 and 291 people respectively.

The results of ANOVA indicate that the three groups differ significantly in their evaluation about the consumption values ($p < 0.001$). The second group has the lowest evaluation about all the consumption values except functional advantage and safety. In contrast, the third group exhibits the highest evaluation of all the other values, with the epistemic value lower than the first group. The first group has most values ranked between that for Group 2 and Group 3, as well as the highest epistemic value and lowest functional advantage and safety.

A model was constructed to examine the difference of the impact on store loyalty from the three dimensions of online-store image—general attribute, service and appearance, and the mediation of satisfaction and commitment in these three groups. We examined the model using AMOS in three groups separately. Statistical results of the path coefficients of all the three models indicate that, the impact from the three aspects of online store image on loyalty differ from one group to another. The mediation of satisfaction and commitment, and the impact of the two mediators on loyalty are also different among the groups.

Group 1 demonstrates the highest level of store loyalty through satisfaction, but the lowest level of transition from satisfaction to commitment, and from commitment to loyalty. Besides, consumers in Group 1 pay more attention to short-term oriented consumption values, like conditional and epistemic value. Those two features lead to the fact that people in Group 1 turn out to be *undecided consumers*, apt to switch from store to store. General attribute is the most important store image for Group 1. Enhancement in general attribute image, like better overall sales performance, higher reputation, may help maintain the undecided consumers in Group 1.

Group 2 has the lowest level of transition from satisfaction to loyalty. And only general attribute image has direct positive influence on their commitment. According to the path coefficients, they are least possibly to become loyal. Along with the lowest evaluation about the consumption values, they are termed as *non-frequent buyers*. Enhancing general attribute is also important for encouraging more purchase from the non-frequent buyers.

For all the three groups, satisfaction and commitment towards online stores will lead to store loyalty, and satisfaction will be changed into commitment. However, path coefficients indicate that, consumers in Group 3 are the easiest to change from satisfaction into commitment. Also, they have the highest level of loyalty through commitment, and relatively high level of loyalty from satisfaction. This result, which is consistent with their high evaluation of the consumption values, indicates that Group 3 is composed of *loyal customers*. In general, consumers in Group 3 are the most valuable to an online-store. For this group, service is the factor which has the greatest influence on loyalty. Taking their evaluation of consumption values into account, service differentiation can further satisfy those consumers. Customized service can meet the high appeal of the social value from this group.

Additionally, in all the three groups, general attribute image exhibits the highest contribution to loyalty, while appearance image shows the lowest, if any.

The Effects of Product Scandals on Parent Brands: Linguistic Signatures of a Protective Mechanism

Simon Ineichen, University of Basel, Switzerland
Arnd Florack, University of Basel, Switzerland

Extended Abstract

Brand architectures involving a parent brand can improve the perception of their associated brands and allow for a simple and cost saving introduction of new products (Smith, 1992). New or established product brands may benefit from associations with parent brands (Aaker & Keller, 1989; Sattler, Völckner, & Zatloukal, 2002). The opportunity of such positive transfer effects, however, comes at a price: The transfer is neither restricted to positive affect, nor is it unidirectional. There are also examples that negative evaluations of product brands can affect parent brands and other associated products. The empirical findings concerning such negative feedback, however, are not equivocal: while Sullivan (1990) found that technical problems with one model of Audi deteriorated the brand image and lowered sales of other Audi products, other researchers did not find negative feedback effects (Aaker, 1996, Loken & Roedder John, 1993, Keller & Aaker, 1992; Romeo, 1991). It seems that, under certain circumstances, parent brands are resistant to effects of negative evaluations of associated product brands. In the present study, we examined whether attribution processes that are specific to parent brands with a strong positive image may prevent strong parent brands from negative feedback effects.

Attribution research is concerned with the judgment of causes for a perceived event. For example, Heider (1958) examined whether the behavior of an individual and his or her individual dispositions are the primary cause of an outcome, or whether external, environmental influences are considered as a primary cause. While attribution research is predominant in research on person perception, there are also a few studies examining causal attribution in the domain of product failures and product-harm crises (e.g., Folkes, 1988; Siomkos & Kurzbard, 1994; Su & Tippins, 1998). Previous research focused on the effects of an incident's severity (Su & Tippins, 1998) and the consumer's personal vulnerability (Laufer & Gillespie, 2004). However, research on expectancy biases in person perception also suggests that the categorization of an actor and the associated expectations influence how causes for negative incidents are construed. For example, Maass, Salvi, Arcuri, and Semin (1998) found that individuals communicate undesirable behavior more abstractly when it was performed by an out-group member than when it was performed by an in-group member. A high level of abstraction can be regarded as a specific form of attribution pertaining the disposition of the actor or the respective group. In contrast, a low level of abstraction can be considered as a more situational attribution in which the undesirable behavior is perceived as caused by external, environmental factors, and is not generalized to the actors' dispositions. The underlying mechanism is that expected behavior is construed and communicated in more abstract terms and considered as more intentional, while unexpected behavior is construed and communicated more concretely and is considered as less intentional (Fiedler, Blümke, Friese, & Hofmann, 2003). Since the behavior expected for the in-group is mostly positive while for the out-group expectations are often negative, this is a good explanation for the findings of Maas et al.

We assume that a similar mechanism moderates the responses to a product scandal or failure related to strong or weak parent brand. As strong parent brands we consider parent brands that are well established in the market and to which consumers hold strong positive views. In contrast, a weak parent brand should be less established in the market and consumers should not have strong attitudes towards these brands. Since strong positive attitudes are directly linked to positive expectations, a product scandal or product failures are not congruent to the expectations towards a strong parent brand. Therefore, we hypothesized that a product scandal that concerns failures of a product associated with a strong parent brand is construed and communicated by consumers in more concrete terms, and does affect the view of the brand to a minor degree than if the same scandal pertains a product of a weak parent brand.

To test our assumptions, participants received information about a scandal associated with a new product of either a strong or weak parent brand. The product was a soft drink and the scandal was that the product did not contain what the consumers expected. The information about the scandal contained a pictograph and two short essays. The information was sparse and allowed for a variety of interpretations about the causation. The pictograph indicated discordance between what the manufacturer was bottling and what the consumer thought he was drinking, but did not provide any clues on how this had happened and whose fault it was. The essays looked like editorial content of some marketing periodical. They described how the respective company prepared the launch of a new brand in several countries. The product behind the new brand was described, the very competitive market was mentioned, and a vague schedule

for the launch was provided. Also, participants were given the information that the planned launch of the new brand had failed and been aborted to avoid further damage. No exact reasons were explained, only a “flop” was mentioned. Participants were asked to carefully study the material. They evaluated both the product brand and the parent brand before, and after the presentation of the scandal. After studying the information of the scandal, we asked participants to retell the story with their own words as if they were telling it to a friend. The space was limited to one page. We analyzed the resulting texts using the Linguistic Category Model (Semin & Fiedler, 1988, 1991, 1992).

Our Data is consistent with our expectations: the language participants used to retell the story was significantly less abstract, indicating a more situative attribution of the events that were described. In line with this, the strong parent brand took significantly less damage than the weak parent brand did.

This finding implies that the risk of imposing a parent brand may be smaller than thought by some marketing experts. The parent brand, if it is strong enough, can clear the path for a more favorable perception, even of negative behavior.

Choosing Between Service Sequences: The Joint Effect of Ego Depletion and Mood on Consumers' Decision Strategy

Miriam de Groot, Maastricht University, The Netherlands
Benedict G. C. Dellaert, Erasmus University Rotterdam, The Netherlands

Extended Abstract

Previous research on preferences for sequences of outcomes shows that people prefer some sequences over others. For example, people prefer sequences where positive and negative outcomes are spread out over time (Loewenstein and Prelec, 1993). Although previous research presents us with valuable insights into the sequence evaluation process, the conditions under which these sequence preferences hold have not received much attention. Previous research has shown that mood and ego depletion have a profound influence on the level and quantity of information that is processed and as a result on the decision making process (Schwarz, 2001; Baumeister, Bratslavsky, Muraven, and Tice, 1998). Therefore, we believe that when looking at sequence preferences, these two mechanisms can not be overlooked.

This research presents the results of an experiment designed to test a theoretical framework in which the combined effect of mood and ego depletion influences preferences for sequences of service experiences. We argue that ego depletion and mood play an important role in service encounters and that the initial mood state of the customer will influence which components of the service are considered important for the evaluation of the service. In addition, certain events within a service encounter require active self-control by the customer,

such as long waiting times, which might result in ego depletion. In turn, ego depletion will determine how much information is extracted from the service for evaluation.

Our theoretical framework treats mood and ego depletion as two separate mechanisms which operate under different principles. These principles are based upon the level and the quantity of information processing. Based upon these operating principles, we identify 6 'rules' for sequence evaluation which determine service encounter preferences of consumers.

The level of information processing is influenced by mood and can be either gestalt-based or components-based. Gestalt-based refers to the fact that people in a positive mood will process information more superficially (heuristics) than people in a negative mood (Schwarz, 2001) and therefore they will look more at the gestalt, or 'overall' appearance of the sequence. Spreading, improvement and the peak-end rule are three sequence characteristics which are important for the sequence evaluation in this case, because spreading, improvement and peak-end are all related to the gestalt or overall 'appearance' of the sequence.

Component-based means that people in a negative mood treat the sequence as consisting of separate components instead of looking at the overall pattern. This is grounded in the fact that negative mood states usually lead to more systematic information processing (Schwarz, 2001). Balanced count, myopia and simplified count are characteristics which are important for the sequence evaluation in this case. Balanced count refers to the fact that people determine the overall utility of the sequence and equally weigh all attributes in this count. Myopia (short-sighted) means that people focus primarily on the first element in the sequence. Simplified count means that people will only look at the utility of their most preferred attribute when evaluating the sequence. These sequence characteristics thus focus on the separate components or one component in the sequence instead of the overall pattern.

The quantity of information processing is influenced by the level of ego depletion and can either be focused on multiple components or few components in the sequence. Multiple components refers to the fact that non-depleted people will focus on more information/components in the sequence when making their choice than depleted people. This is based on the reasoning that depleted people have limited resources available to process information and therefore they will use a more simplified decision strategy and evaluate fewer pieces of information (Baumeister, Bratslavsky, Muraven, and Tice, 1998). The peak-end rule, myopia and simplified count are important for sequence evaluation in this case because in all these strategies of sequence evaluation, the focus is on only a few elements in the sequence. Non-depleted people have more resources available and are able to focus on more information/multiple components in the sequence. Spreading, improvement and balanced count are important for sequence evaluation here. All these strategies require the processing of multiple components in the sequence.

The combination of the different levels of mood and ego depletion make up a 2 x 2 experimental design with 4 experimental conditions: positive mood/no depletion, positive mood/depletion, negative mood/no depletion and negative mood/depletion. We expect important interaction effects between mood and ego depletion, where mood moderates the selection of decision strategies based on ego depletion. In particular, people in a positive mood who are depleted, will focus on the peak and end moment in the service encounter. In contrast, people in a negative mood who are depleted, will use myopia and simplified count as strategies for choosing between service sequences.

We investigate our proposed hypotheses in a computerized experiment using Windows MouselabWEB where we systematically manipulate mood and level of depletion and present subjects in each condition with choices between sequences of positive and negative service experiences. We expect that the choice and the decision making process in each experimental condition are based on the rules for sequence evaluation that are provided by the theoretical framework for that specific experimental condition.

A Need-Satisfaction Model of Superstitious Behavior

Rajiv Vaidyanathan, University of Minnesota Duluth, USA

Praveen Aggarwal, University of Minnesota Duluth, USA

Taihoon Cha, University of Minnesota Duluth, USA

Seungwoo Chun, University of Minnesota Duluth, USA

Extended Abstract

Chinese manufacturers favor the use of digit 8 and avoid using the digit 4 in their pricing as buyers in China connote digit 8 with "enrichment" and digit 4 with "death" (Simmons and Schindler 2003). This numeric superstition also results in a price premium for properties on the 8th floor in Cantonese societies (Chau, Ma and Ho 2001). Many American hotels skip from the 12th floor to the 14th floor to avoid having guests stay on the unlucky 13th floor (Mowen and Carlson 2003).

Why do so many people, usually well-educated members of a modern, scientific society, engage in these behaviors? What motivates such behavior? The objective of this research is to present a comprehensive model of the mechanisms driving superstitious behavior among individuals and highlight its relevance both in terms of theory and practice. There are five basic problems with existing models of

superstition. First, some models view superstitious behavior as a consequence of a superstitious belief system which is based on a superstitious personality trait (e.g., Mowen and Carlson 2003). Such models are narrow in that they do not provide an adequate explanation for a variety of superstitious behaviors that are not based on a lack of belief in science. A second criticism is that current models fail to recognize the differences between superstition in contemporary society and traditional superstitions. Third, even models that accommodate superstitions based on “half belief” ignore instrumentality-based and social-based superstitious behavior. Fourth, existing models have an inordinate focus on *negative* superstitions instead of *positive* superstitions. The most widely used scale measuring superstitious beliefs—the three-item superstition sub-scale of the Paranormal Belief Scale (Tobacyk and Milford 1983; Tobacyk 1988)—only measures the belief that certain omens (e.g., seeing a black cat) are associated with harmful consequences. Not only does this constrain our view of what constitutes superstition, but restricts it to *negative* superstitions instead of also considering positive superstitions such as rubbing a lucky charm to bring good luck (Wiseman and Watt 2004). Finally, superstition models based on psychological therapeutic effects do not fully explain why the superstitious behavior takes on the particular and stereotyped form that it does.

Assuming that superstitious behaviors serve some underlying individual need, we present a need-satisfaction model of superstitious behavior that classifies the needs met by superstitious behavior into (1) Functional Needs, (2) Psychological Needs, and (3) Social Needs. The operating principle underlying functional need satisfaction is the *illusion of control* (Langer 1975). A key construct driving this need is perceived *luckiness*. Luck has been conceptualized as a personal and stable trait that leads individuals to maintain irrational and superstitious beliefs (Darke and Freedman (1997). The illusion of control effect has been found to be a robust psychological effect underpinning lottery gambling (Rogers 1998).

The operating principle underlying the psychological need satisfaction of superstitious behavior is *counterfactual thinking* (cf. Kahneman and Miller 1986). Individuals evaluate outcomes not only in isolation, but also in relation to alternative events that *could* have, *might* have, or *should* have happened. While a gambler may initially engage in a superstitious ritual because of an illusion of control, the literature has often been at a loss to explain why they continue to engage in the ritual when a series of negative observations show that the ritual is not effective in influencing outcomes. The psychological need-satisfaction element of our model suggests that there is an emotional comfort offered by continuing a ritual and having hope in positive future outcomes. On the flip side, should a superstitious behavior (e.g., picking an anniversary date as one’s personal lottery numbers) be discontinued, there is the “emotional amplification” effect associated with the dread that those numbers would be drawn soon after the behavior is discontinued. Since a person can easily imagine the situation of these long-played numbers hitting right after s/he chooses a different number, there is a strong pressure to continue the superstition. Engaging in a superstitious behavior to avoid a negative outcome “might stem not from the belief that bad things are more likely to happen . . . but from the belief that any bad thing that does happen will be more psychologically painful.” (Miller and Taylor 1995; p. 368). Our model expands on the concept of “hope” (MacInnis and de Mello 2005) and invokes “anticipated regret” as an opposite emotion that is just as important in driving behavior.

The operating principle underlying the social need satisfaction dimension of superstitious behavior is *social learning* (Bandura 1962). A great deal of superstitious behavior may be based on observing others and following traditions simply as a way of identifying oneself with the group. Several non-religious superstitious behaviors are driven by social factors without any individual-level belief in its instrumentality. The showering of a newly married couple with rice (interestingly, many modern weddings substitute soap bubbles for the rice suggesting the lack of belief in any instrumental or religious significance of rice), the sharing of rice cakes in Korea before important exam days, and the Indian superstition of crushing a lemon under the wheels of a new automobile are examples of superstitions driven by socio-cultural norms. While it is possible that some of these superstitions were originally developed based on perceived instrumentality, they get adopted as a social ritual over time. The main motivation for individuals engaging in such behavior is to maintain or strengthen their social ties.

This research makes several contributions to the marketing, consumer behavior, and superstition literature. It is the first to present a comprehensive model of superstitious behavior that accommodates a variety of superstition types and different motives consumers may have for engaging in superstitious behavior. The model resolves several problems with prior models of superstitious behavior and provides the operating principle underlying each of the motives for superstitious behavior. We offer a new conceptualization of the emotional underpinnings of counterfactual thinking. Our presentation of hope and anticipated regret as positive and negative emotions associated with counterfactual thinking opens a promising research stream for researchers. The model also lays the groundwork for the development of a more comprehensive scale for the measurement of superstition. Existing scales are grossly inadequate in capturing the variety of factors underlying superstitious behavior. Finally, the model helps those interested in superstition-related marketing communications—both marketers and public policy advocates—to better understand how various communication elements influence consumers to enhance or reduce their superstitious beliefs.

Is There an Expected Trade-off Between a Product's Ethical Value and Its Effectiveness?: Exposing Latent Intuitions about Ethical Products

Michael Luchs, The University of Texas at Austin, USA

Rebecca Walker Naylor, University of South Carolina, USA

Julie R. Irwin, The University of Texas at Austin, USA

Rajagopal Raghunathan, The University of Texas at Austin, USA

This research seeks to demonstrate consumers' intuition that there is an inherent tradeoff between a given product's "ethical attributes" and the product's effectiveness, or functional performance. Ethical attributes are those attributes that reflect a person's conscience and which may relate to a variety of environmental, individual and societal issues. We demonstrate in our first two studies, using toothpaste (Study 1) and laundry detergent (Study 2) as a product context, that the "ethical=less effective" intuition is moderated by the degree to which the consumer believes that the focal ethical issues are important overall. Those consumers who place the highest importance on these ethical issues infer that these products will actually be more effective. This halo effect, however, disappears and ultimately reverses such that the less importance the consumer places on the ethical issues, the less effective they believe the product will be, i.e. products rated "superb" on ethical attributes were rated significantly lower in effectiveness than products rated "poor" on ethical attributes. We also intend to replicate these studies using a broad, nationally representative sample, as well as test moderators of the intuition such as self/other judgments and precommitment to the intuition.

A national survey found that 88% of consumers were more likely to purchase products from a company deemed socially responsible (Public Relations Quarterly Winter 94/95). However, anecdotal evidence suggests that products from these companies receive limited distribution support and capture a minority share of the market when they are available. Anecdotal evidence also suggests that many ethical products are positioned as premium products, and that price, therefore, may be a critical barrier to their mass market appeal. Recent research, however, suggests that the relative lack of success of ethical products is much more complex than just the tradeoff of ethicality and price. For example, Ehrich and Irwin (2005) demonstrate that consumers who are more motivated to buy products positioned as socially responsible are proportionally less likely to seek out information about a product's ethical attributes. This "willful ignorance" is driven by an avoidance of the guilt one might experience upon discovering that a desired product does not perform well on ethical attributes. Ehrich and Irwin's (2005) research also hints at the tradeoff that consumers assume they must make between purchasing a product that satisfies their immediate consumption needs versus one that satisfies their conscience.

In order to more fully understand consumer decision making about ethical products, our research explores both consumers' inferences as well as their judgments about these products. We propose and test the following hypothesis:

- H1: Rated importance of the relevant ethical issue will moderate ethical-effective inferences: As importance increases, respondents are more likely to infer greater product effectiveness from product ethicality. Conversely, as importance decreases, respondents are more likely to indicate that ethical products are less effective.

Thus, consumers who do not believe that a product's ethics are important make inferences consistent with an intuition we believe is widespread in the market place, i.e. that ethical=less effective. Consumers who do place high importance on a product's ethics will, instead, make inferences consistent with a halo effect mechanism, in which ethical products are inferred to be more effective.

While we intend to show that rated importance moderates ethical-effective inferences, we also intend to explore whether expression of the ethical=less effective intuition also depends on how the question is framed. It is likely that responses of subjects who rate the ethical issues as important will be more reflective of social desirability influences than of subjects' beliefs. Belk et al (2003) demonstrate that when dealing with sensitive issues, such as ethical responsibility in our case, projective techniques will mitigate subjects' tendency to respond in a manner consistent with social desirability influences. As such, we propose to test the following hypothesis:

- H2: When subjects are asked to infer what the average person would think about the ethical-effective relationship (vs. what they personally believe), self rated issue importance will no longer moderate responses and instead all subjects will tend to express the intuition that ethical=less effective.

In our first study (n=207), we manipulated product ethicality by telling participants that a new brand of toothpaste had received a rating from the Environmental Sustainability Council (ECS) of either "poor," for a lack of environmentally friendly practices, or "superb,"

for a demonstrated record of environmentally responsible actions. Thus, the study had a 2 factor (ethics: poor vs. superb) design. In order to test H1, participants were given information about the ethical attributes of the toothpaste, which varied by condition, and were asked to infer its effectiveness. The two key dependent variables were how well the toothpaste was inferred to whiten teeth and how well it provided the benefits the participant looks for in a toothpaste. Participants also rated the importance of a product's ethics in general.

Two 2 factor ANOVAs (ethicality of toothpaste x participants' ratings of importance of a product's ethics) were conducted with inferences about whitening ability and the benefits provided as the dependent variables, respectively. In neither case was there a main effect of ethics on inferences. However, consistent with H1, there was a significant interaction between the ethicality of the toothpaste and the importance ratings such that those participants who felt that a product's ethics were less important rated the toothpaste with poor ethics as better able to whiten, $F(1, 203)=4.53, p<.05$, and more likely to provide the benefits they desired than the toothpaste with superb ethics, $F(1, 203)=13.73, p<.001$, while participants who rated a product's ethics as more important showed the opposite effect: they believed that the toothpaste with superb ethics would whiten better and would be more likely to provide all the benefits they desired in a toothpaste.

A second study confirmed the interaction between the ethicality of a product and ethical issue importance ratings in a new product context. Since toothpaste ingredients may also have health consequences for the consumer, we chose a new category without this confound: laundry detergent. Consistent with our findings in Study 1, we found a significant interaction between ethicality of the detergent and ethical issue importance ratings with both dependent measures: likelihood of the product's being recommended by Consumer Reports, $F(1, 179)=17.32, p<.0001$, and likelihood of providing the benefits desired in a detergent, $F(1, 179)=4.84, p<.05$.

While these initial studies support H1, Study 3 intends to test H2, i.e. whether subjects will believe that ethical=less effective when asked to infer what the average person would believe about the focal products (as opposed to what they personally believe). In addition, this study will use a broad, nationally representative sample to improve generalizability of the results. Finally, Study 3 will explore what effect precommitment to the intuition has on subjects' responses. This will be accomplished by varying the order of questions such that we can determine whether the ethical importance ratings were influenced by subjects' prior inferences. While we have no a priori hypothesis for this manipulation, our intent is to understand the degree to which the ethical importance rating is an accurate assessment of subjects' beliefs as opposed to resulting from subjects' desire to be consistent with their prior inference ratings.

Examining the Influence of Prominent on Nonprofit Organizations

Christine M. Bennett, University of Minnesota, USA

Hakkyun Kim, University of Minnesota, USA

Barbara Loken, University of Minnesota, USA

Abstract

Corporate sponsorship is an often used fundraising strategy for nonprofit organizations and is considered to be a "win-win" situation for the sponsoring company as well as the nonprofit. While prior research suggests that corporate sponsorship can positively affect the sponsoring company, little research to date has investigated the impact of such sponsorships on the nonprofit particularly when it is the nonprofit that is communicating the existence of the sponsorship. We address this question and examine the impact of corporate sponsors on people's perceptions of and willingness to support nonprofit organizations. Results from an experiment suggest that revealing corporate sponsors may, under certain conditions, *negatively* affect a nonprofit's effort to garner financial support from the general public.

"I'm Glad I Did" or "I Wish I Had:" The Comparative Effects of Satisfaction and Non-Purchase Regret on Future Purchase Intentions

Henrik Hagtvedt, University of Georgia, USA

Matthew Lancellotti, California State University Fullerton, USA

Vanessa Patrick, University of Georgia, USA

Extended Abstract

It seems counterintuitive that a consumer who does not experience your product may be just as valuable as your most satisfied customers. Even less obvious is the recommendation that marketers design promotions such that they can highlight missed opportunities to consumers who did not take advantage of the offer. In this research we examine regret for a forgone purchase opportunity and

demonstrate that non-purchasers reveal a motivation to purchase the product in the future similar to customers who experienced the product and were satisfied.

Traditionally, marketers have focused a great deal of effort on understanding customers who have tried and used the product. The issue has always been to keep these customers satisfied and to find ways to ensure that they continue to purchase the product in the future. The flip side of this equation is to ensure that consumers feel a minimal amount of dissatisfaction and regret for their purchase. The study of regret has been restricted to regret following some action, most often a purchase (Cooke et al. 2001; Tsiros and Mittal 2000). Such a focus is clearly relevant and justified given the negative effect that feelings of dissatisfaction and regret have on repeat purchase and brand loyalty, among other post-consumption outcomes.

In this research we propose that the feelings of regret following a forgone opportunity, i.e. regret for inaction, represents a potent driver of consumer behavior. Unlike regret for inaction examined in the psychology domain, regret for inaction in the consumption arena might be assuaged by the possibility of a similar opportunity arising in the future.

Prior research on inaction inertia suggests that forgone opportunities increase the likelihood of similar inaction in the future (Arkes et al. 2002). At least this seems to be the case when the current opportunity is less attractive than the forgone opportunity, although still positive in an absolute sense (Tykocinski and Pittman 1998). However, it may not be the case when the current opportunity is as attractive as or more attractive than the forgone opportunity. We theorize that consumers who experience inaction regret tend to idealize the forgone opportunity (Newby-Clark and Ross 2003), construing it to be positive and satisfying and eliciting a necessity to act by the contrasting of present reality with favorable expectations (Oettingen et al. 2001). In this case, regret for inaction serves as motivation not to make the same mistake twice. Indeed, in two studies we examine the impact of inaction regret on future purchase intentions and demonstrate that regretful non-purchasers are just as likely as satisfied customers to purchase in the future, and also to pay a premium for this purchase.

Study 1 used a critical incident method to examine inaction regret arising from forgone opportunities versus the feelings of satisfaction and dissatisfaction arising from taken opportunities in a consumption context. One hundred and eighty-two undergraduates participated. Participants in the regret for inaction condition were asked to think about a product that they had not bought, but wished they had. Participants in the satisfaction and dissatisfaction conditions were asked to think about a product/service about which they felt either "much more happy or satisfied than you expected you would" (satisfaction condition) or "much less happy or satisfied than you expected you would" (dissatisfaction condition). After describing the incident, participants answered questions designed to assess future purchase intent and willingness to pay more. Results revealed no significant differences in either the likelihood of future purchase ($M_{\text{regret}}=5.91$ vs. $M_{\text{satisfaction}}=5.92$) or the willingness to pay more for the future purchase between the inaction and satisfaction conditions ($M_{\text{regret}}=4.67$ vs. $M_{\text{satisfaction}}=5.08$), but significant differences in both between these conditions and the dissatisfaction condition ($M_{\text{dissatisfaction}}=2.78$, $F(2, 156)=63.11$, $p<.05$ for likelihood of future purchase and $M_{\text{dissatisfaction}}=2.11$, $F(2, 156)=51.30$, $p<.05$ for willingness to pay more). These results indicate that consumers who experience regret for inaction are likely to purchase the item the next time they have a chance, and that they are willing to pay a premium for it.

Study 2 was designed to evaluate key findings from study 1 in an ecologically valid environment. One hundred and twenty-five undergraduates who had just returned from spring break completed a questionnaire online. Fifty-one participants had taken a trip during spring break and fifty-eight of the remaining participants wished they had. Next, satisfaction with spring break, regret with spring break, the desire to take a vacation in the future, and the willingness to commit resources to ensure a future vacation were measured. Results revealed that participants who had taken a vacation were significantly more satisfied with spring break than those who had not done so. A median split was conducted on reports of inaction regret for participants who had not gone on vacation, dividing participants into a low regret group (31 participants)³ and a high regret group (27 participants). Participants who had gone on the trip and those who had high inaction regret revealed an equally strong desire to go on a trip at the next opportunity ($M_{\text{satisfaction}}=6.54$ vs. $M_{\text{high regret}}=6.72$), and one that was significantly stronger than those who had low inaction regret ($M_{\text{low regret}}=5.78$; $F(2, 103)=13.43$, $p<.05$). Similar results were revealed for anticipated regret ($M_{\text{satisfaction}}=5.33$, $M_{\text{high regret}}=6.15$, $M_{\text{low regret}}=4.37$; $F(2, 103)=8.21$, $p<.05$) and for the willingness to commit resources to go on the trip at the next opportunity ($M_{\text{satisfaction}}=6.57$, $M_{\text{high regret}}=6.64$, $M_{\text{low regret}}=5.75$; $F(2, 103)=10.67$, $p<.05$). These results indicate that when consumers feel considerable inaction regret, this feeling leaves them just as motivated to seek out the forgone product at the next opportunity, just as likely to anticipate regretting forgoing the product, and just as likely to commit to purchasing at the next opportunity as are those consumers who did avail of the opportunity and enjoyed the product experience.

An important implication of these findings is that potential customers who have missed or declined opportunities to purchase may be more important than previously surmised. Past promotional efforts directed at those customers are not necessarily sunk costs, with no anticipated future value. Instead, managers may take advantage of the forgone purchase opportunities by highlighting them in retrospect, thus intentionally inducing inaction regret.

Food for Thought: Role of Counterfactual Thinking in the Interpretation of Health Claims and Nutrition Information

Khaled Aboulnasr, Florida Gulf Coast, University, USA

Anu Sivaraman, University of Delaware, USA

Extended Abstract

According to the American Heart Association, obesity represents the number two preventable cause of death in the United States and leads to about 300,000 deaths each year (Center for Disease Control and Prevention). This trend is largely driven by an inactive lifestyle, a poor diet and inferior nutrition choices. In an effort to help consumers make more healthful food choices, government agencies have passed measures specifically aimed at strictly limiting misleading health claims used on food packages (Ford et al. 1996). The way consumers use, interpret and attend to both health claims and nutrition information has received considerable research attention due to the significance of the topic to packaged food marketers as well as public policy makers. (Ford et al 1996; Kozup, Creyer and Burton 2003). In the present study, we seek to extend the literature on consumers' interpretation and use of health claims and nutrition information by connecting it to the literature on counterfactual thinking (CFT).

Counterfactual thinking is the practice of mentally generating alternative realities. According to Page and Colby (2003), counterfactual thinking refers to the process of looking back at past events and mentally imagining how these events could have turned out differently. Krishnamurthy and Sivaraman (2003) suggest that the careful elaboration of information involved in the process counterfactual thinking influences future problem solving behavior and future attitude formation. Hence, by mentally creating alternative realities to past events, individuals may outline prescriptive actions for future encounters (Page and Colby 2003). We propose that the process counterfactual thinking may alter prior findings in regards to the relationship between health claims and nutrition information on food packages on the one hand and product nutrition attitudes and evaluations on the other.

We argue that consumers engaged in an elaborative processing of information through attempting to mentally construct alternative realities to a past negative event are more likely to carefully scrutinize subsequently encountered information. Hence, they will be more likely to distinguish between superior and inferior arguments in favor of a food package that promises better health. Accordingly, we predict that health claims will become especially salient to this group of consumers and as a result have a stronger effect on attitude formation and product evaluation. We also expect that this effect will be positively moderated by the presence of favorable nutrition information. In contrast to prior studies suggesting a limited effect of health claims on attitudes and intentions in the presence of nutrition information, we hypothesize that counterfactual thinking may intensify a positive effect of health claims on product nutrition attitudes. Furthermore, we argue that such effect is affected by the alignment of the nutrition information to the health claim.

The design of our first study was a 2(CFT vs. Control) x 2(health claim vs. no health claim) x 2(favorable nutrition information vs. unfavorable nutrition information.) The design for this study is identical to study 1 of Kozup, Creyer and Burton (2003). One hundred and fifty four undergraduate students participated in the study. The stimuli were identical to the stimuli developed by Ford et al. (1996). Subjects in the counterfactual thinking condition were instructed to indicate how this experience could have turned out differently while those in the control condition were asked to indicate how realistic this scenario was. All dependent measures were assessed using items similar to those used by Kozup, Creyer and Burton (2003). All dependent measures were assessed with seven-point scale, and on all scales higher values indicated a more positive response. Mean scores were used in the case of multi-item measures.

Multivariate effects of the health claim (Wilks' Lambda=0.06, $F=3.34$, $p<0.03$), nutrition information (Wilks' Lambda=0.25, $F=15.92$, $p<0.01$) were significant and interaction effect between health claim and nutrition information was not significant. There was no main effect of CFT (Wilks' Lambda=0.03, $F=1.52$, $p<0.22$). None of the other two-way interactions were significant. The three-way interaction between health claim, CFT, and nutritional information was marginally significant (Wilks' Lambda=0.04, $F=2.15$, $p<0.10$). Specifically, follow-up univariate analyses revealed a marginally significant interaction effect of health claim and CFT on nutrition attitude ($F=3.74$, $p<0.09$) in the favorable nutrition information condition. Thus, when the nutrition information was favorable, exposing subjects in the control condition to health claim negatively influenced the nutrition attitude whereas exposing subjects in the CFT condition to the health claim positively influenced their nutrition attitude. The univariate analyses also indicated a main effect of favorability on all three dependent variables (Nutrition Attitude: $F=59.28$, $p<0.01$; Attitude toward the product $F=62.93$, $p<0.01$; Purchase Intentions $F=44.49$, $p<0.01$).

Study 1 examined the influence of counterfactual thinking on the effect of health claim and nutrition information on health-related beliefs. Consistent with prior research, we find that the effects of health claim and nutrition information on judgments and favorability are independent. However, we find that the interaction effect of health claim and counterfactual thinking on nutrition attitude is strengthened in the presence of favorable nutrition information. This result is in contrast to prior research that has suggested that, in the case of packaged food products, the effect of health claims are independent of the effects of available nutrition information.

One of the limitations of this study is that we did not study the effect of counterfactual thinking on health claims when the ambiguity of nutrition information was varied. The use of the nutrition information panel on food packages is known to be influenced by the ability of consumers to interpret such information (Ford et al. 1996). Another limitation of Study 1 is that we did not study the effect of counterfactual thinking on health claims when no nutritional information was present. Study 2 addresses these limitations and also further

investigates the process by which counterfactual thinking influences the interpretation and use of health related claims and nutrition information.

Choosing to Conceal: An Investigation of the Impact of Social Influence on Luxury Consumption

Christine M. Bennett, University of Minnesota, USA

Jane E J Ebert, University of Minnesota, USA

Extended Abstract

Throughout the years various theories have been proposed to explain why people engage in conspicuous consumption. Veblen (1912) suggested that the purchase of expensive goods and services is used to signal status and wealth to others. McCormick (1983) suggests that people buy expensive items in an attempt to "keep up with the Joneses" due to a desire to maintain their self-esteem. Regardless of the motivation, both theories suggest that when people buy luxury goods they intend to make their purchase known by either talking about it or showing it off in some way. However, the current research investigates occasions when people may conceal their luxury purchases from others. In four studies, we examine whether and under what conditions the concealment of luxury purchases from others occurs.

Prior research by Kivetz and Simonson (2002) indicates that people need to force themselves to indulge through pre-commitment and that they need to earn the right to indulge through higher levels of expended effort. This stream of research prompts questions concerning what people do when indulgences have not been earned—will they indulge anyway and conceal their indulgences? In the first of two completed studies we explored the circumstances under which people tend to conceal purchases from others. Findings from this study indicate that consumers were more likely to conceal their purchases from others when the item purchased was a luxury or high-priced item. Also, participants tended to conceal from some friends and not other friends. For example, one participant indicated that she paid \$100 for a pair of jeans because they were an excellent fit. However, this participant decided to conceal the purchase from her boyfriend because "he'd think they were too much money" yet she revealed the purchase to her girlfriends because "they would understand how hard it is trying to find a pair of jeans that fit." Similarly, another participant indicated that he concealed the purchase of a \$400 cell phone from his friends because "it was expensive"; however, this participant revealed the purchase to his parents because he felt "closer to his parents." Overall, the findings from this exploratory study suggest that people do not always want to attract attention to the amount of money they spend on an item and that luxury good consumption does not always occur in order to signal wealth and impress others.

The second study investigated whether type of friend (e.g., friend seen day to day versus a friend seen less often) influenced whether or not participants concealed a luxury purchase. We expected that a friend seen day to day would be more aware of the participant's past purchase behavior and may be more judgmental than a friend seen less often. In general, participants in the day to day condition reported they normally told each other about the products they purchased for themselves to a greater degree than participants in the less often condition shared this information with each other. This is reasonable since participants in the day to day condition have more interaction with their friend as well as more opportunities to disclose information about their lives and consumption patterns. In the experiment, however, after purchasing a luxury good, participants in the day to day condition were more likely to conceal the luxury purchase from their friends than were participants in the less often condition. An investigation of the open-ended responses indicates that participants were particularly concerned about their friends knowing how much they paid for the luxury good. Here, we have converging evidence that concealment of luxury occurs and that people are not always trying to signal status or wealth with their luxury goods purchases. Specifically, people would prefer that their friends *not* know how expensive an item happens to be.

Prior research suggests that people will allow themselves indulgences when those indulgences can be justified (Prelec and Herrstein, 1991; Shafir, Simonson and Tversky, 1993). Kivetz and Zheng propose two routes to justification: through effort or excellent performance or without depleting income. This research raises the question of whether justification needs to be made to self, others or both. In two more studies we explore this question and examine whether effort (high vs. low) and a friend's awareness (public vs. private) of said effort influences the decision to conceal the purchase of a luxury good. In study 3, our manipulation of high effort is a natural one in that the survey was administered during the week of midterms, a demanding time for undergraduates. Low effort will be manipulated by administering the survey during a normal week. Whether the friend is aware or not (public vs. private) of the effort is measured asking participants about their friend's level of awareness. In study 4, both effort and awareness are manipulated. The public versus private factors are included to examine whether indulgence needs to be justified to self, to others or both. We expect that participants will be least likely to conceal a luxury purchase when effort is high and public and expect that participants will conceal most when effort is low and public. In the high effort condition we expect participants to conceal more when the effort is private versus public because participants are less

able to justify the indulgence to the friend who is unaware of their high effort. For this same reason, we expect participants in the low effort condition to conceal more in the public condition versus private condition. Overall, we predict that amount of effort and the ability to justify indulgence will significantly impact a consumer's tendency to conceal luxury goods purchases.

From Egotism to Averseness: The Role of Implicit Self Judgments in Seller Choice

Luke Kachersky, Baruch College, City University of New York, USA
 Hyeong Min Kim, Baruch College, City University of New York, USA

Abstract

Actual bidders in Internet auctions were more likely to participate in auctions when sellers' screen names had the same first character as their own screen name. This is a case of implicit egotism, whereby people gravitate toward things that resemble the self, and the first such case to be driven by a non-birth given characteristic. However, bidders were less likely to win higher-priced auctions under the same conditions. We propose that this reversal of implicit egotism is due to the salience of risk that may have negative implications for the self.

John enjoys participating in Internet auctions. His screen name is *pguy111*. One day he comes across two auctions for a new DVD. One seller's screen name is *patrick6*, while the other's is *matman*. Judging from information like the sellers' feedback ratings, John believes both are equally trustworthy and that neither one's auction represents a potential cost savings over the other. In which auction will John participate? It may be expected that John will be indifferent. In this paper we propose that John will be more likely to participate in *patrick6*'s auction than *matman*'s auction. Further, we propose that if the auction was not for a DVD, but for a more expensive item such as a DVD player, then John might tacitly avoid *patrick6*'s auction.

One reason John may choose to participate in *patrick6*'s auction is because of John's apparent self association with the letter *P*, as indicated by the choice of his own screen name. Research on implicit egotism indicates that for the most part people feel good about themselves and that these positive associations spill over into judgments of stimuli that share even the most superfluous characteristic with the self such as the initial of their first name (Jones, Pelham, and Mirenberg 2002; Pelham, Mirenberg, and Jones 2002). The implicit egotism effect has been shown to be truly implicit, outside of conscious awareness (Jones et al. 2004). Implicit egotism has been shown to influence major life decisions including choices of professions (Pelham, Mirenberg, and Jones 2002; e.g. Dennis is likely to be dentist.), living locations (Pelham et al. 2003; e.g. Florence is likely to live in Florida.), and romantic partners (Jones et al. 2004; e.g. Jennifer is likely to marry Jesse.). It has also been shown to influence brand choices (Brendl et al. 2005).

Based on this line of research, if John associates himself with the letter *P*, then he should have positive associations about sellers who also use the letter *P* to represent themselves. Thus, while his conscious comparison of *matman*'s and *patrick6*'s auctions may deem them equal, we argue that John should be more likely to participate in the latter's auction because his implicit judgment of *patrick6* should be more positive than that of *matman*. This is an important contribution because extant research shows that implicit egotism stems only from a person's birth-given characteristics. This research shows that the effect of implicit egotism is more prevalent than previously thought because other types of self-associations (e.g., pseudonym) may lead to implicit egotism.

To date, research has shown only positive effects of implicit egotism. However, negative effects are theoretically possible. For example, if John encounters someone who resembles himself, like *patrick6*, and that person potentially has negative attributes, would John still gravitate toward this person? Prior research indicates that an individual will distance oneself from a group when the group exhibits undesirable attributes that might reflect negatively on oneself (Cialdini et al. 1976; Snyder, Lassegard, and Ford 1986; Schimmel et al. 2000). When John bids on Internet auctions, he is aware that sellers might act fraudulently. When auction prices are high, the threat of fraud should loom particularly large. John should not want to associate his self-concept with the negative attributes that sellers may possess. Therefore, if auctions for an item have high prices, then John should avoid those auctions in which the seller's screen name shares characteristics with his own. If *matman* and *patrick6*'s auctions are for a DVD player, then John should avoid *patrick6*'s auction because he does not want to associate potentially negative characteristics with his self-concept. As discussed next, our data support this argument. Thus, this research makes another important contribution by demonstrating the reversal of implicit egotism for the first time.

A field study demonstrates the influence of implicit egotism in Internet auction participant behavior. Data was collected from the popular Internet auction site Ebay from November 2005 through January 2006. The set included 123,639 unique auction-bidder-seller combinations and 59,208 unique auction-winner-seller combinations. To ensure that we were studying a truly implicit effect, we examined

the likelihood of bidding on an auction when only the first character of the seller's screen name matched the first character of the bidder's screen name. Indeed, bidders had a greater than chance likelihood of participating in an auction when the first character of the seller's screen name matched the first character of their own. To examine the hypothesis that the implicit egotism effect would reverse for high priced auctions, we looked at winner-seller pairs because auction winners are financially committed to the transaction. Consistent with our theorizing, for auctions with high bids over \$50, bidders had a less than chance likelihood of winning an auction when the first character of the seller's screen name matched their own. Experimental data currently being collected will replicate and extend these findings.

This research has a number of implications. Implicit egotism not only causes people to gravitate toward things that resemble the self. It also drives people away from self-resembling entities when those entities have potentially negative implications for the self. This opens up a new line of questioning in implicit egotism research. For example, would people named Carl have a higher than chance likelihood of living in Compton, California, notorious for its housing projects and gang activity? Additionally, implicit egotism had been primarily demonstrated through birth-given characteristics (name, birthday). This study shows that implicit egotism can also work via characteristics one selects to represent oneself (e.g., job title).

An Exploratory Study on Attitude Toward Luxury Products, Counterfeits and Imitations

Brigitte Muller, HEC Lausanne, Switzerland

Bruno Kocher, HEC Lausanne, Switzerland

EXTENDED ABSTRACT

This research investigates how individual and company-controlled variables affect attitudes toward original luxury goods, counterfeits and imitations. We distinguish original products, which are "goods for which the mere use or display of a particular branded product confers prestige on their owners" (Grossman & Shapiro 1988, p.82), from counterfeits, which are strict copies of genuine products (Kay 1990) and from imitations "designed as to *look like* and make consumers *think of* the original brand" (d'Astous & Gargouri 2001, p.153). Consumer's attitude toward brand imitations and counterfeits has a great impact on brand management decisions and has been recognised as an important stream of research (Keller, 1998). Although several academicians (e.g. d'Astous & Gargouri, 2001; Warlop & Alba, 2004) studied this field, the literature remains scarce and largely incomplete.

The purpose of this research is to study a main effect (the impact of product type on consumers' attitude), a potential moderator (conformity) and several items that may hinder the purchase of counterfeits or imitations.

Hypotheses

Our main proposition is that consumers will respond differently to original products than to counterfeits or imitations. The purchase of luxury goods is primarily intended to "satisfy buyers' appetite for symbolic meanings" (Dubois & Duquesne 1993, p.37). Since originals and counterfeits look exactly the same, the attitude toward these two types of products should not differ. However, imitations may be distinguished quite easily from an original or a counterfeit and should therefore be less liked. We propose:

- H1: Attitude toward original luxury products will be different from counterfeits and imitations. Specifically, attitude toward:
- (a): originals is the same as toward counterfeits
 - (b): originals is more positive than toward imitations
 - (c): counterfeits is more positive than toward imitations

However, this first hypothesis is moderated by a personal variable. "Individual behavior is motivated in large part by social factors [desire for prestige, esteem, popularity, acceptance... which] tend to produce conformism" (Bernheim 1994, p.842), defined as an

individual's behavior in the sense of the conventions of his peer-group. Consumers being highly conform to the rest of the society and wanting to appear as a part of the group (e.g. by dressing similarly to one's friend, Lumpkin 1985), will evaluate original products more favorably than consumers not caring about conformity to the group. Following these arguments, we propose that:

H2: Attitude toward the product will vary according to the level of conformity. Specifically:

- (a): originals are evaluated more positively (the same) than counterfeits by consumers with a high (low) level of conformity
- (b): originals are evaluated more positively (the same) than imitations by consumers with a high (low) level of conformity
- (c): counterfeits are evaluated more positively (the same) than imitations by consumers with a high (low) level of conformity.

Concerning company-controlled variables, we intended to assess factors which could hinder consumers to buy counterfeits or imitations. Eight items were chosen based on a literature review and on a pretest: perceived level of quality, legal issues, image perceived by others during product usage and purchase, external aspect, price, ethical aspects and made in of the product.

Method

Materials: Two brands (handbags and polo shirts) from the luxury industry were chosen because they were familiar to almost everybody and, even if expensive, were not out of touch for the respondents. Additionally, a lot of counterfeits and imitations for these two brands are available on the market.

Procedure: 62 undergraduate students participated in the study, comprised of two ostensibly unrelated surveys. The first one inquired about personal characteristics like dress conformity (Lumpkin, 1985) and other variables not taken into account in this study. In the second part, a 3x2 between-participants experiment was conducted (type of brand: original vs. counterfeit vs. imitation; conformity: low vs. high). The three stimuli of the experiment were composed of a scenario and an illustration (visual / semantic) describing one of the three types of products.

After time for reflection, the respondents were asked to rate their attitude toward the product (Sujan & Bettman, 1989) and the eight items which could possibly hinder their consumption. Every respondent was randomly affected to one of the three scenarios and evaluated the two brands. This gives us a total sample of 124 observations.

Results and Discussion

Manipulation checks indicated that the three types of products were perceived as having different levels of similarity compared to an original product ($M_{original}=6.05$, $M_{counterfeit}=5.45$, $M_{imitation}=4.61$ $F(1, 103)=15.962$, $p<.01$).

A 3 X 2 ANOVA was conducted with attitude toward the product as dependent variable, type of product and conformity as between-participant factors. Low/high groups on the conformity scale were constituted using a conventional median split.

The attitude toward original products, counterfeits and imitations was different ($M_{original}=4.44$, $M_{counterfeit}=3.75$, $M_{imitation}=3.11$, $F(1, 102)=7.38$, $p= 0.01$). Post hoc tests revealed that this difference is only significant between originals and imitations. These results confirm H1a, H1b and infirm H1c.

The two-way interaction between type of products and conformity was significant by Hotelling's criterion ($F(1, 99)=5.45$, $p<.01$). Planned contrasts revealed that the evaluation of the three types of products differed significantly for consumers with a high level of conformity ($F(2, 99)=11.27$, $p<.01$) but not for consumers with a low level of conformity ($F(2, 99)=.632$, $n.s.$). For high conformity individuals, participants evaluated more positively originals ($M_{HC Originals}=5.26$) than counterfeits ($M_{HC Counterfeit}=3.89$, $p<.05$) and imitations ($M_{HC Imitations}=2.98$, $p<.01$). For low conformity individuals, the evaluations of the three products are the same ($M_{LC Originals}=3.56$, $M_{LC Counterfeit}=3.65$, $M_{LC Imitations}= 3.21$, $n.s.$). Therefore, we confirm H2a and b. On the contrary, counterfeits and imitations were evaluated the same way by high and low conformity individuals, which infirms partially H2c.

Concerning the company-controlled variables, results indicate that the legal and ethical issues are not really taken into account when considering purchasing a counterfeit or imitation. The criterions identified as most important concern primarily the external aspect of the product and its quality.

On basis of this first research, high conformity consumers may be identified as an interesting target group since their product attitude is more favorable towards original products. In a second study, we plan to investigate not only attitudes but also purchase intentions and responses to the identified factors hindering the purchase of counterfeits and imitations. Therefore we project to develop several advertising stimuli in order to verify their effects on purchase intentions.

The Effect of Market and Merchant Comparisons on Customer Satisfaction: The Moderating Role of Information Uncertainty and Price Negotiation

Velitchka D. Kaltcheva, Loyola Marymount University, USA
Michael Tsiros, University of Miami and ALBA Graduate Business School, USA

Abstract

We examine whether consumers are influenced by comparisons to other consumers and to the merchant. Past studies have estimated the impact that each type of comparison has on customer satisfaction separately, but have not examined the relative impact of each comparison simultaneously. We also examine the moderating effects of information uncertainty and price negotiation on the relationship between comparison information and customer satisfaction. Results show that unfavorable market comparisons impact customer satisfaction significantly more strongly than unfavorable merchant comparisons. However, no such difference is found for favorable comparisons. Information uncertainty and price negotiation decrease the impact of unfavorable market and merchant comparisons.

Introduction

Past studies have shown that comparative information has an effect on consumer purchase evaluations. For instance, some studies focused on comparisons to other consumers while others looked at comparisons to the merchant. Past research has found that both market and merchant comparisons influence consumer evaluations of a purchase experience.

This research has two contributions. First, we examine the *relative* impact that comparisons to the market and comparisons to the merchant have on consumer evaluations of their purchase experience. Second, we examine the moderating effects of information uncertainty and price negotiation on the relationship between market/merchant comparisons and customer satisfaction.

Hypotheses

Since earlier studies examined only one type of comparison at a time, there is no evidence which type of comparison may have a stronger impact on customer satisfaction. However, people are likely to pay attention to information to the extent that it is relevant to their decision. For example, paying more than the market price implies that the consumer would probably pay less for the same item if s/he went to another merchant. On the other hand, getting more or less than the merchant typically has little direct impact on the consumer's wallet. Thus, we expect:

Hypothesis 1: (a) Favorable comparisons to the market affect satisfaction more strongly than favorable comparisons to the merchant; and (b) unfavorable comparisons to the market affect satisfaction more strongly than unfavorable comparisons to the merchant.

The more ambiguous and uncertain a piece of information is believed to be, the less likely people are to attribute value to it and incorporate it into their decisions. Consumer certainty in the market price and the merchant's net outcome (output–input) varies with the consumer's familiarity with the product category, the market, and the merchant. For instance, whereas consumers typically can only speculate about the merchant's net outcome from a sale, consumers familiar with the merchant's business or the industry (such as market analysts specializing in the industry) may have a fairly accurate idea of the merchant's outcomes. Thus, we propose:

Hypothesis 2: Information uncertainty decreases the impact of (a) comparisons to the market and (b) comparisons to the merchant on customer satisfaction.

Price negotiations are common in farmers' markets, garage sales and flea markets, the real estate market, and in markets for used products such as automobiles. Consumers at such marketplaces are likely to view initial comparison information as less relevant because the outcome of the transaction can potentially be changed through negotiation. Thus, we can expect that:

Hypothesis 3: Price negotiation decreases the impact of (a) comparisons to the market and (b) comparisons to the merchant on customer satisfaction.

Method

Two studies were conducted. In both studies, participants were asked to evaluate 25 hypothetical transactions with a local light fixture store. Participants were asked to imagine considering a table lamp for purchase. The retail price of the table lamp was \$50 in all 25 transactions. Two variables—the market comparative outcome and the merchant comparative outcome—were systematically varied in the hypothetical transactions. The market comparative outcome had five levels. At the midpoint level, the retail price was the same as the market price. There were two levels where the retail price was above the market price and two levels where the retail price was below the market price. Similarly, the merchant comparative outcome also had five levels: the midpoint level where both the consumer and the merchant benefited equally; two levels where the merchant benefited more; and two levels where the consumer benefited more. For instance, in one condition the transaction was described as follows: "The market price is \$50. You save \$10 from the market price. You benefit \$10 less than the store from the transaction."

Manipulation of Information Uncertainty and Price Negotiation. The market comparison information and the merchant comparison information were administered either as an exact number (low uncertainty) or as a range (high uncertainty). In the “no price negotiation” condition, participants were told that prices in the store were final and consumers could not negotiate prices at the store. In the “price negotiation” condition, participants were told that it was fairly common to negotiate prices at the store and were specifically instructed that the 25 scenarios showed transaction outcomes before any price negotiations had taken place.

Measures. Participants were asked to rate their satisfaction with each of the 25 hypothetical transactions on an eleven-point Likert scale anchored between “do not like at all” and “like very much.” Participants also completed manipulation checks.

The main difference between study 1 and study 2 was that, in study 1, participants saw the difference between the item’s retail price and the market price (the market comparison information), and the difference between their outcome from the transaction and the merchant’s outcome from the transaction (the merchant comparison information). In study 2, participants saw the market price, the product’s price, and the merchant’s total product cost and were left to infer the differences in outcomes.

Results

Preliminary results indicate some interesting relationships. More specifically, unfavorable market comparisons had a significantly stronger impact on customer satisfaction than unfavorable merchant comparisons in all conditions in both studies. In contrast, in all conditions in both studies, favorable market comparisons were not more impactful than favorable merchant comparisons. Thus, hypothesis 1b received full support, but hypothesis 1a was consistently disconfirmed.

In addition, information uncertainty significantly decreased the impact of comparison information on customer satisfaction for unfavorable merchant comparisons (when the market comparison was favorable) in study 1, and for unfavorable market comparisons in study 2. Hypothesis 2 was not supported for unfavorable market comparisons in study 1 or for any favorable comparison (market or merchant) in either study.

Finally, price negotiation had exactly the same pattern of effects as information uncertainty. Thus, hypothesis 3 was supported for unfavorable merchant comparisons (when the comparison to the market was favorable) in study 1, and for unfavorable market comparisons in study 2.

Do I Belong? Clothing, Group Membership, and Identity During the College Transition

Mark A. Rademacher, University of Wisconsin–Madison, USA

Clothing has always been “a rich source of signification” for teenagers (Danesi, 1994, p. 76). Fashion has also been described as “salient markers in [individuals’] narratives of personal history” and as “a repository for dreams of an envisioned good life” (Thompson & Haytko, 1997, p. 35). Unlike individuals’ personal possessions, which can be either private or public markers of identity, clothing by definition is a public marker of identity. That is, in a consumer culture clothing reflects various aspects of individuals’ identity to others, including group identity. Consequently when individuals experience identity uncertainty as they transition from one peer culture to another it is likely that they will actively reevaluate the communicative aspects of their wardrobe and adjust it accordingly in an attempt to create and communicate a socially acceptable identity to members of the new peer culture. Moreover, clothing aids in individuals’ attempts to maintain a coherent self-narrative during this period of identity uncertainty.

This paper, therefore, attempts to investigate what role clothing plays in helping individuals negotiate their changing identity during the high school to college transition. The paper begins by discussing how college freshmen engage in anticipatory consumption and pack clothing they believe is appropriate to communicate a college identity. The paper then examines the process by which informants learn to decipher the college fashion-meta code and adapt their fashion to conform to their perceptions of the group norm. Finally, the influence of the college peer culture on students’ fashion for special occasions, especially when they “go out,” is discussed.

Method

Overview and Rationale

The current study answers the call by Corsaro and Eder (1990) to employ longitudinal research to “chart children’s transitions from one peer culture to another” (p. 216). Longitudinal interviews were conducted with college freshmen at the beginning and end of their first semester to examine fashions’ role in the maintenance and creation of identity over time. A longitudinal approach is superior to cross-sectional (e.g., Karp et al., 1998; Mehta & Belk, 1991) and cohort (e.g., Silver, 1996) analysis because it allows the researcher to observe informants’ use of fashion as it changes in relation to both time and make-up of students’ self-concept and social networks. Previous research confirms qualitative methods such as depth interviews are the preferred means of measurement for this phenomenon for their ability to provide detailed descriptions of informants’ lived experiences (e.g., Hill & Somin, 1996; Mehta & Belk, 1991; Silver, 1996). Thus, the current study employed a semi-structured interview format because it provided informants some structure and direction during the interview while allowing them to discuss any additional topics they viewed as relevant. Further, this approach allowed informants to discuss their experiences in their own terms, accounting for the complexities of their lived experiences.

Informant Recruitment

Informants from a large Midwestern university were recruited via flyers posted in heavily trafficked areas around campus and via announcements made in entry-level English, Sociology, and Journalism courses. This approach resulted in 21 inquiries and 19 students (16 female, 3 male) agreeing to participate in the interview process. As compensation for their participation, informants’ names were entered into two random drawings for \$50. One drawing occurred at the completion of each round of interviews. This sample, although limited, is consistent with sample sizes of other studies in this field (e.g., Karp et al., 1998; Silver, 1996) and the goals of qualitative investigation, which values depth of description over breadth and generalizability.

Interview Schedule

Initial interviews were conducted during the first four weeks of the school year (September 9-24, 2004). Initial interviews ranged from 35-60 minutes. Second interviews were conducted between November 30, 2004 and December 9, 2004. Of the 19 informants who participated in the first interview, 14 (74%) participated in the second interview. Interviews during this round ranged from 26-54 minutes. Interviews were conducted either in a location of the informant's choosing (e.g., their dorm lobby) or in the lead author's office. All interviews were recorded using a digital voice recorder for future transcription.

Interview Structure

Interviews began with "broad stroke" questions (Thompson, Locander, & Pollio, 1989), such as "tell me a little about yourself and your family," that were intended to put the informants at ease and make them feel comfortable sharing intimate details of their lives with the interviewer. Follow-up questions covered a wide breadth of topics, with the emphasis placed on the role of fashion in the transition process. The first interviews began with a discussion of informants' high school experience and their preparation for attending college. The interview then transitioned to students' initial experiences and impressions of college peer culture as well as descriptions of their daily lives. The second interview focused specifically on how students viewed themselves fitting into the college peer culture and whether their life had changed since high school and the beginning of the academic year. At the completion of the interview protocol, 33 individual interviews had been conducted, resulting in just over 26 hours of discussion. Interviews were then transcribed, resulting in a total of 308 single-spaced pages of text. Interviews were printed out and bound and this text served as data for the analysis.

Data Analysis

Data were analyzed when all interviews were completed following the hermeneutic method (Thompson, 1997). First, the researchers began with an impressionistic reading and the identification of recurring themes within each individual interview. This initial reading sought to identify instances where informants explicitly discussed the role of media in their lives. Differences in informants' descriptions of media use across the two interviews were also noted so as to gain a better understanding of how the role of media evolved over time. A second analysis of the data involved cross-informant analysis, the goal of which was to identify "global themes" that emerged from informants' descriptions of their experiences. Because any qualitative analysis is an iterative process, a third reading of the transcripts sought to identify any emergent themes not previously identified. Emergent themes were analyzed based on their prevalence, their impact on the students' transition, and whether or not they contradicted any previously identified themes.

Summary

In response to the primary research question explored by this paper, what role do clothes play in the negotiation of identity, it appears that students change their personal style to reinforce and communicate changes in their self-concept, both to themselves and to their new peers. Adjusting their wardrobe allows individuals to express their changing internal identity to others. That is, by wearing certain peer culture approved clothes, students believe that they can communicate to their peers, individuals who possess and use a great deal of consumption stereotypes (Belk et al., 1982), and ultimately themselves, that they belong to the peer culture. This belief allows students to bolster their internal conceptions of self while dealing with the uncertainty associated with this period of transition.

Prior to their arrival on campus, students pack the "identity suitcase" with clothing they perceive as representative of college style in anticipation of their new identity. Once on campus, however, students must decipher the meanings communicated through others' clothing and decide whether to emulate that style, reject it, or use it to reinforce their previous consumption behaviors (Hirschman & Thompson, 1997). Students appear to most often emulate the style they see on campus in an effort to communicate an appropriate college identity to others and reinforce their own conception of self as a mature college student. Despite informants' assertions to the contrary, communicating a college identity typically involves some level of conformity to the group norm. Data illustrate that informants not only relaxed their personal style to reflect their perceptions of the group norm, but also purchased specific status items, all in an attempt to conform to the larger peer culture. The context of the situation (Silver, 1996) also has a direct influence on students' fashion, as both moving to the college campus and "going out" result in changes in students' prior dress. By adjusting their clothing, students can communicate various social identities to their peers that reflect the appropriate social role; wearing relaxed clothing such as that from The Gap and Abercrombie & Fitch, for instance, signifies the "student" role, whereas, specifically in this instance for women, wearing more upscale brands, "anything with a label," and dressing in a provocative manner signifies the adventurous "party girl" role. Clothing, therefore, allows informants to express various, and often contradictory, social identities to others and to themselves as they negotiate their new college identity. At this point it is interesting to note that male informants were less likely to adjust their wardrobes drastically to fit in to the college peer culture in comparison to the more pronounced changes female informants discussed. Whereas women felt a desire to dress in a more casual fashion and consume different brands than they did in high school, it appears male informants did not feel a similar desire. Rather, the casual preppy style males adhered to during high school appears to remain socially accepted within the new peer culture, potentially making the transition to college less stressful, at least in regard to the expression of a college fashion identity.

Overall, informants' descriptions of the high school and college fashion meta-code are extremely similar. Three possible reasons arise as to why this similarity exists: 1) both high school and college students appear to consume similar media and, therefore, become socialized to and emulate the ideal images the media presents depicting youth culture; 2) high school students emulate college fashion in a process that Goffman (1959) calls "anticipatory socialization" where individuals have already been well versed in the "reality" that is just becoming a reality for them; and/or 3) college students simply carry over their fashion from high school and adjust it slightly to distinguish their current identities from their high school identities by incorporating specific items and brands they perceive as being distinct to the college peer culture into their wardrobes. Future research should explore these possible reasons for the similarities between the two peer cultures in more detail. Regardless, clothing and the negotiation of identity during periods of transition seem to be intertwined. As the informants in this sample moved from the high school peer culture to the college peer culture, they purchased and brought clothing with them that they felt best reflected their identity at that point in time. However, as they slowly incorporated their college identity into their self-concept, specifically for female informants, they also adjusted their style to mirror the dominant peer culture, even taking some articles of clothing home with them. Thus, as they gain greater confidence in their ability to use clothing to enact the college identity, informants

became less reliant on their previous high school identity. Thus, they move one step closer to reconciling the identity uncertainty the transition from high school to college initiated.

What do Rats Think While They Run? Goal Distance and Cognitive Effort Acceleration

Shirley Y. Y. Cheng, University of Illinois at Urbana-Champaign, USA
 Jessica Y. Y. Kwong, The Chinese University of Hong Kong, Hong Kong

Extended Abstract

Recent development in consumer goal research pointed out that goal-achieving effort increases as distance from goal decreases (Kivetz, Urminsky, and Zheng 2006). It was found that consumers accelerate their effort (e.g., making purchase more frequently and in larger quantity) when they approach the reward of a reward program (RP). Looking from the behaviorist perspective, these studies regarded the behavior as a manifestation of rats running toward the food. And the inverse relationship between rate of behavior and goal distance are robustly demonstrated in several studies. This paper argues that changes in the physical efforts are just part of the consequence of goal proximity. Cognitive efforts in processing goal-related information should also increase when one gets closer to the goal. Specifically, we propose that the amount of information people will attend to and the depth of processing should increase with goal proximity.

Generally speaking, people are more likely to engage in systematic and thorough cognitive processing when their involvement in a purchase decision is high than when their involvement is low (Bettman, Luce, and Rayne 1998). For people who are far from the goal of an RP (i.e., at the early stage of an RP), their involvement in the purchase decision is probably low because the subjective value of a distant future reward is minimal (Kirby 1997; Kirby and Herrnstein 1995). One consequence of low involvement is the tendency to use heuristics rather than effortful information processing when making decisions. This is consistent with previous findings that decision to join an RP is influenced by heuristics. Kivetz and Simonson (2003) showed that the perception of one's own effort relative to that of other consumers influences RP joining decisions. This heuristic may even lead to preference for RPs with *greater* effort requirement. Their findings suggest that, when the RP goal is far away, consumers tend to base their decisions on effort heuristics (e.g., how achievable is the RP goal?) and may overlook the reward implications of a decision. Such type of information will then make little impact on their decisions.

On the contrary, for individuals who are close to the goal in an RP (i.e., at the late stage of an RP), the subjective value of the RP reward is augmented by the short temporal distance (Kirby, 1997; Kirby & Herrnstein, 1995). The increased subjective value of the reward would lead to high involvement in purchase decisions, in turns, individuals are more likely to attend to and subject information to thorough and systematic processing. Thus, we expect consumers will make more effortful decisions rather than using heuristics. Taken together, we predict that information pertaining to reward value should have a greater impact on purchase decisions when the RP goal is near than far away.

As an initial attempt, we tested this idea by assessing the differential influences of unit value of RP reward on people's purchase decisions across goal proximity. Unit value of RP reward refers to the equivalent reward value earned per purchase. Consider an RP in which participants will be given a \$150 cash coupon for every 10 stamps collected. The unit value of the RP reward is \$15, which equals to \$150 reward value divided by the total number of purchases (i.e., 10). This information informs people the reward implications (i.e., monetary implication of each purchase in terms of the RP reward). In the example, unit value highlights the chance to get \$15 in return for each purchase. Our basic tenet is that the unit value information of an RP should have a greater likelihood in altering purchase decisions when people subject incoming information to deliberate and thorough processing, but not so when the processing appears to be heuristics based (unit value does not have implications on effort heuristic). In short, we predict an interaction between unit value of RP reward and goal proximity that the availability of unit value will have strong impacts on individuals' purchase decisions only when they are close to the goal but not when they are far from the goal.

The above prediction was supported in a study using the RP described above. Participants (180 undergraduate students) were asked to imagine that they joined the reward program of Supermarket A. In the reward program, they would obtain one stamp for every certain amount of purchase at Supermarket A, and would receive HK\$150 cash coupon once they accumulated ten such stamps. Goal proximity was manipulated by the number of stamps (one vs. eight stamps) participants got. Unit value information was manipulated by the information printed on the stamps—" \$15 reward" in the unit value conditions whereas "reward" in the control conditions. Also, a statement "Each stamp is equivalent to \$15 in cash reward!" was included on the stamp cards in the unit value conditions. Participants had to decide whether to do their purchases at Supermarket A or Supermarket B. While Supermarket B did not have any promotional offers, it is more accessible than Supermarket A.

Consistent with our predictions, unit value influenced repurchase intention only when participants were at the late stage of the RP ($M_{\text{absent}}=5.78, M_{\text{present}}=4.71; F(1, 88)=15.12, p<.001$), but not when they were at the early stage ($M_{\text{absent}}=3.73, M_{\text{present}}=3.89; F<1$). We also found that perceived ability to complete the RP (i.e., effort heuristic) influenced purchase decisions only at early stage but not at late stage. One interesting finding of this study is that effort acceleration (Kivetz et al. 2006) is actually reduced by the presence of certain reward information (lower purchase intention when unit value information is available during late stage). It suggests a possible boundary condition of the goal-gradient effect. While physical efforts to attain a goal increase with goal proximity, this study highlights that cognitive efforts increase in a similar fashion. Increased cognitive effort leads to processing of more information and more effortful decision-making.

The Influence of Consumer Altruism on Complaining Behavior

Piotr Chelminski, Providence College, USA
Robin Coulter, University of Connecticut, USA

Extended Abstract

This paper examines the effects of consumer altruism on complaining behavior in the context of a dissatisfactory marketplace experience. Complaining behavior is conceptualized as consumer voicing directed at the company at fault and negative word-of-mouth communicated to others (Singh 1988). Altruism can be conceptualized as a constellation of actions performed by individuals to assist others that make people performing these acts feel good about themselves. Price, Feick, and Guskey (1995) introduced the concept of *market helping behavior* defined as "acts performed in the marketplace that benefit others in their purchases and consumption." Although market helping behavior was studied in the context of consumers helping each other in shopping tasks and providing marketplace information, this construct also captures altruistic tendencies that might motivate dissatisfied consumers to warn others of negative experiences in the marketplace context. Past research has investigated a number of antecedents of complaining behavior including severity of dissatisfaction leading to complaining (Singh and Wilkes 1996), consumer self-confidence (Bearden and Teel 1980), a psychological need to vent dissatisfaction (Kowalski 1996) and culture (Huang 1994, Keng 1995).

Altruism has been examined in past research in the context of charitable donations (Strahilevitz 1997); however, research has not examined the potential influence that altruism may have on consumer complaining behaviors. The purpose of this study is to examine whether consumer altruism is indeed related to the likelihood for both consumer voicing and negative word-of-mouth. Importantly, research on complaining behavior has demonstrated the impact of the severity of consumer satisfaction. Specifically, Singh and Wilkes (1996) have shown that dissatisfaction intensity affects the consumer complaint response process: the greater the dissatisfaction the more likely the consumer is to engage in a complaint action. Bearden and Oliver (1985) provided evidence that a greater problem cost stimulates both voicing and negative word-of-mouth. Additionally, Richins (1983) has shown that severity of the problem experienced by consumers increases the likelihood of negative word-of-mouth. Thus, severity of dissatisfaction is included as a control variable in this study for both voicing and negative word-of-mouth.

A survey methodology with scenarios manipulating the severity of marketplace encounter failure was used in this study. A mailing of 321 questionnaires to a convenience sample of adult, non-student consumers (25-54 years old) recruited by college students resulted in 280 complete and valid responses (87 percent response rate). Respondents were asked to read a description of a dissatisfactory consumption experience and then indicate their likelihood to engage in voicing (i.e., complaining directly to the company at fault) and negative word-of-mouth (i.e., letting others know about the negative experience). The measure of voicing included two items (Pearson $r=.78$) and the construct of word-of-mouth included three items (Cronbach's $\alpha=.88$). Both measures of consumer complaining were derived from past literature (Day and Bodur 1978, Villarreal-Camacho 1983, Blodgett and Tax 1993). Additionally, a five-item measure of consumer altruism, developed based on the market helping behavior measure (Price, Feick, and Guskey 1995), was included in the survey (Cronbach's $\alpha=.85$).

Two multiple regression equations were used to examine the relationships between consumer altruism, the severity of the dissatisfaction with the encounter and the dependent measures of voicing and negative word-of-mouth. The results indicate that consumer altruism is a statistically significant predictor for both voicing (Adjusted $R^2=.23$, $\beta=.223$, $t=4.24$, $p<.001$) and negative word-of-mouth (Adjusted $R^2=.28$, $\beta=.266$, $t=5.24$, $p<.001$), when controlling for the severity of the encounter failure (also a statistically significant predictor, $\beta=.455$, $t=8.98$, $p<.001$, $\beta=.418$, $t=7.94$, $p<.001$, accordingly).

These results have important implications for marketers and consumer protection agencies. Past research has indicated that, in general, the incidence of consumer voicing is low and this behavior needs to be facilitated (TARP 1986, Vavra 1992). Additionally, past studies have provided ample evidence that consumer voicing can be beneficial to companies in providing negative feedback quickly, improving consumer satisfaction, and preventing negative word-of-mouth among consumers (Fornell and Wernerfelt 1987, Tax et al. 1998, Nyer 2000).

The findings of this research imply that one of the important motivators for consumer complaining is an inclination of consumers to help others by warning them about dissatisfactory marketplace experiences and preventing them from experiencing such negative encounters. It appears that the greater the consumer altruism, the greater the likelihood for voicing the concerns to the company at fault and the greater the propensity to engage in negative word-of-mouth to others. Companies interested in facilitating consumer voicing to find about problems quickly so they can be addressed before a major fallout occurs could use altruism appeals to encourage consumers to voice their concerns by emphasizing the helpfulness of complaining not only for the company at fault but also for the welfare of the current and future consumers. Consumer protection agencies might also consider the use of altruistic appeals in soliciting information about shoddy practices in the marketplace.

The Impact of Culture Orientation on Consumption Impulsiveness and Beer Consumption

Yinlong Zhang, University of Texas at San Antonio, USA

L.J. Shrum, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Beer consumption is an extremely important consumer phenomenon. Given this importance, the lack of research examining the determinants of consumer beer consumption is striking. Further, research has never investigated the role of culture orientation in consumers' beer consumption decision. In this paper, we propose that individualism versus collectivism culture orientation has a systematic impact on beer consumption and consumers' self-construal and the consequent consumption impulsivity are two factors that systematically affect consumers' likelihood of engaging in beer consumption.

Examining the role of self-construal in impulsive consumption decision like beer consumption is a unique contribution of our work. More generally, this research is important for four reasons. First, we fill a conceptual gap in the beer consumption literature by investigating the role of culture orientation. Second, we provide ways to reconcile the seemingly conflicting results in the literature. Our results provide a plausible conceptualization to reconcile the divergent results in the literature. Third, we provide both managerial and public policy implications. Through demonstrating the impact of culture orientation and self-construal on beer consumption, we provide a constructivist view on beer consumption, suggesting that beer consumption is a malleable process and there is ample room for policy makers to exert efforts. Fourth, we offer the first ever experimental evidence on the relationship between self-construal and consumption impulsiveness. Accordingly, we provide the complete causal knowledge among the constructs of culture orientation, self-construal, consumption impulsiveness and beer consumption.

Hypothesis Development

What determines consumers' beer consumption tendency? As reviewed by Hirschman (1992), impulsiveness plays a large role in beer consumption tendency. Given this underlying process, our key argument is that a construct that can systematically affect consumers' impulsive tendency should theoretically affect their beer consumption. We posit self-construal to be one such construct.

Self-construal has been defined as "the relationship between the self and others and, especially, the degree to which they [people] see themselves as *separate* from others or as *connected* with others" (Markus & Kitayama, 1991, p. 226). Two prominent dimensions of self-construal include the degree of *independence* and/or *interdependence* of a person.

Research also posits a relationship between self-construal and consumption impulsivity (Kacen & Lee, 2002). Specifically, when an independent self-construal is activated consumers tend to be impulsive. In contrast, when an interdependent self-construal is activated, consumers tend to be less impulsive.

If self-construal systematically affects beer consumption tendency, then consumers from collectivistic cultures should show less beer consumption tendency than those from individualistic cultures. Formally:

H1: Cultural orientation will influence consumers' beer consumption tendency. Specifically, consumers with a collectivist orientation will tend to have lower beer consumption tendency than consumer with an individualistic orientation.

H2: Self-construal will influence consumers' beer consumption tendency. Specifically, consumers with an interdependent self-construal will tend to have lower beer consumption tendency than consumers with an independent self-construal.

H3: Consumption impulsivity will mediate the effect of self-construal on beer consumption tendency.

Next we report results from three studies. Study 1 and 2 are designed to test hypothesis 1, while Study 3—building on Study 1 and 2—tests hypotheses 2 and 3.

Study 1a,b, & 2

Beer consumption per capita data of forty-two countries in 1999 were used to test hypothesis 1. The consumption per capita of liters serves as the measure of central tendency of each specific country's beer consumption.

Country scores on culture orientation are taken from the Hofstede's cultural analysis website (2005). Income data are from United Nation's website.

Hypothesis 1. We ran a regression on per capita beer consumption level. Specifically, the effect of individualism versus collectivism was significant ($t(1, 40)=3.29, p<.05$). Thus, hypothesis 1 was confirmed.

Beer consumption tendency data of fifty states in 2002 were used to test hypothesis 1 in Study 2. State scores on culture orientation are taken from existing study (Vandello and Cohen, 1999). Hypothesis 1 was confirmed through this approach too.

Study 3

A total of 75 undergraduates from a large southwestern U.S. university participated for course credit. We used a 2 (Self-Construal: Interdependent vs. Independent) between-subjects design.

Participants were told that they were taking part in two different studies. The first study consisted of the priming material for activating the self-construal. This approach of priming self-construal was adapted from past studies (Mandel, 2003).

After this, participants were probed on their attitude toward drinking beer on question of "How do you feel about drinking beer at this moment?" They rated drinking beer on bad vs. good and dislike vs. like ($r=0.92$), with higher scores indicate more positive attitude.

Lastly participants were asked their thoughts on the study purpose and then debriefed. No one was correct in guessing the research purpose.

Hypothesis 2. To test hypothesis 2, we ran a regression on the beer consumption attitude scale. We coded the independent self-construal as 1 and interdependent self-construal as -1. Specifically, the effect of self-construal was significant ($t(1, 73)=2.29, p<.05$), indicating that independent tends to hold more positive attitude toward drinking beer than those with interdependent. Thus, hypothesis 2 was supported.

Hypothesis 3. We ran a set of regression analyses based on Baron and Kenny's (1986) suggestions for testing for mediation. We found that consumption impulsivity mediated the effect of self-construal on the beer consumption tendency. These results fully support hypothesis 3.

General Discussion

Our results are consistent with the existing literature on self-construal and impulsiveness. For example, Kacen & Lee (2002) found that consumers with independent self-construals tend to be more impulsive than those consumers with interdependent self-construals. We extend this literature in a number of ways. We provided a stronger test of this connection by manipulating self-construal rather than measuring self-construal only. In addition, we extended the causal linkage between self-construal and consumption impulsiveness to the domain of beer consumption.

Stinkin' Inconvenience! How Consumers Experience and Respond to Disgust

Selin Atalay, The Pennsylvania State University, USA
Melea Press, The Pennsylvania State University, USA

Abstract

We explore how consumers deal with feelings of disgust in consumption situations. We look at the common elicitors of disgust, and discover two categories not previously documented in the literature: (1) ignorance, and (2) things that did not work out as planned, desired, or imagined. In Study 2 we use scenarios to look at responses to disgust in consumption situations, and in Study 3 we manipulate scenarios to see if reported responses in study 2 are how people actually behave.

Introduction

What disgusts consumers? How do consumers respond to their feelings of disgust? Disgust can be elicited in response to physical objects, and to social violations (Haidt 1997; Rozin et al. 2000). Several researchers take the view that the disgust emotion grew with human evolution, from a way to guard the human body from bacteria and illness (Haidt 1997; Rozin et al. 2000), to an emotion that helps humans know how to behave in society (Haidt 1997). In other words the emotion disgust serves an important function in society.

Disgust, as it is researched now, is divided into two major categories, core disgust and socio-moral disgust. Core disgust elicitors include food, animals, body bi-products, sexual deviance, poor hygiene, and contact with death (Haidt 1997). Socio-moral disgust is elicited by contact with evil, or objects that are associated with evil or dirt (i.e., a shirt worn by an evil person). According to Haidt et al (1997), the following are often categorized as disgusting: "racism, brutality, hypocrisy, political attitudes, and violations of important social relationships."

Linked to social wellbeing and social interests, disgust is considered a moral emotion (Rozin et al. 2000). It motivates people to act in a particular ways, and to avoid certain actions.

Disgust has been identified as an emotion with relevant implications for advertising (Batra and Holbrook 1990; Holbrook and Batra 1987). Thus, it is curious that more research on the relationship between disgust and consumer behavior has not been conducted.

In the current study we are interested in how consumers deal with feelings of disgust that arise in consumption situations, and how feelings of disgust influence future perceptions, behaviors, and intentions in similar situations.

Study 1

Methodology. We gave questionnaires to 108 undergraduate students at a northeastern university. Because disgust is a little-studied topic in the marketing literature, our first goal was to verify the meanings of disgust that have been found in the psychology literature. We asked participants to define disgust, to give examples of times when they felt disgusted, or experienced disgust, and to describe what they did in these situations.

Results. Our participants' definitions of disgust overlapped with previous definitions of core and socio-moral disgust. When asked to list what disgusted them, core and social disgust elicitors were equally prevalent. 91.7% and 90.7% respectively.

In line with existing disgust research, our respondents indicated that disgust, or a disgusting object or situation made them angry (20.4%), annoyed them (22.2%), and upset them (22.2%).

Taking existing research further our study revealed that the objects and situations that cause disgust, as well as emotions facilitated by disgust have broadened. The participants included two categories of disgust not previously documented in the literature. These two categories are (1) ignorance, and (2) inconvenience, things that did not work out as planned, desired, or imagined. 19.4% of our respondents stated that they are disgusted by situations that are inconvenient to them (i.e. waiting in a line; going to an early morning class; walking in the cold, etc.), and that these situations are disappointing (23.1%) and frustrating (10.2%).

According to Nabi (2002) there is a difference between the theoretical definition of disgust, which refers to core disgust, and the common use of the word, which takes on a broader meaning including irritation, annoyance, or anger. It is our observation that the experience of disgust has gone beyond physical or social survival situations, to include perceptions of inconvenience, and interruptions to individual comfort. Perhaps this is a by-product of today's high-technology and web-based world, in which individuals are increasingly isolated.

Based on this observation, we see a need to look more closely at a definition for disgust in the consumption context. Our first goal is to create a current definition of disgust, and to describe its elicitors and how people respond to it. We propose that in addition to current definitions of disgust, feelings of disgust are also felt any time an individual's personal space and "ways-of-being" are invaded.

Proposed Studies

Consumer responses to feelings of disgust in consumption situations are not well understood. According to past research, and verified by our participants, disgust yields a passive response.

We are curious about how individuals respond to disgust in consumption situations, where the consumer has more control. Do disgusted consumers try to escape situations, or do they take corrective action? Does the response vary by the nature of the disgust elicitor? Do customers try to avoid socio-morally disgusting situations (i.e. avoid a store in which employees are not treated fairly) and inconveniences while taking action to have a core disgust elicitor fixed (i.e. have the dirty table top at a restaurant cleaned)? We propose two additional studies to investigate these questions.

Study 2

In Study 2 participants will read scenarios about situations that evoke either socio-moral or core disgust. Participants will complete a questionnaire about each situation to indicate the emotions they would feel in each situation, and how they believe they would respond.

In this study our goal is to clarify how different situations that elicit disgust are emotionally experienced by individuals. We aim to test the disgust elicitors that we uncovered in study 1 and verify that the elicitors of disgust have broadened. We are currently pre-testing our scenarios.

Study 3

Study 3 will manipulate similar scenarios to those used in Study 2 in a lab, to see if the reported responses in study 2 are in fact how people behave in the actual situation. The purpose of this study is to understand the passive nature of the responses to feelings of disgust.

Conclusion

Disgust is a core emotion that has known importance in marketing, but has not received much attention in the literature. With known effects on perceptions of advertisements, we believe that feelings of disgust also affect individuals in consumption situations. Disgust is an important, but understudied emotion in consumer behavior research. We hope to shed light on how this emotion functions in consumption situations. How often are you disgusted, and what do you do when you're a disgusted consumer?

How and When Alphanumeric and Suggestive Brand Names Affect Consumer Preferences

Kunter Gunasti, Penn State University, USA
William T. Ross Jr., Penn State University, USA

Abstract

Firms often use alphanumeric and suggestive brand names to influence consumers' preferences, yet how these influences occur has received limited attention. In two experiments, authors show that alphanumeric and suggestive brands can both mislead or guide consumer choices. Brand name effects on choice are moderated by information availability and need for cognition. Suggestive brands cue the attribute levels consumers ascribe to brands with missing information. Consumers use alphanumeric brands heuristically; higher numbers are perceived as associated with better products. High need for cognition consumers are less affected by misleading brands and attend more to guiding brands.

"Alphanumeric brand names include referential or nonsense mixtures of letters and digits, mixtures of words and digits, or any of the preceding where the figure is written out in word form." (Pavia and Costa 1993, pg. 85). There are millions of registered and unregistered alphanumeric trademarks in use (USPTO 2006). For some brands it is fairly simple to draw inferences about the product. For instance, BMW 3.25 refers to a 2.5 liter engine volume for 3 series and you can easily tell that 3.30 is a relatively better product due to its larger engine (3.0 liters). Correspondingly, Audi A8 and A6 indicate larger size and higher luxury level than A4 and A3. However, it is not always so easy to understand brand names. Mercedes has over ten letter classes resulting in a rather complicated set of some forty alphanumeric brand names and not many people can tell the difference among C, S or M class cars. Contrary to intuition, Nokia 6110 is inferior to Nokia 6102 and the average consumer has no idea what 6110 refers to.

Alignable difference is a piece of information for a choice option that has correspondence for other options (Markman and Medin 1995). It is usually weighted more heavily and is more likely to be used for justification of decisions. Alignable attributes tend to be comparable and quantitative (Nowlis and Simonson 1997). Most brand names do not fall into this category due to their qualitative nature. However, alphanumeric brand names may be considered as alignable, semi-quantitative and comparable due to their numerical features and their tendency to follow sequences. Consumers believe that number portions of alphanumeric brands have something to do with measurement of features or signify the product's relative placement in a sequence of products. Therefore, they favor large numbers inferring greater sophistication from them and believing that a product with a large model number in sequence is more recent (Pavia and Costa 1993). However, alphanumeric brands may have no meaning or they may be referring to internal design codes assigned at the discretion of the marketers (Boyd 1985). Depending on the branding strategy, alphanumeric brands may both guide or mislead consumer choices.

Another common type of brand name is suggestive brand names, which convey relevant attribute or benefit information in a particular product context (Keller et al. 1998). Suggestive brands are commonly meaningful words related in some way to product attributes or the problem to be solved (e.g. EverReady or DieHard batteries) (Folkes 2003). Various studies have shown that consumers make inferences

about product attributes using these brands (Peterson and Ross 1972). Firms may also assign suggestive brand names contradicting with their products or referring to an irrelevant attribute. If the suggested product benefit is difficult to observe before product trial, the negative effect on brand image will be delayed until after product experience (e.g. HeavyDuty brand aluminum foil tearing easily during use). In summary, we observe that suggestive brand names may help customers focus on various product attributes and help them make more accurate choices; they may also misdirect consumers to choose inferior products based on fanciful brand names.

In two experiments, we show that on average consumers picked the alphanumeric brands with larger numeric portions whether or not they were the best options. Therefore, alphanumeric brands guided (*misdirected*) choices when the number portions of brands were (*not*) actually related to product attributes or product advancements. On the other hand, suggestive brands guided (*misdirected*) choices when they referred to superior (*irrelevant or essentially inferior*) product attributes. In general, missing attribute information increased the effects of brand name on choice.

Need for cognition moderated the effects of these brand names. When a suggestive brand was misleading, it was incongruent with the general perception of the product or with the attribute it was suggesting (e.g. an *AbsoluteNoFee* calling card with a high fee). High NFCs were more likely to note the discrepancy whereas NFCs were more likely to get misdirected. For guiding suggestive brands, attribute information was congruent with the suggestions, and high NFCs were more likely to scrutinize this match and make more accurate choices. Alphanumeric brands equally guided and misled subjects with both high and low need for cognition. Low NFCs used the *the higher the better* heuristic, whereas high NFCs processed all the information and formed illusory correlations among alphanumeric brands and product attributes.

This research is an important attempt to discover the important effects of brand names on consumer choices. Despite their domination in technical product categories, alphanumeric brands have been largely neglected in past studies. Exploring the guidance roles and manipulative powers of brands will help us understand the underlying mechanism of consumer choices and especially inference making under incomplete information. With the increasing importance of technology nowadays, numerous electronics products are purchased over the internet by viewing product-attribute matrices on portals or e-merchants' websites that seldom have complete information (see Kivetz and Simonson 2000). The systematic effects of brand names on choice indicate potential problems for consumers and opportunities for marketers to manipulate choice sets.

Choice With Inference is Different from Choice without Inference

Kunter Gunasti, Penn State University, USA
William T. Ross Jr., Penn State University, USA

Abstract

Some researchers argued that consumers rarely form inferences. Others proposed ways for inference formation using: within-brand attribute information; other brands in the choice set (across-brand information); or average values. The authors found that choices made with and without inferences were significantly different from each other. Making inferences reduced choice difficulty and indecisiveness (choosing none of the options) and increased the attractiveness of chosen options. Contrary to the averaging hypothesis, inferences were different from mean attribute values. Supporting across-brand processing, inferences made for different attributes of multiple brands were significantly correlated. Need for cognition played a moderating role in inference making.

Products and services are seldom described completely, therefore, consumers often need to form inferences that go beyond the information given (Kardes et al 2004). Some researchers argued that consumers rarely form inferences (Simmons and Lynch 1991). Others found that inferences for non-visible attributes occur on the basis of available attributes or via various rules of thumb (e.g. adding or averaging). Most found that inferred value of a missing value is often discounted (Huber & McCann 1982; Ford & Smith, 1987; Johnson & Levin, 1985). A comparative judgment context increases the salience of the missing information resulting in more spontaneous inference formation (Sanbonmatsu et al., 1997). In a recent study of choice under incomplete information, subjects faced with binary choice task with missing information reported making spontaneous inferences. Kivetz and Simonson (2000) argued that consumers might treat

missing values in a way that supports their preferences or tentative hypotheses. Following the motivated reasoning and motivated inference theories (Kunda 1990; and Pyszczynski & Greenberg 1987), authors explained that people who are motivated to arrive at a conclusion construct a justification, a rationale for it and they search for evidence to support it.

Linear aggregation models (Fiedler 1966) predict illusory correlation as an inferential bias that arises even in the absence of motivational or memory-based mechanisms (Kardes et al. 2004). Correlation-based inferences for missing attribute information may be heavily based on known information about other attributes of the focal brand (known as same-brand, within-brand or attribute-based processing-e.g. Ford & Smith, 1987; Johnson & Levin, 1985); on other brands in the product category or choice set (known as other-brand, across-brand or alternative-based processing-e.g. Huber & McCann, 1982; Ross & Creyer, 1992) or on both (e.g. Lee and Olshavsky 1997). We propose that when consumers are explicitly asked to make inferences, they will engage in a different process and their choices will be affected by the values they infer. Choices made after inferences will be different compared to choices made without inferences.

In study 1, missing attribute information and inference making were manipulated. The choice sets consisted of product-attribute matrices for three product/service categories. A different attribute was missing for each of the three options in all product categories. Participants were randomly assigned to two conditions. Those in the *No Inference* condition were simply asked to make choices, whereas the ones in the *Inference* condition were asked to make inferences for missing attribute values before making choices. Results indicated that making inferences changed the nature of decisions. Choices made after inferences were significantly different from choices made without inferences. Assigning different values to missing attributes significantly decreased perceived choice difficulty and increased attractiveness of chosen options. In addition, inferences made across brands for different attributes were significantly correlated with each other. This finding was in support of the alternative-based correlation inducement (also known as cross-brand or other-brand processing) earlier proposed by Huber & McCann (1982) and Ross & Creyer (1992).

In study 2, an identical design was used with one exception. Besides the three options in each choice set, a “no choice option” was added, such that participants also had the alternative of not choosing any of the options as in real purchase situations. In addition to the replication of results from study 1, analysis showed that making inferences significantly decreased the selection of the “no choice option” (indecisiveness) as well as reducing perceived difficulty and risks of decisions. This effect was prevalent for all product categories.

It has been shown that at least a moderate level of cognition is typically required for correlation-based inference formation (Lee & Olshavsky, 1997) and when cognitive resources are required, spontaneous inference formation is more likely, if the motivation and the ability to deliberate are high (Kardes et al. 2004). Another important finding was that inferences were significantly moderated by need for cognition (NFC). High NFCs made more conservative assumptions regardless of product or attribute types.

While some researchers have argued that consumers do not make inferences, there have been numerous attempts to explain the underlying mechanism and heuristics for making inferences. Past studies have forced participants to make inferences about single attributes for one of the options in the choice set. Our research expanded these by including different missing attributes for multiple options; exploring the effects of multiple inferences; increasing the realism by including a no choice option; and demonstrating the differences in choices made with and without inferences.

Mental Visual Imagery, Authenticity and Consumers' Attitude Formation towards Licensed Brands

Jen-Yuan Martin Liu, University of Warwick, UK
Qing Wang, University of Warwick, UK

EXTENDED ABSTRACT

Licensing is no longer viewed merely as technology transfer or modes of entry. Firms are now licensing assets in forms of brands, designs, trademarks and etc. Many researchers (e.g. Holt 2002; Kozinets 2002; Thompson et al. 2006) have noted that such commercialization undermines the value of the brands. However some examples suggest differently. Haier, China's largest home electronics manufacturer began its ascent by licensing refrigerator technology and the brand from German Liebherr Corp. in 1985 with the original brand name of "Liebherr". Sanyo Fashion House Inc., a subsidiary of Sanyo Shokai in Japan, is licensed to manufacture and distribute "blue label" Burberry products in Japan since 1980. Despite their licensee image, they have both generated strong domestic sales and built strong and positive awareness internationally.

In this paper, we ask the question "when and how licensed brands achieve the same or even higher value than original brands?" and we reason that consumers' assessment of authenticity may hold the key to this question. Most researchers agree that authenticity is not an attribute inherent in an object and is better understood and assessed by a particular evaluator in its particular context (Grayson and Martinec 2004). However, little research has studied the antecedents and consequences of authenticity. This is particularly relevant in brand licensing, as the cues for communicating authenticity of a licensed brand will help consumers' assessment of the value of the licensed brand, and these cues may or may not be related to the attributes of the original brands. Thus this research proposes that there exist multiple dimensions of authenticity as perceived by consumers in the context of brand licensing.

Next, we examine literature in mental visual imagery as one of the mental processes that consumers use to make sense of cues (Richardson, 1999). Assessment of authenticity involves a complex perceptual process (Belk and Costa 1998; Pen˜aloza 2001). A person construes the cues via the formation of mental visual image before further deriving his/her perception about the authenticity of a licensed brand. Finally, we examine consumers' attitude formation toward the licensed brands as consequences of their perception of authenticity.

Indexical and Iconic Authenticity

Grayson and Martinec (2004) identified two dimensions of authenticity based on the semiotic model developed by Peirce (1998): the *indexical authenticity* and *iconic authenticity*. Indexical authenticity refers to the physical or psychological link which distinguishes the "real thing" from its copies (Grayson and Shulman 2000). Iconic authenticity refers to the preexisting knowledge or expectations which a person perceives something being similar to something else (Grayson and Martinec 2004). In order for the licensed brand to be perceived as authentic, the cues for communicating authenticity are crucial, and this process of understanding and specifying these cues is called the negotiation of meaning (Grayson and Martinec, 2004).

Mental Visual Imagery

Past research (e.g. Adeyemo, 1990; Dahl and Chattopadhyay, 1999; MacInnis and Price, 1987) has shown that mental visual imagery is one of the mental processes which one uses to make sense of cues. Mental imagery is a form of internal representation in which information about the appearance of physical objects, events and scenes can be depicted and manipulated (Richardson 1999, P. 3). Research in marketing has distinguished different types of visual mental imagery: the image based on *memory* and *imagination* (Dahl and Chattopadhyay, 1999; MacInnis and Price 1987). These authors define memory image as the event or occasion that a person has personally experienced or observed whereas imagination imagery is a new, never-before-experienced event.

The Link between Authenticity and Mental Visual Imagery

Peirce (1998) explains that to view something as an icon, one usually creates a "composite photograph" (Grayson and Martinec 2004). For instance, to view something as iconically authentic, a perceiver must have some preexisting knowledge or expectations of something being similar to something else. Thus, memory imagery can be interpreted as the cue which links consumers preexisting knowledge toward the perception of iconic authenticity about the licensed brand. For example, when consumers encounter a licensed brand, they form image (i.e. original brand) from memory based on their existing knowledge or previous experience of the brand. Iconic authenticity may be achieved when cues are congruent with their memory. Therefore:

H1: Consumers' memory imagery is positively correlated with perceived iconic authenticity.

Imagination imagery involves the creation of previously unseen image and the capacity of imagination imagery determines one's ability to negotiate meaning out of novel information (Adeyemo 1990). To view something as an index, a perceiver must believe it actually has the "factual" and "spatio-temporal link" that is claimed (Grayson and Shulman 2000). Imagination imagery can be interpreted as acceptance of marketing communications from the licensee toward the perception of indexical authenticity by consumers. Therefore:

H2: Consumers' imagination imagery is positively correlated with perceived indexical authenticity.

H3: The more the licensed brand is perceived with iconic cues, the more licensed brand will be perceived as authentic.

H4: The more the licensed brand is perceived with indexical cues, the more licensed brand will be perceived as authentic.

Although both iconic and indexical cues are likely to encourage consumers to believe that a licensed brand is authentic, iconic cues are likely to be more powerful because consumers possess some preexisting knowledge about the licensed brand or perceive similarities with something they are familiar with. Therefore:

H5: Iconic authenticity has greater influence than indexical authenticity for consumers' assessment of authenticity.

Finally we examine whether assessment of authenticity will in turn influence consumers' attitude toward the licensed brand. Attitude towards a brand can be defined as consumer's overall brand evaluation (Aaker and Keller, 1990). Cognition is part of the belief formation and the salience of beliefs in turn form attitude (Ajzen, 2002). Assessment of authenticity is one type of cognitive associations assisting consumers to negotiate the meaning of brand licensing. Therefore:

H6: Perceived authenticity is positively correlated with consumers' attitude formation toward licensed brands.

Methods and Measures

There are three stages of data collection in this research: exploratory focus group studies, controlled experiments and survey. The focus group studies were completed. The purpose of the focus group studies is twofold. Firstly, we hoped to gain deeper understanding about how consumers perceive the connections among our three focal concepts and to develop a set of hypotheses. Secondly, it would help with the development of relevant measures to be used in the controlled experiments.

Exploratory Focus Group studies

The focus group interviews were carried out to ensure that the dimensionality of the concepts can be discovered as exhaustive as possible. Three focus group interviews were designed and conducted based on the guideline from Krueger (1994) and Yin (1984). Twenty-six informants (20 to 35 years of age) were recruited from both undergraduate and postgraduate students in a west midland university in the United Kingdom. Each focus group lasted around 60 minutes. The informants, 51% of which are female, have Chinese origin. These informants were recruited for the consistency with second stage of data collection in China.

The focus group results were content analyzed according to the guideline of Yin (1984). The preliminary results are the following:

- (a) 22 of our informants pointed out that brand licensing activities were well covered in the Chinese media and were aware of the amount of brand licensing activities in the Chinese market.
- (b) 20 of them stressed that authenticity was an important issue when facing licensed brands.
- (c) 21 informants agreed that when facing licensed brand, they drew inferences from both their past experiences (memory) and their assessment based on the actual licensed brand product they encountered (imagination).
- (d) Based on their past experience with the original brand, majority our informants indicated that quality, country of origin, and trademark were first to come through their mind.
- (e) The novelty of the licensed product, level of involvement of the brand owner, and the distribution channel of the product helped with their assessment of authenticity of the licensed brand.

The focus group results shown that, firstly, the distinction between the use of memory and imagination imagery is important to assess authenticity of licensed brands. Secondly, there exist different antecedents for the two dimensions of authenticity. Two 7-point authenticity measures were developed based on focus group findings:

- (a) Indexical authenticity in brand licensing: novelty, level of involvement of the brand owner, and perception about distribution.
- (b) Iconic authenticity in brand licensing: quality, country of origin, and trademark.

Control Experiments

To examine the use of different imagery types upon the perceptions of authenticity (H1 and H2), the two experimental factors (memory and imagination imagery) will be manipulated in a between subjects design. One hundred and fifty students participated in the study are to be Chinese –origin from an UK university. Chinese market is chosen because of its market size and rapid growth in licensing activities (LIMA 2005).

The independent Variables will be the visual mental imagery types which will be manipulated by instructing participants to rely on images based on either memory or imagination during the experiments. Experimental design will consist of a 2 (imagery type) x 2 (authenticity type) + 1 control mixed model. Imagery types are between-subjects variables, with subjects exposed to a set of either memory or imagination stimuli. In the memory imagery condition, participants will be given a booklet containing a brief description of memory imagery and information regarding the fictitious brand. Participants will be asked to "dig" into their memory and visualize similar brand and product in their daily life when filling out questionnaire on the perception of authenticity. In the imagination imagery condition, participants will be given a booklet containing a brief description of imagination imagery and the same information as in the memory condition regarding the fictitious brand. Participants will be asked to visualize the fictitious brand based on the information provided in the booklet when filling out questionnaire on the perception of authenticity. The measurements for manipulation check will be adopted from Dahl and Chattopadhyay's (1999) 7-point scale. Two 7-point authenticity measures were developed based on focus group findings: (a) Indexical authenticity in brand licensing: novelty, level of involvement of the brand owner, and perception about distribution. (b) Iconic authenticity in brand licensing: quality, country of origin, and trademark. The dependent variable is attitude toward the licensed brand. To measure attitude toward licensed brand, we will adopt Kind and Smith's (2001) 7-point semantic differential scale.

Survey

To examine the effect of perceived authenticity on consumers' attitude formation (H3, H4, H5, and H6), a set of questionnaire will be administrated on-line. Real licensed brands instead of fictitious brands will be employed as subject of study. The original brands will

be selected based on Aaker and Keller's (1990) criteria for parent brand selection. Brands will be selected of being relevant to the subjects, generally perceived as high quality, able to elicit relatively specific associations. Specifically, the chosen brands should have not been largely licensed yet, so that it can avoid the impact of over-licensed situations (i.e. noise generated by multiple licensees). Also, the product category should be new for a given brand. A total of four brands from the same product category (to control for the effect of product heterogeneity on the results) will be selected and each of the two brands maintaining distinct indexical or iconic elements. The questionnaire will contain measures of perceived authenticity developed in control experimental study. To measure attitude toward licensed brand, we adopt the scale recommended by Kind and Smith (2001). All measurement items in this research will be using a 7-point semantic differential scale.

Concluding Remarks

This research intends to make three related contributions. Firstly, we attempt to develop measures for authenticity in brand licensing. Secondly, we will empirically test whether mental visual imagery influence consumers' perception of authenticity. Thirdly, we are to test which types of authenticity determines consumers' attitude formation of licensed brands.

Ambivalence as an Inoculating Agent: A Built-In Defense Against Attitude Change

Mark Forehand, University of Washington, USA

Mark Staton, University of Washington, USA

Brian Tietje, California State University–San Luis Obispo, USA

Overview

The researchers conducted a multi-phase experiment to analyze the effect of initial attitude ambivalence on subsequent attitude change. Regression analyses revealed that subjects were less likely to change their attitude after reading new counter-attitudinal information when their initial attitudes were characterized by high levels of ambivalence ($\beta = -.154$; $p < .05$) indicating the presence of inoculation. These results suggest that ambivalence does not always lead to attitude change, and ambivalent consumer attitudes are actually more resistant to new, potentially biasing information.

Conceptual Background

An ambivalent attitude is an attitude fed by competing inputs that influence overall evaluation in opposite directions. Previous research on attitude ambivalence suggests that it is an aversive condition that people attempt to ameliorate (Lavine, Thomsen, Zanna and Borgida 1998, Nordgren, van Harreveld and van der Pligt 2006) and that it has a negative effect on customer satisfaction (Olsen, Wilcox and Olsson 2005). Indeed, most research on ambivalence has studied the effects of attitudinal ambivalence toward ego-involving socio-political issues, situations in which ambivalence is often aversive (Harreveld and van der Pligt 2006; Hass, Katz, Rizzo, Bailey and Moore 1992). However, in consumer contexts, it is not clear that ambivalence necessarily produces an aversive state. For example, people may possess positive beliefs about Gucci products, negative beliefs about Gucci users, and both positive and negative overall beliefs about the Gucci brand. Although this creates ambivalence about Gucci, many consumers will not have enough of a personal stake in Gucci for this ambivalence to produce cognitive discomfort. We argue that when ambivalence is not aversive, it may actually inoculate a person from change, by providing the consumer with enough data, positive or negative, to refute any presentation of counter-attitudinal information (McGuire, 1961).

One can characterize ambivalence as a self-generated two-sided argument, similar to the research on “inoculation” developed by McGuire (1961, 1985 and Watts and McGuire 1964). In an inoculation procedure, relatively weak content that refutes a held argument is presented and this causes the recipient to strengthen defensive arguments supporting his or her previous attitude. In turn, these new defensive arguments bolster the attitude against subsequent refutational content that is stronger than the initial material. This basic inoculation effect has been demonstrated in response to comparative advertising, especially when the subject is highly involved in the decision process (Pfau, Parrott and Lindquist 1992.) Previous research suggests that a two-sided argument is more likely to trigger the defenses of the recipient than a one-sided message (Hass and Linder 1972; Kamins and Asseal 1987; Burgoon and Pfau 1995). Instead of presenting an ambivalent argument, our subjects will be working with a pre-existing ambivalent attitude and we anticipate that this will work as a similar defense to attitude change.

Method

Participants evaluated six real brands in a multi-phase experiment. In the initial phase, brand attitude ambivalence was assessed and initial brand attitude was collected. Attitude ambivalence was collected using a Griffin measure and brand attitude was collected with an 11-point scale ranging from -5 to $+5$. In the final phase, participants read scenarios that presented new negative information about three of the brands and new positive information about the other three brands. The order of the scenarios, the valence of the scenarios and the order of the brands were fully counterbalanced.

After reading the scenario for each brand, participants responded to five measures, influence of the scenario, attitude change, purchase intention change, attitude toward the brand and purchase intentions.

Analysis and Results

Separate analyses were conducted for observations in which scenario information was consistent or inconsistent with the initial brand evaluation on the 11-point scale (-5 to $+5$). Scores from -5 to -1 were coded as negative, 1 to 5 were positive, and scores of zero (222 cases) were not used in the analysis.

To test the effect of inconsistent information on brand attitudes, regression analysis was used, with the influence of the scenario as the dependent variable. In addition to ambivalence, independent variables included dummy variables for the type of scenario and brand, individual difference measures including need for cognition, advertising skepticism, and need for attitude consistency.

When exposed to counter-attitudinal information, participants reported less attitude change when their initial attitude was characterized by greater levels of ambivalence ($\beta = -.154$, p -value = .013). This finding stands in contrast to prior research that has argued that an increase in the level of ambivalence would lead to a greater change in attitude.

Discussion

Ambivalence is a common occurrence among consumers. Often the best product experiences are attenuated by some flaw. This research suggests that we, as consumer, have accepted ambivalence and do not allow it to sway our opinions in a more univalent direction. By already possessing counter-factual knowledge, ambivalence creates an inoculation against any new information. Further research could review the effect of visceral brand identification (Apple Computers, Harley-Davidson) on consumer ambivalence.

Sacred Songs, Secular Words: Discourse on the Consumption of Religious Music

Jeaney Yip, University of Sydney, Australia

Extended Abstract

The long withstanding debates between sacred and profane have been documented (Belk, Wallendorf and Sherry 1989; O'Guinn and Belk 1989; Arnould and Price 2004), although the sacred in consumer research has been predominantly studied as a metaphoric stance rather than specifically about the 'Sacred' per se (Iacobucci 2001). Secularisation theory argues for the decline in sacredness and religion amidst the backdrop of modernity and progress (Martin 2005), while attributing its replacement with secular, material and spiritual pursuits. This theory neither concurs with the continued popularity of Pentecostal (Charismatic) churches (Anderson 2004), nor the growth of Contemporary Christian Music (CCM, Powell 2002). In an attempt to study the inter-relationships between sacred (expressed through religious music) and secular (expressed through consumer culture), a discourse analysis into Christian music is conducted in this research.

Music, like advertisement, is a cultural text which is an important medium in reading the audience (O'Donohoe 2000). Through the language of songs, music like an advertisement text informs and expresses meanings that are not only in alignment with the targeted audience but the socio-historic conditions of a society. As a religious product, it is a site where ideology circulates as well as a mirror to represent the sacred which is highly visible, audible, saleable and malleable to socio-cultural forces. Music style is never neutral, but is organically wed to the socio-cultural setting in which the music is created and developed (Romanowski 1992) to convey certain meanings to a particular audience.

Studies that relate music and discourse include a reading of Madonna, by Bradby (1992) where her songs, music video clips and news about her as reported in the media, were analysed. Through the song 'Material Girl', discourses of materialism and maternalism, were expressed as advancement in female liberation. Liederman (2004) in a study of 'The Free Monks', a Greek rock band of black-robed Orthodox monks and ordained priests was analysed against the backdrop of the social, cultural and political role of the Orthodox Church in Greece. The 'singers' perform in an MTV-style video, singing modern rock music accompanied by live concerts and initial albums that reached gold and platinum status in sales in Greek pop charts. This phenomenon of 'sacred songs with a secular beat' can be seen as one example of a mutation that has occurred in the Christian discourse as a result of alignment with changes in the macro-societal shifts, but more is needed to understand the intricacies of this alignment in another setting.

A cross section of Pentecostal and Anglican songs dating from 1990–2005 was selected, including traditional hymns. I used close reading (Scott 1994; Stern 1989) to study the lyrics and explored the meaning expressed through the language of songs. Music as an expression of worship has a visual representation in the way it is played, performed and consumed. This produces an assortment of representations and discourses which requires a marriage of visual, audio, and textual data. The visual materials included pictures of the music performance, the congregation, the architectural space, images of the people (audience, song performers, and church leaders), pictures of artefacts produced by the church, and video recordings of services and music events.

Discourse analysis of the data suggests four dominant themes or discourses: 'Empowerment', 'Tradition', 'Today' and 'Individualisation'. There is a theme of the empowered self in the Pentecostal songs as the 'I' is empowered to 'change the world today', to 'move mountains', and to believe that 'life could be all that you want it to be'. Both the 'can be' and 'can do' attitude is an attractive appeal that aligns not only with the so-called 'Prosperity Gospel' Pentecostal churches tend to preach, but blurs with new age spirituality that focuses on potential of the 'self' (Rindfleish 2005). Empowerment is also expressed in the form of blessings, favour, miracles and an answer to dreams.

The discourse on tradition is apparent in Anglican songs and hymns. Expressed in the form of worship, reverence to God, collective nature of the church family, humility, obedience, reference to sin and heaven provide the language in constructing what appears to be a traditional Christian discourse on the sacred. This is in contrast to the 'Today' discourse which construct sacred meanings to a present day context framed in a 'here and now' (as opposed to heaven/after life/eternal) timeframe situating the blessings, dreams coming true, favour and miracles to happen today. This suggests a reconciling of sacred constructions with the secular existence of people in the current world. There is no focus on 'suffering' in the present and reaping joy in the future but it's about harvesting and living to the full *now*. The sacred gets expressed to a 'present help in my time of need' which clearly is situated in the secular.

The 'individuation' discourse express the self (I, me, my) in the songs, especially prominent in Pentecostal songs. Moreover, these words outnumbered those that feature God (Lord, God, Jesus, Father). The word 'you' was evident, although it is not always directed to God but the audience. This different usage of the pronoun 'you' to refer to the one who is being addressed illustrate a language that is couched in a personal relationship as opposed to 'thou' in a traditional hymn. This difference illuminates interesting points of departures between Pentecostal songs and hymns. The intimacy of 'you and I' introduces a spirit of closeness, warmth, and approachability that is more couched in newer forms of spirituality rather than religion. Also, this is interesting to have emerged out of this genre of music as typically hymns are *about* God, while this is directed *to* God or the audience. The notion of ownership ('my God', 'my Saviour') is also evident.

Whilst sacred discourses to do with Christianity are apparent, this is mixed with other secular discourses in the case of contemporary Pentecostal songs. If music is a mirror to meaning and audience values, self-empowerment and individuation of religion framed in the context of 'today' are discourses that reflect the shift in socio-cultural conditions of a modern society. This can be aligned to Inglehart's (1997) post-materialist values which highlight self expression and self empowerment as prevalent in highly developed societies where existential security already exists. Because physical security is already adequate in highly developed societies, the discourse on the sacred appears to play a more self-serving role framed in current consumer culture. Whilst secularisation theory posits a decline in religion at the macro level, the popularity of a certain 'version' of religious form and products suggest at the meso level a resurgence of 'sacred interest'. It appears that a process of appropriation (Thompson and Haytko 1997; Cova and Cova 2000) has taken place whereby religious music is able to align itself to changing socio-cultural shifts to incorporate both sacred and secular discourses into its contents and meaning. This appears to be the version that resonates with current religious consumers. Through analysing the genre, lyrics and aesthetic appeal of a religious song, layers of meaning are 'deconstructed' to reveal an 'acculturation of discourses'. Sacred songs with secular discourses offer the other face to the sacralisation process (Belk, Wallendorf and Sherry 1989), which arguably implies the possible existence of sacred and secular as *yin and yang*.

An Examination of Recall Measures of Sponsorship Awareness

Michael S. Humphreys, University of Queensland, Australia
 T. Bettina Cornwell, University of Queensland, Australia
 Clinton S. Weeks, University of Queensland, Australia
 Anna R. McAlister, University of Queensland, Australia

Extended Abstract

With growth in sponsorship-linked marketing expenditure continuing to increase each year (IEG 2003), consumers are exposed to an ever larger number of brand names in association with various events. In many cases there may be a number of brands linked with a single event, and in some cases several of these brands may be from a single brand category. In addition, many brands may be linked with multiple events. What must be considered when seeking to measure sponsorship awareness in these situations is how the method of measurement may influence results, particularly with regard to the direction of cueing in cued recall.

Due to the nature of memory associations, the associative strength from a brand to an event may not always be the same as the associative strength from an event to a brand. To illustrate, consider a situation where a brand such as Gatorade sponsors an event like the *International Relay Run*. Asking which brand is the sponsor of the International Relay Run as opposed to which event did Gatorade sponsor, may not produce the same proportion of correct responses. This may particularly be the case when a similar competitor brand (e.g., Powerade) is also salient in the mind of the consumer, and when the event name is given as the recall cue. Not all awareness measures provide consistent access to memory, and deciding which measure to use may depend largely on the situation, and what information is sought by the researcher.

Tripodi et al. (2003) have suggested that variation in memory prompts can affect sponsorship awareness responses. Using a telephone survey they reported that the sequence in which memory prompts (event name, brand name, category label) are given to respondents can affect overall awareness measurements. Specifically, in their study respondents prompted with the event name had the highest level of initial recall, but the lowest overall recall after follow-up prompts (including a recognition-type prompt).

In four experiments we examined the nature of recall in measuring sponsorship awareness. We varied recall methods by cueing with the event name, the brand name, the brand category, and we also considered responses using a free recall method. Participants received exposure to sponsorship stimuli using Johar and Pham's (1999) press release paradigm, where brands were real and events were fictitious. All press releases involved congruent sponsor-event relationships and all contained a statement articulating the sponsor's reason for undertaking the sponsorship. Additionally, as a within subjects variable, half of the press release statements mentioned a competitor within the same brand category while half made no such mention. Participants in each experiment were presented with 12 press releases and completed a 10 minute distracter puzzle before beginning the memory task.

Results showed recall differences depending on the cue utilized. In the first experiment, when cueing with the event name, results showed that recall of the sponsoring brand was similar both when a competitor was mentioned in the press release and when no competitor was mentioned ($M_s = .708$ and $.767$ respectively). Overall recall here was 73.8%. In the second experiment however, when cueing with the brand category, recall of the sponsoring brand was adversely impacted by the presence of a competitor. Here there was a marginally significant difference between the competitor present and competitor absent conditions, $F(1, 19) = 4.061$, $p = .058$ ($M_s = .775$ and $.850$ respectively), with overall brand recall at 81.25%.

In the third experiment which used brand cues, we provided participants with either the sponsor or competitor name and examined event recall responses. This was done for both competitor present and competitor absent conditions. Here, as might be expected, there was a main effect of cue, $F(1, 39) = 72.335$, $p < .001$, such that sponsor cues ($M = .538$) were more effective in eliciting the event name than were the competitor cues ($M = .146$). There was no overall main effect of competitor presence, but there was a significant interaction between cue and competitor presence, $F(1, 39) = 5.906$, $p = .020$. Marginal means indicated that event recall was lower in the competitor present condition than in the competitor absent condition for the sponsor cue ($M_s = .483$ and $.591$ respectively), but event recall was higher in the competitor present condition than the competitor absent condition for the competitor cue ($M_s = .183$ and $.108$ respectively). This indicates that interference occurred in the competitor present condition using the sponsor cue, and that cueing with a mentioned competitor can elicit event recall. Interestingly, this result also shows that even if no competitor is mentioned, cueing with a market rival of the sponsor can nonetheless elicit memory for the event.

In contrast to the cued recall experiments, in the fourth experiment where free recall was used, a greater number of events were recalled from the competitor present as opposed to the competitor absent condition, $F(1, 19) = 5.431$, $p = .031$ ($M_s = .650$ and $.508$ respectively). Similarly, a marginally greater number of sponsors were recalled from the competitor present as opposed to the competitor absent condition, $F(1, 19) = 4.108$, $p = .057$, ($M_s = .700$ and $.567$ respectively). There was no significant difference between the level of recall of events as opposed to the level of recall of sponsors ($M_s = .579$ and $.633$ respectively).

With sponsorship-linked marketing expenditure rising each year, it is becoming increasingly important to have a clear understanding of whether the techniques used to measure sponsorship effectiveness are appropriate. For those interested in measuring sponsorship awareness effects, what this study shows is that knowing a brand name can prompt memory for an event, and knowing that an event name can prompt memory for a brand, are not necessarily the same thing. In attempting to assess sponsorship awareness, researchers must first consider the nature of what they want to know in order to be able to ask the right question.

Developing a Deeper Understanding of Scarcity: Contextual and Individual Influences on Demand Scarcity

Morgan K. Ward, University of Texas, USA

Abstract

In this paper, we investigate mechanisms associated with scarcity resulting from public demand not met by supply: demand scarcity. We examine individual and contextual influences on demand scarcity. In four studies we find: 1) Consumers use visual scarcity cues to infer information about products; 2) Consumers' dependence on demand scarcity as a heuristic is particularly effective in low-involvement choices; 3) "Need for uniqueness" independently influences subjects' use of scarcity information and their choices about scarce products, and 4) The effect of uniqueness decreases as the ubiquity of demand scarce products is made salient.

Aristotle summarized the underpinnings of scarcity when he stated, "What is rare is a greater good than what is plentiful." This phrase captures the fundamental elements of commodity theory (Brock 1968) and expresses the robust effect that scarcity has on human behavior. Marketers, having reached the same conclusion (albeit more recently), leverage consumers' desire for scarce products by implying that access to them is limited. Implications of scarcity embedded in advertising language like "time's running out," "limited edition," or "while supplies last" impel consumer action.

Though well-known and intuitive, scarcity is not a simple construct; research in consumer behavior has highlighted a variety of psychological mechanisms that give rise to scarcity effects (see Lynn 1992). A few examples include reactance, whereby people resist restrictions on their choice (Brehm 1966), social proof (coined "bandwagon reasoning") in which consumers rely on others' opinions as a cue for the value of a product or service (Worschel, 1975), and uniqueness, the innate human drive to attain social status by possessing a largely unavailable resource (Veblen 1904).

Though the literature effectively demonstrates types of scarcity and underlying mechanisms, to date there is no overall framework that discusses which mechanisms correlate to specific scarcity appeals. We are initiating the formulation of such a framework with such questions such as: What are the relative effects of reactance and uniqueness for time scarcity appeals (e.g., "time's running out")? And, to what extent, if any, does social proof influence supply-generated scarcity (e.g., "limited edition")? In this paper, we focus our attention on mechanisms associated with scarcity resulting from public demand not met by supply: demand scarcity.

While it has been assumed that people typically use scarcity information as a heuristic cue for value, recent research challenges that assumption (Brannon and Brock 2001). We contend that consumers *do* use demand scarcity information as a heuristic. We further argue that a social-proof mechanism drives the effect of demand-scarce information, and test Worshel et al. (1975) "bandwagon reasoning" which predicts that scarcity resulting from public demand informs the value of the product. In other words, consumers use relative demand to assess a product's worth by inferring that fellow consumers' demand implies value.

We also examine how presumptions of uniqueness influence the effects of demand scarcity. Consumer need for uniqueness is defined as "an individual's pursuit of 'different-ness' relative to others... achieved through the acquisition, utilization, and disposition of consumer goods for the purpose of developing and enhancing one's personal and social identity" (Tian et al. 2001). Since demand-scarce products endow their possessor with uniqueness, we hypothesize that consumers who desire such personal uniqueness will be more likely to desire products that are highly desired by others (and thus scarce). However, the reality of scarcity is realistically moderated by how much of the product already has been sold in the marketplace. When a product already is owned by many others, those concerned with uniqueness should no longer desire it.

Our initial study establishes that people use visual scarcity cues to infer information about products. We presented participants with a hypothetical shopping scenario in which they were asked to choose between two clocks. One clock (the target) was pictured as either scarce or abundant. The comparison clock was always pictured as abundant. We crossed scarcity with the manner of display. In display conditions, clocks were arranged like a typical display of merchandise; in inventory, clocks were arranged like "backstock" (i.e. inventory a store holds of a product). We found that scarce clocks were preferred to abundant clocks, but only when clocks were shown as "inventory". We surmised that participants were using inventory information coupled with scarcity as a cue for public demand.

Study 2 supports the idea that people use scarcity information as a heuristic. We used the "scarce inventory" condition from Study 1 and gave participants either information that the clock was selling quickly (demand manipulation) *or* no information (control). We crossed the manipulation of information with level of involvement, where participants were either highly involved in the choice (they could receive the clock as a prize) or less involved (the choice was hypothetical). We found participants who were highly involved in the choice use demand information significantly less than those who were less involved. In short, we show that consumers' dependence on scarcity as a heuristic is particularly effective in low-involvement choices.

In Study 3 we test how a need for uniqueness influences preferences for scarce items. We primed participants with either uniqueness-related or conformity-related information. Then we showed participants the "scarce inventory" condition from Study 2, again mentioning that the clocks were selling quickly, and asked respondents which clock they preferred. We found the uniqueness prime increased preferences for a demand-scarce clock. The results indicate that consumers predisposed to maintain their sense of uniqueness were more susceptible to social proof cues.

Finally, in Study 4 we tested the prediction that the influence of uniqueness found in Study 3 could be attenuated with the ubiquity of product ownership. We replicated Study 3's effect of uniqueness on the (demand) condition which stated that the clocks were selling quickly. We also added a condition that told participants that the clocks were selling quickly and *many have already been sold* (demand ubiquity condition). Our results indicated that the preference for the demand scarce clock was diminished when the clock had already been sold to many others. Similarly, participants primed with conformity showed an increase in their preference for the clock that was owned by many.

We present contextual and individual factors that contribute to consumers' responses to demand scarcity cues. The results corroborate the notion that consumers use visual scarcity to infer product worth and by extension choose scarce products. Moreover, consumers

motivated to maintain their uniqueness are more susceptible to social proof cues. Finally, the results confirm that demand scarcity is moderated (for participants who are motivated to maintain uniqueness) by whether subjects have information confirming that the product is scarce because many have units already been sold thus implying the ubiquity of the product.

How Consumers Are Affected by the Framing of Numerical Information

Jessica Y. Y. Kwong, The Chinese University of Hong Kong, Hong Kong SAR

Kin Fai Ellick Wong, Hong Kong University of Science and Technology, Hong Kong SAR

Studies on consumer judgments have demonstrated that consumers may consider two options with different attribute levels (e.g., apartments that are 20 minutes versus 15 minutes away from campus) to be vastly different or vastly similar depending on contexts. In particular, research has thus far shown that contextual factors such as the range of the attribute levels (e.g., Gravetter & Lockhead, 1973; Janiszewski & Lichtenstein, 1999; Mellers & Cooke, 1994; Yeung & Soman, 2005), the frequency of the attribute levels (e.g., Niedrich, Sharma, & Wedell, 2001; Parducci, 1965), and their relative spacing (e.g., Cooke & Mellers, 1998; Mellers & Birnbaum, 1982; Wedell, 1994) can influence our perceptions. While these studies noted how the comparisons of two options are altered by changing their peripheral context—that is, what other options are presented in addition to the two target alternatives for comparison—few have attempted to address how our perceptions are shaped by the focal context—that is, the presentation of the two target alternatives themselves.

We proposed that for attribute dimensions that can be described in two equivalent frames (e.g., printing reliability vs. failure rate), the different attribute values associated with each frame (e.g., 97% reliability vs. 3% failure rate) could affect how we compare two options. Our hypothesis is that the presentation format of attribute information can affect the perceived difference between two options. That is, the perceived difference is amplified when the attribute is described in a large ratio frame than when it is described in a small ratio frame.

Two experiments were designed to test our hypothesis. In the experiments, the undergraduate students participated on a voluntary basis and were randomly assigned to one of the two presentation formats (small vs. large ratio). They were given a scenario that described two options differing on two attributes with a trade-off. The scenarios were essentially identical between the two conditions, except that the label and the numerical values of one of the attributes changed according to the presentation manipulations. After reviewing the information, the participants reported their evaluations of each option on each attribute dimension and their preferences for the two options.

In Experiment 1, we showed that when a pair of options are presented in a frame with attribute values in large ratio (e.g., printer A has a failure rate of 3% vs. printer B has a failure rate of 9%), consumers report greater differences in their attribute judgments than when the same pair of options are cast in a frame with attribute values in small ratio (e.g., printer A has printing reliability of 97% vs. printer B has printing reliability of 91%). Moreover, we also found that the preference between two options with trade-offs is altered by the ways the attribute information are presented. Generally speaking, we found that an option is more likely to be chosen when its superior attribute is presented in a large ratio format than when it is presented in a small ratio format.

In Experiment 2, we ruled out an alternative explanation of negativity bias. That is, the effects of presentation format on attribute perceptions are replicated even when positive attribute label is paired with large ratio frame and negative attribute label is paired with small ratio frame. Therefore, our findings cannot be explained by the valence of the attribute label.

In sum, we demonstrated that the same pair of options may appear similar or different depending on how their attribute information is presented. This contextual effect differs from others in that it does not require alternation in the options involved in the evaluation environment.

Contribution of the Concept of Identity to the Understanding of Responsible Consumer Behavior: Application to the Consumption of Fair Trade Products

Nile Ozcaglar-Toulouse, Universite de Lille 2-France

The responsible consumption is not easy to understand: it is a complex phenomenon and characterized by a large diversity of practices (Shaw, 2000; Newholm, 1999). Thus, I find it necessary to propose my own definition of responsible consumption as being '*the set of voluntary acts, situated in the sphere of consumption, achieved from the awareness of consequences judged as negatives of consumption on the outside world to oneself, these consequences raising therefore not from the functionality of the purchases nor from immediate personal interest*' (Ozcaglar-Toulouse, 2005). The originality of responsible consumption as a research area, besides being various and sometimes surprising, is that it assigns to the consumption a significance that passes the only utilitarian aspects of the purchase. Yet, little research has been given in depth to understand the meaning consumers who declare themselves to be 'responsible' give to their consumption (Cherrier, 2005; Connolly and Prothero, 2003; Moisander and Pesonen, 2002).

Fair trade consumption can provide a rich analysis land. According to Foucauldian approach, fair trade products purchase associated with a political project (changing the current economic system) is a 'politics of self' (Foucault, 1978, 1980). It becomes therefore a way to affirm one's own ideas and engagements but also a means to re-construct one's identity. Instead of postulating a 'fair trade purchase' based on self-expression, the responsible consumption may be viewed as an existential choice. Focusing on the purchase of fair trade products as an illustration, this research studies how current social and environmental concerns about consumption are reviving the topic of meaning in consumption practices, through their contribution to identity construction processes among consumers who declare themselves to be responsible.

The notion of identity is considered in this research broader than the classic features used in traditional studies of segmentation—gender, age, social category, incomes... -; it allows to touch the way the consumer interprets himself/herself and on the role that his/her

ethical consumption plays (or his/her/ voluntary no consumption). For a good part of two decades, the term of 'identity' has occupied a fundamental place in the social sciences and humanities. Its uses-in vogue-also refer to the actual feeling for numerous people to find it difficult to carry through their own identity research, as suggested by the literature on the 'post-modern individual'. The Modernity used to possess the capacity 'to evacuate' easily some individuals' anguishes-exit of the micro and macro social risks-and to assure the continuity of a philosophy turned to the future (Giddens, 1990). But the present context is characterized by the end of the 'meta-narrations' and by a process of 'individuation of the social risks' (Beck, 1986). Generally called a 'crisis of meanings', this phenomenon is felt by some individuals as the necessity of a sense research and it seems to encourage the emergency of new behaviors in everyday life, such as responsible consumption.

An interpretative research method and a hermeneutic approach have been chosen in this research. The generation of data from a qualitative approach is based on the propensity of people to talk about their social experiences in their daily lives and the significance of their consumption. Consumers are not used in general to wonder about the meaning of consumption or the existing links between their acts of purchase and their life trajectory. It seems necessary to 'provoke' consumers to make an in-depth look at their consumption story. Such a way of gathering information is known as the method of 'narratives'.

Fourteen narratives of highly practicing responsible consumers, based on individual interviews, have then been studied using a semantic analysis. The individual and comparative results enable us to enter into the details of the meanings these consumers grant to their consumption and the way the concept of identity can be helpful. A responsible consumption typology, based on the meanings given by the narrators to their acts of purchase, is suggested; it distinguishes the acts of 'moral conformity' from the deep critical postures, the latter of which derive either from political intention or from a wish to get free from the actual consumption 'system'. Moreover, a set of common features has been observed among the 'critical consumers' interviewed. Three of them have already been identified by Cherrier (2005): the quest for 'authenticity', the 'social integration' and the 'control'; they are confirmed and deepened here. Two other features appear: the 'suffering' (related to the upstream feelings of the consumer) and the 'compromise' (related to his practices downstream).

It Doesn't Happen to Mine: A Study of the My-Own-Product Positivity Bias for a Defective Product Management

Jae Il Kim, Seoul National University, Korea
Hak Chul Lee, Seoul National University, Korea

Abstract

This paper suggests that self-positivity bias also can occur at product-level and explores how the bias will be reduced. As a follow up study of previous research on self-positivity bias, this study assumes that consumers perceive those products they possess to be better than those possessed by others or than other same product. Also we demonstrated that this bias which highly cost both consumers and companies is moderated by familiarity with a product. Two experiments were employed to demonstrate the bias and to find the effective moderators which increase my-own-product risk perception. Future study and its applications are discussed.

According to previous studies, people are often overestimators of risk (Slovic, Fishhoff and Lichtenstein 1981) and tend to believe that negative events are less likely to happen to themselves than to other people (Perloff and Fetzer, 1986; Weinstein, 1980). The self-positivity bias which results from "unrealistic optimism" (Weinstein, 1980) was well documented in many areas including car accident and various health problems like AIDS, heart attack, cancer, etc (e.g. Raghuram and Menon, 1998; Perloff and Fetzer, 1986; Kemeny and Hammen, 1991).

At the one end of the continuum, this bias often misleads consumers into nonoptimal decisions like ignoring a likelihood of defective in a product or neglecting a recall alarm which often results from disregarding little notices or policies. For example, consumers believe

that their new notebook has no bad pixel, or their chances of defective sheet of paper in a new textbook are lower than those of others. These phenomena can be widely observed from trivial goods to costly service such as lasik or plastic surgery.

However this bias causes many problems for both companies and consumers. Despite companies' efforts to make consumers' attention to possible risks associated with the products, consumers seldom think a problem ever happens to themselves. Because of this bias, the cost which both consumers and companies should pay increases. Consumers may have to visit a store again. Or they may face a fatal accident without replacing a defective product with new one (e.g. ignoring expiration date in daily products). Automakers may lose their chance of early recall and even face a fatal lawsuit together with bad brand image.

As a follow up study of previous research on self-positivity bias, this study assumes that consumers perceive those products they possess to be better than those possessed by others, and other same products. They think that the chance of negative outcome associated with their possessions will be less likely than that associated with products owned by others.

Because self-positivity bias originated from the wrong perception of self-risk, we can seemingly assume that this kind of bias will be related to products we have. In addition previous studies on the cause of self-positivity bias show that the bias also occurs in case of products. That is, the product-level bias can also make people deny possible risk (Raghuir and Menon, 1998), reduce anxiety associated with uncertainty of outcome (Taylor and Brown, 1988) and make self-esteem maintenance (Weinstein, 1980). Moreover many studies of both psychological and qualitative studies in consumer behavior indicated that much of our psychological mechanism has carryover to our product by possession. McClelland (1951) suggested that external object become viewed as part of self when we are able to control over them. And Belk (1988) argued that possessions give us magical psychological identification. With Weinstein's view, self-concept theory and identity theory can also be applied to our hypothesis that the more people own familiarity with self-allied product, the more they may have a psychological bias associated with their products. Therefore we can also hypothesize that the more familiar or self-closer product which satisfies higher self-esteem maintenance has more bias similar to ours. If consumers consider their own product is more familiar, they believe their possessions will not be associated with negative events.

Experiments were employed to demonstrate the bias and to find the effective moderators of this increasing my-own-product risk perception. In the first experiment which was disguised as a blinded test, we used 3(target owner)*3(products by familiarity rating) design to test that people judge (a) their possessions as being at lower risk than other's and (b) possessions they consider to be more familiar to them to be at lower risk than those less familiar to them. Our new familiarity rating was designed by scales used in previous studies of familiarity scale, self score and intimacy scale, including expected use time and perceived closeness, etc. After offering a newspaper article of a rare but critical error about a product, we gave them a sample and asked them to write down the chance of error of their own. Other groups were offered the same article but asked to write down the chance of error before getting product.

The results of this study indicated that people who had his own product estimate the chance of defectives to be lower than those who didn't. A product highly scored in familiarity rating was perceived to have lower risk. These results supported our hypothesis that consumers project some biases to their owned product.

The subsequent experiment in progress focuses on how to develop an effective "notice" for reducing the product positivity bias. In a pilot study using a new textbook ("Consumer Behavior") in our class, we found that noticing a negative event which occurred to a similar group member reduced the bias and eventually increase risk-perception.

From the view of Lin and his colleagues (2003), perceived controllability will be considered to be designed. By showing the notice which says that the end of refund period is coming soon, controllability condition will be manipulated. The effects of some moderators, framing message cue (Chandran and Menon, 2004), information accessibility (Raghuir and Menon, 1998) - will be examined in the experiments.

This paper suggests that self-positivity bias can also occur in case of products and explores how the bias will be reduced. Future study will focus on what and how biases of consumer are carried over to product and its effective method to reduce it.

Consumers Tripping Over Their Roots

Dale Russell, INSEAD, France

"I really did the tour as a 'roots' exercise and to fit many parts of the jigsaw puzzle that is my heritage, the considerable reading and conceptual development of a lifetime of being New Zealand / British in outlook, and to enjoy the 'green, green grass of my ancestral home' so to speak." (Male, 60, New Zealand)

The growth in global tourism is fueled in part by retirees, primarily from developed countries, born immediately following World War II and now entering retirement age. The premise of this research is that these consumers are using their savings to not only explore

the world, but also to seek a sense of self by returning to the lands of their ancestors, a phenomenon we call ancestral tourism. Where hedonic tourism has been deemed a “nonrational” expenditure as it provides only pleasure to the tourist, ancestral tourism can provide a sense of self by glimpsing at one’s ancestral past (MacCannell 2002, 150).

This research documents the phenomenon of ancestral tourism using a multi-method approach and tests a conceptual model that integrates the extant research on aging, the consumption of authenticity and satisfaction. As consumers grow older, they become reflective on life and develop a need of personal fulfillment that cannot be satisfied by tangible goods. Older consumers often enter a phase whereby they look to dispose of their possessions, which have both sentimental and monetary value, while seeking satisfaction from intangibles (Price, Arnould and Curasi 2000), a process likely to be reflected in the consumption of ancestral touristic experiences. Previous research has attributed a consumer’s search for authenticity as a trek for fulfillment, comparable to that of a religious pilgrim seeking enlightenment (Goulding 2000). This is even more salient for cultural tourists, especially those from western cultures, whose desire to partake in authentic cultural experiences is often the primary objective of their trip (Grayson and Martinec 2004; MacCannell 2002; 1999).

The research was conducted in the context of a 25-day guided bus tour of the United Kingdom (UK) and Ireland; a tour selected because nearly all customers who bought this package in the past were of British or Irish descent and generally resided in former colonies. Therefore, this group of consumers would most likely seek ancestral cultural experiences. The methodological approach was threefold, comprising interviews, observations, and surveys. The triangulation of data served as a validity check while also adding a better understanding to the social behaviors and meanings invoked from the experience (Grayson and Martinec 2005; Hammersley and Atkinson 1995; Arnould and Wallendorf 1994). In an effort to better observe the tour phenomenon, the author actively partook in the tour and optional excursions. The researcher’s direct participation in the tour allowed for better understanding and appreciation of the ancestral tourism phenomenon, as well as detailed observations (Belk, Wallendorf and Sherry 1989).

The tour was designed to expose participants to as much of the UK and Ireland as possible in a short period of time. It was led by a professional tour guide with nearly 20 years of experience. The group consisted of 39 people (18 males / 21 females, mean age of 59), all of them from former British colonies, namely Australia, Canada, New Zealand and the US. The interviews were conducted individually, at the onset of the tour. Exploratory in nature, they sought information regarding the pre-trip planning process, tour expectations, and general background and demographic data. The contents of interviews were then assessed to identify themes to develop a survey instrument. Participant observation was conducted throughout the tour with the researcher maintaining an unobtrusive profile as not to detract from the natural tour experience or bias later survey responses and to maintain the ability to observe from the distance (Palmer 2001; Arnould and Wallendorf 1994). The researcher was able to take detailed notes and pictures of events without drawing attention as such activities are normal for tourists. The survey was administered on the final day of the tour to all participants. The constructs captured the themes identified during the interviews and items to measure them were intermixed. The constructs in the model included: pre-trip expectations, perception of tour as ancestral pilgrimage, perception of tour experience as authentic, cultural experience satisfaction, overall tour satisfaction and likelihood to recommend tour. The last series of questions captured the number of optional tours, the number of souvenirs bought for oneself and the number of those bought for someone else. Finally, demographic information was collected, including age, gender, country-of-origin, country-of-residence, and whether the ancestors emanated from the UK or Ireland.

The survey data along with the qualitative interviews and observations provided rich insights into the phenomenon of ancestral tourism. All participants whose ancestors hailed from the UK or Ireland reported that they considered the trip as a pilgrimage, as the opening quote illustrates. Correlational analysis supported the relationships proposed in the conceptual model. For instance, age was significantly and positively related to the overall number of tours options purchased but negatively related to the number of souvenirs purchased for oneself while positively related to the number of souvenirs purchased for other people. Many participants’ comments reflected a detachment from material possessions at the approach of death, some with a humorous view, others with a more pragmatic one. In turn, the consumption of intangible experiences, such as the optional tours, positively affected perceptions of authenticity and, in turn, overall cultural satisfaction. Among the most important findings was the crucial role that perceptions of authenticity and cultural experiences play in assessing the value of the ancestral tourism experience. Albeit limited by the relatively small size of the group studied, this research provides insights into consumers in search of authentic ancestral experiences.

Affect Without Cognition

Jingjing Ma, Peking University, China

Li Zhang, Peking University, China

Xinxin Ma, Central University for Nationalities, China

EXTENDED ABSTRACT

Do you find young fellows emotional? Do you think that their decisions are often whimsical? Have you noticed that they often buy brands and products that they have no idea of? Then why do they buy? These are the questions regarding brand attitude formation mechanism that is universally accepted as a concept model: cognition-affect-conation. This study tests the model using Chinese young consumers as a sample.

Hypotheses

One question this study seeks to answer is whether brand personality identification, as an affective factor, significantly influences brand buying intention, a conation factor. Nowadays Chinese young generation's value system has changed dramatically. Traditional Chinese notions, such as "Restraint and Obedience" and "Connotation and Introversion" have been replaced by "Do what you like" and "Show your own personality". As a result, the consumption notion of Chinese young generation has also changed. Young consumers pay much attention to products that can show their own personality and demonstrate their own life styles. Then our first hypothesis is: For Chinese young consumers, brand personality identification significantly influences their brand buying intention.

The second question this study seeks to answer is whether Chinese young consumers' buying intention of foreign brands is influenced by brand personality cognition. Since late 1970's, Chinese have more contacts with the west and therefore known more about western world. Chinese young generation has grown up with western products and values. As frequently pointed out by both media and academia, foreign brand personality cognition significantly influences Chinese consumers' brand buying intention. Therefore our second hypothesis is: Chinese young consumers' cognition of foreign brands personality significantly influences their foreign brand buying intention.

Method

Thirty college students enrolled in a well-known university located in Beijing were randomly chosen as participants. In-depth interviews were conducted before a questionnaire was developed. The purpose of the interviews was to identify a pair of brands that could best reflect American culture and Chinese culture respectively. Questions were asked for each of the interviewees: 1) Which American drink/restaurant/apparel brand do you think that can best reflect American culture? 2) Which Chinese drink/restaurant/apparel brand do you think that can best reflect Chinese culture? Results showed that Coca Cola (90% responses) and Xihulongjing tea (70% responses) were thought to best reflect the two distinct cultures by the interviewees. Thus Coca Cola and Xihulongjing tea were finalized as the stimulators for the following survey.

A draft questionnaire was developed based on the interviews and relevant literatures. A pilot test was conducted to check the wording and time span for filling up the draft questionnaire. A questionnaire was then finalized. It comprises measurements of brand personality cognitive strength, brand personality distinctiveness and brand personality identification of both Coca Cola and Xihulongjing tea (independent variables), and measurements of buying intention of both Coca Cola and Xihulongjing tea (dependent variables).

Questionnaire survey was conducted in six major universities located in Beijing. A total of 1,000 questionnaires were distributed and 932 usable ones were returned, with a response rate of 93.2%.

Results

Our first hypothesis is supported. The regression results show that brand personality identification significantly influences buying intention of both Coca Cola and Xihulongjing tea. Young consumers would like to buy the brands that can reflect their personality. This result is consistent with many psychology and marketing theories and research findings. Meanwhile it reveals that popular values of Chinese young generation such as showing their own personality, having their own life styles and expressing themselves influence their buying intention significantly.

Our second hypothesis is rejected. Results show that brand personality cognitive strength and brand personality distinctiveness, as cognitive variables, do not have significant influence on buying intention of foreign brand Coca Cola. It is generally accepted by the academia that cognition is the premise of affect and cognition and affect influence conation. However, buying intention of Coca Cola is only influenced by the affective factor, brand personality identification, not by cognitive factors. Here affect functions independent of cognition. On the contrary, buying intention of Xihulongjing tea is significantly influenced by both cognitive and affective factors, fitting the cognition-affect-conation model perfectly.

Discussion

This research comes up with two very interesting findings: brand buying intention of Chinese young consumers is significantly influenced by their brand personality identification, no matter whether the brand is foreign or domestic. However their brand buying intention is significantly influenced by their cognition of the domestic brand but not the foreign brand. The findings suggest that for Chinese young consumers, the impacts of brand cognition and affect on buying intention may vary between domestic and foreign brands. In the discussion section we will explore the underlying reasons of these findings and the conditions under which they happen. We will also discuss theoretical and managerial implications of this research for consumer behavior and marketing strategies. .

Compulsive Buying Questionnaire and Repression: The Impact of Hot vs Cold Data on General and Gender Scoring

Fabrice Pombet, University of Exeter, UK
Stephen K. Tagg, University of Strathclyde, UK

Mall intercept has been conjectured to be more precise and reliable than other methodologies such as phone surveys (Bush and Hair, 1985) in that less questions were eluded in the former, and the latter was usually yielding more "socially acceptable" answers. This could be caused by a memory priming effect (Bower, 1981) when respondents are answering in a "cold" situation (e.g. inside their homes) rather than in a "hot" situation. In other words, their cognitions could be affected by their affect at the moment when they are filling the questionnaire

Despite a relatively important number of studies related to the measurement of Compulsive buying, the use of questionnaires through mail surveys seems to have exclusively prevailed over the use of mall intercept procedures (e.g. Faber and O'Guinn, 1992; Valence et al., 1988), and most of these studies found a significant difference in self-reported compulsive score between males and females respondents.

In a small recent study involving 49 participants in a mall intercept, self-assessing their compulsivity by answering a Lejoyeux questionnaire (Lejoyeux et al., 1996; Lejoyeux et al., 1997), we were however unable to find any significant difference in genders, even though some other elements of reliability and nomological validity with the hedonic/utilitarian value in shopping (Babbin et al, 1993) were congruent with previous studies.

We thought that the main difference between our study and the previous studies on compulsive buying was the methodology (a "mall intercept" vs mail survey) could explain the lack of significant difference between genders in respect of their scores.

We therefore undertook an exploratory meta-analysis with 4 previous studies using the same Lejoyeux questionnaire (Lejoyeux et al, 1996; Lejoyeux et al., 1997) with different methodologies (2 studies in a mall intercept condition, and 2 studies in a "cold" condition, where the interviewing process was done in the respondents' home), totalling 490 respondents (290 in "hot" condition, and 200 in "cold" condition; 218 male respondents, and 272 female respondents).

The studies included the 20 items likert scales of the Lejoyeux test of compulsive shopping and the shopping value questionnaire (Babbin et al, 1993) was included in order to test the nomological validity of the test (Peter, 1981). The internal reliability for both of the questionnaires was very good overall, and consistent with previous literature findings ($r(\text{lejoyeux})=0.78$; $r(\text{hedonic})=0.93$). Nomological validity was achieved, consistent with previous literature findings (Faber and O'Guinn, 1992) through an established correlation between hedonic value in shopping and the compulsive score ($r=0.364$; $p<0.01$)

Although we found a significant effect of gender over the variance of the compulsive score ($F(1,438)=31.486$; $p<0.0001$; males=3.1; females=4.5), showing that female respondents tend to score higher than males overall in these 4 experiments, we also found a significant effect, at the highest level, of the "heat" condition ($F(1,438)=18.56$; $p<0.0001$; hot=3.3; cold=4.3), showing that the overall levels of compulsivity are slightly higher in "cold" condition than in a "hot" one; it can also be noticed that the interaction of gender and heat is also significant ($F(1, 438)=4.312$; $p<0.05$; male-hot=2.8, male-cold=3.4, female-hot=3.7, female-cold=5.3), showing a possible effect of affect priming in female respondents.

It should be noted that the hedonic score stemming from the shopping value questionnaire are showing a small evolution that is consistent with respect to genders ($F(1,486)=64.28$; $p<0.0001$, male=2.57; female=3.33) and reverse with respect to the heat of the test ($F(1, 486)=11$; $p<0.0025$; hot=3.13; cold=2.79).

It is interesting to note that, contrary to what Bush and Hair's (1985) findings could hint at, we do not find a higher mean score of compulsivity in the mall intercept procedure than in the "cold" procedure, but rather the contrary (albeit the overall difference is fairly small).

It is however interesting to note that females seem to be much more sensitive to the change of methodology than men, whose variation does not seem to change much. We can therefore suspect that this variation could indicate the process by which one tends to get a higher difference in compulsive scores between genders in mall intercepts. It could be possible that the females experience a better mood during shopping than at home, thus inducing an affect priming phenomenon that leads them to appraise differently the consequences of their shopping when they have been shopping and when they are in a different condition. Conversely, men could just appraise their shopping experience less emotionally, therefore leading to a more "consistent" evaluation between a "hot" and "cold" condition.

This meta-analysis should however be viewed as an exploratory study, where the results are subject to confirmation in a further study that can truly compare the two conditions in strictly similar methodological settings. We feel however that the results contained herein may foster some reflections on the overall validity of mail surveys with respect to mall intercept, as far as compulsive buying is concerned. A second potential implication of this study is that there may be more explanations to the difference in results between mall intercept methodologies and "cold" surveys than just more involved and expert shoppers in the former methodology.

CAM: A Spreading Activation Network Model of Subcategory Construction

Zsolt Katona, INSEAD, France

Joseph Lajos, INSEAD, France

Amitava Chattopadhyay, INSEAD, Singapore

Miklos Sarvary, INSEAD, France

Extended Abstract

Considerable research has demonstrated that people create mental categories to process and access the information that they receive (Barsalou 1992), and that these mental categories may be arranged in hierarchical structures (Collins and Loftus 1975). People add new categories, or subcategories, to these structures when they encounter novel objects or experiences, such as new products, that do not fit within existing categories (Sujan 1985; Sujan and Bettman 1989). An underlying assumption of previous studies is that the general category within which people will locate a novel entity, and hence a new subcategory created for it, is known. However, some entities, such as innovative new products, could be assigned to multiple categories (Keller, Sternthal, and Tybout 2002; Moreau, Markman, and Lehmann 2001). It is here that managers and marketers could benefit from a deeper understanding of how mental categorization works.

In this paper, we develop a spreading activation model of the process by which individuals construct new mental categories. In an experiment and an empirical study, we show that the Category Activation Model (CAM) reliably predicts where individuals will locate a new subcategory within an existing category structure.

The ways in which consumers categorize products have important implications for firms. For example, previous research has shown that the category to which consumers assign a new product can affect the inferences that they draw about it (Moreau, Markman, and Lehmann 2001), their evaluation of and willingness to pay for it (Sujan 1985), and their likelihood of retrieving it in memory-based choice (Nedungadi 1990; Nedungadi, Chattopadhyay, and Muthukrishnan 2001). Thus, being able to predict and influence how consumers construct and locate subcategories for entire classes of products, especially radically innovative new products, could benefit firms substantially. For example, when Motorola introduced the Envoy, the first personal digital assistant, consumers had to create a new mental subcategory because, although the Envoy shared many features with existing portable computers, pagers, and organizers, it was distinctly different from products in these categories (Keller, Sternthal, and Tybout 2002). Knowing where consumers were most likely to locate the new personal digital assistant subcategory could have helped Motorola design and market the Envoy to better satisfy their expectations.

Whereas previous research has examined how people access information in hierarchical category structures and the general rules that govern how these category structures grow and develop (Freyd 1983; Murphy and Medin 1985; Rosch 1978), the ways in which people construct individual new categories have not yet been investigated. We develop the CAM to predict where people are most likely to locate a new subcategory within an existing category structure.

We build on previous research that shows that priming a category increases its accessibility and subsequent use (Herr 1989; Higgins and King 1981). Consistent with this research, we assume that when a category is accessed some of the resulting activation remains with the category and the rest spreads through the entire network, or category tree. Further, we assume that when a category is more activated, the probability that a new subcategory will be constructed under it is increased. Combining these two assumptions, it follows that by accurately describing the process by which activation spreads through the network, we are able to predict the probability that a new subcategory will be constructed at any given location within it. In the paper, we show that these probabilities depend on the network's link structure, which determines how activation spreads. Specifically, the CAM predicts that the locus of a new subcategory is strongly influenced by the number of subcategories already connected to each category within the existing structure.

We tested the CAM's predictive ability in an experiment involving an innovative new exercise product that shares attributes with existing products in the health and entertainment categories. In the experiment, we first familiarized 91 participants with a category structure for health and entertainment products. Then we presented them with a description of the new product, and gave them the opportunity to create a new subcategory for it under either the health or entertainment category. We manipulated the number of subcategories already existing under these categories, and also manipulated the priming of these categories using an unrelated proof-reading task. The results support our hypothesis that the probability that a person will construct a new category as a subordinate of a particular category i is proportional to the relative number of categories that are already subordinate to i . Furthermore, the results suggest that people are more likely to locate new subcategories within categories that already contain many subordinates precisely because such categories are more activated and accessible than those that contain fewer subordinates.

In a second study, we further tested the CAM's predictive ability by analyzing how computer users create new file folders within their directory trees. In this study, we analyzed data on nearly 70,000 directories created by more than 1,600 users on internet servers at two universities and a high school. We wrote a program to collect data from these servers and provide a snapshot of each user's directory tree, including the exact time at which each file folder within the tree was created. We then showed that the structure of these directory trees and the process by which they developed are consistent with the CAM's predictions. These results provide support for the CAM in an externally valid context.

In addition to categorizing products, consumers also categorize their expenditures by placing them into mental accounts (Thaler 1999). Since consumers utilize these accounts to track their expenses, it follows that the category to which consumers assign an expenditure may affect their willingness to incur additional expenditures that are either similar or different (Cheema and Soman 2006; Heath and Soll 1996). In two extension studies, we show that the CAM can be used to both predict and influence the location of new mental accounts. Thus, the CAM has implications not only for how new products should be positioned, but also for how they should be priced. Influencing category construction is an exciting area that additional research should examine.

The Appeal of Others: How to Avoid the Self-Positivity Bias

Sutapa Aditya, York University, Canada

Kelley Main, York University, Canada

Nearly 50 years of research and numerous articles on fear appeals have attempted to illustrate the behavioral motivation such appeals may generate (Witte and Allen 2000). The logical reasoning of using fear appeals in persuasion links back to the "drive-reduction model" (Hovland, Jains and Kelley 1953). The model suggests that a message becomes successful in persuasion only when it is sufficiently intense to create a drive and present recommendations capable of mitigating the fear (Keller 1999). Keller (1999) found that people engaging in risky behavior were persuaded more by lower fear appeals than those who were already adhering to healthier lifestyle/avoiding those risky behaviors. Such findings can be explained by the fact that people who practice risky behavior become more defensive in response to high fear appeals as they find themselves more vulnerable when exposed to such fear inducing messages. This is consistent with defense motivated processing, which is a fairly close-minded form, that leads to individuals' desire to hold attitudes or beliefs congruent with positive self-concept (Chen and Chaiken 1999). Perceptions of risk for certain health conditions are not congruent with this desire to maintain a positive self-concept. This defensiveness leads to a lower capacity to process the recommendations presented in the message and thereby a higher inclination to discount the message all together with no appreciable influence on risk perceptions (Kunda 1990, Keller and Block 1997, Keller 1999).

This literature demonstrates the importance of understanding how health communications involving fear appeals may or may not influence consumer perceptions. Ideally, health messages should arouse fear only to the extent that the audience perceives increased risk for themselves leading them to adhere to the prescribed behavior. One critical concern of health communications relates to the "self-positivity bias" of the target audience. This bias demonstrates that people have a general tendency to assume themselves as impervious to the threat of being exposed to diseases (Raghubir and Menon 1998) and they do not feel the need or urgency to adhere to the preventative behaviors presented. This self-positivity bias leads people to discount health related messages in order to maintain their self-esteem (Taylor and Brown 1988). This bias does not occur when people are asked to estimate the risk of unpleasant things happening to another person (Perloff and Fetzer 1986, Raghubir and Menon 1998). This opens a new frontier of research studying how self vs. other related appeals can impact on subsequent persuasion.

Recent work on the self-positivity bias has explored how the compatibility between self vs. other-related emotions of the audience and the referent in the message influences perceptions of risk (Agarwal, Menon and Aaker 2006). However, it is yet to be explored how the referent (self vs. other) in a fear appeal message would influence perceptions of risk and behavioral intentions. The current research attempts to fill this gap by manipulating the referent (self vs. other) in the message using a fear appeal and exploring how the perceptions of risk and intention to adopt the recommended behavior changes accordingly. In this case, we anticipate that when a message is self-referent, it will generate more defensive processing and result in self-positivity bias (i.e. lower perceptions of risk). On the contrary, when the referent is someone else, it is not expected to generate the same defensiveness, and the result will be higher perceptions of risk for themselves.

A one-way ANOVA was designed to manipulate the message referent (self vs. other) and measure subsequent influence on risk perceptions and behavioral intentions. A print advertisement for skin cancer was developed for the study. All groups were exposed to the same advertisement that listed the factors leading to skin cancer and preventative steps that could be taken. The only difference in the ads was the first line, which prompted respondents to think of either themselves or someone else while they read the ad. In total, 57 undergraduate business students at a large eastern university participated in exchange for partial course credit. Post exposure measures on risk perceptions and behavioral intentions were collected. Risk perceptions were measured with a single item asking participants if they felt they were at risk for skin cancer and behavioral intentions were measured with 2 items that were mentioned in the advertisements as ways to avoid getting skin cancer (e.g. how likely are you to wear sunscreen and how likely are you to have a doctor check your skin for damage, $r=.50$, $p<.001$).

Results of the one-way ANOVA showed a significant influence on perceptions of risk ($F(1,55)=5.99$, $p<.01$). A comparison of the means indicated that the other-referent message generated higher perceptions of risk among the respondents ($M=4.43$) as opposed to the

self-referent message ($M=3.28$). The behavioral intentions measure demonstrated the same pattern of results ($F(1,55)=7.31, p<.01$) where those reviewing other referent measure had greater behavioral intentions ($M=4.07$) than those reviewing self-referent message ($M=2.91$).

As expected, results demonstrated the effectiveness of other-referent messages in avoiding the self-positivity bias. Participants who reviewed the other-referent messages were significantly more likely to have higher perceptions of risk for themselves of developing skin cancer. Further, these participants were also more likely to indicate intentions to follow the advice from the advertisement regarding wearing sunscreen and seeing a doctor to avoiding the disease. Future research will need to explore more fully/comprehensively the processing involved in risk perceptions to determine the exact influence of defensive response and its role in the self-positivity bias.

The Effect of Discounting the Influence of Sources of Information on Choice and Product Perceptions

Francine Espinoza, University of Maryland, USA

Rebecca Hamilton, University of Maryland, USA

Extended Abstract

In this research, we examine the effect of the source of the influence (e.g., salesperson or friend) and consumers' ability to correct for the source's influence on their product evaluations. Consumer's perceptions of the source of a persuasive attempt have been found to influence the effectiveness of persuasive attempts in previous research (for a review, see Wilson and Sherrell 1993). People may react negatively when they believe a salesperson has an ulterior motive for persuasion (Campbell and Kirmani 2000), yet yield to a recognized persuasion attempt by a friend (Hamilton 2003).

Wegener and Petty's (1995, 1997, 1998) Flexible Correction Model postulates that individuals correct for perceived bias when they are motivated and able to adjust their judgments, and that they make these adjustments based on their naïve theories about how a given source influences their judgments. We propose that the manner in which consumers correct for a perceived influence on their judgments is influenced by the perceived source of the influence. If people hold different beliefs about how strong an influence a source might have on their judgments, they may account for that influence differently.

Consumers may think that a salesperson is trying to persuade them (Campbell and Kirmani 2000; Stafford, Leigh and Martin 1995), but may not perceive a friend's attempt to influence their judgments in the same way. As a result, they may react differently to the same persuasive message depending on whether a salesperson or a friend delivers it. For example, Hamilton (2003) found that under some conditions, consumers were more likely to comply and choose the "suggested" alternative when a friend (rather than a stranger) was trying to influence them, even though the influence attempt was the same. Therefore, we propose that consumers will be more likely to resist the persuasion of a salesperson than the persuasion of a friend.

However, when consumers are instructed to correct their judgments (e.g., if they are told to avoid letting the salesperson or friend influence their judgments), we expect the pattern to reverse. Because consumers naturally resist the influence of a salesperson, they may overcorrect for the influence of the salesperson, resulting in enhanced effectiveness of the persuasive message rather than reduced effectiveness. In contrast, because consumers do not naturally resist the influence of a friend, an instruction to correct may reduce the effectiveness of the persuasion attempt.

We designed an experiment to test these predictions. The study employs a 2 (salesperson vs. friend) x 2 (no-instruction vs. instruction to correct) between-subjects design. The dependent variables were choice and willingness to purchase the product. Measures regarding persuasion knowledge and ulterior motives were also included.

Participants (N=71) read a written scenario (adapted from Campbell and Kirmani 2000) describing a situation in which they imagined they were looking for a jacket. In the salesperson condition, the salesperson makes a comment about one of the two jackets the participant imagines trying on (the target jacket); in the friend condition, the participant's friend makes the same comment. In the no-instruction condition, participants answered the questions immediately after reading the scenario; in the instruction condition, participants were told to "try their best not to let the salesperson's (the friend's) opinion influence their own opinion." Participants then chose between the non-target and the target jacket and completed the other measures.

As predicted, the salesperson was perceived as more persuasive than the friend ($M_s=6.21, M_f=4.58$), indicating a main effect of source ($F(1, 67)=22.13, p<.001$). Participants also perceived the salesperson as being more manipulative ($F(1, 67)=11.79, p<.001$), less trustworthy ($F(1, 67)=54.57, p<.001$), and less sincere than the friend ($F(1, 67)=16.94, p<.001$). Consistent with their desire to resist the salesperson's influence, we found that in the salesperson condition participants chose the jacket that had not been recommended by the salesperson (the non-target jacket) marginally more often (15% of the time) than in the friend condition (7% of the time) ($\chi^2=3.127, p<.07$).

In the no-instruction condition, participants indicated that they tried harder to resist the salesperson's influence than the friend's influence ($M_s=4.5, M_f=2.83$). However, when they were instructed to correct, they tended to resist the salesperson's influence less and the friend's influence more ($M_s=3.71, M_f=3.77$), resulting in a significant interaction ($F(1, 67)=4.6, p<.05$).

Consistent with participants' perceptions of their resistance, participants in the salesperson condition tended to prefer the non-target jacket relative to the target jacket in the no-instruction condition. However, when they were instructed to correct, there was no difference in their willingness to purchase the two jackets. The opposite pattern was observed in the friend condition, resulting in a significant three-way interaction ($F(1, 67)=4.23, p<.05$). Participants in the friend condition were more willing to purchase the recommended jacket in the no-instruction condition; the difference was not significant in the instruction condition.

Our findings show that when they are not instructed to correct their judgments, participants tend to comply with their friends and resist the salesperson's influence, choosing the recommended jacket more when it was recommended by the friend than when it was recommended by the salesperson. Instruction to correct decreased choice of the recommended jacket in the friend condition and increased choice of the recommended jacket in the salesperson condition, making the proportion of choice equal.

This research builds on earlier research on source effects and on correction by showing that providing instructions to correct can moderate source effects. Notably, when people attempt to correct for a source's influence the persuasiveness of a less trusted source such as a salesperson can actually increase. Despite the advantages of a friend in perceived trustworthiness, manipulativeness and sincerity, a simple reminder to a consumer to avoid being influenced by a third party can make a salesperson just as effective as a friend.

Mental Visual Imagery, Authenticity and Consumers' Attitude Formation towards Licensed Brands

Jen-Yuan Martin Liu, University of Warwick, UK

Qing Wang, University of Warwick, UK

EXTENDED ABSTRACT

Many researchers (e.g. Holt 2002; Kozinets 2002; Thompson et al. 2006) have noted that brand licensing undermines the value of the brands. However some examples suggest differently. Haier, a global brand in home electronics began its ascent in China by licensing refrigerator technology and the brand from German Liebherr Corp. Sanyo Fashion House Inc. obtained license to manufacture and distribute "blue label" Burberry products in Japan. Despite their licensee image, they have both achieved strong brand value internationally.

In this paper, we ask the question "when and how licensed brands achieve the same or even higher value than original brands?" and we reason that consumers' assessment of authenticity may hold the key to this question. Most researchers agree that authenticity is not

an attribute inherent in an object and is better understood and assessed by a particular evaluator in its particular context (Grayson and Martinec 2004). However, little research has studied the antecedents and consequences of authenticity. This is particularly relevant in brand licensing, as the cues for communicating authenticity of a licensed brand will help consumers' assessment of the value of the licensed brand, and these cues may or may not be related to the attributes of the original brands. This research intends to make three related contributions. Firstly, we attempt to develop multidimensional measures for authenticity in brand licensing. Secondly, we will empirically test whether mental visual imagery influence consumers' perception of authenticity. Thirdly, we are to test the link between the types of authenticity and consumers' attitude formation of licensed brands.

Indexical and Iconic Authenticity

Grayson and Martinec (2004) identified two dimensions of authenticity based on the semiotic model developed by Peirce (1998): the *indexical authenticity* and *iconic authenticity*. Indexical authenticity refers to the physical or psychological link which distinguishes the "real thing" from its copies (Grayson and Shulman 2000). Iconic authenticity refers to the preexisting knowledge or expectations which a person perceives something being similar to something else. In order for the licensed brand to be perceived as authentic, the cues for communicating authenticity are crucial, and this process of understanding and specifying these cues is called the negotiation of meaning (Grayson and Martinec, 2004).

Mental Visual Imagery

Past research (e.g. Adeyemo, 1990; Dahl and Chattopadhyay, 1999; MacInnis and Price, 1987) has shown that mental visual imagery is one of the mental processes which one uses to make sense of cues. Mental imagery is a form of internal representation in which information about the appearance of physical objects, events and scenes can be depicted and manipulated (Richardson 1999, P. 3). Research in marketing has distinguished different types of visual mental imagery: the image based on *memory* and *imagination* (Dahl and Chattopadhyay, 1999; MacInnis and Price 1987). These authors define memory image as the event or occasion that a person has personally experienced or observed whereas imagination imagery is a new, never-before-experienced event.

The link between authenticity and mental visual imagery

Assessment of authenticity involves a complex perceptual process (Belk and Costa 1998; Pen˜aloza 2001). A person construes the cues via the formation of mental visual image before further deriving his/her perception about the authenticity of a licensed brand. Iconic authenticity may be achieved when cues are congruent with their memory. Because to view something as iconically authentic, a perceiver must have some preexisting knowledge or perceived similarities of a licensed brand with something he or she is familiar with, memory imagery can be interpreted as the cue which links consumers preexisting knowledge with the perceived iconic authenticity about the licensed brand. Therefore:

H1: Consumers' memory imagery is positively correlated with perceived iconic authenticity.

Imagination imagery involves the creation of previously unseen image and the capacity of imagination imagery determines one's ability to negotiate meaning out of novel information (Adeyemo 1990). To view something as an index, a perceiver must believe it actually has the "factual" and "spatio-temporal link" that is claimed (Grayson and Shulman 2000). Imagination imagery can be interpreted as acceptance of marketing communications from the licensee toward the perception of indexical authenticity by consumers. Therefore:

H2: Consumers' imagination imagery is positively correlated with perceived indexical authenticity.

H3: The more the licensed brand is perceived with iconic cues, the more licensed brand will be perceived as authentic.

H4: The more the licensed brand is perceived with indexical cues, the more licensed brand will be perceived as authentic.

Although both iconic and indexical cues are likely to encourage consumers to believe that a licensed brand is authentic, iconic cues are likely to be more powerful because consumers possess some preexisting knowledge about the licensed brand or perceive similarities with something they are familiar with. Therefore:

H5: Iconic cues have greater influence than indexical cues on consumers' assessment of authenticity.

Finally we examine whether assessment of authenticity will in turn influence consumers' attitude toward the licensed brand. Attitude towards a brand can be defined as consumer's overall brand evaluation (Aaker and Keller, 1990). Cognition is part of the belief formation and the salience of beliefs in tern form attitude (Ajzen, 2002). Assessment of authenticity is one type of cognitive associations assisting consumers to negotiate the meaning of brand licensing. Therefore:

H6: Perceived authenticity is positively correlated with consumers' attitude formation toward licensed brands.

Methods and Measures

There are two stages of data collection in this research: exploratory focus group studies and controlled experiments.

Exploratory Focus Group Studies

The focus group studies were completed. The purpose of the focus group studies is twofold. Firstly, we hoped to gain deeper understanding about how consumers perceive the connections among our three focal concepts and to develop a set of hypotheses. Secondly, it would help with the development of relevant measures to be used in the controlled experiments.

Three focus group interviews were designed and conducted based on the guideline from Krueger (1994) and Yin (1984). Twenty-six informants (20 to 35 years of age) were recruited from both undergraduate and postgraduate students in a west midland university in the United Kingdom. Each focus group lasted around 60 minutes. The informants, 51% of which are female, have Chinese origin. These informants were recruited for the consistency with second stage of data collection in China. The focus group results were content analyzed according to the guideline of Yin (1984). The results shown that, firstly, the distinction between the use of memory and imagination imagery is important to assess authenticity of licensed brands. Secondly, there exist different antecedents for the two dimensions of authenticity (detailed findings will be reported in the full paper).

Controlled experiments

A set of controlled experiments will be employed to test our derived hypotheses. Brand selection criteria are based on Aaker and Keller's (1990), i.e. relevance to the subjects, generally perceived as high quality, able to elicit relatively specific associations. Two hundred students will be recruited from a Chinese university to participate in the study. Chinese market is chosen because of its market size and rapid growth in licensing activities (LIMA, 2005).

The independent variables are visual mental imagery and authenticity. Visual mental imagery types will be manipulated by instructing participants to rely on either imagination or memory when evaluating authenticity. The measurements for manipulation check will be adopted from Dahl and Chattopadhyay's (1999) 7-point scale. Two 7-point authenticity measures were developed based on focus group findings:

- (a) Indexical authenticity in brand licensing: novelty, level of involvement of the brand owner, and perception about distribution.
- (b) Iconic authenticity in brand licensing: quality, country of origin, and trademark.

The dependent variable is attitude toward the licensed brand. To measure attitude toward licensed brand, we will adopt Kind and Smith's (2001) 7-point semantic differential scale. Two experimental factors (imagery types) will be manipulated. Experimental design will consist of a 2 (imagery type) x 2 (authenticity type) + 1 control mixed model. Imagery types are between-subjects variables, with subjects exposed to a set of either memory or imagination stimuli. Authenticity types are crossed within-subject, so that all subjects will be exposed to all levels of these variables.

Understanding Value Perceptions in Consumer Relationships: A Look at the Role of Self-Esteem

Sylvia Long-Tolbert, University of Toledo, USA
Raj Suri, Drexel University, USA

Introduction

Value is essential in today's world of marketing. Levere (1992) argues that, "when it comes to value, today's consumers want to know precisely what kind of bang they are getting for their bucks" (p.18). Additionally value has been touted as the central driver of customer satisfaction (Woodruff 1997). Lichtenstein et al. (1990) argue that consumer seek the "lowest priced product that meets his or her specific quality requirements" (p. 56). While these convergent viewpoints suggest that consumers seek low prices, previous research indicates that even though firms might provide a high quality product at an appropriate price, individual differences could influence consumers' processing of product attributes and lead to different perceptions of value (Rao and Monroe 1988; Inman et al. 1997). This affect of individual differences in consumers' evaluation of products raises an issue for firms that decide to compete on offering superior customer value (i.e., lowering prices).

The notion of receiving good value is always welcomed news to consumers. This point has not been lost on behavioral scientists, who have proposed that there is a fundamental human tendency for people to seek positive or self-enhancing feedback (Swann et al 1990). For example, consumers generally feel good when they receive great value from their market choices and will attribute such favorable outcomes perhaps to their decision making capacity or ability to recognize a good deal. However, it has been established that not all people are equally motivated to self-enhance or to feel as confident about generating positive outcomes.

Individual differences in self-esteem, that is, one's global self evaluation is a key factor in explaining how people perceive and construe their own behavior and performance (Baumeister 1982). Furthermore, consumer perceptions of value might vary depending on the type of relationship between consumers and a firm (Woodruff 1997). The extent to which individual differences such as self-esteem and the nature of consumer relationships with retailers impacts value perceptions is the focus of this research.

Theoretical Background

The Role of Self Esteem in Value Perceptions

Self-esteem is known to play a key role in determining a buyer's susceptibility to marketing communications (Maile and Kizilbash 1977). For instance, consumers with low self-esteem tend to be influenced by less credible than the more credible communications whereas consumers with high self-esteem tend to be persuaded by marketing messages only when communications is deemed credible. Those with high self-esteem hold high expectations about outcomes and expect to excel at whatever task they undertake (Tice 1993). As a result, they exert maximal effort towards processing information and are willing to take risks to stand out in self-enhancing ways (Baumeister 1982). Those with positive self views tend to process information deeply even when faced with uncertainties (Swann et al. 1990). In contrast, people with low self-esteem lack confidence to form judgments and are thus not inclined to extensively consider information to form independent judgments that might call attention to their perceived deficiencies (Baumeister 1982; Baumeister and Tice 1985).

The degree of confidence that consumers have in their price knowledge relates to their purchase experience and their attitudes towards the company making the offer. In situations where consumers have established, loyal relationships with a company, their trust and confidence in the company's practices could potentially enhance customer loyalty (Siredeshmukh, Singh and Sabol 2002). Furthermore, Suri and Monroe (2003) showed that when consumers spend cognitive resources to process information they use price more to determine the perceived sacrifice associated with the purchase of a product and consequently its value (i.e., low price represents low sacrifice and high value). On the other hand, when cognitive resources are limited, price is processed more in its role to evaluate a product's quality and value (i.e., low price represents low quality and low value).

Integrating the role of self-esteem and customer loyalty, we expect that consumers with high self-esteem will spend cognitive effort to process information and associate low (high) prices with high (low) perceived value. Because they process information thoroughly and are also tolerant of risk, high self-esteem consumers are prone to draw on their prior knowledge about market prices and likely to utilize internal rather than external reference prices in brand choice decisions even when evaluating price information in uncertain situations (Mazumdar and Papatla 1995). Consumers with low self-esteem, however, want to avoid risky outcomes (Baumeister 1982). To reduce the possibility of making a bad decision, they are apt to trust external information (e.g., provided by retailers) rather than their own prior price knowledge (Brockner 1984) but are likely to feel at a loss when engaged in relationships with multiple retailers. This conceptualization leads to the following hypotheses:

- H1: High self-esteem individuals will perceive low (high) price as high (low) in perceived value irrespective of the consumer relationship with a retailer.
- H2a: Low self-esteem individuals will perceive low (high) price to be high (low) in perceived value when they maintain a relationship with a single retailer (exclusive loyalty).
- H2b: Low self-esteem individuals will not perceive differences in value between low and high prices when they maintain relationships with multiple retailers (divided loyalty).

Methodology

This exploratory study included 196 undergraduate students enrolled in an introductory business course. Participants were randomly assigned to one of the conditions in a 2 (price: high and low) X 2 (customer relationship: single- versus multi-store loyalty) between subjects

design. Participants read a hypothetical scenario describing a customer's relationship with one or two retailers who specialized in selling denim apparel. This scenario was followed by the presentation of price and other attribute information for a pair of Levi blue jeans, available at the focal retailer for either a low price or high price. Participants completed a number of perceptual and attitudinal measures about price including perceived value, loyalty and behavioral intentions. They also completed the Rosenberg (1965) self-esteem scale a week prior to completing the main study.

Preliminary Results

Based on a median split of participants' score on the Rosenberg self-esteem scale, support was obtained for all hypotheses. Consistent with predictions of H1, high self-esteem individuals reported differences in value perceptions between the low- and high-price jeans in both the relationship conditions, with the low price jeans being associated with high perceptions of value and purchase intentions than the high-price jeans. Support was also obtained for H2a and H2b. The results showed that low self-esteem individuals associated high perceived value with the low-price jeans under conditions of exclusive loyalty, but under conditions of divided loyalty low self-esteem individuals found no difference in value between low- and high-price jeans. Additional analyses indicated that self-esteem was a better predictor of the patterns of value perceptions in the relational setting used in this study compared to individual differences in value consciousness (see Lichtenstein et al. 1990).

Conclusion

The results show that not all consumers seek low prices in today's relational environments. It appears that the confluence of strategic (i.e., pricing strategy), situational (relationship type) and individual factors (self-esteem) can have significantly different consequences on how consumers cognitively process price information and the construction of value perceptions. Based on the findings of this exploratory study, the role of value perceptions in consumer relationships warrants further investigation.

Perceived Fairness: Conceptual Framework and Scale Development

Sooyeon Nikki Lee-Wingate, Rutgers University, USA

Barbara B. Stern, Rutgers University, USA

Fairness is a concept that first entered the English language about 1460 as a referent to "equitableness, fair dealing, honesty, impartiality, uprightness" (*Oxford English Dictionary Online*, 2004, 3). From the outset, the concept was associated with morality, commerce, and public life, for its first recorded use is in the line, "it is best that we treat him with fairness," found in religious plays (*Towneley Mysteries*, c. 1460, Cawley 1963) put on for townspeople by medieval craft guilds such as cloth merchants or tanners. The definition has remained remarkably unchanged in six centuries of use, and is now a cardinal concept in social science and marketing research, referring to an individual's social judgment about what is "just" or "deserved." Its importance lies in its influence on an individual's feelings, attitudes, and behaviors in interactions with others (Campbell 1999; Feinberg, Krishna, and Zhang 2001; Tyler and

Smith 1998), for perceptions of fairness have been found to have significant psychological consequences such as associations with feelings of anger (Montada and Schneider 1989), envy (Smith, Spears, and Oyen 1994), psychological depression (Walker and Mann 1987), and self-esteem (Koper, Van Knippenberg, Bouhuijs, Vermunt, and Wilke 1993). Perceived perception has also been found to have significant marketing consequences in reference to consumer satisfaction and repeat purchase intentions (Oliver 1993, 1997; Oliver and Swan 1989a, b). Yet despite the concept's presence across research domains, there is a lack of threaded discourse attributable to the commingling of cognitive and affective elements and the failure to distinguish between antecedents and consequences.

To disentangle the elements and establish hierarchical order, we begin by revisiting the cognitive and affective dimensions in terms of theories of equity (Adams 1965; Austin 1977), relative deprivation (Crosby 1982, 1984), and consumer satisfaction (Oliver 1997). Even though most theorists consider fairness to have a cognitive core, there is no consensus about the presence or nature of a causal relationship between cognition and affect. The reason seems to be that the treatment of fairness as a concept in its own right has been taken second place to treatments of it in reference to positive emotional responses such as satisfaction and/or negative ones such as anger and guilt. In consequence, different studies and researchers yield different lists of antecedents and consequences, and controversy abounds. For example, social psychologists do not agree about whether an individual's degree of satisfaction with a purchase is an antecedent or consequence of his or her perception of fairness (Messick and Sentis 1983). Further, emotion/cognition confounding is perpetuated in recent study findings (van den Bos 2003) that even unrelated moods influence fairness perceptions (van den Bos 2003). Despite efforts to identify satisfaction and fairness as separate concepts in social science research, with satisfaction influenced by one's personal history of outcomes, and fairness influenced by one's comparison of personal outcomes to those of relevant others (Blau 1964; Austin, McGinn, and Susmilch 1980; van den Bos, Wilke, Lind and Vermunt 1998), the issue of hierarchical order remains unclear. Even though satisfaction theorists in marketing generally consider fairness an antecedent to satisfaction (Oliver 1993, 1997; Szymanski and Henard 2001), the order may well be the reverse, depending on how one defines both concepts.

Another problem that arises in studies of fairness vis-à-vis unfairness and negative affect is exacerbated confounding of cognitive and affective antecedents and consequences. Whereas classic accounts of the relationship between judgments of injustice and negative emotional consequences (Adams 1965; Homans, 1961; Walster, Berscheid, and Walster 1978) suggest that cognition of injustice precedes negative affect, later accounts claim (O'Malley and Davies 1984; Scher and Heise 1993; Sinclair and Mark 1991) that in some situations, negative affect may precede and/or influence cognitive ones. Admittedly, limitations are built into these studies, for the virtual simultaneity of unfairness perceptions and negative emotional consequences makes hierarchical ordering difficult. Further, unfairness is an ambiguous state that can be triggered either by receiving less than is fair (anger or resentment) or more than is fair (guilt or fear of retaliation), with the dominant effect of the latter especially difficult to identify. But notwithstanding the limitations, closer study of fairness in relation to similar concepts is required to clarify its attributes, measurement, and outcomes.

Lack of clarity has led to random definitions of fairness with different researchers relying on different ad hoc scales. Some are single-item, and thus lacking in reliability and validity (e.g., Austin, McGinn and Susmilch 1980; Greenberg 1987; Messe and Watts 1983; Seligman and Schwartz 1997; van den Bos et al. 1998). Even though some multiple-item scales have been devised in the social sciences, insofar as their focus is on affective responses, they do not contribute to the understanding of fairness as a multidimensional concept (Scher 1997). In the business disciplines, the study of fairness in organizations is also beset by non-comparable definitions and measures (Blader and Tyler 2003). In marketing research, where the tendency to use ad hoc scales also exists, the dominant focus on price fairness (Darke and Dahl 2003) or service fairness (Clemmer 1993) does not seem sufficiently rich to capture the broad dimensionality of consumer perceptions of fairness. Thus, we find that a theoretically sound scale of fairness in the consumer context has yet to be developed, and to do so, we must first construct a comprehensive framework suited to study consumer perceptions.

Our paper will present a multi-item fairness scale designed specifically for use in consumer research and tested empirically to provide evidence of its construct, internal, and external validity and reliability. Following the fairness research literature, we will conduct experimental studies to develop a new scale that encourages an integrated expansion of fairness perception research. Study findings and the new scale will be finished in time for presentation at the ACR 2006 Conference.

Effect of Mood on Information Processing Style and Consequent Purchasing Decisions

Kang-Ning Xia, National Chengchi University, Taiwan

Extended Abstract

Moods are a transient and slight mental state; they are different from emotions, which are strong and long lasting feelings (Peterson and Sauber 1983). Moods occur and fade away, any time, any place. Small environmental cues, for example, a piece of music, a store display, a smile sign, or some smells can elicit good or bad moods (Schwarz and Clore 1983). Therefore, it is feasible to suggest that moods may be manipulated through advertisements, level of service, shopping contexts and marketing tools. Thus the purpose of this study is to explore the effects of mood arousal by these methods on consumers' cognition of product attributes.

Previous research has shown that people in different moods may be inclined to adopt different information processing styles (e.g.: Mackie and Worth 1989; Gardner and Hill 1988; Kuykendall and Keating 1990). The primary mechanism behind the above is that people in a good mood have the motivation to maintain their good mood, so their cognitive resources are relatively lower than those of neutral or bad moods (Forest, Clark, Mills, and Isen 1979). In other words, due to the instinct to maximize reward and minimize punishment, people in a good mood will exert, consciously or unconsciously, an effect on prolonging happiness; hence, most of their attention and cognitive resources are employed to retain the good mood, and they don't have the capacity and willing to contemplate things in a systematical way. When using the heuristic-systematic model (HSM) (Bohner, Moskowitz, and Chaiken 1995; Bohner, Ruder, and Erb 2002) to classify

information processing styles, a good mood will lead to the heuristic thinking approach, because people with a heuristic thinking approach evaluate events based on available and applicable heuristics and employ less cognitive effort and capacity. On the contrary, a bad mood will lead to the systematic thinking approach, and people with a systematic thinking approach process information in a more analytical style; they analyze events more rationally and don't give judgments based solely on environmental cues.

Furthermore, people with different information processing styles will exhibit varied responses to marketing messages. This study suggests that people with different information processing styles pay attention to different product attributes, meaning that when shopping in a store or making purchasing decisions, the importance and attractiveness of the product attributes will change as the consumers' information processing styles change. Product attributes have been dichotomized into intrinsic and extrinsic cues (Olson and Jacoby 1972): intrinsic attributes are the physical composition of the product, for example, color, texture and size. Extrinsic attributes are external to the product, such as brand name, advertising, and brand image (Olson and Jacoby 1972). Obviously, the evaluation and comparison of intrinsic attributes among several products requires more cognitive labor, while using extrinsic attributes, for example, brand reputation, to determine which to buy requires less cognitive resources. Therefore, it is proposed that the consumers who employ heuristic thinking tend to pay more attention to extrinsic attributes, while the consumers who employ systematic thinking tend to be concerned more with intrinsic attributes.

In this study, the influences of mood on the consumers' cognition of product attributes are examined. All the 60 respondents were randomly assigned to the three experimental conditions: good, bad, and neutral mood. Short films were then applied to elicit good, bad, and neutral moods. After seeing the 2 minutes short movies, all respondents were told to complete questionnaires about their favorite movie styles and movie-watching behaviors as the experimental filler—the purpose of the filler was to avoid the respondents guessing the objective of this study. When the questionnaires were completed the experimenter asked them to help with an “unrelated survey”—the digital camera purchasing decision survey. In the questionnaire, several intrinsic and extrinsic attributes were listed, and respondents were asked to evaluate the importance of every attribute to their purchasing decisions.

The data of this research show that the consumers in a good mood are inclined to focus on extrinsic attributes more than intrinsic attributes ($t=2.21, p=0.0453$); the consumers in a bad mood are inclined to pay more attention to intrinsic attributes ($t=-2.33, p=0.0352$). For the neutral mood respondents, there is no difference between the intrinsic and extrinsic attributes in their decision weight ($t=-0.12, p=0.9401$).

Therefore, this study shows that moods do indeed influence the cognition of product attributes via differing information processing approaches. A good mood results in concerns about extrinsic attributes, whereas a bad mood results in a focus on the intrinsic attributes. This is a meaningful and useful result that can be extended to advertising and market research, for example, the effect of retail settings, the service quality of waiters, or the advertisement context on mood and attitude.

Measuring the Antecedents of Impulsive Buying Behavior on the WWW

Arne Floh, WU Wien, Austria

Maria Madlberger, WU Wien, Austria

Introduction

Marketing practitioners have long realized the importance of impulsive consumer actions and use new technologies like collaborative filtering to enhance unplanned cross- and upselling. Amazon.com, for example, generated 23% of its sales from purchases made by suggesting customers' products which “similar” customers had already bought (Economist, 2000).

However, marketing scholars have not spent much attention on this research topic. Madhavaram and Laverie (2004) state a significant deficit in conceptual and empirical research concerning online impulsive buying behavior. This gap is surprising given the fact that online shopping is an easily mode for making unplanned purchases (Donthu & Garcia 1999).

The purpose of this paper is to: (1) review and analyze existing research (2) broaden and adopt the concept of impulsive buying to the online shopping environment (3) discuss different antecedents of unplanned purchases on the internet and (4) present exploratory research findings of a pilot study.

Conceptual Framework

Impulsive buying is defined as a purchase decision made within the store without an explicit recognition of a need for this purchase before entering the store (Abratt & Goodey, 1990; Bellenger, Robertson, & Hirschmann, 1978). Basically, the four main factors can be distinguished to have a direct or indirect influence on impulsive buying behavior. Most of them have been subject to thorough analysis in store-based retailing (Kollat & Willet 1967; Rook 1987; Youn & Faber 2000), but have not been validated in an online shopping context:

The relevance of in-store *marketing stimuli* for unplanned purchases is evident (Belk, 1975; Kollat & Willet 1969; Rook 1987). Possible stimuli of an e-retailer are banners, pop-ups and newsletters. We add electronic marketing stimuli to our model and suggest a positive effect of banners, pop-ups etc. on impulsive buying behavior. [H1]

Situational factors are environmental conditions that surround the buying process and may hinder or favor unplanned purchases (Stern, 1962). Situational factors are diverse constraints at the time of the purchase as well as the individual's current mood (Dholakia, 2000). The authors suggest a negative influence of constraints on impulsive buying behavior and differ between technical (registration, online payment systems) and other constraints (time, money). [H2]

Personal factors: In their article from 1986, Cobb and Hoyer pointed out that early impulsive buying research had widely neglected the role of consumer characteristics. In social sciences research, impulsivity trait has been identified as an appropriate dimension of impulsive behavior (Plutchik & van Praag, 1995). We suppose a positive effect of impulsive trait on impulsive buying behavior. [H3]

Technical factors: This category of influencing factors has been added due to different characteristics of online shops compared to an offline in-store environment (Adelaar et al., 2003). The authors suggest including website quality and browsing as additional explaining variables (Seethamraju, 2004). Both variables have a supposed positive effect on impulsive buying behavior [H4, H5]

Method

This study is based on a focus group with frequent online shoppers, followed by a data collection using a web questionnaire. The focus group shows (1) the high practical relevance of impulsive buying in online shopping (2) the important role of constraining factors (3) the most frequent unplanned product categories purchased in an online shop (books, CDs and DVDs). Afterwards, an email was sent out to 2,000 students. 290 completed the questionnaire. However, only 91 students quote online impulsive behavior in the past.

Results

All used items and scales meet the recommended levels of fit indices (Hair, Anderson, Tatham, & Black, 1995): (1) substantially high positive factor loadings (2) indicator reliability above .4 (3) factor reliability higher than .6 (4) values greater than 0.5 for the average variance extracted and (5) GFI above .9 (6) RMSEA below the recommended upper limit of 0.08.

Standardized regression weights are significant at .01-level, supporting all hypotheses except H3. Based on these results, we conclude that the model has been validated successfully and can be seen as appropriate for the explanation and prediction of online impulsive buying behavior.

Summary

Literature review of existing impulsive buying research shows a significant lack of studies explaining unplanned purchases of online shops. This paper tries to fulfill this gap by measuring the antecedents of impulsive buying. Additional explaining factors like technical constraints or browsing suggested by the IS literature are added into the causal model. The results of a pilot study show satisfactorily local fit indices indicating high construct validity of the used scales. The supposed hypotheses of the causal are only partially confirmed. The authors suggest conducting further studies focusing on different product categories and personal characteristics.

Uncertainty, Virtual Consumption, and Prolonged Happiness

Cheng Qiu, National University of Singapore, Singapore
Yih Hwai Lee, National University of Singapore, Singapore

Abstract

People generally dislike uncertainty. However, recent research shows that uncertainty associated with positive events may actually prolong people's happiness. The present research further suggests that whether an uncertain positive event (e.g., winning a lucky draw

but not knowing the particular prize won) would lead to prolonged happiness depends on the amount of imagery thought elicited by the event. Positive moods would be sustained only when people can generate sufficient imagery thought about the various possibilities involved in the event. Results from three experiments lend support to the proposed mechanism underlying happiness prolongation following uncertain positive events.

Effects of Interpersonal Influences on Innovation Evaluation

Eva Tomaseti, Polytechnic University of Cartagena, Spain
Salvador Ruiz, University of Murcia, Spain

In the present economic environment, where technological advances happen very quickly and a product's life cycle is cut short, companies need a strategy for innovations development to accomplish the objectives. In this paper, we analyze how the addition of innovations affect product evaluation, and how this influence is affected by the type of innovation, but also by the individual's interpersonal influences. The preliminary analyses confirm that the impact of the interpersonal influences on innovation evaluation depends on innovation type.

The Relationship Between Consumer Guilt and Shopping Behavior

Lien-Ti Bei, National Chengchi University, Taiwan
Yu-Tse Lin, National Chengchi University, Taiwan
Chang-Min Yu, National Chengchi University, Taiwan

Extended Abstract

Guilt is a negative state that an individual experiences in reaction to either a positive but undeserved event or a negative but deserved event (Roseman, 1984). Despite its negative valence, guilt is considered a functional emotion, because it informs individuals that they have violated personal or social standards and motivates reparative action (Tangney, Miller, Flicker, & Barlow, 1996). In a consumption context, guilt has been linked to impulsive buying (Rook, 1987), compulsive consumption (O'Guinn & Faber, 1989), and overspending (Pirisi, 1995). This guilt about consumption is usually named "Consumer Guilt." Furthermore, Burnett and Lunsford (1994) defined consumer guilt as "a violation of one's internal standard and subsequently a lowering of self esteem"; they also suggested four dimensions of consumer guilt: financial guilt, health guilt, moral guilt, and social responsibility guilt. Although previous research has defined consumer guilt, the difference between consumer guilt versus guilt in a general term is not clear. Beyond the several categories of consumer guilt, the construct and measurement of consumer guilt are still not available in previous research. Therefore, this study focuses on the relationship between the consumers' shopping behaviors and consumer guilt and intends to explore the dimensions and evolution of consumer guilt.

In order to find out the relationship of the consumer guilt and shopping behavior, respondents were reminded with a shopping situation which consumers usually have the feelings of guilt, which is self-gift giving. Self-gift giving has been promoted heavily as a reward as "you worth to own it" to oneself in advertising. However, under the constraints of budgets and the influence of traditional values, consumers may still hesitate to buy themselves gifts. Self-gift giving is a situation which can elicit consumer guilt. Thus the interviewees were requested to recall their last self-gift giving situation. This research employed the critical incident techniques. A simple constructed questionnaire was first designed and pre-tested three times before the main field work. The main study contains 60 self-gift giving events.

The results illustrate three major findings. First, before beginning the construct development of consumer guilt, we suggest that guilt is an independent construct that is different from the negative side of satisfaction and happiness. 9 questions about the feelings of satisfaction, happiness, and consumer guilt are asked. The respondents are asked to rate, on a nine-point scale, "Before you buy this gift for yourself, how happy, satisfied, and guilty you are?", "when you are buying this gift for yourself, how happy, satisfied, and guilty you are?" and "After you buy this gift for yourself, how happy, satisfied, and guilty you are?" (1=extremely not satisfied, happy, and guilty; 10=extremely satisfied, happy, and guilty). According to the results of factor analysis, they can divide into four factors. Three questions about consumer guilt, consumer guilt after buying, before buying, and at the point of buying, group to one factor (factor loadings=0.84, 0.75, 0.72). The two questions about satisfaction and happiness before buying group to one factor (factor loadings=0.94, 0.89). The two questions about satisfaction and happiness after buying group to one factor (factor loadings=0.91, 0.91). The two questions about satisfaction and happiness at the point of buying group to one factor (factor loadings=0.93, 0.92). Therefore, the result indicates that consumer guilt is different from negative satisfaction and happiness.

Second, through collecting, sorting and analyzing 60 self-gift giving events, the results pointed out consumer guilt had three dimensions: hesitation, pain of paying, and self-blame. The hesitation means that consumers think they should stop buying these gifts because buying these gifts has violated their value judgment or social standards. In addition, the pain of paying means that consumers have to pay much money when they buy something in a store. Furthermore, the self-blame means that consumers feel something wrong and don't understand why they have bought something and they disagree with their reason for buying them.

Third, the past researches indicated consumer guilt can divide into two categories: reactive guilt and anticipatory guilt (Rawlings, 1970). Anticipatory guilt occurs before buying and reactive guilt occurs after buying. Our study finds that besides anticipatory guilt and reactive guilt, consumer guilt occurs at the point of buying. We name it proceeding guilt. In addition, the three dimensions of consumer guilt, hesitation, pain of paying, and self-blame, can match the three moments of buying. The major dimension of anticipatory guilt is hesitation, the major dimension of proceeding guilt is pain of paying, and the major dimension of reactive guilt is self-blame.

Scarcity's Effects on Evaluation of Prices

Rajneesh Suri, Drexel University, USA
Chiranjeev Kohli, Cal. State Fullerton, USA
Kent B. Monroe, University of Richmond/Drexel University USA

Abstract

This research develops a conceptual framework which incorporates both the motivational and the interference effects of scarcity on information processing. The results from two studies show that scarcity influences consumers' perceptions of price information for a travel package with the pattern of results being dependent on price levels and consumers' motivation to process information. Analyses of thought measures provided further support for the underlying processes.

Consumer Response to Marketplace Deception: Implication of the Persuasion Knowledge Model

Guang-Xin Xie, University of Oregon, USA
David M. Boush, University of Oregon, USA
Courtney N. Boerstler, University of Oregon, USA

Extended Abstract

Deception—intentionally misleading others about the truth—is a fundamental human behavior, commonly practiced in the marketplace by both buyers and sellers. Building upon the Persuasion Knowledge Model (Friestad & Wright, 1994), we propose that consumers develop sensitivity and coping strategies in response to marketers' deceptive attempts. In particular, consumers' deception knowledge functions as a sensor in the formation of a valid attitude towards an advertisement or an influence agent. This process is described as associative decision making in psychology literature (e.g. Massaro, 1994). The basic notion is that consumers are able to recognize similar misleading patterns based on what they learn about marketers' practices. Therefore, they are more likely to perceive advertisement as deceptive and are less likely to be misled.

The Persuasion Knowledge Model (PKM) is a useful framework for organizing knowledge that is relevant to marketplace deception since knowledge of deception can be viewed as a subset of knowledge about persuasion. The PKM argues that from early childhood through early adulthood and beyond, an individual develops knowledge relevant for the two persuasion-related tasks of everyday life: coping effectively with others' persuasion attempts and effectively executing one's own persuasion attempts. In this study, we aim to investigate the functions and limits of deception knowledge when consumers cope with deceptive ads. Both situational factors and individual differences are examined: knowledge or salience of the potentially deceptive tactics used, high and low stake situation (whether the expected consequence of being misled is serious), and cognitive optimism (the extent to which consumers wish the claims were true).

Hypotheses

First, we hypothesize that consumer deception knowledge increases the perceived deceptiveness of advertisements. Deception knowledge refers to consumers' beliefs about a deceptive agent's motives, strategies and tactics, and how to cope with deception episodes. Although deception knowledge does not necessarily lead to an accurate judgment, it makes consumers more skeptical toward advertisements. Second, we argue that high or low stake situation moderates the effect of perceived deception on consumers' attitude. In high-stake situation, consumers believe that being misled may cause serious consequences to themselves or others (e.g. safety and health problems), so they will form a stronger negative attitude. Third, we argue that consumers' attitude is also influenced by the degree to which consumers would like to believe the advertising claims are true. Advertisers often encourage consumers to believe that purchasing a product or service will make them more attractive, sexy, glamorous, popular, etc. The mechanism of cognitive optimism that leads to wishful thinking reduces consumers' negative attitude toward deceptive advertisements. Even though consumers do not completely trust advertisers' claims, positive thinking brings hopeful comfort and triggers an intention to try.

Method

The experiment used a 2 (instruction of deception knowledge vs. no instruction, between) X 2 (high vs. low stake situation, between) X 2 (deceptive ads vs. non-deceptive ads, within) mixed design and was administered to one hundred and thirty-three college students on personal computers. Deception knowledge was manipulated by instructions placed at the beginning of the questionnaire. The one-page instruction described the nature of deception knowledge, common deceptive tactics and cues to detect deception in advertising. Participants in the control condition were not given the instruction. The seriousness of expected consequences and advertisement deceptiveness were manipulated by having the participants view different types of print ads. In the high-stake situation (with serious consequences), participants rated six ads, half of which were higher in deceptiveness, and half of which were lower in deceptiveness. This was repeated in the low-stake situation (without serious consequences). A total of 12 stimuli were selected out of 248 print advertisements in major U.S. popular magazines published during the past two years. Stimuli were carefully examined along the manipulation dimensions in a pretest with 48 college students.

Results and Discussion

The repeated-measure ANOVA results show that deception knowledge significantly increased perceived deception but did not change attitude toward advertisements. Participants in the instruction condition (Mean=5.19, SD= 1.51) rated the ads as more deceptive than those in the no instruction condition (Mean=4.63, SD=1.38), $F(1, 130)=6.007, p<.05$. Also, perceived deceptiveness had a significant negative impact on attitude toward ads, $F(1,128)=31.581, p<.001$, when deceptive ads led to stronger negative attitude (Mean=4.96,

SD=1.33) than non-deceptive ads (Mean=5.63, SD =.99). There was no significant interaction between deception knowledge and high vs. low-stake situation, $F(1,128)=2.51, p>.05$.

There was a significant interaction between perceived deceptiveness and high vs. low-stake situation, $F(1,128)=41.63, p<.001$. Consumers' attitude toward deceptive ads (Mean=4.23, SD=1.24) was more negative than that toward the non-deceptive ads (Mean=5.63, SD=1.03) in high-stake situation. In low-stake situation, however, participants' attitude toward deceptive ads was not significantly different from that toward non-deceptive ads. Further, when individuals' cognitive optimism was controlled for, the interaction between perceived deceptiveness and high vs. low-stake situation remained significant; however, the main effect of perceived deceptiveness was no longer significant, which suggests that participants who wish the claims were true tended to hold less negative attitude toward advertisements despite perceived deceptiveness.

This study extends the Persuasion Knowledge Model to marketplace deception. Deception knowledge appears to make consumers more skeptical toward advertisements. However, whether it involves with a high or low stake situation moderates the effect of perceived deception on attitude. When consumers foresee more serious consequences, they tend to hold stronger negative attitude toward deceptive advertisements. Also, individuals' desire to trust advertised claims appears to moderate the negative effect of perceived deceptiveness on attitude. As consumers want to believe ads, they tend to hold less negative attitude.

Consumer Consideration Sets: Altering Memory, Brand Evaluations, and Choice

Antonia Kronlund, Brock University, USA
Carolyn Yoon, University of Michigan, USA

Brands that have increased memory accessibility have an advantage to less accessible brands (Nedungadi, 1990). The present work focuses on the effects of prior experiences on consumer memory for brands in choice situations. Previous research suggests that only minor (i.e., relatively low share) brands within a product category will benefit from advertising effects of competitors (Nedungadi, 1990). For example, advertising for Sprite would be more beneficial to a minor brand such as 7-Up than to a major brand within that category, such as Coke.

The DRM Effect

The pattern of priming effects found on only the minor brand is surprising in light of the DRM effect (Deese; 1959; Roediger & McDermott, 1995). The DRM paradigm consists of showing participants lists of related words such as *thread, pin, sewing, sharp, point*, and so on; participants falsely report having seen the non-presented critical lure, *needle* (in the context of either an explicit or implicit memory task; e.g., McDermott 1997; McKone and Murphy 2000; Hancock, Hicks, Marsh and Ritschel 2003), and are even more likely to do so if longer lists are used (e.g., Robinson & Roediger, 1997). Warning participants about the illusion right before the memory task does not eliminate the effect (Gallo, Roediger and McDermott 2001); however, if the warning occurs before the exposure session, the instruction serves to attenuate the effect (Gallo, Roberts and Seamon 1997; Gallo et al. 2001), suggesting that the illusion is created by the encoding process.

Hypothesis Development

The DRM findings suggest that advertising effects of competitors would be of more benefit to major rather than minor brands in the same category. That is because the major brands have many more schema-based associations in memory than do the minor brands. For example, Hilton (major) could be linked to, or expected from lobby, lounge, front desk, swimming pool, comfort, and so on, whereas Days Inn (minor) may not be linked to all of those associates. Following this logic, the schema-based associations created by advertising of competitors are more likely to overlap with already existing associations of the major versus the minor brands. This would cause more facilitation of the major than the minor brands.

We speculated that Nedungadi's (1990) results may have been restricted by the limited set of brand categories he used. Moreover, his hypotheses were derived from assumptions of the separate systems account of memory, assuming principles of activation and inhibition. Recent evidence for the DRM effect has been inconsistent with simple activation accounts (Watson, Balota and Roediger 2003) and has favored attributional accounts (Gallo and Roediger 2003; Whittlesea 2002). Thus we performed a re-inquiry into the work of Nedungadi (1990) to investigate the extent to which his findings may or may not be consistent with the DRM effect; we used more categories and drew our predictions from the current DRM literature.

Current Work

We conducted extensive pilot testing to develop 28 stimulus sets, each comprising a product category (e.g., vehicles), major brands (e.g., Toyota), minor brands (e.g., Nissan), and associates to those brands (e.g., car, drive). In our preliminary studies, we observed that

participants reported having been exposed to “major brand lures” such as Coke, when in fact they had only been exposed to associates (e.g., caffeine) and direct competitors of those lures (e.g., Pepsi). This effect was attenuated when participants were warned about the illusion before the memory test.

We also examined preference ratings of major brand lures. Participants had higher preference ratings for major versus minor brands, and for brands seen earlier versus those not seen. Thus, preliminary testing demonstrated that brand accessibility does influence brand evaluation. It thereby provided the basis for using the present stimulus set to investigate the effects on brand choice and to assess the relationships among consideration set inclusion, brand evaluation, and choice.

In an initial study conducted in a mixed-choice (a combination of memory-based and stimulus-based) setting, prior exposure to associates and competitors had minimal influence on the choice of major brand lures; and more importantly, such prior exposure had *no influence* on the choice of minor brand lures. Further, prior exposure to associates and competitors had no effect on brand evaluations (of either major or minor brands), although in the absence of prior exposure, evaluations were consistently higher for the major versus minor brands. These results appear to contradict those of Nedungadi (1990). We are currently investigating the reasons for the divergence in the results we obtained compared to those of Nedungadi (1990).

We suggest that stimulus-based and memory-based, as well as mixed choices may be influenced by (a) one’s evaluation of the match between the current fluency of processing and the expectations developed “on the fly” (Kahneman and Miller 1986) that are acquired through the exposure situation that increases accessibility (cf. Whittlesea 2002; 2004), and (b) people’s intuitive theories of cause and effect (Marcel 1983; Ross 1977).

In contrast to Nedungadi’s (1990) assertion that priming can affect accessibility without having any influence of brand evaluation, we hypothesize that accessibility and choice are both based on the same mechanisms, and that the processing style and outcome involved in brand memory are the same as those in brand evaluation (for a similar perspective, see Kronlund and Bernstein 2006). In addition, we assume that stimulus- and memory-based choices are influenced by the same factors (cf. Whittlesea and Leboe 2000), even though the decision-making for each type of choice has been found to differ (e.g., Lynch et al 1988).

Adaptive Selling Behavior among Retail Salespeople: The Use of Overt Cues and Consumer Stereotypes

Lynnea Mallalieu, UNC Wilmington, USA

Extended Abstract

In traditional bricks and mortar retailing, salespeople play a key role in helping to grow and sustain a loyal customer base. Yet as consumers continue to be presented with more ways to make purchases, building consumer loyalty is becoming increasingly difficult; thus even more emphasis is placed on the role of salespeople in terms of ensuring that consumers' needs are met and that lasting relationships are formed. In theory, in order to best meet the needs of consumers, salespeople must be able to quickly identify consumers' needs and respond to them with selling behaviors that are most appropriate. The preceding statement is based on the widely accepted notion that a salesperson who adapts his or her behavior to different types of consumers is going to be more successful than a salesperson who uses the same pre-determined approach; thus we might assume that effective retail salespeople practice the concept of adaptive selling (Weitz, Sujan and Sujan 1986). Is this really the case however, that retail salespeople practice adaptive selling and if so how do they go about it?

In order to begin to shed some light on these issues it is necessary to have a detailed understanding of retail salespeople's actual behaviors with consumers and an understanding of their thoughts and beliefs about how a salesperson should behave with a consumer and what makes a good salesperson. Our first step was to examine their thoughts and beliefs by conducting depth interviews with retail salespeople working for a large consumer electronics/home computer retailer.

Sample Characteristics

The sample consisted of 20 retail salespeople. All informants were male with a median age of 27. The oldest informant was 45; the youngest was 22, and the average length of employment with the company 3.5 years with the shortest length of employment 3.5 months and the longest 8 years. All informants were employed as full-time retail salespeople associated with a specific department—either computers or home electronics/home theater.

Interview Format

A semi-structured depth interview format was used and one researcher conducted all 20 interviews. All interviews were audio-taped with the permission of the informants and were later transcribed verbatim for analysis. Interviews lasted anywhere from 32 to 76 minutes.

Data Coding and Interpretation

The informants' transcripts were coded using NVivo qualitative software which allows the researcher to customize searches, create nodes within the data of related topics, and search for themes within the data based on key words and phrases.

Excerpts from the interviews illustrate some of the key findings.

Behavior with Customers.

We were interested to see if informants altered their selling behavior with customers, and if so, what caused them to do this. The majority of responses indicated that age, appearance and gender were often used as cues for altering selling behavior

I had this young guy who kind of knew what was cool now and what he wanted and he wanted to take me in a certain direction, so I just treated him like he was my friend and we went from there, but when I had an older gentleman I treated him with a lot more respect and in a more polite manner. Like I didn't use slang or anything like that (Jeff age 24).

I look at age and gender but not dress style. I look at old people and feel that they are different because they value their money more so they might take a bit more time than say a young person would because they always think they know exactly what they want. Young people tend to spend their money more freely. Sometimes I help the young person first so I can get them out of the way and then I help the older person because they'll probably take more time and they'll tell me how their grandson is or whatever and take up about 20 minutes of my time. I don't look at somebody and say they look rich or they look poor and treat them differently that way (Tim age 26).

When you get somebody like a grandma that comes in, she is going to want extra attention because you know she is an old lady and you have to adapt to that. If you have a guy coming in and he is from the country and he is looking for the latest NASCAR electronic game he won't want to know about a TV that has progressive scanning and high definition. He's going to be like what the hell is that and he will get frustrated if you bring that stuff in. You just have to be simple (Pete age 28).

It seems there are clearly preconceived stereotypes about consumers based on very overt characteristics. Informants use these characteristics as indicators of consumer knowledge and/or spending power and spending habits. Using this type of classification system is questionable at best and clearly these observable characteristics do not provide any indication of what the customer's needs are for the specific interaction with the salesperson.

After hearing these kinds of statements from all 20 salespeople we wondered how the salespeople in the sample would define or describe a successful salesperson. Do they feel that in order to be successful, a salesperson simply needs to observe overt characteristics and then select behaviors based on a stereotype or are there other beliefs about successful salespeople? What we found was a belief that successful salespeople do not behave in the same manner with every customer. Successful salespeople quickly 'read' a customer and then select the appropriate selling style. Theoretically, we found that our informants were articulating the concept of adaptive selling, which we would argue is what salespeople should practice in order to best meet consumers' needs, but what is the troubling aspect are the cues

the salespeople use when attempting to adapt. They use overt cues and associated stereotypes as opposed to really attempting to understand consumers' needs. By adapting in this manner, the dangers are many including missed opportunities for initial sales and missed opportunities for really connecting with a consumer on a deeper level, which helps to create loyal consumers.

The next step in the research is to conduct additional depth interviews with retail salespeople in different sectors of retailing, e.g., clothing and home furnishings in order to ascertain how wide spread some of the issues we have initially uncovered are among retail salespeople. Following that we plan to gather observational data of retail salespeople in actual selling situations to see if it corresponds with what the salespeople tell us they do.

Luxury Good Expenditures of Husband and Wife Dyads Incorporating User Attitudes

Carrie Heilman, University of Virginia, USA
 Frederick Kaefer, Loyola University, USA
 Samuel Ramenofsky, Loyola University, USA

Extended Abstract

Luxury is defined as, "something adding to pleasure or comfort but not absolutely necessary; an indulgence in something that provides pleasure, satisfaction, or ease." (Merriam-Webster Dictionary, 2004). In the broadest definition of luxury, the U.S. luxury goods retailing market, which includes product categories such as perfume, jewelry, watches, cars, champagne and crystal, to name a few, surpassed the \$500 billion mark in 2004 (*SmartMoney*, 2004). Despite its size, the luxury industry as a whole is relatively under researched in the marketing literature. Those that have studied luxury goods have focused on the consumer psychology of consumption, such as materialism, symbolism, and social identity (Prendergast and Wong 2003; Vickers and Renand 2003), to name a few. However, no study in the academic literature has investigated the unique buying behavior of husbands and wives in luxury goods categories, or the impact of user attitudes, spousal purchasing behavior, and individual and household characteristics on either of these.

This paper investigates luxury good expenditures of husband and wife dyads within a household, where all purchases are made for the wife. This allows us to compare the purchasing behavior of user and non-user within a household as well as that of husband and wife dyads. Our main interest is to understand how the purchasing behavior, attitudes, and personal characteristics of one member of the dyad affect the purchasing behavior of the other.

We begin by developing a conceptual model of the dyadic purchasing behavior of husbands (non-users) and wives (users) for luxury goods. To explain the purchasing behavior of each of the two members of the dyad, we include as explanatory variables in our model, 1) the wife's (user's) attitudes towards the product and product category, 2) the purchasing behavior of the other member of the dyad, and 3) individual and household characteristics. Figure 1 provides a pictorial view that captures this logic.

As Figure 1 shows, our dyadic model of husband and wife expenditures for luxury goods is influenced by exogenous and endogenous factors. The three rectangles represent the exogenous variables of the wife's attitudes towards jewelry, individual characteristics about the husband and the wife, and household characteristics. The two circles represent the endogenous variables of the expenditure of each spouse, and are determined by the model.

To test our dyadic conceptual model we conduct an empirical study that utilizes 2003 diary panel data provided by Ipsos, a global market research company which ranks 3rd among all global survey-based research companies with 2004 revenues of 605.6 million euros. The data tracks husband and wife expenditures on jewelry for the wife only, for up to a four month period. The jewelry category is a large and important sector of the luxury goods category. U.S. jewelry sales were estimated at \$45B in 2004 and in the same year jewelry represented the fastest growing advertising category for many luxury magazines including *Vogue* and *Town & Country* (*Advertising Age*, 2004).

We first use factor analysis to reduce a set of thirteen original variables capturing wives' attitudes towards jewelry. The thirteen original variables are reduced to five main user attitudes, which we label, "Guilty Consumer", "Romantic Consumer", "Enthusiastic Purchaser", "Involved Recipient", and "Infrequent User". We then use the method of instrumental variables to estimate the parameters of our dyadic model of luxury good expenditures where the dependent variables are the husband's expenditures on jewelry for his wife and the wife's expenditures on jewelry for herself during the window of observation. The explanatory variables in our model include the five user attitudes mentioned above, the spending behavior of both members of the dyad, and personal and household characteristics of the husband and wife.

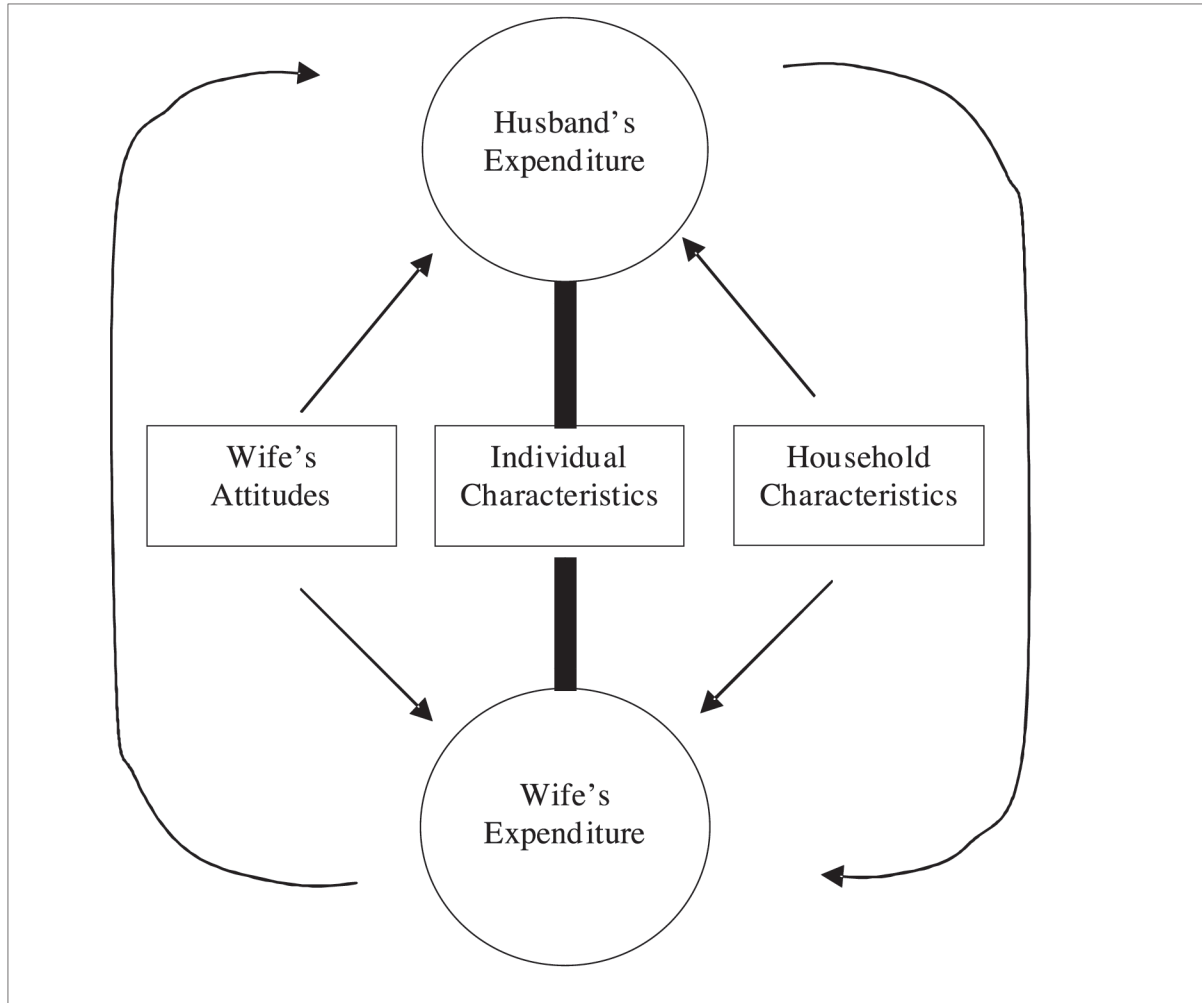

Our findings reveal that while household income is a useful predictor of luxury good spending, income has a different impact on the expenditure of husbands ("non-users") than wives ("users"). We also find that "user" attitudes of the wife affect her self-purchases differently than the purchases made for her by her husband, and that spousal purchasing behavior and individual and household characteristics affect a wife's purchases of luxury goods for herself differently than they affect the purchases made for her by her husband.

Our results are useful for marketers of luxury goods where both wives (users) and husbands (non-users) within a household are purchasers of the product, but they behave differently and therefore developing a differentiated approach to market to both is advantageous.

Does a Broken Heart Lead to an Empty Wallet? Social Exclusion Affects Impulsive Spending

Nicole Mead, Florida State University, USA
 Kathleen Vohs, University of Minnesota, USA
 Roy Baumeister, Florida State University, USA

Extended Abstract

Impulse purchases are made spontaneously, without deliberation, and without regard for the consequences of making the purchase (Rook 1987). Hoch and Loewenstein (1991) argued that the decision to purchase is determined by 2 factors: The desire to purchase and the amount of willpower one has to overcome this desire. When the urge to purchase becomes stronger than the amount of willpower, purchasing becomes more likely.

Recently, Vohs and Faber (in press) demonstrated that people with a reduced capacity to exert self-control are more likely to spend money impulsively. That is, participants who engaged in prior acts of self-control, and therefore had a reduced capacity to exert self-

control, spent more money than participants who had not engaged in prior acts of self-control. Research on social exclusion has shown that when people are socially excluded they engage in behavior indicative of low self-control (Baumeister, DeWall, Ciarocco, & Twenge 2005). For example, they eat more cookies, drink less of a healthy but unpleasant-tasting drink, and give up on difficult tasks sooner than participants who were not socially excluded. Thus, socially excluded people are less able to implement a more desirable response than participants who are not socially excluded. Taken together, these results suggest that social exclusion should lead to increased impulsive spending via reduced self-control. One laboratory study supports this hypothesis.

Social exclusion was manipulated using a procedure developed by Baumeister and colleagues (2005). After arriving to the experiment, participants completed the Eysenck Personality Questionnaire (EPQ). The experimenter scored their questionnaire; based on random assignment, the experimenter gave the participant bogus feedback regarding their personality score. Participants in the *future belong condition* were told they would have rewarding relationships throughout life, a long and stable marriage, and lasting friendships. Participants in the *future alone condition* were told they would end up alone later in life; their current friends and relationships would fade away, their (several) marriages would all dissolve, and they would essentially be alone later in life. Participants in the *misfortune control condition* were told they would be accident prone later in life. This condition served as a negative feedback control, allowing us to attribute increases in spending to the specificity of negative feedback regarding social relationships, not negative feedback in general. After the feedback, we checked for differences in affect by administering the Brief Mood Introspection Scale (BMIS; Mayer and Gaschke 1988).

Next, we measured amount willingness to spend, using a Feinberg (1986) method adapted by Vohs and Faber (in press). Participants were given a binder, which contained 15 glossy pictures of various mid to high end products (watch, car, fridge, sofa, jewelry, etc.). Participants were asked to indicate the maximum price they would be willing to pay for each product. Independent raters classified the products according to three categories: 1) Products one purchases for the self (e.g., Widescreen Flat-Panel TV) 2) Products one purchases to indicate status or resources, that is, conspicuous consumption products (e.g., Audi, Rolex) and 3) Products one buys for practical purposes (e.g., table, sofa).

We summed amount willing to pay for all 15 products as an overall index of willingness to spend. An ANOVA with condition as the predictor showed that participants in the *future alone condition* were willing to pay significantly more than the *future belonging condition* and the *misfortune control condition*. Willingness to pay was not significantly different between the *future alone condition* and the *misfortune control condition*.

We also summed amount willing to pay for the three categories of items: Conspicuous consumption items, items for the self, and practical items. Three separate ANOVAs using condition as the predictor showed that participants in the *future alone condition* were willing to pay significantly more for conspicuous consumption items and items purchased for the self than participants in the *future belonging condition* and *misfortune control condition*; however, there was no difference between the three groups in willingness to pay for practical items.

Our experimental design precludes the possibility that obtained results are attributable to receiving negative feedback. Participants in the *misfortune control condition* also received negative feedback; however, they were willing to pay less than participants in the *future alone condition*. The increase in willingness to spend seems more specific to the negative feedback of social exclusion.

No differences in emotion, measured by the BMIS (Mayer and Gaschke 1988), were found as a result of the feedback. This is consistent with previous laboratory social exclusion manipulations (e.g., Baumeister et al., 2005). Furthermore, correlations between amount willing to pay and emotion indicated there were no significant relations between our dependent measures and emotion.

In sum, this study provides evidence that social exclusion leads to increased willingness to spend. Participants who have been socially excluded indicated they would pay more for products that demonstrate status and resources, as well as for products one purchases for the self, relative to participants who were not socially excluded. Social exclusion did not, however, lead to an increased willingness to pay for practical items.

It's About Time: Sex Differences in Estimating Time for Shopping in Five Contexts

Elaine MacNeil, Cape Breton University, Canada
Peter MacIntyre, Cape Breton University, Canada

Traditional sex roles hold that women not only spend more time shopping than men, but also enjoy shopping far more than men do. Indeed, there seems to be as much pride among men when they announce how much they "hate" shopping as among women who proclaim their prowess (Dennis & McCall, 2005). If retailers and researchers wish to alter males' perceptions of shopping, we require a better

understanding of the processes that maintain those sex differences. To help fill this gap, this research will test the hypothesis that sex differences in shopping behavior are reflected in, and influenced by, the amount of time women and men estimate in advance for shopping tasks, and more fundamentally, in how they arrive at these estimates. Men, more so than women, may be falling into a form of planning fallacy (Kruger & Evans, 2003) where time estimates become unrealistic, leading to unpleasant experiences.

Time estimation and shopping enjoyment are linked in a close, reciprocal relationship that can have dramatic effects on the retail environment (Donovan, Rossiter, Marcolyn & Nesdale, 1994). Previous research shows that enjoyment of a task may lead to an underestimation of time elapsing as the task unfolds, as when people lose track of time doing something they enjoy (see Chaston & Kingstone, 2004). Conversely, underestimating time in advance of an activity will tend to create a sense of time pressure that can interfere with the task and reduce enjoyment. Time pressure has been identified as a significant source of shopping stress (Aylott & Mitchell, 1999; Fram, 1991, 1992; Fram & Axelrod, 1990; Suján, Suján, Bettman, & Verhallen, 1999). Time pressure is an important variable for marketers to understand because it affects attitude towards shopping (Mowen, 1993) and consumer behavior (Van Kenhove & De Wulf, 2000). The amount of time allotted for shopping, and the way in which shopping time is estimated, can either exacerbate or relieve time pressure. For this reason, time estimation holds the potential to be a lynchpin in understanding the psychological differences between men and women shoppers; there is little previous research in this area.

To test the hypotheses underlying this study, we required a diversity of shopping contexts experienced by both sexes and a relatively homogeneous sample of shoppers. We selected a sample of men and women enrolled full-time in the Business program at Cape Breton University. This allowed for with the added benefit of a “member check” (Maxwell, 2005) of our interpretations of the results with a subgroup of 30 study participants. After pilot testing, we asked the main sample of 203 respondents to estimate the time required to perform specific shopping tasks with which they had experience. The self-report questionnaire had several elements, but our focus in this paper is on the time estimation data.

Shopping is a contextualized act (Buttle, 1992). Therefore, we asked respondents to imagine shopping in 5 different contexts commonly experienced by both men and women. In each context we presented respondents with a product acquisition motive. The specific contexts were shopping for (1) a gift, (2) a computer, (3) a leisure product such as sporting goods, a book, or music, (4) clothing (specifically jeans or casual pants) and (5) a short list of grocery items. We tested the hypothesis that men and women estimate time differently within each of the contexts (MacNeil, 2006).

In analyzing the time estimates provided by men and women in the five shopping contexts, significant main effects were found for both sex ($F(1,162)=17.2, p<.001, \text{partial eta-squared}=.096$) and shopping context ($F(4,648)=28.9, p<.001, \text{partial eta-squared}=.151$), and the interaction was significant ($F(4,680)=5.91, p<.001, \text{partial eta-squared}=.035$). The main effect for sex indicates that women and men differ significantly in their estimates of shopping time, and the significant interaction indicates that sex differences in time estimation depend on shopping contexts.

Results showed that in all contexts women estimated longer amounts of time than did men, but sex differences were statistically significant ($p<.05$) in only three of the five shopping contexts: gift, computer, and clothes. In two contexts, gift and computer, women estimated it would take almost 50% more time than did the men. In the clothing context, women’s estimates were almost twice as high as those given by men. The estimates of time were very similar and not significantly different for leisure product and grocery shopping.

To better understand why men and women are providing different estimates of time, we examined sex differences in the methods by which those estimates were generated. In three of the shopping contexts, we asked respondents to indicate the method of time estimation by selecting one of four options (ballpark, desired time, recall, and subtasks). Using 2 x 4 cross-tabulations and the chi-square statistic we found significant differences in both the gift and leisure product contexts, where men preferred the cursory “ballpark” estimation method, and women preferred to estimate by recalling a previous shopping trip. No significant differences were found in the method of estimating the time required to purchase a computer.

The major results of this study both support and qualify the hypotheses we had in approaching the research project. We found that women tend to allocate more time to shopping than men, but the difference depends on context. We also found that men tend to use more cursory methods of time estimation, though again the shopping context has an impact. Finally, when asked to use the same time estimation procedure, breaking the task into subtasks and estimating the time allocated to each, men and women differ in one context (clothing) and not the other (grocery). The complexity of the results and their implications for retail environments suggest that time estimation for shopping will be fertile ground for future research.

The Role of Prior Knowledge in Advertisement Evaluation

Yu Hu, Virginia Tech, USA

Extended Abstract

As an important construct in consumer research, prior knowledge has garnered researchers' attention for more than two decades. Previous research traditionally focuses on prior knowledge's impact on consumers' information search, information processing and learning behaviors. Very few studies (e.g. Roehm and Sternthal 2001) have directly explored the role of prior knowledge in advertisement evaluation. The attempted contribution of this research is to broaden our understanding in this area by investigating the processes by which knowledge has its impact on consumers' evaluation of advertising messages.

The angle from which this study looks at prior knowledge is different from past research in which knowledge is often operationalized as a dichotomous variable (i.e. high vs. low or objective vs. subjective). This study distinguishes itself by focusing on knowledge accessibility and its applicability in judgment. Advertising messages are usually seen or heard by consumers for a very brief period of time. It is unlikely that consumers will mull over their stored knowledge before forming impressions of the ads. In these circumstances, the accessible knowledge ought to play a major role in making judgments. What remains unclear is the interaction between the accessible knowledge and the salient features of the messages to which they attend.

Higgins (1995) proposes that the relation between the stored knowledge and stimulus information depends on whether the perceivers have a priori expectancies or goals. When expectancies or goals are absent, only those salient features of the stimulus that match stored knowledge are relevant. When expectancies or goals are present, "both features that match and features mismatch stored knowledge are relevant" (p.137). Armed with the popular persuasion models such as Elaboration Likelihood Model (Petty and Cacioppo 1986), I translate Higgins' proposition into the following research hypothesis: (1) when message processing motivation is low, consumers will give more positive evaluations to the advertisement whose salient feature matches their accessible knowledge about the advertised product; (2) when message processing motivation is high, consumers will not rely on their accessible knowledge to make judgments. There will be no significant difference between the evaluations of matched and mismatched advertisements.

A 2 (processing motivation: low vs. high) x 3 (knowledge accessibility: match vs. mismatch vs. control) between-subjects laboratory experiment was conducted to test the research hypothesis. In the experiment, student subjects' prior knowledge about a specific product feature was made accessible by a priming task. A no-prime control condition was also included. After the priming, subjects were presented with a print newsletter that contains the focal advertisement. Subjects' processing motivation was manipulated by instructing them either to produce a detailed evaluation (high motivation condition) or to provide reading time estimation (low motivation condition).

The results confirmed the hypothesis. Under the low processing motivation condition, matched ads received more favorable evaluations and the mismatched ads were judged worse than those in the no-prime control condition. Under the high processing motivation condition, no significant difference was found across all conditions.

A second study is proposed to test the external validity of the findings from the first study and to provide managerial implications of this research to marketing practitioners.

I Self Gift Therefore I am: An Examination of Self-construal and Consumers Attitudes Towards Self-gifting

Suri Weisfeld-Spolter, Baruch College, City University of New York, USA
Maneesh Thakkar, Baruch College, City University of New York, USA

Extended Abstract

Up until the last decade, gift giving theory and research had been primarily dyadic or interpersonal in nature (e.g. Belk, 1979). Nonetheless, it was acknowledged that people may sometimes give gifts to themselves, and suggested that the self-gift phenomenon may be widely occurring in American society (Mick and DeMoss, 1990a, 1990b).

More specifically, it appears that gifts to oneself are ubiquitous, at least in American society. (Mick and DeMoss, 1990b). Other research has substantiated the notion that self-gifts are a fairly common and important phenomenon particularly in western consumer

behavior (e.g. Faure and Mick, 1993). According to social researchers, Western individuals have become increasingly self-oriented in their purchases and consumption behavior (Mick, DeMoss and Faber 1992), and an example of this phenomena has been labeled self-gifts. Similarly, McKeage et al. (1993) believe that people have been giving gifts to themselves since the early beginnings of self-indulgence.

Self-gifting is clearly prevalent in western consumer behavior. The question then becomes whether the propensity to self gift is confined to the United States, or a more wide spread phenomenon. For example, it is well established that people with different cultural backgrounds may behave differently and have different reactions to similar situations. More specifically, research has shown that different cultural identifications have an impact on the way people think, feel, and behave (e.g. Markus and Kitayama, 1991). How does this effect self-gifting behavior? This research proposes to answer this question by investigating whether self-gifting is a universal phenomenon or one simply confined to Western societies by examining consumers self-construal and attitude towards self-gifting.

Overall, it has been suggested that self-gifts represent a complex class of personal acquisitions that offer intriguing insights on self-directed consumer behavior (Mick and DeMoss 1990b). "Self gift theory will likely benefit from drawing on additionally relevant psychological research" (Mick and DeMoss, 1990b p. 329) since "with rich and complex qualities, self-gifts provide a window through which consumer behavior can be viewed in some of its most adaptive, dramatic and personal significant forms" (Mick and DeMoss, 1990b p.331).

As demonstrated by its name and definition, one of the predominant aspects of self-gifting is the direct focus on the self. Clearly, if people view the self differently, they will react differently to self-gifting. Taken together with the recommendation above by Mick and DeMoss (1990), we propose to draw on the psychological research of Markus and Kitayama (1991) that identified two dimensions of the self that can be used to characterize consumer's self-construal as well as explain and identify differences between cultures: independence and interdependence.

According to Markus and Kitayama, self-construal can be conceptualized by the degree of independence/interdependence that a person possesses. They further state that all people contain both an independent and interdependent self, but that the culture in which they are brought up in influences which one dominates. For example, Europeans and Caucasian Americans are typically said to be independent because they tend to emphasize the individual whereas people from Asian cultures are typically interdependent because they tend to emphasize the group as more important than the individual. People with independent self-construals strive to develop and express their unique characteristics, whereas people with interdependent self-construals place value on harmonious relationships with others and acceptance in their community. Those with well-developed independent self-construals gain self-esteem through expressing the self and validating their internal attributes, whereas harmonious interpersonal relationships and the ability to adjust to various situations are sources of self esteem for the interdependent self-construal (Singelis 1994). After reviewing an extensive array of studies, Markus and Kitayama (1991) argue that these independent and interdependent views of the self influence cognition, emotion, and motivation and help to explain individual differences between cultural groups.

It seems reasonable then to propose that consumers' self-construal will have an impact on their attitude and likelihood to self-gift. More specifically, it seems that people with an independent self-construal will be more likely to self-gift, as they tend to have self-benefiting motivations, such as the need to achieve, self-enhance, or affiliate. Conversely, people with an interdependent self-construal will be less likely to self-gift as they tend to derive their motivations from what benefits others and a group as a whole, such as the need to be agreeable to others, to accommodate to their needs, and to restrain one's own wishes or wants.

To test the above propositions, a survey was distributed to 84 college students in the New York area that measured their self-construal, attitude, subjective norm, and likelihood to self-gift and some other demographic information. As predicted, subjects with high independent self-construals had a significantly more favorable attitude towards self-gifting, and subjects with high interdependent self-construals had a significantly less favorable attitude towards self-gifting (Mindependent=5.37, Minterdependent=4.87; $p < .01$). We also tested subjects' attitude towards self-gifting advertisement slogans (e.g. "The perfect little thank me" (Andies candy) and "Because I'm worth it" (L'Oreal). Overall, Independents had a significantly more favorable attitude towards self-gifting slogans and Interdependents had a significantly less favorable attitude towards them (Mindependent=6.42, Minterdependent=5.98; $p = .018$).

The results of this research have important implications for managers, particularly when choosing an international advertising strategy. It will help companies who market their products in the United States using self-gift appeals in their advertisements decide whether they should use these messages in other countries or need to modify them to successfully sell their products. Based on our study, it seems that they cannot standardize these ads for countries that have consumers typically classified as having Interdependent self-construal. However, the results of this analysis provide some direction to marketers as to what appeals they should use. More specifically, rather than the slogans used in the United States that emphasizes the worth of the individual, (i.e. you deserve it), to better target Interdependents, the slogans should emphasize family and friends and their happiness.

Anomie Goes Online: The Emo Microculture

Tracy A. Rickman, , Auburn University, USA

Michael R. Solomon, Auburn University, USA

Abstract

Whether the palliative is jazz or emo, it is common for fringe youth microcultures to identify with a musical genre that gives voice to feelings of alienation. However, the place where these youth connect—their *touchspace*—has morphed from yesterday's coffeehouse to today's website. The purpose of this first stage project is to chronicle how adherents of the emo microculture relieve alienation by finding and communicating with other "like me" participants. As part of a larger project focusing upon youth microcultures centered on the common theme of anomie, we are collecting data from a variety of sources to identify emergent themes relative to communication, ritual, and resistance within this new cyber-mediated anomic microculture.

Introduction

Back then, they were hanging out in the coffee shop. In the 1960 British movie *Beat Girl*, "teenage bad girl" Jenny sneaks out of the house to hang out with her "beatnik" pals at the local coffee shop where they talk about alienation and jazz.⁴

Today, they are commiserating on the Internet. In this excerpt from a typical interview with an "emo kid," a girl who could be Jenny's daughter says:

"...I had a bit of an abusive childhood, and I was the fat ugly kid in class until high school...My best friend Nina—the one who introduced me to emo bands seemed to think I didn't like her...That brought me down real hard...Music has always helped me out. Nina and I are a lot alike, and the first thing we found out about each other was that were it not for music we'd probably both either be stuck in a crisis center or dead by now. I rely a lot on music to get me through the day. When I get home from school the only things I do are go online and listen to music." (Greenwald 2003, p. 307)

⁴A plethora of online sources richly document the experience of beatniks and other youth microcultures, cf. for example (<http://www.stim.com/Stim-x/0896August/Automedia/beatnik.html>)

Whether the palliative is jazz or emo, it is common for fringe youth microcultures to identify with a musical genre that gives voice to feelings of alienation. However, the place where these youth connect—their *touchspace*—has morphed from yesterday’s coffeehouse to today’s website. The purpose of this project is to chronicle how adherents of the emo microculture relieve alienation by finding and communicating with other “like me” participants. We will identify emergent themes relative to communication, ritual, and resistance within this new cyber-mediated, anomic microculture.

Adolescence is for many a tormented period characterized by an approach-avoidance conflict—the need for connectedness (cf. Edgette 2002) coupled with feelings of alienation from adults and social institutions. We can view adolescent alienation within the framework of *anomie*, originally articulated by Emile Durkheim as instability within society due to normlessness. This void produces a “...personal sense of unrest, alienation, and uncertainty” (Garfield 1987, p. 276). Although these concepts have been used to explain congregational behaviors from union organizing to mafia social clubs, there have been few attempts to study anomic youth-oriented groups like emo.

Microcultures form and evolve on the basis of strong identification with an activity or art form.⁵ Gans (1974) proposed that people can be categorized into taste cultures based on their individual orientations toward popular culture—in this case, musical taste. We regard the emo phenomenon as a taste culture characterized by shared anomie and the strong propensity to communicate this central theme by constructing a community (offline or online) that shares and reinforces preferences for music and associated clothing styles, hair styles, hang-outs, etc.

McLeod and Chaffee (1972) suggest that social reality is created when an individual receives information from a mediated source such as television or a website; the verisimilitude of this information often rivals that of direct physical observation or real world (i.e., offline) social interaction. The evolving emo genre is a mass-mediated microculture.⁶ Like the beatniks that preceded them, “emo kids” find and connect with one another through music, slang, rituals, and clothing. Emo, short for emotional, is a label both for a musical genre and for the youthful adherents to that genre. Although there are different manifestations of this microculture (e.g. hardcore—extremely abrasive, screamo—screaming lyrics, or post-emo indie rock—softer lyrics), the common thread uniting emo kids is a strong current of alienation, bridging feelings of anger and hurt. Emo song lyrics are histrionic, often desperate, and maybe even whiney. These lyrics from the song “Three Weeks” by the emo artist Aaron Anatasi are typical of this angst: “You are treating me so differently / so different, I can’t explain / I feel like I’m invisible to you.”

Emo kids tend to look like they have just shopped at a garage sale. They often sport work jackets, too-small jeans, and old Chuck Taylor sneakers. The emblematic hairstyle is short, slick, dyed-black hair with pronounced bangs. Their “stores of choice” are retailers that carry the look Hot Topic stores have popularized, although most purchases are made at thrift stores for economy and originality. Emo kids interact primarily on the web, though they may also at times link up at small independent shows. Emo has yet to penetrate mass youth culture. Although a few emo bands have “made it” to MTV, emo kids generally view this commercial success as a form of betrayal.

Method

We will sample a diverse set of photos, movies, websites (including MySpace.com, the emos’ primary gathering place in cyberspace) and blogs to document the emerging emo microculture. Our goal is to identify emergent themes relative to communication, ritual, and resistance as part of our quest to understand how the consumption practices of significant numbers of youths are mediated by this anomic microculture.

Expected Results

We will report results from the first stage of an ongoing project that will chronicle the successive waves of alienation-based youth microcultures since WWII, from the Beatniks of the 1950s to the emos of today (e.g. Mods, Hipsters, Punks). The ongoing study will identify emergent themes relative to communication, ritual, and resistance/alienation as expressed both in offline and online venues by successive generations of anomic consumers.

We expect that this study will uncover emergent themes associated with varying levels of anomia dependent upon the centrality of the emo experience to the respondent. Emos who are at the core of the movement, participating at every level (e.g. music, clothing, rituals) to construct a lifestyle will demonstrate greater degrees of anomic behavior. As participation ripples toward the periphery (e.g. ‘posers’ that just like the distinctive hair but not the music), we expect to observe less anomic behavior as the intensity of identification with this musical genre decreases.

Returns: A Motivational Perspective

Jordan Holtzman, U.C. Berkeley, USA

Background & Conceptualization

Product returns are a vital issue among retailers and distributors in today’s marketplace. Cost of returns range from 5% to as much as 30% of sales in some according to a recent article in the Wall Street Journal and, in aggregate, cost retailers billions of dollars a year (Hess and Mayhew, 1997). This is in addition to various hidden costs that are frequently difficult to model such as consumer disloyalty resulting from disappointing product and unpalatable return experiences and the logistics costs of managing the reverse supply chain.

Research conducted on returns phenomena has been sparse and, where existent, has tended to focus on modeling financial and demographic aspects of returns processes. Padmanabhan (1997) modeled the financial feasibility of various return policies; Hess and

⁵Researchers have historically referred to these groups as subcultures (e.g. Hall and Jefferson 1976; Hebdige 1979), but some analysts are starting to prefer the term microculture to distinguish taste subcultures from those defined by gender, race, ethnicity, and so on (Solomon 2006).

⁶Members of this microculture never capitalize the label emo.

Mayhew (1997) modeled a consumer's likelihood of returning a product given demographic, product-specific and behavioral characteristics of consumers; and Wood (2001) provides experimental evidence that return policy leniency affects consumers' transaction dynamics in a remote ordering (i.e. internet, catalog, etc.) environment.

The remainder of the extant product returns research has focused on the supply side issues, while indirectly tapping into the motivational aspects of consumers' thought processes. Hess, Chu and Gerstner (1996) provide theoretical evidence of the efficacy of non-refundable charges in discouraging "inappropriate" (i.e. opportunistic) returns. Davis, Hagerty and Gerstner (1998) document the popular managerial mindset that ease of completing returns (i.e. cost to consumer) correlates highly with the likelihood of making returns.

The purpose of this study is to examine consumer motivations for returning products. Although previous research has tangentially concerned itself with consumer motivations in a returns decision context, no study has comprehensively examined an exhaustive set of reasons why consumers could return products and the effects of those reasons on key behavioral variables of interest.

The major hypothesis of this paper is that return motivations affect consumers' likelihood of returning products, the level of costs consumers will incur to return products, and the amount of guilt consumers experience in returning products. In short, this paper hypothesizes that not all returns are created equal from a motivational perspective.

The managerial implications of this study are potentially far-reaching. Retailers and distributors are constantly striving to minimize or altogether eliminate product returns, despite their adoption of liberal return policies which serve to maximize sales through low-risk trial. Knowing consumers' principal motivations for returns would allow distributors to address these issues in their marketing and merchandising plans. This holds true especially in a world of increasingly pervasive internet and catalog (i.e. remote) sales where experiential product trials are diminished for consumers.

Methodology

Subjects are presented with thirteen different reason-for-return (i.e. motivational) scenarios each about a paragraph in length. They include: (1) Being Overcharged, (2) Functional Failure, (3) Aesthetic Failure, (4) Mistaken Needs Assessment, (5) Better Competitor Functionality, (6) Money Generation, (7) Simultaneous Comparison, (8) Sense of Accomplishment, (9) Extracted Use, (10) Cheaper Competitor Product, (11) Combating Feelings of Inadequacy (Failure Salience), (12) Counteracting Impulsive Tendencies and (13) Undue Pressure from Seller.

For each scenario, subjects are told to assume that the price paid for the product being returned is either \$10, \$100, or \$1,000, representing small, moderate and large purchase amounts respectively. Subjects are then asked to report, using a nine-point scale: (1) the maximum amount of cost they would incur to make the return (MaxCost), (2) their likelihood of making the return (RL), and how guilty they would feel about making the return (Guilt). Subjects are subsequently asked to report how responsible they believe both they and the seller are for causing the return, given the particular scenario described.

All scenarios were presented using a within-subject design so as to make the manipulation conditions more salient and evoke relative ratings on the dependent variables.

Results and Major Findings

51 respondents completed the surveys. The major hypothesis of the paper is confirmed: The motivation employed in making a return affects (1) the amount of cost consumers will incur to make the return, (2) how likely consumers are to make the return, and (3) the guilt experienced while contemplating making the return.

Correlational Findings

Purchase Price correlates very strongly with the Maximum Cost (Max Cost) subjects are willing to incur to return product ($r=.57$, $p < .001$), and less strongly, but still significantly, with Return Likelihood ($r = .29$, $p < .001$). Purchase Price does not correlate with Maximum Cost as a % of Amount Spent (MaxCost/Amt). The Maximum Cost (Max Cost) subjects are willing to incur correlates moderately well with Likelihood of Return ($r=.21$, $p < .001$). Lastly, Return Likelihood correlates negatively with Guilt ($r=-.28$, $p < .001$).

ANOVA Results

For the Maximum Cost respondents are willing to incur dependent variable (MaxCost), only Purchase Price (Amount) is significant. For the Maximum Cost as a Percentage of Purchase Price dependent variable (MaxCost/Amt), only Scenario is significant ($p=.014$). For the Return Likelihood dependent variable, Scenario is significant ($p < .001$), Purchase Price (Amount) is significant ($p < .001$) and the Scenario*Purchase Price interaction is significant at about the 10% level.

For the guilt experienced while contemplating the return dependent variable (Guilt), only Scenario is significant ($p < .001$). For both the Perception of Seller Responsibility for causing the return and Perception of Buyer Responsibility for causing the return, Scenario was significant ($p < .001$ for both) while Purchase Price was not.

Specific Results Discussion

Maximum cost consumers were willing to incur as a percentage of price (MaxCost/Amt) was highest for Money Generation and Functional Failure and lowest for Being Overcharged and Cheaper Competitor Product. Return Likelihood was highest for Being Overcharged, Functional Failure, Cheaper Competitor Product and Undue Pressure from Seller and lowest for Sense of Accomplishment and Extracted Use. Guilt was highest for Extracted Use, Sense of Accomplishment and Simultaneous Comparison, and lowest for Better Competitor Functionality, Cheaper Competitor Product and Undue Pressure from Seller.

A Designer is Only as Good as a Star Who Wears Her Clothes: Examining the Roles of Opinion Leaders using the Persuasion Knowledge Model

Suri Weisfeld-Spolter, Baruch College, City University of New York, USA

Maneesh Thakkar, Baruch College, City University of New York, USA

Extended Abstract

A basic assumption in diffusion theory is that some individuals, referred to as opinion leaders, are influential in persuading others to adopt products within a given social structure. They directly affect the diffusion of innovation by being the early adopters and spurring new product interest as well as trial. The diffusion of information pertaining to the innovation and its influence depends on the opinion leadership. Many attempts have been made to identify the characteristics of opinion leaders, and the findings have typically shown that opinion leaders are individuals who are knowledgeable about various topics and whose advice is taken seriously by others. They also tend to be very socially active and highly interconnected within the community (Darley and Johnson, 1993). Moreover, effective opinion leaders tend to be slightly higher than the people they influence in terms of status and educational attainment, but not so high as to be in a different social class (Rogers, 1995). This way, the leaders are still a part of their audience's reference group. And as opinion leaders these individuals are looked upon by the follower-group to make their assessments about the worth of the innovations.

The theoretical contribution of this research arises in the form of empirical evidence that the Persuasion Knowledge Model (PKM) (Friestad and Wright 1994) can explain some of the anomalies in the Diffusion of Innovations (DoI) model. We suggest that the perception of the opinion leaders, as endorsers or adopters, is the key variable in determining how much influence the opinion leaders would ultimately have upon the follower class.

Fashion is an area where interpersonal communications has been found to be highly important in the diffusion of information. Additionally, the frequent introduction of new clothing styles each season makes the fashion market a desirable study for diffusion research focusing upon innovativeness (Baumgarten, 1975). Thus, we focused on fashion as the domain of the first study.

According to Rogers (1995,) an innovation is any idea, practice or object perceived as new. Fashion is characterized by constant innovations, whether real or perceived that often include small changes from the previous season or year. Because fashions are constantly changing, but the fashion changes are not extreme innovations, they can be classified as dynamically continuous innovations (Rogers, 1995). Understanding the diffusion process for fashion therefore is crucial to marketers in the industry since fashion is so dynamic in nature.

Fashion opinion leaders represent a significant target market with high sales potential for the fashion marketer and furthermore, beyond their individual purchase capacity, they represent important change agents in disseminating fashion information to others during the fashion season (Summers, 1970). The goal of the marketer in reaching these opinion leaders is to stimulate positive word of mouth communication via them to the masses. In other words, the communication message should be tailored so that it's communicable in interpersonal channels, and can therefore lead to the diffusion of the particular fashion (Summers, 1970).

Opinion leaders are crucial for the social legitimation of new innovations and fashion ideas (Rogers, 1995). If a new look is adopted by fashion opinion leaders, then it has an increased chance of becoming a fashion adopted by the rest of the population, and the teen market is no exception. Opinion leadership is defined as "the degree to which an individual is able to influence other individual's attitudes or overt behavior informally in a desired way with relative frequency" (Rogers, 1995). If designers can determine who these opinion leaders are, and target them effectively, then the introduction of a particular fashion has a much higher probability of becoming adopted.

It is often difficult to determine who the opinion leaders are for a particular segment, and even more difficult to figure out how to target them effectively. However, for the fashion industry, and specifically the teenage market, we propose that celebrities may serve as opinion leaders, in that that through them interpersonal communication about the latest fashions are facilitated.

To gain more insight into our proposed phenomenon of celebrities as fashion opinion leaders for this segment, we conducted 3 focus groups (8 subjects each) and 6 in-depth interviews with 4 females and 2 males who lived in the New York City area. We found overwhelming support for our notion that teenagers view celebrities as fashion opinion leaders. Specifically, there was a lot of interest in celebrity singers, who were considered to be 'cool, stylish and real,' and limited interest in younger celebrities. Additionally, depending on the style, (i.e. funky vs. classy) different types of celebrities (i.e. singers vs. actresses) were preferred.

One of the more interesting findings that our research yielded was that teens seemed to discriminate between celebrities wearing a particular style in a commercial or some other paid form of advertisement and celebrities wearing a particular style on an award show or pictured casually in a magazine, the latter of which they felt displayed a more real and legitimate image. Apparently, credibility was a big issue for the teens and they felt that being paid to wear something was not reflective of personal tastes or likes by the celebrities and therefore would not be influential in getting them to adopt a new fashion.

Our findings are also in tune with robust findings of persuasion knowledge model that suggests that consumers who perceive the persuasive attempts of marketers react in a way to neutralize such attempts (Friestad and Wright 1994). In this research also we show that consumers do perceive the celebrity endorsements in the commercials as persuasive attempts by marketers and thus, try to undermine them by actively rejecting the claim that such an endorser indeed uses or likes the endorsed product (fashion).

When We Practice to Deceive: An Exploration Into the Accommodative Role of Deceptive Practices in Market Exchanges

David M. Hunt, University of Wyoming, USA
 Scott Radford, University of Missouri, USA

Since early in the history of studying consumer markets, scholars have maintained an interest in the use of deceptive practices in market exchanges (Deighton and Grayson 1995; Zinbarg 2001). Much of the deception research that appears in consumer and marketing journals addresses the potential of consumers to be deceived by advertising (e.g. Barone, Palan, and Miniard 2004; Johar 1995; and Burke, DeSarbo, and Oliver 1988) and public policy aimed at protecting consumers against deceptive marketing practices (e.g. Burke, Milberg, and Moe 1997; Ford and Calfee 1986). The understanding of deception that emerged from these studies has greatly informed consumer researchers and policy makers as to the various ways consumers may be deceived and the potentially detrimental outcomes of deceptive market practices.

Most consumer research on deceptive practices assumes that a misleading representation, omission, or practice on the part of a seller ultimately results in injury or loss to the consumer. However, not all deceptive practices result in consumer injury or loss. Evidence from the negotiation and mediation literature suggests that the deceptive practices employed by buyers and sellers involved in a negotiation actually *facilitate* rather than hinder exchange between the two parties. The accommodative function of deception is particularly important in the management of complex protracted negotiation where mutually beneficial resolutions can "...seldom be accomplished by pure rational analysis and logic alone" (Benjamin 1995, pg. 4). Many consumer market exchanges such as the purchase of a new automobile, a new home, major appliances, etc., involve complex negotiations between buyers and sellers. In capturing the full extent to which deceptive practices operate in complex market exchanges, the conceptualization of marketplace deception currently reflected in the consumer literature falls short in two ways. First, with the exception of a recent study of consumers' interpersonal deceptive practices (Argo, White, and Dahl 2006), extant research accounts only for the deceptive practices of sellers while virtually ignoring the deceptive practices of buyers. Second, extant research does little to inform the potential efficiencies that may be gained from buyers' and sellers' use of deception in negotiation processes.

The purpose of this study is to explore the structure and strategic use of deception in negotiated exchanges between buyers and sellers. Specifically, we examine the question, how might deceptive practices, used by both buyers and sellers, serve an accommodative role in the negotiation between parties in a complex, protracted exchange?

Theoretical Background

This study is theoretically grounded in the sociological concept of accommodative moral schemas. The underlying principle of accommodative schemas asserts that describing the ideological orientations of each party in a social exchange does not sufficiently

describe the interactions of the two parties (Lidz and Walker 1980). For instance, buyers and sellers approach market exchanges with opposing ideological perspectives. These ideologies provide meaning and structure to the roles played by both parties in a social exchange. Buyers are guided by an ideology of maximizing their value and minimizing their costs while sellers are guided by an ideology of maximizing their profit. However, these opposing ideological orientations place the parties in conflict with one another. Yet clearly, to achieve a mutually beneficial outcome, buyers and sellers must not approach the exchange process guided exclusively by their independent ideologies. Instead, they require a shared moral schema that facilitates cooperation with the opposing party in the exchange.

The position here is that buyers' and sellers' moral orientations toward the use of deceptive practices accommodate the exchange between two parties with otherwise conflicting ideologies. Therefore, in the present context, an accommodative schema refers to an ideology of the morality of deception that is *shared* between buyers and sellers. An accommodative schema can be thought of as serving the same function as the rules of sport that allow two teams with opposing objectives to play on the same field under prescribed rules of engagement. They are necessary for the cooperation of two groups whose independent ideologies otherwise mandate conflict.

Proposed Study

The purpose of the proposed empirical study is to analyze the strategic use of deception by buyers and sellers to elucidate the potential accommodative role of deception in negotiated market exchanges. To support the notion that deception accommodates exchange, it is important to demonstrate that the use of deception serves two functions. First, the use of deception by both parties must provide one or more reference points which allow and facilitate cooperative action. That is, the moral schemas that guide interaction in the context of a market exchange must be specific to the exchange context and independent from macro-societal moral codes. Second, the use of deception must provide parties in an exchange with "...ways of neutralizing the binds of their mandating ideologies so that they are released from the moral obligations inherent in those ideologies" (Lidz and Walker 1980, pg. 110).

The position here is that criteria to evaluate the accommodative function of deception are embedded in the motivations that drive buyers' and sellers' strategies employed in the negotiation process. As such, we propose a study employing qualitative methodology that will attempt to "un-bundle" the motivations associated with the use of deceptive practices by both buyers and sellers. Data will be collected in depth interviews with both buyers and sellers in the context of new car purchases. As a context for exploring the present research question, the new car market is desirable for two reasons. First, the exchange process for new cars is relatively protracted and typically involves a complex negotiation process. Second, the exchange between buyers and sellers in the new car market is typically unmediated. That is, negotiation occurs directly between a consumer and seller rather than between a consumer and an agent of the seller. This second condition is desirable to avoid the complexity of isolating the use of deception by buyers and sellers from the use of deception by the third party in an exchange.

Results of the proposed study potentially will contribute to consumer research in three ways. First, the study represents the first attempt to articulate the role of accommodative moral schemas in a consumer context. Second, the study will extend current research on marketplace deception to include deceptive behaviors practiced by consumers. Finally, by challenging and elucidating the current conceptual boundaries of marketplace deception, this study will provide a holistic account of when and how deceptive techniques are used by buyers and sellers involved in negotiation. This in turn will inform the debate of possible limits that should be observed in the use of deception in consumer market exchanges. As such, the study will be of interest to consumer researchers, marketing researchers, and public policy makers.

The Influence of Impression Management Concerns on Product Evaluation

Laurence Ashworth, Queen's University, Canada

Margaret Matear, Queen's University, Canada

EXTENDED ABSTRACT

Impression management goals are an important motivation across a wide variety of social situations (Tedeschi 1981). Much research has focused on the tactics individuals use to manage their impressions (e.g. enhanced self-descriptions; Leary 1995). In marketing, research has demonstrated that possessions can affect observers' impressions (Christopher and Schlenker 2000) and it has been suggested that consumers will strategically display products to achieve impression management goals (Burroughs, Drew, and Hallman 1991). However, there is little research examining the effects of impression management goals on product evaluation. The current research contributes to the literature by demonstrating that impression management goals can exert a powerful influence on consumers' evaluation of a product. It also highlights the importance of impression management as an avoidance motivation—consumers may avoid certain products, despite their functional benefits, because of the impression the product will convey.

Impression Management

Impression management refers to attempts to regulate behavior in order to influence observers' impressions. Leary (1995) identified a number of different goals associated with impression management, including positive material and social consequences (e.g. positive emotions that stem from being regarded favorably); constructing and maintaining one's self-concept (Baumeister 1982); and avoiding socially and materially deleterious consequences associated with negative impressions.

Much of the research on impression management has focused on the tactics individuals use to influence others' impressions (e.g. expressing similar attitudes to observers (Tetlock 1985), engaging in helping behavior (Deutsch and Lamberti 1986), etc.). Other research has focused on the impression created. For example, Burroughs et al. (1991) showed that observers formed an impression of individuals based on their possessions that was consistent with the image owners were attempting to convey. Gosling et al. (2002) found that observers were able to form consistent and accurate impressions of occupants based on the content of their offices and bedrooms.

The current research contributes to this literature by examining the influence of consumers' impression management concerns on product evaluation. Specifically, it is shown that consumers' will pay substantially less for a product when they believe it will convey an undesired impression.

Study 1

The purpose of Study 1 was to examine the influence of consumers' impression management concerns on their evaluation of a product. We chose a product that was likely (at least occasionally) to be used in public—in this case a portable MP3 player that could be worn around the arm. The color of the product was manipulated in a way that was expected to influence impression management concerns. Specifically, we predicted that when the product was offered in a feminine color (vs. a neutral color), men—but not women—would be concerned about their impression. We also tested the alternative explanation that product evaluation was affected by liking of the color rather than impression management concerns per se.

Method

Ninety-eight students (47 men and 51 women) participated in a 2 (product colour: pink vs. black) x 2 (gender) between-subjects factorial design. Participants were told that they would be participating in an auction for an MP3 player (a "Creative MuVo" with 256Mb of storage). All participants saw the player prior to the auction and were told that they were bidding for that particular MP3 player and that its retail price was \$185 after tax. In half of the cases the player was pink, otherwise it was black. The two players were identical in every other respect.

All participants submitted sealed bids. The winner would only pay the amount bid by the second highest bidder though, which creates an incentive for individuals to bid their true maximum willingness to pay. Participants were provided with a detailed example of the procedure to ensure they understood this. After placing their bid, participants completed a questionnaire designed to assess their attitude towards the product ($r=.81$), liking of the color (single item measure), and the extent to which they would be concerned about using the product in front of other people (impression management concerns, $\alpha=.91$). All items were measured using 5-point scales.

Results

As expected, there were significant interactions between gender and product color on all dependent variables (willingness to pay (WTP): $F(1, 94)=19.34, p<.001$; attitude: $F(1, 94)=10.44, p<.01$; liking of colour: $F(1, 94)=21.98, p<.001$; impression management concerns: $F(1, 94)=45.53, p<.001$). Simple effects analyses indicated that men bid less for the pink player (M 's=\$41.20 vs. \$84.43; $F(1, 94)=22.54, p<.001$), liked it less (attitude: M 's=1.27 vs. 2.13; $F(1, 94)=12.38, p<.001$), liked the color less (M 's=.25 vs. 2.48; $F(1, 94)=44.62, p<.001$), and were more concerned about the impression they would convey using the pink player (M 's=1.29 vs. 2.95; $F(1, 94)=73.17, p<.001$). Women made no distinctions between the players (no differences were significant). Mediation analyses (Baron and Kenny 1986) conducted on the men's results demonstrated that the effect of product color on WTP was mediated by impression management concerns (product color–WTP: $\beta=.52, p<.001$; product color–impression management–WTP: β 's=.08 and .58, $p>.66$ and $p<.001$), but not liking of the color (product color–liking of color–WTP: β 's=.35 and .22, p 's=.09 and .29). Similar effects were obtained when examining the mediation of attitudes by impression management concerns and liking of the color.

General Discussion

The current study demonstrated that consumers' desire to avoid creating a particular impression exerted an important influence on their attitudes and ultimately their willingness to pay for a product. The experimental manipulation was designed to create impression

management concerns that would primarily influence men. Specifically, a gender-typed color was chosen that was expected to be inconsistent with the image most men would want to create. Supporting this prediction, men liked the pink MP3 player less and consequently bid less than half what they offered for a functionally identical black player. In contrast, women showed no aversion to the pink player, presumably because they were not concerned about the impression it would convey. Future research will examine the influence of impression management goals on product choice and the nature of the specific impressions consumers wish to avoid or convey.

Nostalgia Advertisements: A Content Analysis

Robert Madrigal, University of Oregon, USA

Courtney Boerstler, University of Oregon, USA

Extended Abstract

Background. Very little work has been done on the use of nostalgia as an advertising tactic. Holbrook and Schindler note that "nostalgia has received relatively little attention from academicians in general and from scholars devoted to the study of consumer research in particular" (1991, p. 330). Research on nostalgia is now in its infancy and has focused on nostalgia proneness (Holbrook, 1993), the emotions produced by nostalgic advertisements (Holak and Havlena, 1998), and the consequences of its use in advertising (e.g., attitudes toward the ad, brand, etc.; Muehling and Sprout, 2004; Pascal et al., 2002). The research has shown that nostalgia preferences occur in a wide range of product categories (Schindler and Holbrook, 2003), that advertisements with a nostalgic theme are capable of producing nostalgic reflections (Muehling and Sprout, 2004), and that nostalgic ads create more positive attitudes toward the ad and the brand (Muehling and Sprout, 2004; Pascal et al., 2002). However, none of the research has actually considered the incidence of nostalgia cues in print advertisement. Our purpose is to extend the current research in this area by reviewing the actual occurrence of nostalgia-themed ads used in popular magazines.

A variety of definitions of nostalgia exist in the literature. We borrow from a number of these (Holbrook and Schindler, 1991; Hirsch, 1992; Baker and Kennedy, 1994; Holak and Havlena, 1998) in defining *nostalgia* as a bittersweet emotional state comprised of many discrete emotions produced by reflection on things (objects, persons, experiences, ideas) associated with an idealized past. This definition was used in classifying ads that used a nostalgia appeal from those that were not.

Method. Using the *Top 100 ABC Total Paid Circulation* list of magazines for 2004, the authors distinguished ten different categories of magazines. The two most popular magazines from each category were selected. Two issues from 2004 were then randomly selected and reviewed. A total of 40 magazines were included in the current analysis. Two judges reviewed advertisements in the magazines looking for nostalgia ads one-third of a page or larger.

Havlena and Holak (1991) categorized nostalgia products and advertisements into two categories: (1) products or ads directly from the past and (2) new products or messages that "create a 'period' feeling" (p. 323). We adapted this framework in distinguishing the use of nostalgia in advertisements from that of products. Each ad was reviewed in detail to determine how nostalgia was being used. Three types of nostalgia were identified: Actual Nostalgia, Borrowed Nostalgia, and Classic Nostalgia.

Actual Nostalgia maps directly onto Havlena and Holak's first category, and is defined as the use of nostalgia for products from or relating to the time period from which the nostalgia was taken. For example, advertisements promoting CD's as "A Goldmine of Musical Memories" or movies described as "Timeless Classics" would be categorized as Actual Nostalgia. Havlena and Holak's second category is split into two different uses of nostalgia, borrowed and classic. *Borrowed Nostalgia* is defined as the use of nostalgia for current or modern-day products. For instance, Johnson and Johnson's use of black and white photos depicting a mother and child drawing together at the kitchen table with other crayon drawings hanging on the refrigerator in the background would be categorized in this type of nostalgia. *Classic Nostalgia* is defined as the use of nostalgia for modern products using old advertisements or memories for the same products from the past. An example of this is Jack Daniel's use of an old advertisement and pictures of their old distillery and trucks in a current ad.

Results. Of the 2,354 ads reviewed, a total of 88 were identified as using a nostalgia theme. Interjudge reliability, using the Perrault and Leigh (1989) measure, showed agreement of .979. The use of the three types of nostalgia varied little, with borrowed nostalgia being

the most common type used, 93.2% or 82 ads (interjudge reliability=.99), and actual and classic nostalgia being far less used, with 5.7% (5 ads) and 1.1% (1 ad), respectively.

Our results also showed that the magazine categories of Family and Home & Garden were the two most popular types of magazines for nostalgia ads with 21 and 19 ads respectively. Also, the results indicate that nostalgia ads appear in a wide variety of product categories, from cars to cell phones, but most often in advertisements for consumable goods. Nostalgia ads were predominantly visual (86.3%, n=76). Far fewer of the ads combined visual with copy that included nostalgic statements. The ads in the actual and classic nostalgia categories all combined visual and copy (100%, n=6), while only 6 ads in the borrowed nostalgia category used both (7.3%).

A number of conclusions are drawn from this study. First, while research has been done about the effect of nostalgia ads on consumers, none has actually done a content analysis on the frequency of nostalgia in print ads. While nostalgic ads are not as common in print as was found for guilt appeals (Huhmann and Brotherton, 1997), previous research shows that the use of nostalgia has a number of practical implications for marketers including more favorable attitudes toward the ad and brand (Muehling and Sprott, 2004; Pascal et al., 2002), as well as increased intentions to purchase the product (Pascal et al., 2002). Given the ramifications of the tactical use of nostalgia, it is surprising that the actual incidence of ads using nostalgia is so small.

Previous research showed that the use of nostalgia is effective; the current research indicates that nostalgia is not a method used widely in print advertising. Further research can be done to show how nostalgia works in the ad, determining which type of nostalgia (actual, borrowed or classic) and which mode (visual, copy, or both) is most effective. Borrowed nostalgia appeared most often in our research, but that does not indicate it is the most effective. Lastly, research could ascertain whether nostalgic ads are more effective for certain product classes or in certain types of magazines.

The Impact of Information Format on Consumer Search Order and Choice in an Online Setting

Ying Jiang, University of Connecticut, USA
Girish Punj, University of Connecticut, USA

Extended Abstract

Consumers are having more control over the information flow on the Internet, which helps them to find information that better matches their preferences and be more confident in their judgments (Ariely 2000). However, it is also recognized that the information on the Internet is overloaded and highly manipulative, which can largely influence consumer information search and decision making. For example, research shows that the background picture and color of a web page can influence both novice and expert consumers' choice and such an effect is mediated by the search behavior for novice consumers (Mandel and Johnson 2002).

This research builds on the literature of online consumer information search and preference construction and further investigates how online information presentation format influences consumer search order and choice. The objectives of this research is to examine (1) how attributes presented in digital versus non-digital format and salient versus non-salient format influence consumers' search order of attribute and alternative information, and (2) how the search order affects consumer choice.

Built on Lal and Sarvary's (1999) definition of digital versus non-digital attribute, we consider digital attribute information as information that is presented by numbers, scales, or categories; whereas non-digital attribute information is presented by detailed description. It is much easier and faster to examine digital attribute information. Consumers can easily apply a cut-off point on digital

attribute information to quickly screen all the alternatives. They can even use digital attribute information to make inferences about non-digital attribute information if they perceive there is certain correlation among the attributes (Kardes et al. 2004). Thus, we expect

H1: Consumers tend to examine the same digital attribute information earlier when a product is presented by more non-digital (vs. digital) attribute information.

We argue that an attribute examined earlier (vs. later) will have more impact on choice and such an impact is over and above the effect of attribute importance. First, an attribute examined earlier is more likely to be used as a screening criterion to exclude other alternatives. Second, given consumers do not always examine all the attributes, an attribute examined earlier tend to be accessed more frequently. This will make the attribute more accessible in the memory, which increases its impact on choice. Therefore, we predict

H2: Consumers' tendency to search the same digital attribute information earlier when a product is presented by more non-digital (vs. digital) attribute information is likely to increase the impact of that digital attribute information on choice.

Consumers' need for cognitive closure (NFCC) may moderate the hypothesized effect. NFCC relates to consumers' motivation for information processing and judgment (Webster and Kruglanski 1994). It refers to individuals' desire for definite knowledge, thus avoiding confusion or ambiguity. Individuals with high NFCC tend to reach a conclusion quickly and are reluctant to process further information (Kruglanski and Webster 1996). Therefore, we hypothesize that

H3: The impact of digital attribute information on choice is stronger for consumers with high (vs. low) NFCC.

Visually salient information can be created by increasing the object's size and contrast (Janiszewski 1998). It is much faster and easier for consumers to locate and pay attention to visually salient information (e.g., Janiszewski 1998). It is also easier for consumers to visually screen and sort all the alternatives according to the visually salient attribute. Therefore, we predict that consumers tend to examine alternatives with higher values on the visually salient attribute earlier. They will examine alternatives with lower values on the visually salient attribute only when they are not satisfied with the alternatives examined earlier.

H4: Consumers tend to examine alternatives with higher values on the visually salient attribute earlier.

It is found that the amount of attention focused on an attribute directly affects its importance (MacKenzie 1986). Hence, visually salient attribute will receive higher importance in choice. In addition, as consumers process higher values of the visually salient attribute much earlier and more often in the search, they are more likely to anchor on those values and perceive choosing alternatives with lower values on the visually salient attribute as a loss. Given consumers' general tendency of loss aversion, we predict that consumers will prefer the alternatives examined earlier, i.e., those with higher values on the visually salient attribute. Therefore, we expect

H5: Consumers' tendency to examine alternatives with higher values on the visually salient attribute is likely to increase the impact of the visually salient attribute on choice.

Sorting alternatives according to the visually non-salient attribute may reduce such an effect. When alternatives are sorted by the visually non-salient attribute, that attribute will distract consumers' attention and change consumers' search order. Hence, we hypothesize that

H6: The impact of the visually salient attribute on choice is stronger when alternatives are not sorted by a non-salient attribute.

We propose to conduct two online experiments to test our hypotheses. Results from our pretest show that participants tend to examine the same digital attribute information earlier when there is more non-digital (vs. non-digital) attribute information. Study 1 focuses on the impact of digital attribute information on choice and study 2 examines the influence of the visually salient attribute on choice.

Our research adds to the literature of online consumer information search and preference construction by showing when digital attribute information can have more impact on choice and how visually salient attribute influences consumer preference. This research also shows the underlying processes of these effects: consumers' search order for attribute and alternative information. Finally, this research discusses how individual difference and information organization may moderate these effects.

The Effects of Reciprocity in a Triadic Relationship

Andrew S. Gallan, Arizona State University, USA

Naomi Mandel, Arizona State University, USA

Robert Cialdini, Arizona State University, USA

Eugene Schneller, Arizona State University, USA

Extended Abstract

The norm of reciprocity reflects both a socially stabilizing function as well as a relationship-initiating role, and is universal (Gouldner 1960). Reciprocity involves both rights and duties for each side of a gift exchange (Gouldner 1960), such that individuals have the obligation to give, to receive, and to give back (Mauss 1954 (1925)). Studies within dyadic relationships have shown that gifts, whether or not they are searched for or expected, elicit a sense of obligation in the recipient (Regan 1971). Despite the fact that these theories were developed to explain the role of reciprocity in networks, research designed to understand effects beyond the context of dyads has not been done. It has been proposed that "triadization either supports and reinforces or inhibits and upsets a dyadic reciprocity" (Lebra 1975). Examining the effects of reciprocity beyond dyads has important implications for researchers of social influence in many disciplines, public policy makers, and practitioners.

Consider the following scenario: A pharmaceutical salesperson visits a healthcare provider, intent on increasing prescriptions for a particular product. After delivering a sales message about the product and its benefits, the salesperson leaves some samples. The samples are presented so the provider can facilitate initiation of therapy with a patient, with purported convenience and financial benefits. But the provider may also utilize these pharmaceutical samples for his or her own use, to treat an existing condition. In practice, both transference and personal use are fairly common (Tesoriero 2006).

In healthcare, voluntary professional guidelines developed by both physician groups like the American Medical Association and the pharmaceutical industry, have limited gifts to items of relatively low value, such as pens and pads, as well as the distribution of free samples (AMA 1998-1999; PhRMA 2002). While it has been argued that items of nominal value such as pens and pads may elicit obligations that alter provider behavior (Katz, Caplan, and Merz 2003), in practice their use has become more limited recently (Tesoriero 2006). We focus instead on the effect of samples, as these are *designed* to be utilized in a triadic relationship.

We hypothesize that samples will be perceived as gifts, both in the dyad (salesperson-provider) and in the triad (salesperson-provider-patient) scenario, and will elicit obligation due to the norm of reciprocity. The provider will feel obligated to the salesperson in either situation, personal use or transference; the end-user patient will feel obligated to the provider or the pharmaceutical firm, or both. But in which scenario (dyad or triad) are obligations the strongest? How can the salience of a message of obligation affect compliance behavior? What is the nature of the underlying relationship, whereby each member of a triad can repay another? Finally, can liking be ruled out as an alternative explanation?

Instances when samples are retained by the provider, creating a dyad, seem to converge with research showing positive effects on reciprocal behavior (Guéguen and Pascual 2003; Regan 1971). Marketing literature has documented small positive effects of samples upon prescribing behavior (Gönül, Carter, Petrova et al. 2001; Mizik and Jacobson 2004). These studies, however, remain empirical in nature, not explicitly examining the underlying theoretical mechanism. Our study utilizes a similar context, yet diverges in its purpose: we aim not to explain an empirical observation, but instead to test and extend theory and to resolve competing explanations for underlying causes.

Among seven proposed triadic relationships (Lebra 1975), we suspect that acts of repayment in this context may be explained by either circular transference, where the end user attempts to repay the initial giver, or lineal transference, where the provider is involved in linked dyads as a 'middleman.' The role of the provider is such that "there is a distinct breach in the traditional buying decision process: the decision maker...chooses among an array of...alternatives" (Gönül, Carter, Petrova et al. 2001); the end user ultimately acquires the product and evaluates its utility. For us, a gift is a tangible sample relevant to a recipient's role as a decision-maker, an object capable of either being utilized by the expert or transferred through to a third party.

Two arguments offer divergent predictions of the strength of the norm of reciprocity between dyadic and triadic relationships. On one hand, "triadization may bind the actor more effectively than does a dyadic bond," while on the other hand, a triad may "reduce the intensity of an interpersonal bond characteristic of a dyad" (Lebra 1975). The conditions under which triads are more or less binding than dyads will be investigated here.

The first perspective stems from work on dyadic reciprocation. Posing as a vehicle for information, this "not-so-free sample" can automatically invoke a "natural indebtedting force" (Cialdini 1993), in a healthcare setting (Wazana 2000), and represents a lineal transference, where the provider is involved through the linking of two dyads.

Alternatively, when a sample is transferred to the patient, it is being utilized as intended, and the provider may feel indebted from value provided to the patient. However, in this situation the provider does not realize the direct benefits of the sample, and may be less apt to reciprocate. The patient's receipt of the sample, however, may lead to a desire to reciprocate directly to the pharmaceutical firm (Oldani 2004), creating a circular transference. We suspect that the effects found in a circular transference are weaker than those in a lineal transference.

Salience of the obligation may play a significant role. In conditions of high message salience, the salesperson may be exhibiting “creditor ideology,” where “creditors prefer to have others in their debt because they believe that the norm of reciprocity will produce generous repayments” (Eisenberger, Cotterell, and Marvel 1987). This may be perceived by the recipient, thereby producing ‘reciprocation wariness’ (Cotterell, Eisenberger, and Speicher 1992) or ‘persuasion knowledge’ (Friestad and Wright 1999). A recipient can mentally acknowledge that a gift is a ‘sales device,’ thereby sidestepping the obligation altogether (Cialdini 1993). This may be true in both dyads and triads. In conditions of low message salience, a sense of obligation may not manifest at all.

A pretest on high-expert students (n=52), utilizing sunscreen samples, found a significant interaction between sample condition, motivation orientation (extrinsic/intrinsic), and likelihood to recommend ($F(1, 33) = 4.88, p = .05$). Our next experiment will be a 2 (gift retained/transferred) x 2 (high/low salience) + 1 (control group) experiment conducted with approximately 150 physician assistant (PA) students. Our instrument will be a questionnaire where hypothetical scenarios focus on a fictitious PA’s liking of the salesperson, likelihood to recommend the sampled product, the perceived benefits of the samples, and sense of obligation toward the salesperson.

Healthcare providers overwhelmingly believe that the acceptance of gifts has little or no impact on their recommendation decisions (Harris 2006; Murray 2002). Therefore, conducting an experiment with providers requires overcoming some level of social desirability bias (Neeley and Cronley 2004). We propose an experiment that will utilize indirect-report questioning formats to mitigate this bias, where “participants will project their own opinions and behaviors onto [an in-group] referent person” (Cronley, Neeley, and Silvera 2006).

Comparative Content Analysis of Thai and Vietnamese Ads, 1994 and 2004

Sela Sar, University of Minnesota, USA

Abstract

Thai and Vietnamese print advertisements were content analyzed to examine how content and advertising expression differed in the two countries at two different time periods, 1994 and 2004. Analysis focused on traditional Eastern and Western, and Informational and Emotional appeals. As hypothesized, Vietnamese ads contained more traditional and informational appeals than Thai ads, while Thai ads were found to contain fewer informational and traditional Eastern appeals than Vietnamese ads. Implications for practitioners and theoreticians are discussed.

In Southeast Asia, Vietnam and Thailand are among the countries most visible in the West. Although adjacent and culturally quite similar, they differ dramatically in their political systems and economic foundation. Thailand is a constitutional monarchy, with a widely revered king who exercises his powers through the National Assembly, the Council of Ministers (Cabinet), and the Courts. Vietnam is a socialistic democracy governed by a single-party parliamentary system, with an Executive and Judiciary chosen by the party. Vietnam, of course, was deeply affected by the war, while Thailand managed to stay largely out of the conflict.

Thailand enjoys a vital consumer economy built on gold, gemstones, and other natural resources, and has been active trade with the West since the 1970s. Only in recent years have international trade and modern consumerism begun to emerge in Vietnam, and then only in the large cities like Hanoi and Ho Chi Minh City (Saigon). In economic terms, the Thai per capita GNP was roughly \$ 5,500 in 1994 and \$ 6,500 in 2004, an 85% increase. Vietnam's was \$1,200 in 1994 and \$1,700 in 2004, a 70% increase (Global EDGE, 2004). This promising growth has attracted the attention of business leaders throughout Europe and North America.

With economic growth often comes an increasing interest in advertising, along with new challenges for Western advertising agencies that want to work in non-Western cultures (Zhou and Belk, 2004). Advertising practitioners and researchers are well aware of the dangers of applying American and British approaches in other countries. Many scholars have warned of the perils, e.g., Hofstede (1980), and some have done empirical studies in their efforts to understand international audiences better. For example, Biswas, Olsen, and Carlet (1992) observed that French advertisements employed more emotional appeals, humor, and sex, while American advertisements used more informational cues. Partially consistent with these findings, Cheng and Schweitzer (1996) reported that more Westernized countries such as France, the US, Finland, the UK, Japan, Korea, Taiwan, Singapore, and Philippines use emotional appeals more often than do traditional Asian countries such as China, Malaysia, and Indonesia.

In Southeast Asia, Wongthada and Leelakulthanit (1997) in Thailand and Schutz and Que (1997) in Vietnam pointed out the substantial effects of socio-political transition on advertising, and Sar and Doyle (2002) showed that Thai ads expressed more Western values than Cambodian ads. The importance of all these studies, of course, is that they help refine the practice of advertising, especially advertising designed by Western firms for use in Eastern countries. They may also contribute to cross-cultural audience analysis and theory-building, and to theories of cultural transmission and "hegemony."

The present study tries to advance our understanding of Southeast Asian audiences and culture by focusing on changes in the content of advertising in the ten years from 1994-2004. It applies tried-and-true comparative techniques, and adds a development dimension seldom seen in the cross-cultural advertising literature.

Method

This is a content analysis in which we draw inferences about the development of Thai and Vietnamese cultures from the Eastern versus Western content of Thai and Vietnamese magazine advertisements over the past ten years. We shall argue that practitioners who understand this cultural development better will be able to produce more effective ads and campaigns, and that theorists who peruse these data will be able to make finer distinctions than they previously could, particularly within Southeast Asia.

The Magazines. According to the Thai daily newspaper *Thairath* (2004) the three most widely read monthly magazines in Thailand are *Bangkok Metro*, *Prail* ("Shining"), and *Bambi News*. According to the Vietnamese daily newspaper "*Vietnam News*" (2004), the three most popular monthly magazines in Vietnam are *Song Manh*, *Phu Nu Viet*, and *Que Huong* ("People"). In both sets, the first magazine is a general-interest publication similar to *Life* or *Look* in the United States; the second is a women's magazine similar to *Home and Garden*; and the third is a popular magazine similar to *People*.

The Ads. In the twelve 1994 and twelve 2004 issues of each of these magazines, we identified all ads for household products, personal and non-personal. Personal household products included shampoo, soap, body lotion, sanitary pads, and toothpaste; non-personal household products included detergent, fabric rinse, and dishwashing liquid.

From the total number of these ads—79 in 1994 and 90 in 2004 for Thailand; 56 in 1994 and 45 in 2004 for Vietnam—we randomly selected 35 from each year and each country, for a total final sample of 140 ads.

Content Analysis. The focus of the analysis was the relative frequency of traditional Eastern versus Western appeals (per our literature review) and emotional versus informational cues, in the two countries in the two years.

To define the first of these terms, twenty Thai and Vietnamese students studying at a large Midwestern university in the United States participated in a focus group in which they were asked to define traditional "Eastern" appeals. This discussion identified four principle characteristics of traditional appeals: Respect for Elders, Collectivism, Conservative Sexual Morality, and Modesty.

To define the second of these terms, Western Appeals, we used Hong and Zhu's (1995) scales: Sexy, Humorous, Comfortable, and Convenient. These scales have been used in numerous studies of international advertising, e.g., Lai Man So (2004), Zhang and Shavitt (2003), Tai (1997), and Wang, Pinkleton, and Morton (1997), and Graham, Kamins, Oetomo (1993).

To define Emotional Appeals, we used Plutchik's abbreviated Mood Rating Scale (1980), which relies on four adjectives selected from his longer checklist. The four elements on the abbreviated scale are Happiness, Pleasantness, Interest, and Surprise. These scales were used in Hong, Muderrisoglus, and Zinkhan's (1987) study of cultural differences in Japanese and American magazines.

Finally, we defined Informational Appeals with four elements from Stern and Resnick's (1981) conception of "informativeness": Price/Value, Quality, Guarantees/Warranties, and New Ideas, or Novelty. These scales, too, were used in Lai Man So's (2004) study of cross cultural comparison between Hong Kong and Australia's women magazines; Hong, Muderrisoglus, and Zinkhan's (1987).

We created a five-point semantic differential scale for each of the 16 elements, e.g., Not Happy to Very Happy. Four judges then used these scales to code the Thai and Vietnamese ads for Eastern versus Western appeals, including emotional versus informational cues. Two Thai graduate students, one male and one female, coded the Thai ads, and two Vietnamese graduate students, also one male and one female, coded the Vietnamese ads. All coders were fluent in English as well as in their home languages. Reliability coefficients for this coding ranged from .79 (Traditional, Thai 1994) to .85 (Emotional, Vietnamese, 2004), with an average of .81, well within the recommended range for studies of this sort (Kassarjian, 1977); and Nunnally, 1978).

Results

With regard to Traditional Eastern Appeals in Vietnamese versus Thai ads for the two years combined, Table 1a indicates significant differences on Respect, Collectiveness, and Modesty, and a borderline-significant difference ($p=.08$) on Sexual Morality. These differences uniformly depict Vietnam as the more traditional of the two countries:

With regard to differences in the extent of Traditional Eastern Appeals between 1994 and 2004, Table 1b shows significant difference across years on all four variables for the Vietnamese ads, and on two of the four variables—Collectivity and Sexual Morality—for the Thai ads.

In the Vietnamese ads, the Respect, Collectivity, and Modesty means are higher for 2004 than for 1994, the Morality mean lower. In the Thai ads, the situation is partially reversed: The Collectivity mean is lower for 2004, the Morality mean higher. At the same time, the Respect and Modesty means are unchanged. According to these data, over the past decade the Vietnamese ads have become more Respectful, more Communal, and more Modest, but also more sexual (lower Morality). The Thai ads have become less Communal and less sexual (more Moral), but remained unchanged in Respect and Modesty.

With regard to Traditional Western Appeals in Vietnamese versus Thai ads for the two years combined, Table 2a indicates significant differences on all four dimensions: Convenient, Sexy, Comfortable, and Humorous. These differences again depict Vietnam as the more traditional Eastern, the less Western, of the two countries.

With regard to differences in the extent of Traditional Western Appeals between 1994 and 2004, Table 2b shows significant differences on three of the four dimensions—all except Comfortable—for both the Vietnamese and the Thai ads. In the Vietnamese ads, the Convenient, Sexy, and Humorous means are all higher for 2004 than for 1994. In the Thai ads, the situation is again reversed: The 2004 means are all lower. In the Vietnamese ads, the 2004 mean ratings are always higher than the 1994 mean ratings. According to these data, the Vietnamese ads have become a little more Western than they used to be, but they remain less than Thai ads.

With regard to Emotional Appeals in Vietnamese versus Thai ads for the two years combined, Table 3a shows higher Thai means on Surprised, Pleasant, and Interesting, and a non-significant difference on Happy. The Thai ads for the most part use more emotional cues than the Vietnamese ads.

With regard to differences in the extent of Emotional Appeals between 1994 and 2004, Table 3b shows significant differences on two of the four variables—non-significant on Surprised and Pleasant—for the Vietnamese ads, and on all four variables for the Thai ads. In the Vietnamese ads, the Happy mean is higher for 2004 than for 1994, the Interesting mean lower. In the Thai ads, all 2004 means are higher than the corresponding 1994 means. According to these data, the Thai ads have increased in all four kinds of emotional content, while the Vietnamese ads have increased in Happy content, decreased in Interesting content. The ads depict Thai culture as more emotional than Vietnamese culture, and Thai ads more emotional—happier, more interesting, more surprising, more pleasant—and growing still more so.

With regard to Information Appeals in Vietnamese versus Thai ads for the two years combined, Table 4a indicates significant differences on all four dimensions of Informational Appeal: Price Value, Quality, Warranty, and New Ideas (Novelty). These differences consistently depict Vietnam as using more informational cues than Thailand.

With regard to differences in the extent of Informational Appeals between 1994 and 2004, Table 4b shows significant differences on two of the four variables (Quality and Warranty), a borderline significant difference on one variable ($p=.07$ for New Idea), and a non-significant difference on one variable (Price Value) for the Vietnamese ads. Table 4b also shows significant differences on two variables (Price Value and Quality), a borderline difference ($p=.06$ on New Idea), and a non-significant difference (Warranty) on the Thai ads.

Again, the Vietnamese and Thai patterns are substantially opposite. On Quality—the only Informational dimension on which the change is significant for both countries—the 2004 Vietnamese mean is lower than the 1994 mean, but in the Thai ads, the 2004 mean is higher. On Novelty, borderline-significant for both countries, the 2004 Vietnamese mean is higher than the 1994 mean, but the 2004 Thai mean is lower. Vietnamese culture, per the above less emotional than Thai culture, is growing less concerned with quality information and more interested in novelty, while Thai culture, more emotional, is growing more concerned with quality information, and less concerned with Novelty. The inference we draw is that, just as the two cultures are moving toward each other in terms of emotional cues, so they are becoming more similar in terms of informational cues.

Discussion

The principal strengths of this study are that it is built on random samples of ads from the most widely read magazines in Thailand and Vietnam and that it evaluates those ads according to attributes identified as important in respected previous studies. The principal weaknesses are that the study analyzes only print ads, indeed only magazine ads, and that it samples ads from only two points in time. Despite these weaknesses, we believe the results are consistent enough that practitioners and theorists may draw conclusions from them.

Our analysis identified a number of important patterns: First, that Vietnam is the more traditional, less Westernized of the two cultures; second, that Vietnamese ads have become more Western over the past ten years, Thai ads in many (but not all) ways less Western (Collective, Sexual, Humorous); third, that Vietnamese ads have become more emotionally cued in the past ten years; and, fourth, that Thai ads have become more informationally cued in some ways (Quality), less so in others (Novelty), while Vietnamese ads showed just the opposite pattern, less informationally cued as to Quality, more so as to Novelty. The Thai patterns were often just the opposite of the Vietnamese patterns, despite the proximity and apparent cultural similarity of the two countries.

What are advertising practitioners and theorists to draw from these findings? The most obvious conclusion is that, despite the proximity and superficial similarity of the two cultures, they should not be treated the same. In more technical terms, they are not samples from the same population.

More specifically, practitioners and theorists can expect that Vietnamese print-ad audiences will respond positively to more traditional Asian appeals—those that rest on Conservative Sexual Morality, Collectivity, and Product Information—while Thai audiences will respond positively to somewhat more Western appeals. We cannot escape the image of a fundamentally Confucian culture (Doyle, 1999, pp. 89ff) in Vietnam growing increasingly Western as it sheds its Communistic history and takes its place on the international stage.

The Thai ads seem to reflect a culture that may have peaked in terms of Western influence and is finding its identity in a cosmopolitan blend of East and West.

More specifically still, our data suggest that sexual images and allusions, a staple of Western advertising, will be more problematic in Southeast Asia than in most parts of the United States and Great Britain. Whether measured as traditional Eastern "Sexual Morality" or Western "Sexiness," our data indicate that Vietnamese ads have grown more sexual, Thai ads less so. We take this as a sign that the two cultures are seeking a level of sexuality in advertising that fits their changing circumstances. Vietnam, newer to the game, is still experimenting with sexuality in advertising; Thailand, more experienced—Bangkok is well-known for its free if not libertine sexual culture—may be retreating to a more conservative state.

Both sets of ads seem to depict cultures that are more light-hearted than they were ten years ago. That is, "happy" cues are higher in both cultures, "surprising" and "pleasant" cues higher also in Thai culture, perhaps a sign of distancing from the turmoil of the 1970s, perhaps an indication of growing equilibrium between Eastern and Western influences. In either event, both Vietnamese and Thai audiences should respond well to "happy" cues as long as these do not overpower the essential information needs of Vietnamese culture.

From a theoretical view, our study supports and extends the findings of the relatively few studies of comparative Asian culture in advertising. It identifies both cultures as fundamentally Asian, but goes on to offer distinctions that, so far as we know, have not been made before, in particular the movement toward Eastern/Western and Information/Emotional equilibrium. As such, it is compatible with theories of "globalization" (e.g., Tomlinson, 2000) and even "hegemony" (e.g., Gramsci, 1992), although our data are not sufficient to determine whether or not such cultural diffusion is welcome.

Like all research, our study raises as many questions as it answers. Among them, will these patterns hold up in broadcast as well as print media? Are the changes speeding up or slowing down? What differences will we find within these cultures, among older versus young audiences, for example, or males versus females, highly educated versus less so? Further empirical work should address these questions.

Are “Paradigms Lost” in Marketing? Some Twenty Years Later...: A Content Analysis

Saleh AlShebil, University of Texas at Arlington, USA

Extended Abstract

In the fall of 1983, Rohit Deshpande wrote an article in the *Journal of Marketing* entitled “Paradigms lost: On Theory and Method in Research in Marketing.” The article presented a discussion of the dominance of the positivist or quantitative paradigm over the much neglected qualitative one in marketing. Our objective in this paper is an attempt to provide a more statistical account of the article’s claim that quantitative research dominates the marketing literature, but after some twenty years later.

The quantitative-qualitative debate is a lengthy one that dates back to the late nineteenth century with the growth of the interpretive approach (qualitative approach) to social inquiry which was considered a reaction to the positivist approach (Giddens, 1976; Hughes, 1958; Outhwaite, 1975, 1983; Polkinghorne, 1983; Smith 1983a, 1983b). Several researchers point out the need for and importance of qualitative research which would help provide a better understanding of the complex nature of the social world we live in (Cronbach 1975; Hirschman 1986). Others disagree and state that such qualitative research is purely subjective (Smith and Heshusius 1986) and some go as far as claiming that “it doesn’t constitute market research” and that “two people doing the same qualitative study can obtain totally different results” (Achenbaum 2001, p. 14).

On comparing the two methodologies, some say that they can be considered as mutually exclusive (Tauber 1987) and each method has its own set of different evaluation criteria (Lincoln and Guba 1985). Brodbeck (1968, p. 573) states that “the quantitative-qualitative dichotomy is spurious,” and Seymour (1989) argues that consumer research should not be an “either/or” case when it comes to the type of methodology used but rather it should be able to encompass and build a more comprehensive understanding of the consumer. He further recommends staying away from being too focused on the method and the “technique-driven-and lose track of the real purpose in generating information” (p. 27). Likewise, Kassarian (1989) offers a similar view as he says that “the appropriate question is whether or not it is good science, rather than what kind of science it is,” and “is it making a contribution to knowledge?” (p. 126).

In the “Paradigms Lost” article, the focus of our paper here, Deshpande argues that the marketing literature has been dominated by one paradigm and that is the logical empiricism/positivism or the quantitative paradigm. He offers a discussion on the dominance of the quantitative paradigm over the often abandoned qualitative one which may be responsible for the low development of theory construction in marketing research. He suggests attaining a balance between the two paradigms and calls for more triangulation of methods and using each method more appropriately. This would be in an attempt to reduce the current bias that exists especially when addressing the issues of theory discovery versus theory verification.

In this study we used a content analysis procedure to investigate our research question of whether quantitative methods research does dominate the marketing literature even after twenty years of the “Paradigms Lost” article. We reviewed all the articles for the top three marketing journals (Hult, Neese, and Bashaw 1997), namely: the *Journal of Marketing* (JM), the *Journal of Marketing Research* (JMR), and the *Journal of Consumer Research* (JCR) from the years 2002 to 2004. We chose the past three years to reflect a “snapshot” of the recent trend. We basically classified each article on whether it was a quantitative study, a qualitative one or both based strictly on the research methodology used. Thus articles that do not include any methodology used were considered not applicable.

We analyzed a total of 394 articles (109 in JM, 115 in JMR and 170 in JCR). Almost half (47.2%) of all the articles published were of the quantitative methodology. Purely qualitative articles made up a mere 7.1% and articles containing both quantitative and qualitative research methodologies made up 32.7%. Articles that were considered not applicable made up the remaining 12.9%.

When looking at the journals more specifically, we found that JCR had the highest percentage of purely quantitative articles (65.3%) and at the same time it had the highest percentage of qualitative articles (13.5%). JMR had the lowest percentage of qualitative articles with only *one* article in the three years investigated! And JM also had a very low percentage of qualitative articles (3.7%). However, both JMR and JM had the highest percentage of articles with both methodologies used. Based on this analysis, it may be feasible perhaps to say that a researcher looking to publish a purely qualitative study maybe far better off shooting for JCR than JMR or even JM.

In terms of the types of methodologies used, experiments showed up as the highest percentage of methodology used, accounting for 41.4% of all the journal articles. Surveys, interviews and secondary data analysis were all almost similar in the percentage used (15-17%). To be more specific, quantitative articles were dominated by experiments and qualitative articles were dominated by interviews. Furthermore, in terms of the journals, JM was dominated by surveys, JMR was dominated by secondary data analysis and JCR was dominated by experiments. These particular findings provide further evidence of the dominance of the quantitative methodologies in marketing journals and perhaps indicate the preferences of certain methodologies over others.

In conclusion, based on our limited study, we have attempted to provide some preliminary evidence of the dominance of the quantitative paradigm over the much neglected qualitative paradigm in the marketing literature, even after more than twenty years of the “Paradigms Lost” article. However, the clear sign of studies including both methodologies provides growing evidence that even though purely qualitative studies are still minimal, there integration with quantitative studies maybe catching pace.

Compulsive Buyers and the Emotional Roller Coaster in Shopping

Anna Saraneva, Hanken-Swedish School of Economics, Finland

Maria Saaksjarvi, Hanken-Swedish School of Economics, Finland

Extended Abstract

Shopping is increasingly seen as a recreational activity in which consumers are emotionally involved. Instead of going to a store to buy necessary items, consumers often stroll around and browse for hours just for the fun of it. Shopping provides a necessary escape for consumers whose lives are hectic or otherwise troublesome. However, for some consumers, shopping can become more than recreation. Compulsive shoppers are consumers who are addicted to shopping. For these consumers, shopping is part of their lifestyle, and strongly related to emotional goals.

The emotions compulsive shoppers go through influence their feelings and satisfaction of the shopping activity. For example, consumers who have a bad day might go shopping to cheer themselves up, or consumers who have completed a difficult task at work might reward themselves by going shopping. For compulsive shoppers, the emotions involved with the shopping activity are particularly important, as they play such a large part of the consumer's life and influence their happiness as a whole. Feelings such as joy, anticipation, thrill during the shopping activity can quickly shift over to guilt, depression, and dissatisfaction with managing one's finances. Based on previous research results, literature has termed these consumers bulimic shoppers, who crave for shopping in excess, but afterwards get emotional qualms.

The emotions involved with shopping activities have usually been studied by examining how consumers feel before and after the shopping activity. The purpose of this paper is to extend on this view by examining consumers feelings with the shopping activity before, during and after the shopping process, to receive a more comprehensive picture of the emotional shifts consumers go through during the shopping activity. By examining all three stages, we expect to get a more refined picture of how emotions can change during the shopping activity, and what the triggers involved in these changes are.

To achieve the goal of the study, a three-step research methodology was employed. We first utilized an online questionnaire to identify consumers who could be classified as compulsive shoppers. Then, we conducted a digital ethnography study by communicating with consumers using their mobile phones. By communicating with consumers before, during, and after the shopping process using SMS and picture messages, we were able to be sensitive to the emotional changes consumers go through while shopping. Finally, we conducted personal interviews with the compulsive shoppers to hear them describe their feelings involved with the shopping activity, and their emotions towards shopping in their own words. The three steps complemented each other, and provided us with the ability to cross-check and validate results across the different kinds of data collected.

The results show that compulsive shoppers go through an emotional rollercoaster during the shopping process. The trigger involved with the emotions is closely linked to finding a bargain. A bargain is defined as a good deal, or a situation in which the consumers perceive they get mental satisfaction from their purchase. If compulsive shoppers make a bargain, they feel pride, happiness, and goal achievement. However, if they do not manage to find a bargain, they feel disappointed, sad, and unsuccessful. These emotions switch back and forth during the shopping activity. The largest disappointment for these consumers comes if they think they have managed to find a bargain, but realize that it was not one, after all (e.g., the item is too expensive, or they do not have it in the customers' size). However, this disappointed can be overturned if another bargain is found. These findings expand on those found by previous literature by showing the emotions consumers go through during the shopping process are not predominantly negative or positive before or after the shopping process. Instead, consumers move up and down on an emotional continuum during shopping, and can also feel pride and satisfaction after shopping if they manage to find a bargain.

Knowledge Transfer and Rhetoric: The Influence of Rhetorical Figures on Consumer Learning

Marjorie Delbaere, University of Manitoba, Canada

Malcolm C. Smith, University of Manitoba, Canada

Extended Abstract

Recently, researchers in marketing have begun to investigate the processes of internal knowledge transfer that consumers engage in when learning about a new, unfamiliar product (Gregan-Paxton, Hibbard, Brunel and Azar 2002; Gregan-Paxton and Moreau 2003; Moreau, Lehman and Markman 2001; Moreau, Markman and Lehmann 2001, Roehm and Sternthal 2001). This stream of research promises to expand our understanding of how consumers use existing knowledge to help them learn about unfamiliar products as well as ways in which this learning process can be influenced. Based on work done in cognitive psychology, the dominant theory driving this stream of research is analogical reasoning, which holds that we learn about new products much in the same way as we solve analogies (Gentner and Gentner 1983; Genter, 1989; Holyoak, Gentner, and Kokinov 2001; Markman and Gentner 2001; Vosniadou 1989). In applying and testing this theory in marketing, consumer researchers have often employed analogies in the headlines or copy of advertisements used as experimental stimuli. The use of an analogy in an ad has been found to influence the way consumers learn about the products being advertised (Gregan-Paxton, Hibbard, Brunel and Azar 2002; Gregan-Paxton and Moreau 2003). In spite of this explicit use of analogy, consumer researchers have failed to acknowledge the fact that an analogy is a rhetorical figure and thus have neglected to incorporate findings from the literature on rhetorical figures (McQuarrie and Mick, 1992, 1996, 1999, 2003) and persuasive communication.

This research seeks to answer the following question: what influence does the use of rhetorical figures in marketing communication have on consumer learning? Specifically, the impact on consumer learning will be examined from the perspective of internal knowledge transfer and the validity of the inferences consumers draw after exposure to a persuasive communication containing a rhetorical figure. One goal of this proposed research is to expand the scope of studies on knowledge transfer to a different context: the health care industry, specifically prescription drugs. Prescription drugs represent a different category of products than consumer electronics on many levels: consumers cannot directly buy prescription drugs; prescription drugs are incredibly complex in terms of interactions with other medications and/or lifestyles; prescription drugs have a direct and potentially powerful impact on consumers' health and well being as well as a far reaching impact on public policy and society in general (for example Coney 2002; Lexchin and Mintzes 2002; Roth, 1996; Menon, Deshpande, Zinkhan and Perri 2004; Narayanan, Desiraju and Chintagunta 2004).

In an initial study, 260 undergraduate students from the introductory marketing course at a large Canadian university were exposed to six versions of a print ad for Gentrex, a fictitious brand name for a medication to treat genital herpes. This study was intended to serve as a test of a selected medical condition (genital herpes) and drug therapy as well as to investigate whether there were any substantial differences among subjects at processing similes versus metaphors. Even though metaphors and similes are both technically analogies, they represent different forms (implied versus explicit) and may have a differential impact on knowledge transfer processes.

The experimental design for the study was a 3 x 2 between subjects design. The first factor refers to the type of rhetorical figure used in the headline, with the following three conditions: simile, metaphor or declarative (non-figurative) statement. A declarative statement

was included as a third headline in order to have a baseline against which to evaluate the simile and metaphor headlines. The different headlines for each category were: Gentrex is like a sleeping pill for genital herpes (simile); One Gentrex a day keeps genital herpes at bay (metaphor); Gentrex suppresses genital herpes (declarative statement). The second factor pertains to the copy that appeared in the ad, with the following two conditions: no copy, and copy. The amount of copy contained within the ad was varied to test for any differences in processing due to the inclusion of additional information.

A one-way ANOVA revealed a significant difference in the mean levels of perceived creativity between the figurative headlines (simile and metaphor) and the non-figurative headline, suggesting a successful manipulation. As expected, no significant difference was found between simile and metaphor, suggesting subjects perceived the two forms of analogy similarly. Following previous research on knowledge transfer in consumer research (Gregan-Paxton and Moreau, 2003), the nature and extent of subjects' internal knowledge transfer was captured by having subjects complete two cognitive response tasks. Thought protocol analysis revealed that simile and metaphor comparisons were not significantly different at encouraging relational knowledge transfer. This suggests that simile and metaphor should have similar effects on consumer knowledge transfer.

More than one quarter of all subjects (26%) made the inference that Gentrex cures genital herpes. Currently, there is no cure for genital herpes and no information in the ads shown to subjects indicated that Gentrex can cure genital herpes; however, it is conceivable that subjects might have inferred this from the ad headline. When the ad contained no copy, subjects in the analogical comparison conditions were significantly more likely to make the curative inference than subjects in the declarative condition. This finding suggests that subjects exposed to analogical comparisons engaged in further elaboration of the message than subjects exposed to the declarative statement, but that the additional inferences made were not valid. All subjects were relative novices, and therefore might not have been able to judge the validity of their inferences. When the ad contained copy, there were no significant differences among conditions at making the invalid inference (proportions were .14 for simile, .25 for metaphor and .16 for declarative). Additionally, the finding points to the potential danger of analogical comparisons involving medication. If there is no text that corrects for invalid inferences, or, as is more likely the case in a natural setting, consumers do not pay attention to the copy and only read the headline, consumers are in danger of drawing invalid, misleading conclusions about the advertised medication.

Distrust: An Alternative Source of Power For Consumers

Ahmet Ekici, Bilkent University, Turkey

Extended Abstract

The broad objectives of this article are to make theoretical arguments and to provide empirical support for the significance of studying consumer distrust. More specifically, we study consumers' distrust in various key institutions in the food system, and describe how consumer distrust in various social institutions shapes their beliefs about food safety. It has been argued that trust plays an important role in shaping consumer beliefs about food safety in general and beliefs about the novel food applications in particular (e.g. irradiated foods and genetically modified foods) (Juannillo 2001; McGarity and Hansen 2001). In this paper, we argue that, in order to have a more complete understanding about consumer beliefs in food safety, in addition to trust, consumer researchers and policy makers should also pay attention to the concept of distrust. A review of the literature both in consumer research and in other areas of social sciences suggests that as most researchers have dealt with the concept of *trust*, very limited attention has been paid to the concept of *distrust*.

Marketing literature does not provide a definition for distrust for the same reason that it treats distrust as the negative polar of a single trust continuum. Scholars in other disciplines provided a view of distrust; however, they, too, have mainly conceptualized distrust as "lack of" trust, not as a separate construct (these points will be elaborated in the next section). Deutsch's (1962) conceptualization of trust and distrust appears to make clearer distinctions between the two. Deutsch (1962) viewed trust as an individual's confidence in the intentions and capabilities of a relationship partner and the belief that a relationship partner would behave as one hoped. His view of distrust builds around suspicion and fear: confidence about a relationship partner's undesirable behavior, stemming from knowledge of the individual's capabilities and intentions. More recently, Lewicki, McAllister, and Bies (1998) mentioned distrust as confident negative expectations involving fear of another's conduct.

We conceptualized distrust in terms of confident negative expectations regarding another's conduct. More specifically, distrust in social institutions is conceptualized as consumers' confident negative expectations regarding institution A's conduct (words, actions, and decisions), and confident negative expectations as a fear of, a propensity to attribute sinister intentions to, and a desire to buffer oneself from the effects of institution A's conduct.

Institutional distrust (described as distrust directed at social institutions such as the government or manufacturers) can be studied in two ways. One is to view distrust as "lack of," "loss of," or "decreased" trust, and therefore study it in "trust" terms. Another way to deal with institutional distrust is to call it by its name and work to understand what caused it and what is maintaining it. Most studies have followed the former view, which I see as shortsighted. For example, in their study of distrust in institutions in nine post-Communist societies, Rose and Mishler (1997), conceptualized distrust as "lack of trust" and introduced subjects with the statements "There are many institutions in this country, for example, the government, courts, police, and civil servants. Please show me on this 7-point scale, where 1 represents great distrust and 7 represents great trust, how much is your personal trust in each of the following." (p.8). When distrust is conceptualized as "decreased" or "lack of" of trust, and measured along the same trust/distrust continuum, then it assumes that distrust exists in terms of trust, not as a separate concept (i.e. low levels of trust would mean distrust). As a result, respondents are forced to indicate either trust or distrust toward an institution. This generalized approach does not allow the possibility that individuals can trust an institution in some areas and distrust it in others. In other words, this view omits the possibility that distrust in institutions may exist independently of the level of trust individuals might have in these institutions given different contexts. For example, government may be trusted to deal with foreign threats but may be distrusted to eliminate corruption. In this case trust and distrust may grow or decline based on different elements and may be caused by different antecedents.

We believe that current conceptualizations of trust and distrust (distrust as opposite of trust) leave us only with the "tool" of trust to deal with social problems. However, when trust and distrust are considered as separate constructs, both can be utilized independently to deal with complex social phenomena. In other words, our view also suggests that elements of trust and elements of distrust towards an institution separately may be used as strategy tools by individuals in a complex social system. The Rose and Mishler (1997) study, mentioned above, reported that individuals scored low on the 1-7 distrust/trust scale for most institutions, and therefore concluded that distrust is the persisting attitude in these societies. A summary analysis that low trust would actually mean distrust may lead us nowhere in solving social problems. In the end, the study concluded that as long as distrust exists, many post-Communist countries will remain far from idealized models of civic democracies. However, as we know, in most civic democracies distrust (and also trust) in institutions exists and persists, perhaps even as the backbone of these democratic societies. As Barber (1983) suggests "A democratic polity requires legitimate criticisms based on democratic allegiance, some distrust, in this sense, is essential for viable democratic order. Others have point this issue as paradox of democracy: "the more there is institutionalized distrust, the more there will be spontaneous trust" (Sztompka 1999, p. 140).

In summary, we believe that there is both merit and need in investigating distrust as a separate concept. We further believe that insights gathered through such attempts can provide guidance for public policy makers in their attempts to handle social issues and problems. For example, by studying consumer distrust in the context food safety (like in this paper,) we can have a more comprehensive understanding about consumers' orientations for various novel food applications including irradiated foods and genetically modified foods. In this paper, after providing an overview of our research context and activities that took place between 1999-2003 in the Midwest, we report our findings related to consumer distrust in social institution. Based on the data collected through in-depth interviews, we identified three dimensions of consumer distrust within which social institution of the food system can be viewed. Then, we conclude the paper with a general discussion of contributions and implications for consumer, for academicians, for practitioners (e.g. the food industry) and for public policy makers.

Spinning Fantasies into Consumer Attitudes: A Fantasy-Realization Perspective of Attitude Formation

R. Justin Goss, Montana State University-Bozeman, USA

Ian Handley, Montana State University-Bozeman, USA

Extended Abstract

Every consumer fantasizes about obtaining better things such as a better car, a new flat panel TV, or a dream vacation. Yet, as ubiquitous as such fantasies are, they are often times not realized. One reason individuals' positive fantasies become doomed to the limbo of the mind is that individuals do not possess the goal, or at least a strong enough goal, to make their fantasies into reality. Interestingly, fairly little empirical attention has been given to determine how or why people set goals in the first place, and how committed individuals become to their goals. Yet, such empirical considerations are important if marketers are to understand when and how consumers form goals to purchase products.

Potentially guiding such considerations, Oettingen (1996) has suggested that how individuals think about the future may be important in understanding how they come to set goals and commit to them. She offers that individuals can think about the future in two ways—by generating or considering expectations about what outcomes are likely to occur in the future, or by indulging in free fantasies. Free-fantasies involve individuals' imagination about what it would be like to attain a desirable future outcome (e.g., buying a desired new car). Importantly, free-fantasies can occur independently of individuals' expectations that the events about which they fantasize are likely to occur. For example, many consumers can fantasize about owning a new Ferrari, yet fully expect that actually owning such a car will never be within their financial reach.

In her Fantasy Realization Theory (FRT), Oettingen (1996) offers three ways an individual might deal with fantasies about the future and relate them back to their current situation as a means toward realizing the fantasy. That is, FRT offers three ways by which individuals' fantasies may influence goal formation and commitment. Two of the possibilities create a readiness to act that is independent of expectations that the goal is attainable (e.g., the Ferrari example), whereas the third entails an expectancy-based readiness to act.

First, individuals may largely disregard positive fantasies about the future and instead dwell on a negative reality that stands in the way of a desired future. When individuals engage in this type of thinking they are left without the necessity to act. Further, and more importantly, by not fantasizing about the positive future individuals also lack a direction in which to act. As a result, goal commitment will only be influenced by the negative aspects one considers about the current reality. That is, expectations about the attainability of the positive outcome do not tend to influence goal commitment.

Second, individuals can think about positive fantasies without considering current situations that may impede their fantasy-realization, a type of thought akin to daydreaming. In this situation, individuals merely fantasize about the future and consider no information in the present reality that would cause them to reflect on the fact that their fantasy of the future has not been realized. Further, because individuals in this frame of mind do not ponder their reality, their expectations for attaining the positive outcome is not considered and, therefore, does not influence their commitment to achieving the outcome in their fantasy. Rather, the positive incentive of the desired future outcome within the fantasy supplies the only motivation to act.

Third, individuals may indulge in an expectation-based type of thinking in which a positive fantasy is contrasted with a negative reality that blocks the potential realization of a fantasy. In essence, mental contrasting reveals the desired future as something that is to be attained, and the negative reality as something that needs to be overcome. A necessity to act is produced that questions whether reality can be turned into fantasy. Goals are enacted or forgotten based on the individual's degree of expectation of achieving that future. If expectations are high, then a committed goal will be formed, if expectations are low, a goal will not be formed.

To this point, FRT studies have relied on identifying expectations already held by participants. Of note, persuasion research (e.g., Fishbein and Ajzen 1975) indicates that the presentation of strong or weak arguments influence individuals' expectations that an attitude object is likely to produce positive or negative consequences. Thus, by manipulating argument quality, it is possible to manipulate individuals' expectations that a fantasy is attainable (e.g., that they can, or cannot, purchase a car). Further, individuals form favorable attitudes toward the topic of the message when it is supported by strong arguments, but relatively unfavorable attitudes about a message if it is supported by weak arguments (Petty and Wegener 1991). Thus, FRT would suggest that individuals who compare positive fantasies and negative realities should be particularly influenced by the expectations induced by strong or weak arguments. As a result, these individuals should form favorable attitudes toward a message topic if it contains strong, relative to weak arguments. However, individuals who only consider positive fantasies, or negative realities, should not be influenced by their expectations, and thus should form attitudes independent of the quality of the arguments they read.

Testing these predictions we manipulated participants' mindset using methods similar to those used by Oettingen et al. (2001). Specifically, participants were induced to either dwell on negative realities that stand in the way of buying a new car, positive fantasies

about buying a new car, or to mentally contrast both. They were then presented with an advertisement that offered excellent incentives for buying a new car (strong argument) or an advertisement that offered lackluster incentives for buying a new car (weak argument). We then administered a questionnaire about their expectations that buying a car was feasible and their attitudes toward buying a car in the near future.

As predicted, participants in the mental contrast condition who received a strong advertisement demonstrated more positive attitudes and higher expectations of buying a desired new car than those who received a weak advertisement. Further, participants in the other two conditions did not differ in their expectations or attitudes, regardless of which persuasive advertisement they received. These findings indicate that FRT can be usefully applied to research in consumer behavior.

The Influence of Line and Surface Modifications in Product Design on Brand Recognition and Novelty

Robert Kreuzbauer, University of Illinois at Urbana-Champaign, USA
 Jan Schoormans, Delft University of Technology, The Netherlands
 Dirk Snelders, Delft University of Technology, The Netherlands

Extended Abstract

The choice between novelty and familiarity when introducing a redesigned product is a crucial decision. How similar should the appearance of a redesigned product be compared to the old product to ensure brand familiarity? And, to what degree should the redesign look new in order to avoid boredom? A look into the processes of object perception reveals that novelty and similarity/familiarity are not two poles of the same dimension. Instead it is possible that consumers can perceive new products as both novel from and similar to a former product. According to the 4-stage model of object perception (cf. Palmer 1999; Palmer et al., 2003; Kreuzbauer & Malter 2006) a product which is perceived by a consumer passes 4 different stages until it becomes categorized within consumer memory. The first stage describes a 2-D *retinal image* which is a first impression of visual product stimuli that are projected to the viewpoint of the observer's eyes. A retinal image is perceived without the consumer's attention, and the information is unstructured and 'uninterpreted' (Julesz, 1984; Treisman, 1993). In the second stage, the 2-D retinal product impression is further processed, so that elements such as lines and edges of the stimulus are detected and "sharpened" (*image-based stage*). Further in the *surface-based stage*, general surface and spatial information is recovered. True 3-D processing first occurs in the final stage, called the *object-based stage*, since the product perception process does not end with the mere representation of all the visible lines and surfaces. Instead, it is assumed that during perception surface information is related to general stored knowledge about the intrinsic nature of the 3-D object (Biederman, 1987; Palmer, 1999). An example would be aspects of products that are occluded from the current viewpoint (e.g., the backs or undersides of a camera, TV, car, bottle, etc.). By simply perceiving the curved lines and surfaces of a bottle, the observer is able to make clear predictions regarding the probable appearance and properties of the back of the bottle. Therefore, hidden assumptions about the nature of the visual world are also required to enable the inclusion of information about unseen surfaces or parts of surfaces.

Since line perception is an earlier process than other processes such as surface and texture perception, lines are the major visual elements that determine object recognition and similarity (cf. Biederman & Ju, 1992). Based on the ideas of Biederman & Ju, one can expect that products of a brand that share major line characteristics (e.g. the car grill or line-silhouette of the lights of a BMW car or its overall silhouette) should be considered as more similar (i.e. stronger brand familiarity) than products that share similar colors, textures or other surface elements but have different line-structure. When companies introduce redesigned products, consumers are confronted with differences between the lines and surfaces of the old and redesigned product. These modifications are hypothesized to influence both the perception of product novelty and brand recognition in the following ways:

H1: Line modification has a strong (—) negative effect on brand recognition. Surface modification has a small (-) negative effect on brand recognition.

H2: Line modification has a strong (++) positive effect on novelty. Surface modification has a strong (+) positive effect on novelty.

To test our hypotheses, we redesigned the appearance of a Nokia phone. The 2-D stimuli were designed by a professional designer and differed on the degree of line and surface modifications. Stimuli were black and white sketches, no brand name was included. Our benchmark stimulus was a sketch of the most sold Nokia cell phone among our respondents. In study 1 (N=17), we assessed perceived line and surface changes to check our manipulations. Experts (Bachelor in design) compared 6 stimuli with the benchmark. Our stimuli indeed differed in line and surface modifications. Next to assess brand recognition, we asked the same respondents to indicate the brand of the stimuli and their degree of certainty on this. To test hypothesis 1, we correlated the perceived line and perceived surface modifications with brand recognition. Analyses showed a significant negative effect of both line (Pearson $R=.47$; $P<.001$) and surface changes (Pearson $R=.28$; $P<.01$) on brand recognition. Partial correlations showed that controlled for surface changes [line changes] the correlation remained significant (Pearson $R=.41$; $P<.001$) [correlation become insignificant (Pearson $R=.10$; $P=.32$)]. This confirms our hypothesis.

In a second study (N=17), we tested hypothesis 1 and 2. We asked respondents to compare our stimuli (differences in degree of line and surface change based on study 1) with our benchmark stimulus on newness and aesthetic evaluation. Results in this study for hypothesis 1 are comparable to those in study 1. Hypothesis 2 was tested with the use of partial correlations because of high correlation between surface and line change. Partial correlations showed that controlled for surface changes [line changes] the correlation was significant (Pearson $R=.26$; $P<.001$) [correlation was insignificant (Pearson $R=.10$; $P=.32$)]. This partly confirms our hypothesis 2.

As a next step we will make experiments with a bigger sample and with different products. In addition to that we will measure the interaction between line and surface changes on brand recognition and novelty as well as overall preference. The results will be presented at the conference.

The contribution of this research to consumer science is two fold: Firstly, it shows how different types of visual characteristics (line and surface) affect brand recognition, novelty and preference. Secondly, it provides an in-depth understanding of processes of product perception and should motivate further research into that direction. Whereas consumer information processing has mostly concentrated on the part of categorization and knowledge representation, this research focuses on the mostly overlooked part of (product) perception.

Heuristic and Systematic Information Processing when Valuating Multiple Gains and Losses

Dorothea Schaffner, New York University, USA
Andreas Herrmann, University of St.Gallen, Switzerland

Extended Abstract

This research attempts to enhance our understanding of people's preferences for separating or combining gains and losses. According to the normative decision theory of rational choice, people should demonstrate indifference towards the combination or separation of negative and positive events (Thaler, 1985). However, there are many examples and empirical studies demonstrating that preferences systematically violate normative decision theory (Kahneman & Tversky, 1979, 1984). E.g. winning \$90 all at once is not perceived as being equal to winning \$40 and \$50 separately. Inspired by Kahneman and Tversky's Prospect Theory (1979) a substantial body of literature has investigated the patterns of preference formation when judging consolidated versus segregated gains and losses. Thaler's hedonic editing rules are based on the value function of the prospect theory and predict a preference for consolidating multiple losses and integrating multiple gains; empirical research confirmed these predictions (Thaler, 1985). Later studies confirmed the preference for segregating gains but stated—contrary to theory—a preference for segregating losses also (Linville & Fischer, 1991; Thaler & Johnson, 1990). Explanations for these findings refer to the theory of renewable resources (Linville & Fischer, 1991) or to the quasi hedonic-editing hypothesis (Thaler & Johnson, 1990). However, this previous research focuses on the emotional impact of segregated versus integrated gains and losses and the role of motivational underpinnings of preference formation for multiple gains and losses remain unclear.

Based on the heuristic-systematic model (HSM) of human information processing (Chaiken, 1987) this research attempts to shed light on the underlying logic of judgment of multiple gains and losses. The HSM differentiates systematic from heuristic information processing. Whereas heuristic processing is characterized by a relatively effortless application of simple decision rules, systematic processing is marked by a more cognitively demanding comprehensive analysis of judgment-relevant information. Which mode of information processing predominates depends on the individual's current motivation (Chen, Shechter, & Chaiken, 1996). It is stated that accuracy motivation will enhance systematic processing (Chaiken & Maheswaran, 1994). Numerous studies have demonstrated the differential influence of the two modes of information processing (heuristic and systematic) on judgment and decision making: Hsee and

Rottenstreich's (Hsee & Rottenstreich, 2004) experiments demonstrate the influence of the two modes of information processing on valuation and subsequently on preferences for segregation and integration of gains and losses. Additionally, research by Agrawal and Maheswaran (Agrawal & Maheswaran, 2005) lends support to the assumption that accuracy motivation eliminates outcome-biased judgments.

Based on the previous research on dual process models and valuation we predict that accuracy motivation will foster systematic information processing and will therefore take a substantial impact on how segregated versus integrated gains and losses are perceived and valued. To test the predictions an experimental study was conducted. 160 undergraduate students completed the study for a payment of \$5. Participants were randomly assigned to one of four groups. They were primed either to be accuracy motivated or to value by feelings and assigned to either a gain or a loss scenario. They were presented both an integrated and a segregated scenario and indicated their preference for one of the scenarios.

In general, the current research establishes that accuracy motivation strongly influences or even reverses preferences when people value segregated versus integrated gains. However, the results obtained by this research raise interesting issues on how the type of event (gain versus loss) elicits different valuations of multiple events. We assume that loss aversion and specific emotions related to losses influence the way outcomes are valued. Therefore, further work is needed to scrutinize the effects of emotions in the context of the valuation of segregated versus integrated losses.

On the Importance of Non-dominant Cultural Dimensions: Effects of Vertical Individualism on Consumer Behaviour in Norway

Alexander Jakubanees, Norwegian School of Economics and Business Administration, Norway
Magne Supphellen, Norwegian School of Economics and Business Administration, Norway

Introduction

Countries and cultures are typically characterised in terms of some dominant cultural variables. For example, the US is described as a vertical individualistic country, whereas Japan is vertical and collectivistic (Triandis 1995). Scandinavian countries are typically found to score high on horizontal dimensions (Nelson and Shavitt 2002; Silveira and Seger 2004). In this paper we promote the point that non-dominant cultural dimensions may play a more important role in explaining culturally related consumer behaviors than dominant dimensions.

Individualism-collectivism (INDCOL)

The original typology was later expanded with a new dimension of vertical vs. horizontal INDCOL (Singelis et al. 1995; Triandis and Gelfand 1998). Vertical dimension of INDCOL captures the degree of status and inequality present in this orientation whereas horizontal dimension captures the degree of egalitarianism (Singelis et al. 1995; Triandis and Gelfand 1998). Intracultural variation in INDCOL is conceptualised as idiocentric vs. allocentric tendencies (Triandis et al. 1985).

Effects of vertical and horizontal INDCOL

Vertical individualist subjects preferred domestic products only when they were perceived as superior, whereas vertical collectivist subjects were found to prefer domestic products regardless of product superiority (Gurhan-Canli and Maheswaran 2000). When individuals with independent self-construal were presented with promotion focused appeals, i.e. emphasizing gains, hopes and aspirations, the messages were more persuasive than when they were presented with prevention focused appeals, i.e. emphasizing avoidance of losses, duties and obligations (Aaker and Lee 2001). The reverse was true for individuals with interdependent self-construals. There is also evidence that these effects may hold only for vertical cultures.

The Norwegian culture

The Norwegian culture has been characterized as horizontal rather than vertical (Nelson and Shavitt 2002; Silvera and Seger 2004). The literature points to the predominance of the horizontal value orientations in the Norwegian culture so the researchers tended to use these to explain consumer behavior. However as we argue further and as our data shows other non-dominant dimensions may account for important differences in consumer behavior.

Cultural Embeddedness of Products (CEP)

The concept of CEP is defined as the degree of the various types of national cultural meanings that are transferred from the culturally constituted world (McCracken 1986) to the product category by means of various cultural media (Jakubaneč and Supphellen 2004; Jakubaneč and Supphellen 2005). For instance a product category that has high degree of CEP can serve as a symbol of the national culture. Consumers can draw on the meanings embedded in the product category in order to build their private and social self-concepts as a certain national, promote their national identity and distinguish themselves from other nations (Jakubaneč and Supphellen 2004; Jakubaneč and Supphellen 2005). The dimensions of INDCOL are in turn likely to have effects on CEP due to the importance of INDCOL in the definition of self.

Hypotheses formulation

Intracultural variation becomes an important factor when non-dominant dimensions are likely to account for important consumer behavior. The case is illustrated by the Norwegian example. The horizontal dimensions of INDCOL do not focus on hierarchies or status, which are important in the concept of CEP. Consequently we do not expect these dominant cultural orientations to have effect on this consumer behavior variable. Vertical individualists are likely to engage in national identity construction in order to enhance their status, provided that having strong national identity has a positive connotation. Being a good citizen is valued in the Norwegian culture.

Based on this discussion we formulate the following hypothesis:

H1: Vertical individualism has a strong positive effect on CEP (Cultural Embeddedness of Products) even in countries where vertical individualism is a non-dominant dimension (e.g., Scandinavia).

Methodology

The hypothesis was tested on a non-student sample from Norway (N=158). Vertical-horizontal INDCOL construct was measured by a 16-item, 7-point Likert scale (Singelis et al. 1995). The survey included 8 product categories: ketchup, bunad (a Norwegian national costume), cars, meat cakes (a national meat dish), make-up, goat cheese, pizza, cross-country skis. The concept of CEP was measured by a 22-item, 7-point Likert Cultural Embeddedness of Products (CEP) scale (Jakubaneč and Supphellen 2004; Jakubaneč and Supphellen 2005). The CEP Scale items included such as: "If I traveled abroad, and was asked about a typical Norwegian product, I could mention this one", "When I was a child my family referred to this product as one of the symbols of our Norwegian identity", "If other Norwegian were to see me using this product, he or she would perceive me as a typical Norwegian".

Results

Consistent with earlier studies, horizontal collectivism is the most dominant dimension in the Norwegian culture followed by vertical collectivism. Norwegians are also high on horizontal individualism and as expected rather low on vertical individualism.

EFA of CEP Scale resulted in the three-dimensional structure (Tradition, Identity-building and Relationship CEP) for the eight product categories. The data was subjected to path analysis via LISREL (Jøreskog and Sörbom 1993). Some of the LISREL model fit indices were: for ketchup- $\chi^2/df=2.895$, GFI=.981, CFI=.974, RMSEA=.110; for pizza- $\chi^2/df=2.122$, GFI=.983, CFI=.979, RMSEA=.085. The results strongly support H1. Vertical individualism has strong effects on the Tradition CEP (e.g. .359*** for meat cakes, .239*** for cars; ***= $p < .01$), Identity-building CEP (e.g. .510*** for meat cakes, .335*** for ketchup) for most product categories, whereas very few effects are observed for the other INDCOL dimensions.

Discussion

The most dominant cultural orientation of the Norwegian society-horizontal collectivism has little explanatory power when it comes to perception and construction of the national identity. The same conclusion applies to the other dominant dimension-horizontal individualism. Instead the dimension of vertical individualism, existence of which previously was ignored in the studies of the Norwegian culture, provides consistent explanations in this behavior cluster across the product categories. It could be the case that in the Norwegian culture, the national cultural meanings could serve status-enhancing purpose of being a good citizen which is important to vertical individualists.

Implications

We find support for importance of recognising and measuring allocentric and idiocentric tendencies when conducting cross-cultural consumer behavior studies. Reliance on nation-level studies and ignorance of the intracultural variation may weaken research validity.

Flip-Flopping of General Action and Inaction States: A Study on the Mental Representation of Action and Inaction Goals

Kathleen C. McCulloch, University of Florida, USA
 Kenji Knoguchi, University of Florida, USA
 Dolores Albarracín, University of Florida, USA

Extended Abstract

Being active or inactive is essential to human life. People, cultures, and eras appear to vary in requisite levels of energy and productivity. Thus, we examined the possibility that general tendencies to engage in or abstain from behavior irrespective of the domain (e.g., buying, using drugs, exercising) can be due to the setting of general action and inaction goals. We have investigated *general action goals* that reside at the meta-level of goal systems (for goal-facilitation of specific behaviors, see Ajzen & Fishbein, 1980; Chartrand & Bargh, 1996; for the concept of general action and inaction goals, see Albarracín, in press). Action goals are generalized goals to engage in action (e.g., activated with instructions such as "go"). The counterpart to these action goals are *general inaction goals*, which are generalized goals to not engage in action (e.g., activated with instructions such as "rest"). Importantly, general action/inaction goals are diffuse desired ends that can mobilize the execution of more specific activities. Hence, their activation may trigger the pursuit or interruption of *any* particular (overt or covert) behavior that is subjectively relevant to the goal. Action goals imply a need to "do" irrespective of what one does; inaction goals imply a need to abstain from doing, irrespective of the domain of abstinence.

Research by Albarracín and her colleagues (see Albarracín, in press) have shown that people with general action goals preferred action-oriented tasks, identified more behaviors, performed better on a text comprehension task, and formed attitudes on a novel topic more than people with inaction goals. Given these differences in performance across these domains, we wanted to further explore these goals at the level of mental representations. In this study, we explored the activation of the action/inaction goals via a priming task with icons related to action and inaction and in turn, identified the conditions that led to the satisfaction of those goals. Our basic hypothesis is that the action goal is "turned off" via satisfaction of that goal and as a result, the inaction goal is "turned on." Thus, the purposes of this study were 1) to identify if general action and inaction goals are mentally represented and 2) to examine the "on and off" manner of action and inaction goals.

In the first part of study, half of the participants were exposed to the action primes while the rest were exposed to the inaction primes. To prime action goals, black and white icons concerning specific actions (e.g., running, throwing, and dancing) were employed. To prime inaction goals, black and white icons concerning specific inactions (e.g., lying down, meditating, and relaxing) were used. Participants in the action prime condition were exposed to 10 pictures related to actions and 14 pictures neutral to action. Those in the inaction prime condition were exposed to 10 pictures related to inaction and 14 pictures neutral to inaction. The participants' task was to identify whether the black part of a picture was larger than the white part.

After the priming task, all participants were given a lexical decision task (LDT) to measure the activation level of action-related and inaction-related concepts. The LDT contained 10 action-related words (e.g., go, move, and create), 10 inaction-related words (e.g., relax, stop, and halt), 20 words neutral to action/inaction matched with inaction/action words on word length and frequency, and 20 other neutral words. The task had 10 blocks and each block contained 12 words. The blocks were divided into first and last five blocks to examine if the participants changed their action/inaction goal states.

Following the LDT, the participants were given an opportunity to either choose to work on questions from GRE (graduate record examination) or to rest. The choice made by participants served as our measure of the "on-off" nature of these goals. For instance, participants who are primed with action and then perform the LDT should "flip" to an inactive state and choose to rest.

First, it was hypothesized that action/inaction priming should lead to activation of associated concepts. Results showed differences in activation, such that the participants primed with action goal icons identified action-related words more quickly than the participants primed with inaction goal icons in the first five blocks of the LDT. However, in the last five blocks there was no significant difference between these two goal conditions on reaction times for action-related words. These results suggest that after performing half of the LDT, participants primed with action might have satisfied this goal by performing the LDT.

Second, it was hypothesized that participants in the action goal condition should flip to an inaction state following the LDT. Results showed that participants primed with an action goal were more likely to choose to rest than perform the GRE, and were more likely to do so than those primed with inaction. In sum, the results verified that these general goals can be activated, and suggest the “on and off” nature of these goals.

The study of these general goals may yield many practical applications in tandem with theoretical advances in goal theory and self-regulatory processes. For instance, action goals may exert effects inadvertently by being included in the title of an intervention such as “Youth in Action Against Drugs” (Lowell Housing Authority, 2005; the emphasis is ours). The richer effect here is that not only might people be primed for action, but that people with action goals are more likely in some instances to be persuaded as well. Albarracín and her colleagues (see Albarracín, in press) have shown that people are more likely to employ external information when they do not have prior attitudes about the topic, hence, are more apt to be persuaded. However, once the primed action goal is satisfied, then perhaps the window for persuasion is closed.

How Do Consumers Categorize Websites?

Anjala Krishen, Virginia Tech, USA
 Kent Nakamoto, Virginia Tech, USA
 Pushkin Kachroo, Virginia Tech, USA

Background

Similarity judgments have been used in many fields of research to serve as a cognitive categorization mechanism. This research presents the results of the perceptual mapping of stagnant (or mouse-free) images of multiple websites from the consumer perspective. The goal of our research is not from a decision making perspective, but more from a consumer perception framework. We aim to disentangle the internet into multiple separable pieces or frames, gather information from consumers on those frames, and then elaborate on ways in which they are categorized and conceptualized.

One of the key foundations of this pilot research effort is the de-activation of an otherwise interactive medium. Our effort was to gain insight as to how consumers may initially view websites—as images rather than “clickable” interfaces. We contend, then, that at first glance, a user categorizes websites according to some set of attributes. Those attributes, if further understood, can help guide our understanding of deployment of “effective” websites, from a consumer-centric viewpoint. Although the foundations of cognitive categorization are principally psychological, many other fields have employed them through use of mathematical techniques. Broken down at the lowest level, we see or discuss “things”, which then, in order to control for chaos and cognitive boundaries we have, we must categorize. (Smith and Medlin, 1981)

The fields of human factors, information systems, and marketing have also focused on the interesting implications of the internet as an interactive medium. Marketing research often studies the internet as an advertising medium and sees similarities with other forms such as television, where we have visual cues to stimulate action on the part of the consumer. Yet, we make note of something entirely unique in internet environments—the ability to have constant interaction with our consumer. (Hoffman and Novak, 1996) Consumer choice and decision making thus drives much of the literature on how a consumer can interact with the internet. (Peterson et al, 1997; Mandel and Johnson, 2002)

Hence, the contribution of this initial study is to break down and attempt to ascertain “first impressions” of consumers by using static as opposed to dynamic images. We posit that clickstream data, by focusing on either one consumer or one website, and presenting the internet in its full interactive complexity, may not be able to capture those initial categorizations which consumers make.

Experiment

Sixty-seven marketing undergraduates participated in this within subject study by completing a two part survey. Due to the subject matter of this study, namely internet websites, and the experience level of the participants, we considered this a homogeneous data set. Given a total of ten websites, part 1 of the study design called for a set of forty-five paired similarity/dissimilarity judgments. Two context areas, cameras and tourism, were selected, within which we selected five websites each. Our conjecture is that the participants in our study

had approximately equal exposure to these two context areas and thus would not show significant experience or gender bias. The ratings were given from 0 to 10 with 10 being the most similar and 0 being the most dissimilar. Since ALSCAL and INDSCAL algorithms expect dissimilarity measures, the results were converted into dissimilarity measures before being entered into a matrix. (Kruskal, 1984; Schiffman, Reynolds and Young, 1981).

Results

The three steps completed during the analysis phase of our study, namely ALSCAL, INDSCAL, and preference mapping, allowed us to determine four possible attributes which could explain the dimensionality of our stimulus configuration. In order to visually examine the resultant vectors, we plotted these four attributes. Studying this plot indicated that uniqueness and trustworthiness showed the closest match to two possible representative dimensions for our model. Interestingly, we could see domain clustering of the websites on two different sides of the uniqueness vector, i.e. the “C” websites on one side and the “T” websites on the other. The concept of uniqueness as a representation of this dimension, therefore, is intuitive. The remaining three vectors, classifying the website images as trustworthy, personalized, or educational, were all considered as possible attributes for the second dimension. We chose trustworthiness as the second dimension mainly based on its geographic representation.

There are several possible interesting implications when thinking of these two attributes as our dimensions. One of the interesting facets of the attributes we chose is their interpretation if viewed in terms of temporal significance, or what we are terming *dynamism*. Essentially, we are asking the question, “Does the consumer have to interact with the website in order to make this determination?”

Conclusions

The most interesting finding of this study centers on the relevance of several “non-dynamic” attributes as salient. This, given that we are making the web a static interface for the study, is a significant result. One may ask the question of whether or not it is effective to freeze a website and assess a consumer’s perception of it—or cognitive categorization of it. Our reasoning behind this study centers on what we see as a very important facet of the internet as an advertising medium. The fact that consumers constantly assess corporations using not only their websites, but the entire picture the consumer creates of that corporation. This assessment may consist of experience gleaned from other advertising media (television, magazines, newspapers, store presences, to name a few) as well as interaction with the website itself. But where does the consumer classify the website he/she interacts with? What motivates the consumer to interact with one website over another? These are questions we believe are at the foundation of the need to be able to classify key attributes consumers identify at an initial, static, level.

The quantitative analysis in this paper resulted in the finding of four salient attributes for mouse-free website impressions—uniqueness, educational value, personalization, and trustworthiness. The implications of this study are that we truly can freeze this otherwise interactive medium, allow consumers to categorize the images, and possibly use this information to help design the navigational aspects of a website.

The Use of Images of Dead Celebrities in Advertising—History, Growth Factors, Theory, Legality, Ethics and Recommendations

Denver D’Rozario, Howard University, USA

Ross D. Petty, Babson College, USA

Leah C. Taylor, Howard University, USA

Frank K. Bryant, Howard University, USA

Extended Abstract

A practice that has increased in frequency and scope in the advertising and merchandise licensing industries is that of the use of the images of dead celebrities. According to some in the advertising industry, this interest in dead celebrities is part of a larger trend that is currently taking place in America, namely an increasing interest by an aging baby-boom generation in imagery and experiences from yesteryear (Rodkin 1989).

One indication of the importance and significance of this practice is the annual exercise that *Forbes* magazines started in 2001, of compiling information on and ranking the “top earning dead celebrities” in America (see DiCarlo (2003), DiCarlo and Patsuris (2004), Fong and Lau (2001) and Kafka (2005) and Schiffman (2002)).

In this paper, we examine this practice, its history, growth, causes, dynamics, legality and ethics in detail.

First, we take the reader through a brief, but comprehensive survey of the most significant developments that have taken place in this area of the advertising (and the related law) industry, beginning in the mid-1800s and extending up to the present time. detailed time-line. We include a detailed time-line, to help the reader keep track of these developments and their sequence.

Next, we analyze some of the major demand-side and supply-side factors that have caused this practice to become so significant, especially lately. Some examples of these demand-side factors include the demographic ‘bulge’ moving through the American population, loosely referred to as the ‘baby-boom’ generation and their increasing (as they grow older) yearning for imagery and experiences from yesteryear (Rodkin 1989), which we refer to as ‘nostalgia’ in this paper.

Some examples of these supply-side factors include the increasing consolidation and shakeout that is taking place in the Archival (Digital) Image Acquisition, Storage and Licensing industry, as exemplified by the rise of Corbis, owned by Bill Gates (CNN 2006) and the challenge it is beginning to pose for the older, more established giant in the industry, namely Getty Images.

Following this, we look at two streams of literature to: (a) see how similar the practice we are interested in (i.e., consumer interest in dead celebrity images) is to the related practice, namely consumer interest in live celebrity images, and, (b) to see how different the

practice we are interested in (i.e., consumer interest in dead celebrity images) is different from the related practice, namely consumer interest in live celebrity images.

Nostalgia theory (e.g., Holbrook and Schindler 1994, 1996) is the first stream of literature we look at, because: (a) nostalgia is one of the most important factors driving demand for images of dead celebrities, and, (b) we wish to see if there are any new insights which this dead celebrity image preference trend can add to the extant base of theory on how Nostalgia drives consumption behavior.

A second stream of literature we look at is that pertaining to the use of celebrities (dead or alive) in advertisements (e.g., Kamins 1990). This stream of literature is important to look at because many of the principles/generalizations that dictate the use of live celebrities in advertising may not be substantially different from those that govern the use of dead celebrities as well. However, it must also be said that we are equally interested in seeking out those principles/generalizations/issues that: (a) must be different when the celebrity is dead (e.g., rights of heirs/estates), and (b) could be different (e.g., working with a static/time-frozen image versus a dynamic image).

Following this, we look briefly at some of the major legal issues in the area of dead celebrities' image rights. Because the state of the law vis-a-vis the rights of those who claim ownership of the images of dead celebrities' images is 'not as developed' in America as it is in other countries (e.g., France) we do the next logical thing: we examine some of the major ethical issues (i.e., harms and benefits) that surround the usage of images of dead celebrities. This is because in the absence of clearly-defined law (especially at the Federal level), the responsible user of these images must let their sense of ethics (i.e., who is harmed and who is benefitted) to guide how they use these images.

Finally, we conclude, by offering the reader a set of recommendations, for deciding when it is most appropriate, effective &/or efficient for using a dead celebrity's image in advertising and when it is not.

In conclusion, in this paper, we are interested in the issue of how and why images of dead celebrities are being increasingly used in Advertising (and Merchandise licensing), with a particularly close examination of: (a) the confluence of events (i.e., the history) that made this practice possible, (b) the factors (both demand- and supply-side) that are driving this trend, (c) two major streams of literature that could explain why this practice works and is growing, (d) the legal issues that are intertwined with this type (i.e., dead) of image-usage, (e) a set of ethical issues that must be noted, for those who are concerned with responsibly using these images, and (f) a set of recommendations, for those who are concerned with using these images effectively.

Coping with Mixed Emotions

Colleen C. Bee, University of San Diego, USA

Robert Madrigal, University of Oregon, USA

EXTENDED ABSTRACT

Consumer purchase decisions, particularly those that are important or highly involving, can be very stressful. The current research considers the effect of corporate social responsibility information on the dynamic relationship between consumer emotional responses and subsequent coping strategies in a purchase decision context. Discrete and mixed emotional responses are assessed and open ended responses are evaluated for the specific coping processes that consumers use when presented with either positive, negative, or conflicting information (i.e. both positive and negative information) about a company they are either considering a product purchase from or have already made a product purchase.

Theoretical Background

Coping occurs when a situation is sufficiently important to consumers and when they perceive a potential threat to their goals. This situation is often characterized by negative emotions, which have been the focus of the majority of coping research. Recently, however Folkman and Moskowitz (2000) considered positive affect in the presence of negative affect in the coping process. The relationship between emotions and coping is complex and people are likely to experience multiple and conflicting emotions (Folkman and Lazarus 1988). Our research focuses on coping in the context of positive, negative, and conflicting mixed emotional states.

Three coping strategies are emphasized in this research: problem-focused coping, emotion-focused coping, and social support coping (Folkman and Lazarus 1988; Folkman and Moskowitz 2004; Duhachek and Iacobucci 2005). Problem-focused coping relates to ways the consumer can solve or manage the problem or change the conditions surrounding the stressful situation. Two specific examples of problem-focused coping include confrontive coping or planful problem solving. In confrontive coping, consumers stand their ground, try to get the company to change or express displeasure at the company, whereas with planful problem solving, consumers make a plan of action or make an effort or come up with solutions.

In emotion-focused coping, consumers attempt to change their understanding or the meaning of the perceived source of stress. There are four different areas of emotion-focused coping: distancing (e.g., acting as if nothing is wrong), self-control (e.g., keeping things to oneself), accepting responsibility (e.g., realized brought the problem on by oneself), and positive reappraisal (e.g., seeing the situation differently).

Social support coping is a form of coping where consumers seek either instrumental support, such as talking to someone who can do something about the problem or emotional support by accepting understanding from a friend (Folkman and Moskowitz 2004). This type of coping was identified by Duhachek and Iacobucci (2005) as important in consumer research because of its similarity to word-of-mouth behavior.

Method

Participants were undergraduate students enrolled in business administration classes. The information was presented via a series of internet websites and emotional responses and comments were collected with a web based survey. Participants were asked to read corporate social responsibility information about a fictitious company. The corporate social responsibility information was presented as if it were from an objective third party, The Calvert Group. This information was used to present positive information (e.g. the company was environmentally friendly, produced high quality and safe products, etc.), negative information (e.g. the company was not environmentally friendly, produce low quality and unsafe products, etc.), or mixed (e.g. the company was environmental friendly but produced low quality and unsafe products, etc.). Participants were either asked to imagine they were about to make a purchase from this company or they were told they had just made a purchase from this company. Their emotional response toward the purchase situation was assessed, and in an open-ended response format they were asked what thoughts and feelings they had, what decision they would make, and what they would do in this situation.

Results

As expected, respondents receiving positive information experienced significantly more positive emotion ($M=5.24$) than either the negative or the mixed conditions ($M=2.59$; $t(161)=10.79$, $p<.01$). Additionally, the negative condition was rated as being significantly more negative ($M=4.98$) than either the positive or mixed conditions ($M=2.66$; $t(161)=10.68$, $p<.01$). Finally, participants exposed to conflicting information experienced significantly higher levels of subjective emotional ambivalence ($M=3.59$) compared to participants in either the positive or negative conditions ($M=2.54$; $t(161)=4.68$, $p<.01$).

Based on the content analysis of three independent coders, consumers exposed to positive information did not seem to actively engage in coping strategies. However, consumers exposed to negative information engaged in problem-focused coping, both confrontive and planful problem solving, as well as social support coping. Those exposed to conflicting information seemed to engage in emotion-focused coping.

For participants exposed to negative information, specific examples of confrontive coping included statements about their displeasure with the company's behavior, switching companies, and writing letters to the local paper about the company's substandard levels or writing letters to the company or CEO to inform them of their displeasure. Planful problem solving strategies included plans to return the product, look for alternatives, or buy from another company. Following a purchase decision, respondents were still upset about their situation and engaged in similar coping strategies, however it seemed they were less likely to engage in complaining behavior and seemed more likely to keep the product.

Instances of social support coping were also found with the negative information. Participants stated intentions to engage in negative word of mouth or complaining behavior, stating they would talk to friends and family to tell them to about this company's negative business practices and to avoid this company and any of their products.

Consumers presented with conflicting information engaged in emotion-focused coping, mostly distancing and positive reappraisal. Some respondents were found to use social support coping. Prior to purchase, participants tried to see the company in a positive light, wanted the company to be good, and thought they weren't doing anything wrong by thinking about this purchase. Following a decision, participants tried to justify or rationalize their decision and continued to reappraise the situation.

These findings are consistent with research in the area of coping and emotions. Negative emotions have been found to be negatively related to some emotion-focused coping (reappraisal) and positively related to some forms of problem-focused coping (Folkman and Lazarus 1988). Coping responses related to conflicting mixed emotions have not been assessed in previous research but it is understandable that consumers would try to reappraise the purchase situation, especially after having already made a purchase decision. Future research should further examine the relationship between emotions and consumer coping responses.

Website Image Transfer: Perception of Uninformative Online Ads

Xiaojing Yang, University of Wisconsin, Milwaukee, USA

Jihui Chen, University of North Dakota, USA

Extended Abstract

This paper examines the role of context effects in online advertising, aiming to provide marketers with appropriate strategies to promote products in the new media. In the traditional media, effective ads typically provide vivid and specific information. An online ad is considered effective if it arouses curiosity and induces consumers to click through it. Thus, unlike traditional advertising, online ads often contain low level of information, due to high interactivity of the new media (Sicilia, Ruiz, and Munuera, 2005). Such ads may omit two types of information, product category related and personality related (Aaker, 1997).

Studies in social psychology have found that human judgment is highly context-dependent. Ad context can influence consumers' perception and evaluation of ads, and thus ad effectiveness (e.g. Singh and Churchill, 1987). In the present paper, we address one important emerging context on consumers' judgment due to the development of Internet–website image. From an associative memory net viewpoint, we define *website image* as “consumers' perception of a website as reflected by the associations related to the website (including sub-sites) held in memory.”

We study website image from two dimensions: function and personality. Function of a website refers to the types of products and services it provides, which is reflected in the context and design of the website. Following the literature, we use brand image of a website to define its personality.

In this paper, we propose that function and personality of a website will impact consumers' perception of and attitude towards online ads through an image-transfer process. Site image transfer is defined as “consumers use their perceived site image to infer product-category related- and brand-personality related-information in uninformative online ads.”

The first set of hypotheses is concerned with the contingency under which such image transfer occurs. Website function is more likely to influence consumers' perception of the product category of a brand, while website personality is more likely to influence their perception of brand personality in ambiguous online ads than in unambiguous ones.

The second set of hypotheses is related to the psychological process of website image transfer. We propose that consumers can “restore” or “interpret” the two types of omissions in online ads through either a systematic or heuristic way, depending on the level of cognitive resources.

The third set of hypotheses deals with specific context (website image) of an online ad. With a high (low) level of cognitive resources, consumers systematically (heuristically) interpret or “restore” the missing product category related-information in an ambiguous online ad. In contrast, when cognitive resources are highly available, personality-based image transfer is less likely to occur (Martin, 1991; Meyers-Levy and Tybout, 1997), while consumers engage in personality-based image, with a low level of cognitive resources at the time of ad exposure.

The last hypothesis indicates the consequences of site image transfer. Depending on the relevance between the actual and perceived (through a process of site image transfer) information, consumers' attitude-toward-website may vary. The higher is the relevance, the more favorable is consumers' attitude-toward-website, and vice versa.

An Influential Minority: Reaching the New Values-Based Consumers

Jenny Mish, University of Utah
Melea Press, Penn State University

Introduction

According to Morris Holbrook (1996), consumer *value* refers to the experience of a relativistic consumption preference, while consumer *values* are “the standards or criteria on which the former depends.” Beyond this clarification, the exact definition of *values* remains fuzzy throughout the social sciences (see Rohan, 2000 and Hitlin & Piliavin, 2004). For the purposes of this paper, *values* will be defined as “desirable transsituational goals, varying in importance, that serve as guiding principles” (Schwartz, 1994, p. 21).

As guiding principles, values operate in all consumption contexts. Yet the plurality of consumer values is not well understood. Much consumer behavior theory has assumed that “mainstream” American values are the ones that matter most. If we are concerned with trends, history would suggest that the “mainstream” is not the place to look. Significant social change begins not at the center but at the margins. There are many indications that a values-based social trend has been emerging in recent years, not from the center but from what was an initially a marginal edge. Evidence of this can be seen in the social responsibility clauses of corporate mission statements, the appearance of organic and fair trade food sections in “mainstream” stores, and consumer demand for hybrid cars.

One Quarter of American Consumers

To understand this trend, sociologists Paul Ray and Sherry Anderson analyzed the role of “transformational values” in American life (Ray & Anderson, 2000). Over thirteen years, they gathered more than 100,000 survey responses and conducted hundreds of focus groups. Ray and Anderson's 70+-item scale assessed consumer views related to gender, success, spirituality, altruism, optimism, financial solvency, corporate power, cultural diversity, violence, political polarization, environmental destruction, and global interconnectedness. This combination of values is not normally captured by national values surveys.

Ray and Anderson found that over 50 million adults in the United States (about one-quarter of American consumers), and approximately 80-90 million in Europe, hold values that are markedly different from the mainstream in the measured dimensions. These values drive consumption decisions for this mostly middle-class group. They have money to spend (\$228.9 billion per year, according to www.lohas.com/about.htm), but their spending is not typical of mainstream American consumers.

Ray and Anderson see these consumers as catalysts of cultural change, and thus call them “cultural creatives.” They are difficult to reach through typical media and publicity channels because they hold worldviews that are in opposition to most national media and are not covered by, or targeted by, mainstream media (Ray and Anderson, 2000).

Research Questions and Methodology

Interviews conducted during the initial phase of this study suggest that these new values-based consumers watch little to no television, read multiple independently published news sources, and get most of their news online. However, it is not clear what forms of marketing they consider valuable. Specifically,

1. What are the media habits of “cultural creatives”?
2. How do they understand the role of their values in their media habits?
3. What challenges would they expect marketers to have in reaching them?
4. What forms of marketing are consistent with their values?

The second phase of this study involves structured interviews with ten “cultural creatives.” Potential informants are being approached outside stores where organic foods are sold, and screened using Ray’s criteria. Demographic diversity is being sought for a theoretical purposive sample with maximum variation. Each interview begins with a written media habits questionnaire, addressing each media type, including new forms such as podcasting and online communities. Each of the four research questions guides a section of the interview, following McCracken (1988). In the final section, informants are asked to imagine a marketing environment consistent with their values and needs as consumers. They are then asked to compare this projected scenario with marketing resources currently available. Analysis is concurrent with data collection.

Preliminary Findings

Completed interviews confirm that these individuals consume media very selectively and that they are skeptical of mainstream media for values-based reasons. The most salient values informing their media consumption decisions relate to the importance they attach to truthfulness, spiritual purity, education, and connections with people around the world. These informants interpret financial incentives and corporate ownership as an inevitable loss of objectivity and credibility in media content. They want uncompromised honesty in reporting, and they believe that while marketers are not usually deliberately or overtly deceptive, accuracy is reduced because “there are motives that are not for the bigger picture.” These interviewees envision ideal media environments in which they can access accurate information easily via light or sound, without being “bombarded,” which is their experience of the current media environment.

Each of these informants spontaneously talked about personal transitions from former mainstream media consumption habits to more selective media habits. These transitions occurred 5-15 years prior to the interviews, and involved discoveries of specific information about media ownership and psychological impacts of mass media. These informants applied their values to this new information to arrive at new meanings of the role of media in their lives and in the world, catalyzing more selective search behaviors. This suggests a developmental process of personal evaluation of media use driven by the application of personal values to new information received about the media and its impacts. Parallel developmental processes may operate in other contexts where consumers apply personal values to new information received.

Look Who’s Talking! Technology-Supported Impression Formation in Virtual Communities

Claire Dambrin, HEC School of Management, Paris
Kristine de Valck, HEC School of Management, Paris

EXTENDED ABSTRACT

The growing availability of consumer-generated information on the Internet about products, services, and companies has increased market transparency. Power is shifting from producers to consumers who share their knowledge, experiences, and opinions via virtual communities, electronic discussion forums, online opinion platforms, chat rooms, and weblogs. However, this abundance of readily available information also comes at a cost. How do you distinguish an expert from a fraud? Who is credible and trustworthy, and who isn’t? We form impressions of others based on cues such as age, gender, manner of dress and speech (e.g., Hamilton & Huffman 1971). But how do we construct and evaluate impressions in an online environment that lacks social cues normally present in face-to-face settings?

Cyberspace is in many ways distinctly different from the physical world. Two characteristics stand out. Firstly, interaction takes place through a technological interface, i.e., a computer, mobile phone, or an interactive television with Internet access. This means that the primary relationship is not between the sender and the receiver of information, but rather with the technology-mediated environment (Hoffman & Novak 1996). The second defining characteristic of cyberspace is its textuality. Communication and interaction online is based on the written word, audio, images, icons, and hyperlinks to other Web sites. This allows for new ways of self-presentation in which the physical self does not necessarily have to coincide with the digital self (Schau & Gilly 2003).

Schau and Gilly (2003) have demonstrated that consumers make active use of signs, symbols, material objects, and places to construct a digital self on their personal Web site. In this paper, we want to extend their research into online self-presentational strategies by looking more closely at the receivers’ side. The objective of our research is to investigate how consumers form impressions of senders in the context

of word-of-web recommendations within virtual consumer communities (Kozinets 2002). Specifically, we focus on the role of the technological interface. According to Foucault (1977), technology can be considered as a disciplinary mechanism that is embedded in power devices. Examining how technologies are used to form and manage digital impressions, may help us to understand how individuals influence each other online. Gaining systematic insight in this process is necessary for improving and developing tools that aim to aid consumers in their assessment of online contributions (e.g., reputation systems, member profiles, contribution accounts).

Method

The virtual community that serves as our focal research site is broadly organized around health issues. Its topics of interest include health, medication, pregnancy, nutrition, beauty, psychology, and sexuality. The community has been developed by a French independent company that exploits it by means of advertising. The community generates a total of 60,000 new postings per day (posted by French-speaking users worldwide) in its many discussion forums, chat rooms, and weblogs.

Our exploratory inquiry consisted of 3 semi-structured interviews; with the CEO, a moderator, and a back office technician. These interviews have given us insight in how the technological interface is constructed, managed, and used to exert control over member profiles and contributions by the administrators. Furthermore, we have conducted two online focus groups and follow-ups with animators (total of 18 informants). Animators are members selected by the administrators to serve as volunteer moderators. They play an important role in the day-to-day problem detecting and solving related to member behavior. Their extensive knowledge of community dynamics due to their double role as members and moderators has proven a valuable source of information. Combined with detailed observations and content analyses of the virtual community under study, this first round of data collection has given us a deep understanding of the process of technology-supported impression formation in virtual communities.

Next, we will systematically examine technology-supported impression formation in the context of word-of-web recommendations. Which signals are consulted and how are they interpreted? Does the impression formation strategy differ between member types (e.g., long-time versus short-time members, posters versus lurkers). Does it differ with the decision process at stake? We intend to collect data by means of an online survey among the members of the community under study.

Preliminary findings

Based on our first round of data collection, we can draw some preliminary conclusions of the interplay between technology and impression formation.

Technology *uniforms* impression formation. All members have the same tools at their disposal that serve as common references to form impressions on others; e.g., username, avatar, signature, personal web page with photo's and hyperlinks, administrator-controlled member type label, orthography, emoticons.

Technology *speeds up* impression formation and makes it *more reliable*. Members have continuous and exhaustive access to all contributions of any member. Members' past on the community is transparent.

Impression formation technology are *self-nurturing*. Members share tips to master the technology and they develop new tools, e.g., introducing group labels aimed at impression management.

Technology *destabilizes* impression formation. Technology enables members to have multiple identities, while it simultaneously serves as an identifier by means of, for example, orthographic style or IP address. Members who build multiple identities that are too different risk to loose their reputation. Similarly, if technology shows that formed impressions do not correspond with reality, for example by exposing markers of true identity, the backlash may be severe and technology is used as a release tool to express extreme 'corrected' impressions.

It is clear that the administrators play an important role in the *dynamics* of the impression formation process. They interfere by creating status, e.g., by introducing member type labels based on the number of contributions (regular, loyal, bronze, silver, and gold member), and by appointing members to be forum animators. Understanding the differential effects of the various technologies (member-controlled, administrator-controlled, administrator-bounded) on impression formation will aid both managers and consumers in optimizing the power of virtual communities as credible, trustworthy, and expert information sources. Our final aim is to contribute to this goal.

When A Good Impression Goes Bad: The Effect of Goal Changes on Repeated Attitudes Enquires

Xiuping Li, University of Toronto, Canada

Extended Abstract

Past consumer research has shown consumption goals impact product information processing, weighting and retrieving, which results in variances in the reported attitudes (Huffman and Houston 1993; Markman and Brendle 2000). However, the extant research has only examined how goals impact an initial attitude (Garbarino and Johnson 2001; Huffman and Houston 1993). In reality, a consumer's goal can change from time to time. It remains unclear whether attitudes formed under different consumption goals impact each other. For instance, when consumptions goals change, will the prior goal-driven evaluation influence the later evaluation? If yes, why and in which direction (i.e., assimilating or contrasting)?

We answered the above two questions by relying on Selective Accessibility Model (SAM, Mussweiler 2003) proposed in social judgment literature. The model suggests that whether the evaluation target is judged as similar or dissimilar to the comparison standard will decide whether the contrast or assimilation effect will be resulted. If the target is judged as similar, the assimilation effect will be observed, but if the target is judged as dissimilar to the comparison standard, the contrasting effect will happen. Based on SAM, we argue that an initial positive (bad) attitude formed under a certain consumption goal can be used as a comparison standard, makes the later evaluation of the same object under a conflicting goal worse (better) off.

The current paper suggests that consumers use the relationship between consumption goals as a way to judge similarity or dissimilarity between the current and prior evaluations, (not only judging the applicability of the stored attitudes as suggested in extant attitude literature). Such judgment can be made quite quickly and colors the new evaluating process. In particular, we predict when two conflicting consumption goals activated at different times, attitudes reported under the later consumption goal would be judged as dissimilar to the initial attitudes formed under the earlier consumption goal, resulting in contrast effect. Our prediction was supported with two lab experiments.

Experiment 1 was a 2 (Consumption goal: Best driving experiment vs. economy to drive) by 2 (Timing of the attitude: First time Initial attitude vs. Second time later Attitude) mixed-design experiment. All participants were asked to learn the information of a luxury car (faked brand) and reported their attitudes towards under one consumption goal (i.e., initial attitude), and after a 10-min filler task, they were asked to read information again, and reported their attitude under a different consumption goal (i.e., later attitude). We found that when evaluation was made under economy goal, the later attitude was poorer than the initial attitude; but when evaluation was made under performance goal, the later attitude was better than the initial attitude. A clear pattern of contrast effect between evaluations under conflicting consumption goals were demonstrated in Experiment 1.

In Experiment 2, we demonstrated that the contrast effect was more robust when the cognitive resource was limited. In this one factor (cognitive load: high-rehearsing 7 digits vs. low-rehearsing 2 digits) design experiment, all participants first reported their initial attitudes under performance goal (the same car information as in Experiment 1 was used), and after a filler task were asked to reported their attitudes under economy goal (i.e., later attitude). Cognitive load was manipulated before the second time evaluation. Results revealed that though the initial attitudes reported under performance goal remained same, compared to participants under low cognitive load, those under high cognitive load evaluated the car less positively under economy goal. Our results in experiment 2 suggested that the comparison to the initial attitudes happened as a default, which was consistent with SAM.

Taken together, the current research suggests that when contextual cues (in this research, consumption goals) are salient, consumers can depend on the relationship between those cues to come up with an initial judgment and adjust from there. More specifically, when contextual cues are in conflict, the prior evaluation can serve a comparison standard rather than an anchoring point, resulting in a contrast effect that impacts attitudes reported later.

Understanding Consumers' Perceptions of Fashion

Jingyun Zhang, Bowling Green State University, USA

Ayşe Banu Elmadag, University of Alabama, USA

Extended Abstract

Despite the prevalence of fashion in the consumer market, previous research on fashion has primarily focused on the characteristics, motivations and behaviors of fashion innovators/leaders (e.g., Cassill and Drake, 1987; Goldsmith Flynn and More, 1996; Goldsmith, Moore and Beaudoin, 1999). Therefore little is known about the meanings of fashion to the broader range of consumers and their perceptions of fashion. This research attempts to fill this void.

The major objectives of this article are twofold. First, we aim to provide a conceptual foundation for understanding consumers' perceptions of fashion. Second, as one of the first attempts in the literature, we develop and assess the validity of the consumer fashion orientation (CFO) scale that measures the different orientations toward fashion across consumers.

Based on a review of the literature as well as qualitative research inquiries (20 interviews), we identified three fashion orientations/focuses adopted by consumers toward fashion.

Brand focus: More than any other consumer brands, the fashion brand sustains itself on the image of the brand rather than aspects inherent to the product (Auty and Elliott 1998). It appears that many consumers use fashion as a way to communicate their status. In this regard, fashion serves as a symbol or sign. Moore (1995) stressed the positive association with brand, quality and status if the fashion brand is perceived to have a distinctive image. Auty and Elliott (1998) found that consumers perceive branded fashion items to be of higher quality therefore a better conveyer of their self-image.

Trend focus: Trend aspect is inherent in the definition of fashion. One of the very early definitions of fashion states that "Fashion is the prevailing style at any given time" (Nystrom, 1928). Adopting the current trend is a way for consumers to communicate their desire to be "a part of the community". According to Simmel (1904), social tendencies are essential for the establishment of fashion, namely the need of becoming a part of the group on the one hand and the need for uniqueness on the other. Miller et al. (1993) emphasized the desire of consumers to be current by adopting styles that will identify themselves as up-to-date with the people whom they admire in a given situation.

Design focus: It appears that for many individuals, the actual design is another important aspect of fashion and that is what they focus on when it comes to fashion consumption. Many consumers wish to communicate their uniqueness via what they wear (Tian, Bearden and Hunter, 2002). A unique design is usually the answer for individuals who have such concerns when approaching fashion.

A total of 5 studies were conducted in developing and validating the CFO scale.

Study 1: Item development. Besides gleaning on published research related to fashion consumption, we conducted 20 in-depth interviews with undergraduate students in a southeastern university to generate a pool of items for CFO. A total of 33 items were generated (11 items for each dimension).

Study 2: Initial item refinement. The content validity of these items was assessed according to Bearden et al. (1989). After eliminating items that did not receive the appropriate categorization by at least two of the three judges used in this study, 23 items remained (9 items for brand focus, 7 items each for trend and style focuses).

Study 3: Item refinement. Each item was formatted into a seven-point Likert-type response scale in the questionnaires. A sample 98 undergraduate business students (45 females) was used in this study. Based on the data, items that did not have corrected item-to-total subscale correlations above .40 were deleted. Items that did not have statistically higher correlations with the dimension to which they were hypothesized to belong in comparison with item correlations with remaining dimensions' total scores were also deleted (Bearden et al. 1989). These analyses resulted in a reduced scale of 15 items (5 items each dimension).

Study 4: Scale validation-latent structure, reliability and discriminant validity. A non-student sample of 133 consumers (64 females, average age 36) was used to validate the CFO scale. Respondents were recruited by students as an extra credit assignment. Using this data, first, the latent structure and reliability of the scale were assessed. Results show that the three-factor oblique model provided a better fit relative to five more restricted competing models. The hypothesized model was the only model to exhibit acceptable fit. Within the CFA setting, reliability of each dimension was calculated using the procedures outlined by Fornell and Larcker (1981) based on the work of Werts, Lin, and Jöreskog (1974). The reliabilities for the three dimensions ranged from .894 to .954 and the variances extracted ranged from 64 to 80.4 percent, which are highly satisfactory. In an effort to establish scale construct validity, we also conducted discriminant validity tests of the measure by analyzing CFO along with need for uniqueness and fashion innovativeness as pairs of constructs in a series of two-factor CFA models (Bagozzi and Phillips, 1982). The results provided evidence for discriminant validity.

Study 5: Further scale validation-nomological validity. A sample of 243 non-student respondents was used to further validate the scale by focusing on the nomological validity of the scale. We developed our tests based on the established models of fashion clothing consumption (e.g. O'Cass 2004). Age and gender of consumers were included as control variables in our tests. Our test of antecedents revealed that materialism and involvement were positively related to CFO. Moreover, our tests of the consequences found that individuals who are high on CFO scale also had higher self-confidence, tended to spend more and made more impulse purchases. Our results also showed interesting differential effects of the CFO dimensions. While all three dimensions of CFO were positively correlated with impulse buying tendency, only brand focus was significantly correlated with level of spending, and only design focus was significantly correlated with self-confidence.

This research offers both theoretical and practical implications. Theoretically, this study provides an important contribution to current fashion research by first attempting to focus on consumers' in general, rather than the limited number of fashion innovators/leaders' perceptions of fashion. CFO may fit into a broader theory of fashion and fashion consumption (Miller et al. 1993). As such, CFO should be useful in empirical studies of consumers' purchasing and consumption patterns of fashion products. This study also offers many important implications to fashion retailers to better understand and segment their market.

Information Search due to Extended Separation

Kurt A. Carlson, Duke University, USA

Aner Tal, Duke University, USA

Extended Abstract

Information search allows consumers to learn about relevant product dimensions, compare alternative options, and ultimately select the product they prefer. Many factors contribute to consumers' information search processes, including: uncertainty (Urbany et al., 1989), domain knowledge (Brucks, 1985; Ozanne et al., 1992), breadth of alternatives (Iyengar & Lepper, 2000), and the magnitude of perceived difference between choice options (Russo & Carlson, 2002). Oddly, little is known about how expectations influence search in situations where consumers know very little about the choice options.

Expected separation is the non-directional anticipated difference between the overall values of choice alternatives. As a belief that relates to the choice set, expected separation can exist even when consumers have too little information about the specific choice options available to warrant a clear directional prior belief. For example, sometimes consumers confront: really new products, as in the constantly changing realm of consumer electronics; product categories that are new *to them*; new choice options in existing categories, like major redesigns of auto models, or restaurants in a new city. Broadly speaking, any situation where the choice options are novel to the consumer is one where clear directional priors may not exist, but where expected separation may operate.

The effects of beliefs on product evaluation and choice have been demonstrated in numerous domains within consumer research (Allison & Uhl, 1964; Moorthy et al., 1997; Carlson & Russo, 2001). However, we know of no work that has focused on how expected differences among options influences information search. There are two possibilities in this regard, leading to opposite predictions.

It is well-known that the closer options are in value, the longer and deeper consumers will search, at least when they have sufficient expertise to evaluate the acquired information (Bockenholt et al. 1991; Huber and Klein 1991). Thus, if expected separation operates in the same manner as actual separation between choice options, then greater expected separation may lead to less overall search.

The prediction of less information search as expected separation increases is intuitively appealing. After all, if two options are expected to be very different from one another, one would expect to be able to easily tell the options apart, and thus, require less extensive information search to pick one.

However, when expected separation is high the anticipated costs of selecting the wrong option should be high. Thus, consumers may be more likely to fear making a mistake than under conditions of low expected separation. Consequently, search depth may increase as expected separation increases.

Two studies were conducted to test these competing predictions. To begin, we pre-tested expected separation manipulations in a variety of product domains. The manipulation effectively altered expectations of differences between options, as measured by perceived differences among options.

Study 1 employed a mixed 3*3 full-factorial design. The first factor included three levels of expected separation, manipulated by telling participants that the options given in the domain are either “very different,” “slightly different,” or “almost the same”. The second factor consisted of three product domains chosen following pre-testing.

Participants saw descriptions of three simulated scenarios, one in each product domain (hotels in a foreign city, vacation destinations, and imaginary products called gimpers). Each domain was coupled with an expected separation condition. Following each scenario participants answered a series of questions regarding their projected information search behavior.

Results showed that across product domains participants anticipated they would engage in more information gathering the greater the expected separation among alternatives. Participants expected to spend more time gathering information, examine a greater number of options, and use more choice criteria in higher expected separation. Our hypothesis regarding perceptions of cost of picking the wrong option was borne out by higher ratings of risk perception under higher expected separation.

Study 2 was designed to examine actual, rather than anticipated, information search behavior. In addition, the study was designed to allow us to examine potential interaction effects between expected separation and actual (objective) differences between options. Participants were given a simulated scenario where they were asked to choose between two potential date candidates for a friend. The study employed a between subjects 2*3 (expected separation*actual separation) design. Expected separation was manipulated by referring to the two candidates as either very similar or very different. Actual separation was manipulated by varying the average difference in candidates' ratings across a variety of traits.

Participants read a description of the task and examined information about the two candidates. A trait “menu” listed different trait categories where evaluation information was available. Participants were asked to look through traits until they've gathered enough information to make a choice. The main DV was number of trait categories participants chose to examine.

As predicted by participants in study 1, participants in this study examined significantly more trait categories under high rather than low expected separation. While expected separation yielded a main effect on information search, no similar effect was found for actual separation, even though power analysis revealed sufficient power to detect an effect. Additionally, there was no interaction between expected and actual separation on information search.

Participants were more certain of their choice in high rather than low expected separation. This might demonstrate compensatory conviction in response to greater uncertainty during the search process (e.g., McGregor et al., 2001).

To sum, our studies thus far show non-directional expectations of difference between options lead consumers to search for more information. This is borne out in both expected and actual information search. Effects were demonstrated across a variety of consumer domains, adding to the generalizability of the findings.

Further steps in this research include an examination of the effect in real choice, to establish ecological validity, and an investigation of possible mechanisms underlying consumers' extended search for information when expecting greater differences between options. We also wish to clarify the causal role of uncertainty in prompting greater information search following expected separation. This, and other factors, may play in as boundary conditions on the effects of expected separation.

Do We Really Need a Reason to Indulge?

Jing Xu, University of Michigan, USA

Norbert Schwarz, University of Michigan, USA

Extended Abstract

Consumers often need (seek) reasons to justify their decisions or choices (Shafir, Simonson, and Tversky, 1990). More importantly, decisions to indulge oneself (e.g., purchasing luxuries, going on a cruise) may require legitimate reasons because hedonic indulgences may be construed as wasteful and are likely to evoke guilt and (anticipated) regret (Kivetz and Simonson, 2002; Lascau, 1991). As a result, consumers are more likely to choose utilitarian/necessity items over hedonic items because it is easier to justify their purchases (necessities are simply needed as opposed to wanted). But do people actually enjoy more when indulging with a reason than without a reason? Do people enjoy more when indulging with a better reason? The answers depend on how consumers' hedonic experience is assessed, with important implications for research methods and consumer decision making.

A large body of research has studied the decision inconsistency: i.e., people make decisions that do not seem to maximize their experienced utility and alternative explanations have been offered. One of the account on which this paper is based argues that people may hold incorrect beliefs or naïve theories that are rarely updated about how they will feel in certain consumption situations and that this belief or expectation does not correspond to their actual hedonic experience (Robison and Clore, 2002). According to Robison and Clore's accessibility model, when people report on their current feelings, the feelings themselves are accessible, allowing for accurate reports. When they report their feelings during a specific past episode, they can often draw on episodic memory, retrieving specific moments and details of the past. In contrast, global reports of past feelings and predictions of future feelings are based on semantic knowledge. In this case, people draw on their general beliefs about the event class to infer what their feelings "must have" been or will be. These different sources of information give rise to systematic differences in people's self-reports of emotion.

Study one is 2 (reason: yes vs. no) by 2 (reports type: global vs. episodic) between subjects design. We asked half participants to imagine they are consuming a hedonic item either with a reason (as a reward for hard work) or without a reason and to report their affective experience in that situation (*global report condition*). Half participants were directed to recall their most recent hedonic consumption episode and to report their feelings (*episodic report condition*). They then indicated whether there was a reason associated with that last consumption episode and how much they spent on this indulgence occasion. Our study shows that participants expect to experience more negative affect (e.g., guilt) if consuming a hedonic item without a reason than with a reason when asked in a global report fashion. However, when asked in an episodic condition, their hedonic enjoyment was unrelated to reasons or justifications. This is consistent with Robison and Clore's (2002) accessibility model, which suggests that the information that is chronically or temporarily accessible at that point in time drives the differences in emotional reports. Interestingly, we did find that people reported higher spending on indulgence occasions where a reason was present ($M=\$127$) than those where a reason was not present ($M=\$98$). This provides empirical support for consumers' willingness to spend more on an indulgence when it is justified for than when it is not justified.

Study two is a 2 (reports type: prediction vs. experience) by 2 (reason: reward vs. consolation) between subjects design. We hypothesize that people expect to enjoy an indulgence more as a reward (e.g., passed the exam) than as a consolation (e.g., failed the exam). We predict, however, actual consumption experience would not differ when indulging with different reasons. Participants in one condition (consolation) worked on some difficult GMAT math problems and were told that these problems are indicative of their success at a future GMAT test. We expect participants in this condition to feel bad about their performance and seek indulgence as a consolation. Participants in the other condition (reward) worked on the same math problems but were told that these were very difficult math problems (aimed for math major students) and were asked to give a shot at it. We expect them to feel good about their performance and seek indulgence as a reward. All subjects received feedback (right or wrong) after finishing each individual problem. Participants were then asked to choose between two items, two pieces of chocolate truffles or toothpaste (at equal dollar value) as a token of appreciation for their participation. Participants in prediction condition were asked to imagine that they are consuming the truffles (only those who chose the truffles) and report their affective experiences of eating the truffles. Participants in experience condition actually received their choice. Those who chose to have chocolate truffles were asked to eat as much as they want and report how they feel while eating the truffles. Consistent with previous work (Shafir et al., 1990), participants were as likely to indulge (i.e., choose the truffles) when they think they did well in a test

(i.e., reward condition) as when they think they didn't do well (i.e., consolation condition). As expected, the predictors in consolation condition expected to enjoy the truffles less than those in reward condition. However, the experiencers' actual enjoyment did not differ systematically between the two conditions.

Our findings suggest that a lack of justification does not limit the immediate pleasure of indulging and that a better reason does not make an indulgence more enjoyable, in contrast to what consumers expect.

Effects of Self-Affirmation and Individualistic-Collectivistic Appeals on Open-mindedness and Advertising Effectiveness

Mary Lou Kohne, University of Cincinnati, USA

EXTENDED ABSTRACT

Background and Scope

Psychological research has demonstrated how self-affirmation in one domain leads people to be more open-minded and acknowledge the merits of counterattitudinal messages they would otherwise reject. Affirmation-induced openness to counterattitudinal information works because open-minded people are more objective (less biased) and more sensitive to argument strength, and thereby judge an argument on its merits. (Correll, Spencer and Zanna, 2004). Little research has been published within the consumer research or marketing literature about self-affirmation and its effects on consumer cognitions and behavior. It is hypothesized that self-affirmation will result in more open-mindedness and elaboration on information about an advertised product.

Theoretical Basis:

Psychological literature suggests close-mindedness stems from an individual's concern for self-regard; in effect, a person resists and rejects conflicting information to protect a sense of self-worth derived from their "right" beliefs and attitudes. Self-Affirmation Theory (Steele, 1988; Steele, Spencer and Lynch, 1993), suggests that every person strives for positive self-regard, and draws on personal successes within a constellation of domains for its achievement. One of its crucial tenets is that the ultimate goal of a defensive reaction is the security of the global sense of self-worth.

Individual differences among consumers in their Need for Cognitive Closure (Kruglanski and Webster, 1996) may differentially affect consumers' responses; people who have a strong Need for Cognitive Closure often will "seize" and "freeze" without elaborating on the full information available. It is expected that NFCC will moderate the relationship between self-affirmation on open-mindedness and advertising effectiveness.

Potential Contribution

This research contributes to extant literature in several ways. First, it expands what little is currently known about how self-affirmation works to influence consumer behavior. Second, it adds to literature focused on information processing in high involvement product categories. Finally, this research contributes to the understanding of the circumstances in which there is an opportunity for more unbiased consideration of products by considering the cognitive processing of the open-minded consumer.

Research Methodology

A sequence of experiments has been conducted to test the affects of self-affirmation on consumers' responses to advertising regarding high involvement products. Respondents were recruited to participate in an experiment about the effects of advertising content on consumer elaboration, cognitions, and intentions. Subjects were randomly assigned to a treatment cell, received a disclosure sheet about the study, and then were asked to view an ad promoting a high involvement product. (The actual headings and phrases in the ad stimuli varied based on cell assignment). Reactions to the advertisement and trait and state measures were then collected.

Study 1 was designed test the impact of positive self-affirmation (ego inflation) on consumers' responses to advertising. A hypothetical on-line job search portal was selected as the advertised product representing high involvement categories. Study 1 involved the use of a 2 x 2 experiment of the Self-affirmation treatment condition versus a neutral condition by high/low Need for Cognitive Closure. After viewing one ad, subjects first performed an open-ended thought listing. They next rated the advertising as to its effectiveness and were then asked to simulate a job search by rating their interest in a series of job postings. Next they were asked a series of questions about their attitudes and beliefs. Students from undergraduate business classes participated in the research in exchange for class participation credit. A total of 160 respondents completed Study 1.

Study 2 further examined the impact of self-affirmation on advertising effectiveness. A total of 52 undergraduate marketing students received only the affirmation treatment advertisement, and were also asked additional questions related to self-esteem and locus of control

in addition to the other dependent variables and ratings from Study 1. This phase allowed more in-depth analysis of the relationship between individual differences related to self-esteem and effects of self-affirmation on advertising effectiveness.

Study 3, which is in process now, is designed to examine self-affirmation's effects on advertising, in conjunction with individualistic/collectivistic appeals. In a 3 x 2 x 2 experiment, consumers will react to advertising that includes self-affirmation by individualistic or collectivistic appeals by high/low Need for Cognitive Closure. A minimum of 30 respondents per cell is planned (240 respondents.) The study is being conducted for hybrid/alternative fuel vehicles as the context for a public service announcement ad. The approach will be identical to that used in Study 1. Medialab software is being used to administer the survey in Study 3, allowing the ad to be presented as a prototype for a 30-second television ad. After viewing one ad, subjects are being asked a series of questions related to their attitudes and beliefs about hybrid/alternative fuel vehicles. Then they will give reactions to the advertising's effectiveness and asked a series of questions about their general attitudes and beliefs, including an individual difference measure related to individualism/collectivism.

Variables of Study:

The following variables will be included.

- Independent Variables of "Affirmation Condition (positive affirmation, control)" and "Type of Appeal" (Individualistic, Collectivistic) will be tested.
- A Mediating Variable (Openness/Skepticism) will be assessed.
- The Dependent Variable is "Persuasion to Consider the Advertised Product."
- Moderating Variables are:
 - o Individual Trait Differences related to Preference for Individualism/Collectivism
 - o Individual Differences on Need for Cognitive Closure (NFCC)

Analysis involved using ANOVA/ANCOVA and special procedures to test for mediation/moderation as outlined in Baron and Kenny (1986).

Hypotheses

The hypothesized relationships among variables are as follows:

- H1: Affirmations will lead to more openness.
- H2: More openness leads to more elaboration.
- H3: More elaboration leads to more persuasion.
- H4: "Individualism" will intensify the results: Individualistic appeals will be stronger than collectivistic appeals among "Individualists", and Collectivistic appeals will be stronger than individualistic appeals among "Collectivists."
- H5: People low in NFCC will respond better to positive affirmations.

Experimental Stimuli

All advertising stimuli were pretested prior to conducting the experiments. The following headlines are being provided as illustrations of the advertising conditions to be tested.

Studies 1 and 2: On-line Job Search Portal

- Self-Affirmation Treatment Condition 1: "Smarter People Find the Best Jobs" (positive self-affirmation treatment condition)
- Neutral Control Condition: "People Find the Best Jobs" (represents non-affirmation condition)

Study 3: Hybrid/Alternative Fuel Vehicles

- Affirmation Treatment Condition/Individualistic Appeal: "You can work hard and do whatever it takes to overcome challenges and to accomplish your goals. You are smart. When faced with difficult and important decisions, you carefully analyze which choice is the right one for your unique situation. You can make more informed decisions. You can act now to make a difference for your future."
- Affirmation Treatment Condition/Collectivistic Appeal: "We Americans work hard and we do whatever it takes to overcome challenges and accomplish our goals. Americans are smart. When faced with difficult and important decisions, we carefully analyze which choice is the right one for our unique situation. We can make more informed decisions. We can act now to make a difference for our future."
- Control: No affirmation language

Consumer Weighting of Hedonic and Utilitarian Dimensions across Judgments

Laura Smarandescu, University of South Carolina, USA

Douglas Wedell, University of South Carolina, USA

Extended Abstract

A fundamental assumption in the theory of choice is that of procedure invariance which suggests that individuals have well-articulated preferences and beliefs that remain constant regardless the method of elicitation. However, studies of decision and judgment show that people do not have well-defined values and beliefs and often construct these during the elicitation process (Fischhoff, Slovic & Lichtenstein, 1980; Shafer & Tversky, 1985; Tversky, Sattah and Slovic, 1988; Schkade and Johnson, 1989). Thus, different elicitation procedures highlight different aspects of options and may result in inconsistent responses, or preference reversals.

In two studies we examined situations that involved trade-offs between utilitarian and hedonic dimensions across three elicitation methods: choice, pricing and liking. Previous work by Hsee et al. (2003) shows that when decision makers are faced to trade-offs between cold and hot factors they exhibit a systematic inconsistency between predicted experience (i.e., a liking judgment) and choice. They suggest that individuals weight more hot factors when predicting their experience, but place more emphasis on cold or rational factors in choice. Hsee and Zhang (2004) provide further evidence that easy-to-quantify attribute differences (i.e. quantitative differences) are weighted more in a joint evaluation mode (e.g., choice) than in single evaluation mode (e.g., predicted happiness judgments). For example, individuals overpredict the experiential difference between easy to quantify differences such as having an annual salary of \$60,000 and an annual salary of \$70,000 and between living in a 3,000 sq. ft² house and a 4,000 sq. ft² house, but are less likely to overpredict the experiential difference between doing an interesting and a tedious job or between having to walk to work and having to drive to work.

In study 1 we used a stimulus composed of two attributes, a utilitarian and a hedonic attribute. Individuals made 240 judgments of three types: choice, pricing (essentially a matching judgment when participants had to price one of the option with the objective of matching a second option in value) and liking. The decisions were made in two consumer categories, cars and apartments, and were framed as acquisition decisions. In addition, we manipulated the size of the trade-off by including three levels of utilitarian and hedonic attributes. Consistent with the prominence hypothesis, we expected that utilitarian attributes would be weighted more in choice than in pricing (matching) and liking decisions, since they seem more important and provide a better justification for choice. In agreement with Hsee et al. (2003), we predicted that options described as high on hedonic dimensions, would be rated higher in liking judgments than options described as high on utilitarian dimensions. Our first prediction, the prominence of utilitarian attributes in choice in comparison to pricing and liking, was confirmed when the size of the trade-off was large. Thus, utilitarian attributes were weighted more in choice than in pricing ($t(79)=25.93, p <.001$), or liking ($t(79)=5.19, p <.001$). However, when the size of the trade-off was small, individuals placed greater weights on utilitarian attributes in liking judgments than in choice ($t(79)=10.95, p <.001$) or pricing ($t(79)=10.25, p <.001$). In conclusion, although decisions were largely driven by high utilitarian values, the size of the trade-off had an impact on the weights assigned to hedonic attributes in a joint evaluation context. Hence, smaller trade-offs resulted in increased weighting of hedonic attributes in choice and pricing decisions.

Study 2 tested whether framing a decision in terms of a loss (forfeiture) or a gain (acquisition) may further moderate attribute weighting across elicitation procedures in situations when the size of the trade-off is large. Dhar and Wertenbroch (2000) suggest that in choice, hedonic attributes receive a greater weight in forfeiture than in acquisition decisions, due to more extensive elaboration in a forfeiture context. In agreement with Dhar and Wertenbroch (2000), we expected that in forfeiture, options described as high on hedonic attributes would better predict preferences across elicitation methods in comparison to options described as high on utilitarian attributes. Our data presented only partial support for this hypothesis. We found that framing a decision as a forfeiture results in a greater weighting of hedonic attributes in liking judgments ($t(83)=9.50, p <.001$), consistent with an elaboration hypothesis. It can be concluded that individuals anticipate more regret associated with forfeiting a high hedonic option than with a high utilitarian option. This effect was not present in choice or pricing judgments. However, we found that, hedonic attributes were weighted more when individuals made pricing judgments in an acquisition context ($t(83)=7.44, p <.001$) than in forfeiture. This suggests that in acquisition, individuals expect to pay more for high hedonic options than for high utilitarian options. However, it is possible that the null effect for choice was caused by the nature of the stimulus. On each choice screen, participants were presented with three options: a reference option, which provided the acquisition or forfeiture frame, and two choice options. It is possible that individuals used decision short-cuts and failed to take into consideration the reference item in choice. Further studies are necessary to rule out this potential explanation.

Dimensions of Attitude Towards A Sales Promotion Offer

Maneesh Thakkar, Baruch College, City University of New York, USA
Suri Weisfeld-Spolter, Baruch College, City University of New York, USA

Extended Abstract

Walk into a supermarket and you will not be surprised to see a great many products on promotion of one kind or the other. Promotions have rightfully become the ubiquitous element of consumers' shopping experience with US marketers spending more than \$100 billion in the form of annual promotional expenditure (Kerin et al, 2003).

The present study contends that consumers' responses towards various sales promotions depend on their attitudes towards a given sales promotion and such attitudes depend on the intrinsic characteristics of a given promotional offer. Blattberg and Neslin (1990). They define a sales promotion as "an action-focused marketing event whose purpose is to have a direct impact on the behavior of the firm's customers."

Different sales promotional tools serve different objectives. Some promotions such as in-store display and 'two-for-one' help generate un-planned purchases (Inman et al, 1990; McClure and West, 1969) and Mulhern and Padgett (1995) show how retail promotions induce consumers to buy regular priced merchandise. Sales promotions are also used to increase store traffic (Grewal, Manroe and Krishnan, 1998; Lichtenstein and Bearden, 1989) increase number of visits to the store (Walters and Rinnie, 1986) and reduce retailers' inventory carrying costs by inducing consumers to stockpile (Blattberg, 1981; Soo Ong, 1999).

Prior research has studied the variations in consumers' responsiveness to deals by product category, market, and type of consumer (Blattberg et al 1995). Evidently, there hasn't been much of an attempt, bearing a few exceptions, to study the differences in consumers' responsiveness to different promotions arising out of variation in the intrinsic characteristics of a promotional offer. We propose that consumers view promotions as a bundle of some combination of these attributes and each promotional offer represents a unique bundle of attributes. Based on literature review, the initial set of attributes viz. monetary benefits, non-monetary benefits, efforts needed, risk involved, ambiguity of benefits, imprecision in benefits, benefit delay, and effort delay were identified.

Monetary benefits are defined as the economic incentive offered by a promotion, the basic purpose of promotions is to offer an economic inducement to consumers for making the purchase of the product on promotion (Blattberg and Neslin, 1990). Many research findings suggest that consumers do respond to sales promotions for benefits other than monetary savings viz. joy of getting a good deal, the hedonic value of a free gift etc. (for a comprehensive analysis see Chandon et al, 2000). Some promotions involve immediate expense of efforts at the time of availing promotional offer e.g. early bird incentive, clipping coupons, entering in a lucky draw (sometimes entries for draws can be sent at a later date) etc. Sometimes consumers exert efforts in advance of the promotional benefit viz. registering for frequent flyer programs. Research in behavioral decision theory explicates procrastinating behavior by reasoning that future efforts are substantially discounted (Akerlof, 1991; Loewenstein, 1996). A promotional offer may offer an incentive at future date after the purchase is made with or without any additional conditions. Promotions like price-discounts are instantly received at the time of purchase but the benefits of many promotions arise only at a later date. The winners of contests, sweepstakes etc. are determined much after they have made their purchases. The 'worthiness' of all promotions is not easily determinable e.g. win a dinner with a TV star. Ambiguity also arises when the promotion is attached with many qualifications. Some promotions like lucky draws are risky where in the consumer may not gain anything and finally, in some instances the benefits offered are imprecise e.g. all items with red tags on sale, up to 75% off etc.

A composite scale representing all eight dimensions was developed and presented to 57 undergraduate students. The same scale was used for each of the seven most widely used consumer promotions viz. Coupons, Mail-in-rebates, Lucky draws, free gifts, price breaks, Contests, etc. The popularity of different sales promotions was assessed through literature review and consultations with an expert. The underlying dimensions were then identified by factor analysis techniques. The study also incorporated measures for testing convergent validity and criterion / predictive validity.

Based on the recommended scale development procedures (Gerbing and Anderson, 1988), the data analysis began with checking the dimensionality underlying the attitude towards sales promotions. The procedure undertaken involved factor analysis (both exploratory as well as confirmatory factor analysis), inter-item correlations (across entire scale and more importantly within each facet) and validity tests for criterion and convergent validity. The six components derived by factor analysis have eigen values of more than 1 and collectively they explain 67% of the total variance. All the components have alpha more than 0.6 except monetary benefits, which has alpha of 0.56. To ascertain the criterion validity the correlations between perceived dimensions (six components) and the predicted likelihood of use of that sales promotion were measured. Except Effort-delay (.05 level) all the correlations are significant at .01 levels providing a strong support for criterion validity. Finally, based on the empirical analysis the identified factors are 1) Perceived effort-return benefit, 2) Benefit transparency representing the degree of precision in stating the promotional benefits and the clarity with which the promotional benefits are communicated 3) Non-monetary benefits 4) Effort delay 5) Risk impact and 6) Perceived monetary benefits. We also discuss the explanation and interpretation of these derived dimensions.

Affect, Affective Precision, and Primacy Effect in Stock Choices

Namika Sagara, University of Oregon, Decision Research, USA

Ellen Peters, University of Oregon, Decision Research, USA

Extended Abstract

The role of affect in everyday decisions has received an increasing amount of attention in recent literature. Epstein's (1996) dual processes describe that we have analytical and experiential systems that are interrelated, and most of the time we use both of the systems to make decisions. Slovic et al. (2002) proposed the idea of the affect heuristic, which states that we often use affect as a shortcut to guide judgment and decision making processes. Zajonc (1980) claimed that all perception contains some affect, and it is capable of influencing the ensuing cognitive process to a significant degree.

However, until recently, numerical information was considered to be processed purely cognitively, therefore, free from affect. A few exceptions exist. Peters et al. (2006) demonstrated that affect can be calculated from numbers and used to guide decisions. Kida et al. (1998) also suggested that affect guides choices that involve numerical information. In their study, they presented two sets of stock information. When asked, about 80% of the participants chose the clearly better firm in the first set, although two firms from the second set were actually better. Combining this with other findings in their study, they concluded that participants chose the best firm in the first set because they did not remember the actual financial characteristics of stocks. Instead, they remembered having a higher affect toward that stock option, due to its clear superiority within its own set. An alternative explanation for this finding, however, is an order effect, specifically, participants may feel greater positive affect and choose the best options in a set presented first.

In our study, we investigated the role of affect in stock choice by replicating and extending Study 3 of Kida et al. (1998).

Hypotheses

H1a: The majority of participants will choose the best firm in Set A when the options are presented in the same order as those in Kida et al. (1998).

H1b: The majority of participants will *not* choose the best firm in Set A when the sets are presented in a reversed order as those in Kida et al. (1998).

- H2: Participants have significantly higher positive affect toward the best choice in each set.
 H3a: Affect toward stock choices will significantly predict choices independent of set order.
 H3b: Affective precision toward stock choices and its interaction with affect will significantly contribute to the prediction of choices above and beyond affect and option order.

Method

We replicated the methodology used in Study 3 of Kida et al (1998). As in their study, each of two information sets (Set A and Set B) contained financial characteristics of five firms. The best firm in Set A was far better than the rest of the firms in its own set, and the best firm in Set B was not as clearly the best within its set. However, the best and second best firms in Set B were better than the best firm in Set A.

In our study, half of the participants were presented with Set A first, then Set B (a replication of Kida et al.); the other half of participants were presented with Set B first, then Set A. All participants were then asked to choose their most preferred stock from either set. They also rated their affect and affective precision towards each firm.

Results:

Hypotheses 1a and 1b were supported. Although the majority of participants (83%) chose the best stock in Set A when Set A was presented first, only 25% of participants chose the best stock in Set A when Set B was presented first; the remaining 72% chose the best from in Set B.

Hypothesis 2 was supported. Affect toward the best firms in each set was calculated by subtracting the mean of the raw affect ratings toward the rest of the firms from raw affect ratings toward the best firm. Affective precision was calculated in a similar manner. Participants had significantly higher positive affect and affective precision toward the best firms in Set A and Set B compared to affect toward the average of the rest of the firms.

Hypotheses 3a and 3b were also supported. Logistic regression indicated that affect and the order in which information sets were presented significantly predicted choices. Our new construct, affective precision, and its interaction with affect significantly contributed to the prediction of choices above and beyond the affect and primacy effects. These findings indicate that people developed higher affect and affective precision within the local context of each set and that they used their affect to guide their decisions.

Conclusion

Over the last couple of decades, research has demonstrated that decision makers use affect to guide decisions: to decide where to go to vacation or which car to buy. However, numerical information in decisions is still thought to be processed very cognitively. Results of our study demonstrated that people develop affect not only to events, persons, and material objects, but also to numbers. Decision makers appear to draw affective meaning from numbers and to use this affect to guide their decisions. They may be even more likely to rely on affect when information is unavailable at the moment of choice and they have to make decisions from memory. Our findings can also be applied to many other decisions that involve numerical information, such as prices, nutritional facts about food and drinks, and drug information.

Our study also suggests that people are very susceptible to primacy effects with numerical information. This may be because once people develop affect toward a particular option, they tend to stick with it. Therefore, they are not very open to other choices. Further investigations are needed for clearer explanations. Affect's role in judgments and decisions that involve numerical information is ubiquitous in everyday decisions. Yet, not many studies have been done on this topic. It is important to understand how people rely on affect to make choices and decisions so that we can facilitate better choices and decisions among managers and consumers.

The Role of Emotional Attachment in Consumers' Responses to Service Changes

Maura Scott, Arizona State University, USA
 Martin Mende, Arizona State University, USA

Extended Abstract

Consumers are often faced with changes to services they consume; their ability to adapt to changes is moderated by their emotional attachment to the service. We explore the following research questions: (1) What is the relationship between a consumer's emotional attachment and the level of human interaction the service provides? and (2) How does the level of emotional attachment to the service influence a consumer's satisfaction, word of mouth, and repurchase intentions, in response to service changes?

For consumers, the "human interaction" element is an important service factor (Zeithaml and Bitner 2003). The level of human interaction consumers receive from services ranges from higher levels (e.g. financial advising) to lower levels (e.g. ATMs) (Schmenner

2004; Mersha 1990). Consumers develop strong emotional attachments to consumer packaged goods (Fournier 1998), as well as fulfill complex emotional needs through service consumption (Rosenbaum 2003). We propose:

H1: There is a positive relationship between the consumer's perceived level of human interaction with the service provider and the consumer's level of emotional attachment to the service.

Loss aversion and the status quo bias predict that consumers are reluctant to change and prefer the status quo (Samuelson and Zeckhauser 1988; Tversky and Kahneman 1991). We examine changes as gains (positive service changes) and losses (negative service changes).

In a service failure context, Mattila (2004) finds that high affective commitment consumers exhibit higher post-failure behavioral intention ratings than low affective commitment consumers. We propose a Favoritism Effect in which consumers with higher levels of emotional attachment (HEA consumers) have a positive bias toward service providers and would therefore rate the same services higher, after a gain, than low emotional attachment (LEA) consumers do.

In Mattila's (2004) study, low affective commitment consumers are more "forgiving" with a successful recovery effort, while high affective commitment consumers feel "betrayed" from the failure. We propose that HEA consumers seek validation of their emotions through the reinforcement of service gains. Fiske (2004) notes that in interpersonal relationships people expect reciprocity. HEA consumers expect the service to exhibit gains that reciprocate the consumer's high emotional attachment. We propose:

H2a: In the case of gains, consumers with high levels of emotional attachment to a service provider will have a higher level of favorability, than consumers with low levels of emotional attachment, to a service provider.

When HEA consumers experience service losses, the favoritism effect is positive, but invalidation of emotions is negative. The effects are in opposing directions, effectively canceling each other out. Consequently, HEA and LEA consumers have comparable ratings. We propose:

H2b: In the case of losses, consumers with high and low levels of emotional attachment will have comparable levels of negative responses to service losses.

Study 1

A 1-factor (gain, loss) between subjects field study was conducted ($N=32$, 71% male, mean age 37) in a sandwich shop. Emotional attachment was measured using the Thomson et al. (2005) emotional attachment scale, dividing high and low with a median split. The dependent variables were satisfaction, word of mouth, and repurchase intention. Purchase frequency and perceived level of human interaction were also measured. For example, the "gain" level was manipulated as follows:

"Imagine that [this restaurant] is extending its hours of operation. Specifically, it would be open 2 hours earlier each morning and close 2 hours later each evening. In total, [this restaurant] would be open 4 additional hours each day."

In addition to hours of operation, product selection, and number of available servers (both gains and losses) were examined. Results are presented in aggregate.

The test of H1 showed that the level of human interaction perceived by the consumers has a small positive effect on how emotionally attached consumers feel. These results are directionally consistent with H1; pearson correlation=.334, ns.

Supporting H2a, in the case of a service improvement (gain), high emotional attachment consumers have higher levels, than low emotional attachment consumers, of satisfaction (LEA $M=3.0$, HEA $M=4.8$, $n.s.$), word of mouth (LEA $M=3.0$, HEA $M=5.6$, $p=.034$), and repurchase intention (LEA $M=3.0$, HEA $M=6.0$, $p=.007$) levels.

When there is a service reduction (loss), high and low emotional attachment consumers have comparable satisfaction (LEA $M=3.67$, HEA $M=3.67$, $n.s.$), word of mouth (LEA $M=4.67$, HEA $M=5.50$, $n.s.$), and repurchase intention (LEA $M=4.67$, HEA $M=4.83$, $n.s.$) levels, supporting H2b.

Study 2

A 1-factor (gain, loss) between subjects lab experiment was conducted ($N=155$, includes respondents who have visited the Starbucks coffee shops in question at least once in the last 30 days). Measured variables and dependent variables were consistent with Study 1. An example of the "loss" level manipulation is as follows (hours of operation and product selection were also examined):

"The Starbucks on campus typically have two cash registers and three employees available at a given time. Imagine that the Starbucks on campus now had only one cash register and two employees during busy times. This would be a staff reduction to two employees. The result is that it takes longer to get your order."

The results for study 2 replicate the results of study 1 in a more controlled environment. H1 was supported with a pearson correlation=.467, sig (2-tailed)=.000.

When there is a service improvement (gain), high emotional attachment consumers have higher levels, than low emotional attachment consumers, of satisfaction (LEA $M=5.57$, HEA $M=6.46$, $p=.002$), word of mouth (LEA $M=5.43$, HEA $M=6.41$, $p=.002$), and repurchase intention (LEA $M=5.83$, HEA $M=6.70$, $p=.002$) levels, supporting H2a.

In the case of a service reduction (loss), high and low emotional attachment consumers have comparable satisfaction (LEA $M=2.39$, HEA $M=2.11$, $n.s.$), word of mouth (LEA $M=2.39$, HEA $M=2.89$, $n.s.$), and repurchase intention (LEA $M=2.74$, HEA $M=3.00$, $n.s.$) levels, supporting H2b.

Inferential and Perceptual Influences of Affective Expectations on Judgments of Experienced Affect

Ian Handley, Montana State University, USA
 Dolores Albarracín, University of Florida, USA
 Rick Brown, University of Florida, USA
 Hong Li, University of Florida, USA
 Ece Kumkale, University of Florida, USA

Extended Abstract

Marketers often instill either positive or negative expectations for how an experience with a product will make consumers feel (i.e., affective expectations). After all, doing so will often congruently influence attitudes toward, and intentions to purchase, a product. However, one limitation of focusing on expectations is that the *actual experience* with the product is a fundamental attitude determinant (e.g., Regan and Fazio 1977). That is, the consumer attitudes created from implanting an affective expectation for a product are likely weaker and less predictive of behavior than are the attitudes formed following a direct experience with a product. Thus, the present research is an attempt to fill gaps in our knowledge about the interface between affective expectations, affective experiences, and the actual judgments of those affective experiences as well as resultant attitudes and intentions among consumers.

We propose that both inferential (conscious; Clore and Schnall 2005; Wyer, Clore, and Isbell 1999) and perceptual (nonconscious; Sherif and Hovland 1961) processes can govern the effects of affective expectations on judgments of affect. Further, we suggest that both processes often lead to an "ironic effect" by which negative, relative to positive, affective expectations produce more positive affective reactions following an encounter with a product. Critical for the manifestation of this ironic effect is that the consumer is able to sufficiently identify, or focus on, their feelings (Albarracín and Kumkale 2003).

Whether an inferential or a perceptual process predominates depends on whether people endorse a naïve theory that affective expectations congruently influence affective experiences. Individuals who hold this belief may arrive at judgments of experienced affect in a predominantly inferential or reasoned manner. This naïve theory can lead consumers to believe that their affect resulting from an encounter with a product has been influenced by their expectation. Thus, they likely conclude following a negative (positive) affective expectation that the affect they currently experience is actually more (less) positive, producing the ironic effect. Further, individuals holding this naïve theory should spontaneously identify their feeling because they attempt to determine the influence of their expectations on their feelings. Thus, ironic effects should be commonly observed for these individuals unless they are artificially distracted from identifying their feelings.

Alternatively, individuals without this naïve theory may arrive at judgments of experienced affect only in a perceptual or nonconscious manner because they do not consider the influence of their expectations on their experiences, nor should they spontaneously focus on their feelings. Thus, these individuals will not demonstrate ironic effects as readily as will endorsers of the naïve theory. Rather, their judgments of affective experiences should be assimilated to their expectations. This prediction is consistent with research (e.g., Stapel, Koomen, and Ruys 2002) which suggests that judgments of an object (product) tend to be assimilated toward a context (or expectation) when the object and context are not seen as being distinct. However, if these individuals are experimentally induced to focus on the affect induced by the product, this affect will be seen as discrepant from an inconsistent expectation. In this case, contrast effects should be observed, producing perceptual ironic effects.

In two reported studies, participants received information instilling a positive or negative affective expectation for a "mood-altering" simulated-alcohol product, and then, a short time later, sampled the beverage. This beverage was associated with pleasant or unpleasant affect because it was immediately preceded by a mood induction in which participants wrote a letter about a happy or angering event to a friend. This mood induction (positive for Experiment 1, and positive or negative in Experiment 2) was presented to assure that participants had some affect identifiable since the beverage did not actually alter mood. Finally, participants reported judgments of their affective state,

beverage attitudes, and intentions to use the beverage. As well, we measured participants' endorsement of the naïve theory and conducted a median split to isolate high and low endorsers of this theory.

Importantly, in Experiment 1, some participants were distracted by an audio-taped conversation from identifying their affect while they completed the main dependent measures, whereas others were not. For high endorsers of the naïve theory, we predicted that an inferential ironic effect would emerge under normal affect-identification conditions, but that no effect would be observed when a distraction was present. By contrast, under normal affect-identification conditions, low endorsers should perceive their experienced affect as being consistent with their expectation, but this effect should disappear when a distraction was present. The results of an analysis in which affect, product attitudes, and intentions to drink the product were combined confirmed these predictions.

In Experiment 2 we tested our prediction that consumers without a naïve theory may demonstrate perceptual ironic effects, but only when they are led to focus on their feelings. To do this, some participants were prompted to focus on their feeling just prior to completing the main dependent measures, whereas others were not. In these conditions, we expected low endorsers, and all high endorsers, to manifest the ironic effect. Otherwise, low endorsers were expected to demonstrate expectation-consistent effects. The results of an analysis in which affect, product attitudes, and intentions to drink the product were combined confirmed these predictions.

The proposed model is unique in positing two processes by which judgments of affect, and resultant consumer attitudes and intentions, are influenced by affective expectations. Importantly, this model predicts an ironic effect, which is related to other effects observed in the consumer behavior and social psychological literature (e.g., Oliver 1980; Mellers, Schwartz, Ho, and Ritov 1997; Wegener and Petty 1997) but also predicts an expectation-consistent effect under some conditions. Thus, the present model accounts specifically accounts for a variety of effects following affective expectations. Therefore, this model can prove useful in predicting when, and with whom, marketers will find most advantageous the creation of consumers' positive or negative expectations for how a product will make them feel. Notably, careful advertisements may alter individuals' naïve theories, and marketers can vary the extent to which consumers are likely to identify their feelings, thus controlling what effects are observed.

Consumer Evaluation of Brand Deletion and Feedback Effect: A Motivational Approach

Saurabh Goorha, Cornell University, USA

EXTENDED ABSTRACT

Introduction

Companies are increasingly deleting brands to rationalize their portfolios. This is usually a financial decision with little to no consideration for the consumer who actually bought the brands. An important question is to identify the repercussions of deletion decision on the existing consumers. This gap in the academic literature and management practice on brand deletion is addressed in this research, with the studies focusing on brand extension deletion.

Most new products, typically 80-90% in any year, are extensions. Many researchers studying consumer evaluation of brand extensions have followed a categorization perspective (e.g. Broniarczyk & Alba, 1994), much of which is driven by using the consumer learning approach. For example, a successful brand extension contributes to parent brand image by improving the strength, favorability, or uniqueness of its associations (Aaker & Keller, 1990.) Parent brand dilution has been shown to occur as a result of the introduction of an extension that has attributes inconsistent with consumer beliefs about the parent brand, but the flagship products have been shown as less vulnerable to dilution (John, Loken, & Joiner, 1998; Loken & John, 1993.)

This current research utilizes a motivational approach to study consumer evaluation of brand deletion and feedback effects. It is hypothesized that deletion of a brand extension, if it is the most preferred brand in the extension category, generates psychological

reactance (Brehm, 1966) in consumers. This reactance can be conceived as goal-directed motivational state (Brehm & Brehm, 1981; Wicklund, 1974.) It is proposed that liking towards the parent brand and the brand extension would be adversely affected by the brand extension deletion. One key variable moderating consumers' evaluation of parent brand and its brand extension is consumers' attribution of the responsibility of the extension deletion. If consumers believe that the transgression, i.e., deletion decision is made by the manufacturer, it is proposed that liking towards the manufacturer and the parent brand would be lower (as compared to no deletion controls). However liking towards the deleted brand extension would be higher as compared to no deletion controls, as the reactance generated leads to increased liking for the lost freedom (e.g. deleted brand extension).

Method

A lab based, primary experimental setup was utilized. The studies used a 'before-after with control group' design. In Study 1, mouthwash as the extension category was used, whereas in Study 2, ketchup as the extension category was used. All participants were exposed to credible information conveying that their preferred brand extension in a category had been deleted. A no-deletion group served as control. Pre-tests were conducted to identify participants' involvement with multiple product categories. For a conservative test, categories with relatively low involvement were used. Pre-tests also confirmed that availability of most preferred extension was perceived as offering greatest freedom, and that Consumer Reports was perceived as the expert source to communicate deletion news. Additional data (e.g. close substitutes, usage etc.) was also collected.

In both the studies, all participants initially rated their preference for brands and extensions in multiple categories. Only relevant category information (mouthwash and ketchup respectively) was then used to manipulate deletion. Participants read a scenario informing them that their favorite extension had been deleted by the manufacturer due to financial performance. Finally the participants re-rated their liking towards the manufacture, parent brand and the deleted extensions.

Major Findings

The findings from Study 1 (mouthwash extension category) are reported here. These were replicated in Study 2 (ketchup category). The initial and final attitudes towards manufacture (e.g. P&G, Pfizer), the parent brand (e.g. Crest, Listerine) and the brand extension (e.g. Crest mouthwash, Cool Mint Listerine mouthwash) were measured using either three 11-item measures or points allocation from 1-100. Paired-sample t-tests were conducted on the pre-manipulation and post-manipulation scores. There were *no differences* in the no-deletion pre-post control group scores.

For the *deleted extension*, this difference was significant, $t(64)=2.27$, $p<.05$ for Cool Mint Listerine, indicating that the preference for Cool Mint Listerine mouthwash post deletion was significantly *higher* as compared to their initial preference for Cool Mint Listerine mouthwash ($M_s=88.63$ & 91.80 , pre-post deletion.) Similar findings were observed for the deleted Crest mouthwash. This indicates that consumers liking of their favorite brand extension *increases* after they become aware of the deletion, irrespective of it being line or category extension.

For the *manufacturer*, this difference was significant, $t(64)=11.36$, $p<.001$ for Pfizer, indicating that the subjects attitude towards Pfizer post deletion was significantly *lower* than their attitude towards Pfizer pre deletion ($M_s=8.36$ & 5.24 , pre-post deletion.) Similar findings were observed towards P & G, manufacturer of Crest mouthwash. This indicates that consumers' attitude towards the manufacturer of their favorite brand extension *decreases* strongly after they become aware of the decision of the manufacturer to delete the mouthwash brand.

For the *parent brand*, this difference was significant, $t(64)=4.04$, $p<.001$ for Listerine, which indicates that the subjects attitude towards Listerine brand post deletion was significantly *lower* than their attitude towards Listerine brand pre deletion ($M_s=8.41$ & 7.32 , pre-post deletion.) Similar findings were observed for Crest brand. This indicates that consumers' attitude towards the parent brand, whose extension is deleted, *decreases* strongly after they become aware of the decision of the manufacturer to delete the mouthwash extension.

Discussion

Evidence from initial experiments suggests that awareness of brand extension deletion leads consumers to develop negative attitude towards the manufacturer and its core brand. On the other hand, the liking towards the deleted brand extension increases significantly after awareness of deletion, if the deletion decision does not lead to quality questions. However, the attributions towards the company are only generated when the company is held responsible for the deletion.

This research implies that companies with multiple brands require a systematic consumer-focused brand deletion process in place. This would control the adverse impact of brand deletion on parent brand, as well as limit damage on corporate reputation.

The initial studies have focused on brand extensions to study brand deletion. Brand extensions are unique in their associations and future research would delineate extension specific effects from consumer evaluation based on the loss of a choice option.

Motivational Reasons for Misremembering Past Negative Events

Leonardo Nicolao, The University of Texas at Austin, USA

Rajagopal Raghunathan, The University of Texas at Austin, USA

Extended Abstract

In recent years, a significant amount of research attention has been focused on documenting the relationship among experienced, predicted and remembered utilities of negative experiences. Much of this work points to discrepancies between how much an event is actually enjoyed and how much it is predicted to be enjoyed (Gilbert, Pinel, Wilson, Blumberg, & Wheatley, 1998; Redelmeier & Kahneman, 1996; Wilson, Meyers, & Gilbert, 2003). Across these papers, findings indicate that people expect future negative events to be even more negative than they actually are. Two conceptually distinct sets of mechanisms have been proposed to explain these findings. One set of theories (Trope and Liberman 2000) suggests that a perceptual mechanism underlies these findings. Specifically, these authors propose that people have a tendency to focus on the “central” aspects when events are far in the future and on more peripheral aspects when events are closer. Since a central aspect of negative events is, by definition, their negativity, these events appear more negative in the future than in real-time.

The work by Gilbert et al. (1998) hints at a motivational mechanism underlying the discrepancy between actual and predicted utilities. These authors offer a “psychological immune system” perspective to suggest that once a negative event has occurred, a series of mechanisms are triggered with the objective of ameliorating the negative feelings. These mechanisms work to protect the individual from harmful effects of negative feelings. Because people do not have an intuition about the functioning of the immune system, they expect future negative events to be even more negative than they actually are.

In this research, we advance the past research by examining the relationship between actual and *remembered* (rather than predicted) utilities of negative events. In doing so, we document the moderating role of the self-relevance of the negative event (events are high in self-relevance when they are diagnostic for assessing a relevant aspect of the self, such as one’s ability in math for a math student). Specifically, we find that past negative events portrayed as being more (vs. less) self-relevant are remembered as being less negative than they actually were. Because the functioning of the immune system should be especially appropriate in situations where the negative experience is more (vs. less) self-relevant, this pattern of findings suggests that a motivational mechanism biases memory for past events in a more palatable direction. Results from a second study provided further directional support for the idea that a motivational mechanism underlies the discrepancy between remembered and actual utilities for negative events.

Experiment 1

In order to test this effect of self-relevance on the recollection of negative experiences, we conducted a pilot study (Study 1) with 158 undergraduate students. Each student was randomly assigned to two experimental conditions—low self-relevance and high self-relevance. In both conditions, participants were asked to hold a plastic bag full of ice cubes for 120 seconds. This activity was chosen as a manipulation for two reasons. First it is a non-invasive pain-induction procedure (Chapman, 1976). Second, it is an unambiguously negative experience.

In the high self-relevance condition, participants read a mock article from a medicine journal, right after the ice cube task. This mock article reported high correlations between immune system strength and cognitive performance. The article also reported that the longer an individual can hold a plastic bag full of ice cubes, the stronger the individual’s immune system. In the low self-relevance condition, participants read a mock medicine article, from the same journal, with the exact same story. However, no link was made between the ability to hold ice cubes and the strength of the immune system in this condition. Consistent with these manipulations, the article was thought to be more relevant in the high vs. low relevance conditions ($M_{high\ self-relevance}=5.02$ and $M_{low\ self-relevance}=4.20$, on a 7-point scale, $F(1,156)=11.33$, $p=0.001$).

After the relevance manipulation, participants proceeded with an unrelated filler task for about 7 minutes. Finally, participants were asked to rate how painful the ice cube manipulation was. They did so by marking a point in a straight line, with no markers, anchored by not at all painful and very painful, with somehow painful as the midpoint on this scale. The intensity of remembered pain (our dependent variable) was calculated by measuring the distance to the point that the participant marked on the line-scale from the (left) point of origin of the line.

The ice cube task was remembered as being less painful in the high self-relevance condition than in the low self-relevance condition ($M_{high\ self-relevance}=7.74$ and $M_{low\ self-relevance}=8.89$, on a 15.2 cm scale, $F(1,130)=3.89$, $p=0.05$). These results are consistent with our initial predictions. However, they also impose a series of further questions. First, one may argue that holding a plastic bag full of ice cubes is an unusual task, and one that involves physical, rather than emotional distress. As such, one may wonder whether the effects would be obtained in more cognitive tasks. Experiment 2 was designed with this aspect in mind. We also wished to provide additional evidence that people’s memories of negative events are revised through a motivational mechanism by using the tenets of the mood-as-a-resource (cf. Raghunathan & Trope 2002) hypothesis.

Experiment 2

According to the mood-as-a-resource hypothesis, positive moods act as a buffer against the affective costs of negative (but useful) information, enabling individuals to better cope with such negative information. On the flip side, the theory holds that negative mood decreases the ability to cope with negative information (Raghunathan & Trope, 2002). As such, we predict that, under positive mood, individuals in the high self-relevance condition will not remember the experience as having been less unpleasant than those in the low-self relevance condition. This is because the positive mood would have provided the buffer necessary to cope with the negative event, and, as such, allowed these participants to accurately remember the intensity of the past negative event. By contrast, we expect that individuals in the negative mood condition would continue to revise their memory of the intensity of the past negative event downwards. In this study, 347 undergraduate students were assigned to one of the 2 (low self-relevance, high self-relevance) x 3 (negative mood, neutral mood, positive mood) between-subjects condition.

The negative task consisted of a problem solving exercise, which was borrowed from Raghunathan and Trope (2002). The task consisted of responding to six multiple choice questions that purportedly measured the participants' "Lateral Thinking Ability". After responding to each of the six questions, participants received the same negative feedback (a "below average" score). Subsequent to this, participants in the high self-relevance condition read a paragraph in which they were informed that people with greater lateral thinking ability were better placed in better jobs, perform better at work and earn higher salaries. Participants in the low self-relevance condition were not exposed to this information. Confirming that the manipulation worked, the LTAT was rated more relevant ($M_{high\ self-relevance}=3.71$ and $M_{low\ self-relevance}=3.05$, on a 7-point scale, $F(1,345)=16.56$, $p<0.01$) in the high self-relevance condition.

Following this task, participants' mood was manipulated using a procedure adapted from Trope and Neter (1994). More specifically, participants described, in details, a situation where they had performed either well (positive mood) or bad (negative mood) in an exam. Participants in the neutral mood condition were asked to describe, in details, their daily routine. Confirming that the mood manipulations worked as intended, participants in the positive mood condition reported significantly less negative ($M_{positive\ condition}=2.61$, $M_{neutral\ condition}=3.02$ and $M_{negative\ condition}=4.44$, on a 7-point scale, $F(1,345)=65.10$, $p<0.001$) and more positive moods ($M_{positive\ condition}=5.13$, $M_{neutral\ condition}=4.52$ and $M_{negative\ condition}=2.70$, $F(1,326)=152.16$, $p<0.001$). After the mood manipulation, participants proceeded with a filler task and, finally, reported their memory for the overall unpleasantness of the LTAT experience, using a 12-point scale, anchored in "not unpleasant at all" and "very unpleasant".

Consistent with our predictions, initial analyses point to a two-way interaction between relevance and mood (linear) ($F(1,321)=4.21$, $p=0.04$). Under negative mood, individuals in the high self-relevance condition remembered the experience as being less unpleasant than individuals in the low self-relevance condition. However, consistent with our predictions, the results were reversed under positive mood.

Concluding Remarks

This paper sheds light on the accuracy of remembered utility and its antecedents. More specifically, it clarifies the importance and pervasiveness of motivational mechanisms influencing the memory for negative events. More important, the results of our first study contradict the predictions made by the literature focusing on perceptual mechanisms. This literature predicts that individuals would remember negative, self-relevant, events as being more unpleasant than they actually were.

This relationship between self-relevance and remembered utility is further qualified by an interaction. Specifically, the effect of self-relevance on remembered is moderated by mood valence.

Marketing Leisure Services to Sensation Seekers: The Relationship between Personality and Emotional Response in Novices Using an Artificial Climbing Wall

Stephen R. McDaniel, University of Maryland, USA

Woo-Young Lee, University of Maryland, USA

Abstract

The market related to so-called extreme sports, such as rock climbing and sky diving, has burgeoned since the 1990s. Consumer behavior research has linked the personality trait of sensation seeking (SS) with involvement in the above sports. However, work on participation in risky sports has not thoroughly examined the influence of personality and subsequent emotional response, on behavioral intentions in this context.

The current study investigated the effects of the SS personality trait, along with demographics, on novice artificial wall climbers' ($n=241$) emotional responses (PAD scale: pleasure-arousal-dominance) and related behavioral intentions to climb again. Results suggest participants' emotions (e.g., arousal) and future intentions to climb are both a significant function of personality and gender.

Theoretical Background

The consumption of risky sports has dramatically increased over the past few years (Shoham, Rose, & Kahle, 1998). For instance, participation in artificial climbing walls has grown by roughly 60% in the three-year period from 1999 to 2001, while participation in some classic team sports, such as baseball, dropped by 6% (Flagg, 2005).

Arousal theory suggests that every individual has a characteristic optimum stimulation level (OSL) and this is the foundation of personality (Raju, 1980; Zuckerman, 1988). Based upon the OSL paradigm, Zuckerman (1979) defined sensation seeking as a trait

characterized by “the seeking of varied, novel, complex, and intense situations and experiences and the willingness to take physical, social and financial risks” (1979, p. 10). Furthermore, research findings have indicated high sensation seekers are more likely to participate in risky sports, such as hang-gliding, and rock climbing (e.g., Jack & Ronan, 1999; Zuckerman, 1983).

Hirschman and Holbrook (1982) suggested that consumers’ multi-sensory and emotive aspects of consumption experiences are crucial motivation for leisure and sport activity. Arnold and Price (1993) also argued that seeking emotional arousal drives sport consumers to participation in risky sports. Further, there have been evidences that enduring personality traits play a significant role in organizing transient emotional states (Eysenck & Eysenck, 1985). Although Shoham, Rose, and Kahle (1998) provided support for the notion that the sensation-seeking trait is related to intentions to participate in risky sports, it is important to note that their study did not include the potential additive effects of emotions on behavioral intentions. Moreover, little empirical research has examined emotional experiences provided by risky sport (e.g., post-consumption emotions) and their relationship to OSL traits and behavioral intentions.

The advent of artificial climbing walls has created the possibilities for extreme sports to be marketed to consumers in urban settings. Moreover, it provides a relatively controlled setting, in which to study this form of hedonic consumption. To date, consumer psychology research on extreme sports has not thoroughly examined the potential additive effects of personality and emotion on participation. Therefore, the focus of the present research is to explore the influence of sensation seeking and consumption-related emotions (Pleasure-Arousal-Dominance) on novice (artificial wall) climbers’ behavioral intentions for using the facility again.

The following hypotheses were created, based on the literature dealing with consumption-related emotions and personality in this context:

H₁: Respondents’ climb-related arousal level is a function of age, gender and ImpSS ($\alpha < .05$).

H₂: Respondents’ climb-related level of pleasure is a function of age, gender, ImpSS, arousal and dominance ($\alpha < .05$).

H₃: Respondents’ behavioral intentions for using the artificial climbing wall again are associated with their age, gender, ImpSS, and PAD, after controlling for prior level of climbing experience ($\alpha < .05$).

Research Methods

Data for this study were collected at the artificial climbing wall facility of a large university in the eastern United States, over a several week period, during “Beginner’s Night.” Novice climbers (n=241) 18 years of age and older were chosen for this study, in an effort to examine how their initial experiences with this activity, along with their OSL, might influence their future usage of the facility (cf., Shoham et al., 1998). In an effort to gauge their experience and expertise (cf. Shoham et al., 1998; Holbrook, Chestnut & Oliva, 1984), respondents were asked to rate their level of climbing experience on a scale from one (inexperienced) to five (experienced). Based on responses to this question, 55 of the 296 climbers queried were excluded from the final analyses as they rated their experience levels higher than two.

Respondents’ Impulsive Sensation Seeking (Zuckerman, 1991) and demographics (e.g., age, gender) were also reported before they ascended the artificial climbing wall. Immediately upon completing their climbs, participants filled out self-reports of their emotional response to their consumption experience, by responding to an abbreviated version of the PAD (Holbrook et al., 1984) and multi-item scaled estimates of their future intentions to use the wall again (at both similar and more difficult grades).

Results

The sample was comprised of 55.6% males (n=131) and 44.4% females (n=110), with a mean age of 26.2 years old (S.D.=10.19). Reliabilities for ImpSS, PAD, and behavioral intentions were .82, .73, and .89 respectively. To check the construct validity of ImpSS, a two-way (age x gender) analysis of variance (ANOVA) procedure was used. The results showed significance differences by both age ($F=7.36, p < 0.05$) and gender ($F=4.64, p < 0.05$), which is in line with research on the above psychobiological trait (Zuckerman, 1994).

The results of multivariate linear regression analysis provided partial support for H₁, as gender and ImpSS significantly predicted post-climb levels of arousal (df=3/238, $F=7.45, p < .001, R^2=.10$). The directionality of the beta coefficient for gender indicated that females reported higher levels of the above emotion.

The second hypothesis also received partial support. Regression results indicated that respondents’ gender (being female), post-climb levels of arousal and dominance were significant predictors of post-climb levels of pleasure (df=5/236, $F=14.99, p < .001$). The model explained 25% of the adjusted variance in the dependent variable.

Multivariate linear regression results for intentions to use the wall again at a similar degree of difficulty (H₃) showed that and post-climb levels of Arousal and Pleasure were significant (df=7/234, $F=10.76, p < .001$). The model accounted for 25% of the adjusted variance explained. Results for predicting intentions to climb at steeper angles showed that age, gender, ImpSS, climbing experience, and post-climb levels of Pleasure and Dominance were significant (df=7/234, $F=17.32, p < .001$). This model explained 35% of the variance in behavioral intentions.

Discussion

Findings suggest that climb-related emotions and future intentions are significant functions of personality (i.e., sensation seeking) and demographic factors. Furthermore, the more participants experience post-climb arousal and pleasure, the more they are likely to use the wall again. The results of the empirical research support the notion that personality and consumption-related emotions are significant predictors of hedonic consumption (e.g., participation in risky sport) (Holbrook et al., 1984). In addition, this is the first known work to examine the relationship between personality and emotional responses in participation in so-called extreme sports. The research also contributes to the literature for sport marketers in that the use of personality variables might prove useful as a segmentation tool in marketing facilities, like climbing walls, to sensation seekers (Shoham et al., 1998).

Lost in Translation: Consumers Difficulty in Estimating Expiration Time with Redemption Caps

Richard Hanna, Boston College, USA
 Scott Swain, Boston University, USA
 S. Adam Brasel, Boston College, USA

Extended Abstract

More and more, firms are using redemption caps as a form of promotional restriction. For example, GM ran a promotion tied in with a television show (the Apprentice) for their new vehicle, the Solstice. The offer was available for the first 1000 callers. The promotion cap was reached within hours of the show ending, yet a large number of consumers called for days after the promotion expired. In another example, a regional health club franchise ran a promotion for membership upgrade good for the first 100 responses. The promotion cap ran out on the second day, yet many members were still trying to redeem the offer weeks later. In this research, we examine how consumers process promotions that have redemption caps.

Prior research on promotional restrictions has focused on concrete and well-defined time limits (e.g., Raghubir, Inman, and Grande 2004). The findings have been mixed. Some studies find that consumers perceive short promotion durations as inconvenient, thus lowering their purchase intentions (Sinha, Chandran, and Srinivasan 1999), while other studies find that shorter durations can increase purchase intentions by increasing perceptions of deal scarcity (Inman, Peter, and Raghubir 1997) or by heightening the anticipated regret associated with not acting (Inman and McAlister 1994; Simonson 1992).

We propose that consumers evaluate redemption cap promotions, in part, by estimating the reach, response rate, and duration of the promotion. The reach of the promotion refers to the number of other consumers exposed to the promotion and the response rate refers to the percentage of exposed consumers who will act on the promotion. We argue that consumers' estimates of these quantities are anchored off of the redemption cap itself. Thus, the larger the redemption capsize, the larger the estimates of reach, response rate, and duration. However, since the actual promotion duration will be negatively related to the reach and response rate of the promotion, consumers may tend to overestimate how much time they have to redeem. If this reasoning holds, we would expect that providing consumers with the actual reach of a promotion should diminish the anchoring effect.

We conducted an exploratory study using a 3 x 2 between-subjects design with redemption cap size (40, 400, and 4000) and promotion reach (known vs. unknown) as between-subjects factors. Participants were 145 undergraduate business students and were randomly assigned to one of the six experimental conditions. Prior to receiving the stimulus promotions, the participants were provided with a brief scenario asking them to imagine that they had just received a coupon via email from MostlyPosters.com. The stimulus promotions were for a 30% discount off any poster, and contained one of the three redemption cap size treatments. Participants in the known market size conditions were told that the promotion was only sent to the 9000 undergraduate students of their university. Those in the unknown market size condition were not provided with any information regarding the reach of the promotion. Participants evaluated the coupon and were asked a series of questions regarding purchase intent, deal evaluation, promotion reach, and redemption timing.

When the promotional reach was unknown, participants' estimates of promotional reach (9500, 114000, 128000), response rate (.147, .248, .300), and duration (51.7 hours, 84.3 hours, 161.5 hours) all increased with redemption cap size, respectively. We also scaled the participants' self-reported redemption timing estimates (e.g., the percent that said they would redeem in 1 minute, the percent that said they would redeem in 1 hour, etc.) to their estimates of promotional reach and response rates. This allowed us to determine actual expiration times in each condition by cumulating the number of responses. We found that in all three redemption cap size conditions, the actual coupon would expire in less than five minutes. Given that the participants' estimates of response rates may be overestimated, we ran the same

analysis using only the proportion of subjects that stated they would definitely redeem this coupon (8.2%). We found that the 40 cap promotion would still expire in less than 5 minutes, but that the 400 and 4000 cap promotions would expire in approximately one hour. The results are not significantly different when even more conservative estimates of response rates are used. Thus, we conclude that at all levels of redemption cap size, participants grossly overestimated the duration of the promotion.

By comparison, when the promotional reach was known, participants' estimates of response rates (.116, .247, .309) and duration (14.7, 25.6, 157.9) increased with redemption cap size, respectively. Although the estimated duration increases with redemption cap size, the actual estimates are significantly smaller in this condition than for the unknown promotional reach conditions. However, the estimated response rates for the known and unknown promotional reach conditions differ only slightly with the largest difference between the estimates for a redemption cap size of 40. Thus, providing participants with the actual promotional reach removed the anchoring effects from estimates of promotional reach but not from estimates response rates and duration. Computing the actual redemption time as before, we again find that the redemption cap of 40 would expire in less than 5 minutes. However, the redemption cap of 400 would take 1.5 hours to expire and the redemption cap of 4000 would only be half used after two months. Again if we use a more conservative estimate of response rate (8.2%), the redemption cap of 40 would still expire in less than 5 minutes, while redemption caps of 400 and 4000 would take 10 hours and over 2 months to expire, respectively. Thus, while the estimated expiration time is overestimated for the redemption caps of 40 and 400 (14.7 hours vs. <5 minutes and 25.6 hours vs. 10 hours, respectively), the expiration time for the redemption of 4000 is grossly underestimated (157.9 hours vs. more than 1440 hours). Additionally, subjects reported greater confidence in their ability to redeem the coupon as the redemption cap increased, regardless of whether the promotional reach was known or unknown.

It would appear that estimates of duration are disconnected from estimates of reach and response rates. In the examples mentioned earlier, Solstice sold out within hours of the show ending. Many more continued to call for days after the promotion expired. Similarly for the health club; this promotion ran out in the second day yet consumers tried to redeem the offer weeks later. However, questions still remain. We intend to extend this research to examine the impact of risk aversion on estimation. Additionally, we will investigate perceptions of fairness, scarcity, and blame.

The Role of Expectations in Set-Size Evaluations

Richard Hanna, Boston College, USA
 Scott Swain, Boston University, USA
 S. Adam Brasel, Boston College, USA

Extended Abstract

There has been a surge of research in recent years re-examining the effects of choice set size and alternative proliferation on a number of issues from choice confidence to perceived responsibility. Most of this research uses objectively limited and overwhelming sets in a direct manipulation design. But what effect do expectations of set size have on set-size perceptions? While research has begun to examine how set sizes affect expectations (Diehl and Poynor 2005), there remains a need for research exploring how expectations can affect judgments of set size (Van Raaj 1991).

It is proposed that set-size expectations create a sort of anchor. If one expects a limited set, the expectation is bounded by two, the smallest set possible. If one expects an extensive set, the expectation is bounded by an estimate of the total number of products available in that category, usually a quite high number. When the actual set size is truly limited or very extensive, reality should win out over expectations and the set should be perceived accurately as the set size should be near one of these perceptual boundaries and thus easy to put into a particular perspective. However, when the actual set size is of a moderate nature, the set will appear less like the expectation being held. So will the moderate set be assimilated or contrasted with expectations (Biernat 2005)? Prior work has suggested a general trend towards contrast instead of assimilation, but this was conducted in a more hedonic setting and did not explore set sizes (Zellner, Stickhouser, Tornow 2004).

To explore this issue, an online study was conducted using choice sets of digital cameras at a fictitious online electronics store. 106 undergraduates at a large east-coast private university participated in the experiment. A 2*3 (expectations by set size) fully-crossed factorial design was conducted. Before exposure to the online choice set of digital cameras, participants were randomly assigned to an expectation condition and read a page telling them "Please note, the product selection at this online store is known to be very limited (extensive), and you will probably have to pick from only a few (a very large number) of alternatives." Then participants were exposed to a set of digital cameras that was very limited at four alternatives, moderate at twelve alternatives, or very extensive at twenty-four

alternatives. These set sizes had been extensively pre-tested and shown to be considered too small and quite limiting (four), an average or moderate number of products in this category (twelve), or far too large and overwhelming (twenty-four). After making their selection, participants were asked to record the degree to which they found the set restrictive, overwhelming, difficult to choose from, incomplete, and the likelihood they selected a non-optimal choice (all multi-item Likert scale measures collapsed into constructs). The data was then analyzed by way of a multivariate ANOVA, and planned-contrast t-tests for specific comparisons.

First, there was a main effect for expectations on all outcome variables ($F > 8$ for all, $p < .01$ for all). Planned-contrast t-tests reveal that participants who expected an extensive set viewed choice sets in general as more incomplete ($p < .01$) and restrictive ($p < .05$), less overwhelming ($p < .01$), and felt they were less likely to pick a suboptimal choice ($p < .05$) than participants who expected a sparse set. There was also a significant expectations by set-size interaction effect in the ANOVA ($F > 5$ for all, $p < .01$ for all). Planned-contrast t-tests here reveal that the effect of expectations is actually largely confined to the moderate set size. When the actual set-size is limited or extensive, no differences between extensive and limited expectations participants on the outcome variables is significant above .05. When the actual set-size is moderate, however, all outcome variables are significant.

Consistent with our propositions, the pattern of results in this moderate-set conditions suggests that the actual set size is viewed in contrast to expectations, rather than assimilated to expectations (Fiske & Taylor 1984). When participants were expecting a limited set, they view the moderate set as having reduced incompleteness and reduced choice restriction, but elevated error likelihood and increased perceptions of being overwhelmed. In short, the results looked not significantly different from when the limited expectations participants viewed the actually extensive set (all $p > .05$), but significantly different on all variables from the actually limited set (all $p < .02$). A similar pattern emerges for the extensive set expectations participant. When expecting an extensive set, participants view the moderate set as very restricted and incomplete, but not overwhelming with little choice error. In short, they view the moderate set as not significantly different from the actually limited set (all $p > .05$), but significantly different from the actually extensive set (all $p < .01$).

In summary, when participants viewed a truly limited or extensive set, reality trumped any expectation-based effects on size judgments. But when the choice set was of moderate size, participants expecting either a limited or extensive set exhibited a contrast effect, where extensive expectations made the moderate set appear limited while limited expectations made the moderate set appear extensive. This not only has implications for retailers and consumers in how they react to common moderate set sizes, research suggests that the act of expectation disconfirmation itself can lead to lowered satisfaction regardless of the positivity of the outcome (Bennet, Ordonez & Gilliland 2003).

Investigating the Additive Effects of Demographics, Lifestyles, and Personality on Physical Activity Levels in Adult Consumers

Stephen R. McDaniel, University of Maryland, USA

Dae Hee Kwak, University of Maryland, USA

Extended Abstract

Obesity and its related health problems are a growing concern in the U.S. and abroad, which has prompted a call for transformative consumer research in this area (Mick, 2006). For example, it was recently reported that nearly 40% of adult consumers in America are sedentary and 65% of adults are overweight (body mass index $\geq 25.0 \text{ kg/m}^2$) (National Center for Health Statistics, 2005). Given that engaging in regular vigorous physical activity is not only beneficial for the general wellbeing of consumers but also important in terms of the related financial cost to government and businesses, it is imperative for health marketing professionals to understand various determinants of physical activity levels. The objective of the current study is to investigate the additive effects of demographics (e.g., age, gender, and ethnicity) lifestyle (e.g., TV watching, smoking, and drinking) and personality (e.g., sensation seeking) on physical activity levels, which can have implications to effective segmentation and targeting of health communications about the latter.

A growing body of evidence suggests that age and gender are the most consistent determinants of physical activity levels in adults (Caspersen, Pereira, & Curran, 2000; Ingram, 2000; Nelson, Gordon-Larsen, Adair, & Popkin, 2005; Sallis, 2000). Studies have found males tend to exercise more vigorously than females and overall exercise levels decline with age. Age-related decline in exercise levels has been well supported in non-human studies as well, indicating that age-related decline has a strong biological basis (Ingram, 2000; Sallis, 2000). In addition to age and gender, ethnicity has also found to be related with exercise levels in adults. Caucasians are reported to be more physically active than non-Caucasians (Caspersen & Merritt, 1995). Lifestyles characterized by certain types of consumption

(i.e., drinking, smoking and excessive TV viewing) can adversely affect physical activity levels as well (Sale, Guppy, & El-Sayed, 2000; Tucker, 1986; Tucker & Bagwell, 1991). The current study builds upon the literature which has found the above demographic and lifestyle variables to impact physical activity levels. In addition, the biologically-based personality trait, sensation seeking (Zuckerman, 1994), is also examined given its negative relationship to age and its use as a segmentation tool in other health marketing research (Palmgreen, Lorch, Donohew, Harrington, D'Silva, & Helm, 1995).

A telephone survey methodology was employed here, to investigate the relationship between adult respondents' demographics, lifestyles and personalities and the reported physical activity levels (n=790). A stratified random sampling technique was used to generate a list of names and telephone numbers for adults 18 years of age and older, from two top 25 DMAs in the eastern United States. Demographic data were collected on respondents' age, gender, and race (Caucasian/minorities). Respondents were also questioned about certain consumption behaviors, including the amount of time they spent watching TV (average hours of daily viewing and average days viewed) and health related behaviors such as smoking (smoking/non-smoking) and drinking (drinking/non-drinking). The personality trait of sensation seeking was measured using the 19-item Impulsive Sensation-Seeking scale (ImpSS, Zuckerman, 1994; 1996). Finally, respondents' level of physical activity was gauged by asking them how many days during the past week that they engaged in vigorous physical activity that lasted 20 minutes or more (0 to two days per week/three or more days per week), based on the recommended criterion suggested by the Healthy People 2000 (U.S. Public Health Service, 1991).

Caucasians made up 69% of the sample, which had a mean age of 42.5. Slightly over half of the study participants were female (56%). Logistic regression analyses were used here and findings are as follows: Males were significantly more likely than female to exercise three or more days per week. Caucasians were significantly more likely than non-Caucasians to report that they exercise three or more days per week. Non-smokers were significantly more likely to report exercising three or more days per week. Heavy TV viewers were significantly less likely to report exercising three or more days per wk, compare to those who are light viewers. Lastly, high sensation seekers were significantly more likely to report exercise three or more days per week than low sensation seekers.

In line with previous studies, results suggest that demographic variables (i.e., gender, race), lifestyle (i.e., smoking, TV watching), and personality (i.e., sensation seeking) were significantly related to self-reported levels of physical activity among adults. For high sensation-seekers, they were more likely to involve in regular physical activity than low sensation-seekers. This finding suggests that a biological-based trait such as sensation seeking might account for the age-related decline trends in physical activity levels. Moreover, this biosocial phenomenon is in line with what Sallis (2000) and Ingram (2000) found with physical activity declines in non-human species. This suggests that more research in this area should be conducted looking at the relationship between optimum stimulation level (OSL) constructs like ImpSS, and physical activity. The present study also provides some practical implications as well. Along with demographic segmentation, targeting consumers via psychographic and lifestyle patterns can advance the goals of public health communication (Albrecht & Bryant, 1996; Maibach, Maxfield, Ladin, & Slater, 1996). Thus, studies in this area might help answer the call for transformative consumer behavior research in this context (Mick, 2006).

The Effects of Recurrent Mortality Salience Mediated by the Availability Heuristic on Risky Behavior and Subjective Probability

Evidence from AIDS Related Cognition and Sexual Behavior of Indian Truckers

Joseph Thomas Paniculagara, University of Central Florida, USA

Extended Abstract

Cognitions related to HIV/ AIDS as well as sexual behaviors of Indian truckers have been the targets of attention from social marketers, as well as the foci of research by academic researchers yielding intriguing results. For example, it was found that only 14% of Indian truckers were aware that using condoms reduces their chances of contracting HIV/ AIDS, yet 79% of them were aware that AIDS is incurable. These and other findings suggest that Indian truckers demonstrate better knowledge of HIV/ AIDS in general than of the specific knowledge that condoms are effective in preventing the spread of the disease. In addition, 75% of Indian truckers believed that the women they had casual sex with could have HIV/ AIDS, but 92% of them believed that there was "no chance" that they would contract the disease in their lifetimes (Bryan, Fisher and Benziger, 2001). It can be assumed that persuasive messages targeted at Indian truckers would urge them to use condoms and such messages would be placed in media patronized by them. Why then, do Indian truckers exhibit low awareness of the protection against HIV afforded by condoms, demonstrate low usage of condoms and believe that they are immune to HIV despite their beliefs that their partners are highly susceptible to HIV? The answer may lie in the high rate of fatalities among Indian truckers on the highways.

The highway network in India is comparatively unsafe with the majority of accidents involving dilapidated trucks driven by truckers who are often either intoxicated or under the influence of cheap narcotics. Major accidents result in wrecks of trucks that are pushed to the side of the highway where they are visible to other truckers (Mohan, 2004). As a result, death due to a highway accident is made much more salient to Indian truckers than that due to diseases such as HIV/ AIDS. In general, death as a result of an accident is highly visible as opposed to death as a result of disease-which claims one victim at a time in a private space.

People who are non-professional drivers judge accidents to cause as many deaths as disease, although disease causes 16 times as many deaths as accidents (Slovic, Fischhoff and Lichtenstein, 1982). This effect might be exacerbated for Indian truckers due to the visibility of instances of fatalities resulting from truck accidents, which would probably increase truckers' subjective probability of death due to accident, owing to the operation of the availability heuristic (Tversky and Kahneman, 1973). Support theory (Tversky and Koehler, 1994) describes subjective probability as a relation between the judgment of the support for a focal hypothesis (description of an event) and that of the alternative hypothesis (description of the other event). Refinements of support theory suggest that if truckers judge the focal hypothesis of death due to accident as highly probable, it would result in discounting of the alternative hypothesis of death due to causes other than accident, as a result of the enhancement effect (Koehler, Brenner and Tversky, 1997). Unpacking the alternate hypothesis into components such as death due to HIV/ AIDS would result in implicit subadditivity. Implicit subadditivity results when the aggregate of the subjective probabilities of the components of the alternate hypothesis exceeds that of the alternate hypothesis. However, a reminder of the typicality of the behavior for the trucker population may result in implicit superadditivity for oneself, since the individual trucker would like to distance himself from the delinquent behavior and implicit subadditivity typical of the trucker population (Sloman et al, 2004) based on a finding related to terror management theory (Arndt et al, 2002).

It is likely that seeing wrecks of trucks by the side of the highway would induce mortality salience in Indian truckers. It would also seem plausible that seeing a number of accidents and wrecks of trucks would result in recurrent mortality salience. Mortality salience effects have been explained by terror management theory. According to terror management theory (Greenberg, Pyszczynski and Solomon, 1986), self-esteem serves to protect individuals from anxiety under conditions that remind them of their mortality. Individuals seek to deny their mortality by embracing a cultural worldview and deriving self-esteem from living up to its values. When mortality salience occurs, individuals seek to defend their cultural worldview as well as to increase their self-esteem. An example of the former effect would be resistance to persuasion that carries messages counter to their worldview (Shehryar and Hunt, 2005) especially if the source of such messages was seen to be a member of an out-group (Harmon-Jones et al, 1997). The latter effect could be seen in efforts to reinforce self-esteem in domains that are held to be most relevant to the level of self-esteem of individuals (Goldenberg et al, 2000; Ferraro, Shiv and Bettman, 2005).

Due to the perceived deficiency in self-esteem as a result of mortality salience, it is likely that Indian truckers perceive a loss in self-esteem relative to their subjective reference points. As a result, Indian truckers might be exhibiting risk-seeking behavior due to their perception of relative loss as described in prospect theory (Kahneman and Tversky, 1979). Risky driving behavior has been induced as a result of mortality salience in those for whom driving is important to their self-esteem (Ben-Ari, Florian and Mikulincer, 1999). Similarly, risk-seeking hedonic behavior of unprotected casual sex would probably result due to recurrent mortality salience. Further, it is suggested that release from recurrent mortality salience would serve to boost self-esteem resulting in risk-averse behavior as described in prospect theory.

It is expected that this paper will contribute to social marketing. Apart from Indian truckers, there are myriad other groups who labor under recurrent mortality salience such as the military on active service and even the general population living under threat. It might be seen that the military on active service display a greater frequency of non-combat injuries and fatalities. An understanding of the attitudes toward risk and risky behavior will enable description of risk behavior and cognition under recurrent mortality salience.

The Director's Cut: Exploring Cultural Implications in HIV/AIDS Communication from the Producer's Perspective

Andrea D. Scott, Pepperdine University, USA

Stacy-Ann A. Williams-Smith, University of the West Indies, Jamaica

Abstract

Negotiating the challenges of communicating HIV/AIDS messages, which include stigma, conflicting cultural ideals, and politically-charged resource constraints, requires a systematic stream of research. Using a series of phenomenological interviews in our exploration of the main constituencies in successful message development and delivery, namely the creative producers, the message developers, and the target audience, we acknowledge the contributions of Cultural Studies theory (Hall 1993) and to a lesser extent the Political Economy of Media (Schiller 1995).

Summary

According to UNAIDS, in 2003 approximately 38 million people globally were estimated to be living with HIV and nearly 3 million died from the disease (www.unaids.org). In fact 95% of the people living with HIV/AIDS are in the developing world with the African, Caribbean and Pacific (ACP) countries suffering the most. Although awareness and knowledge of AIDS levels are steadily increasing among targeted populations, the spread of AIDS in these countries continues to rise at alarming rates.

In response to repeated calls for transformative research and to the moral mandate for a compassionate response to the world's AIDS crisis, this paper—on an admittedly micro level—investigates the impact of culture and government in mediated communications about HIV/AIDS awareness and prevention in the Caribbean (Rothschild and Anderson 1998; Nowak and Siska 1995; Hill 1993; Mody 1991). Negotiating the challenges of this sensitive topic, which include stigma, conflicting cultural ideals, and politically-charged resource constraints, requires a systematic stream of research. Using a series of phenomenological interviews in our exploration of the main constituencies in successful message development and delivery, namely the creative producers, the message developers, and the target audience, we acknowledge the contributions of Cultural Studies theory (Hall 1993) and to a lesser extent the Political Economy of Media (Schiller 1995). This study focuses on the perspective of the producer of the messages (i.e., creative personnel).

Conceptualization

Cultural Studies theory's most applicable assertion in the context of this study is its challenge to the linear "sender-message-receiver" pattern of traditional communication theory. According to Hall (1993), there are several complex relationships within each step of the communication process and they are often iterative and vulnerable to what is termed that "oppositional readings" where the intended

meaning of the message is lost or misinterpreted. As a result the audience is empowered and can now be seen as active participants in the communication process. This concept of audience participation is not new to the marketing literature and has been addressed in terms of message comprehension (Burnkrant and Unnava 1995; Greenwald and Leavitt 1984), ascribing meaning (McQuarrie and Mick 1992, Mittal 2002; Thompson, Pollio and Locander 1994), and experiential consumption (Arnould and Price 1993; Bitner 1992) among other concepts.

Additionally, Cultural Studies theory holds that in the course of communication another series of relationships determine what is produced and how it is produced. It is this aspect of the process that is the focus of this particular endeavor—the relationship between the message producers (i.e., advertising agencies and creative shops) and the message developers (i.e., government and community-based organizations). The cultural background of the message designers themselves is significant as the collective experiences of the message designer may help or hurt the message production process. For example, a message producer who belongs to the same cultural background of the audience “...may be more knowledgeable about their problems, but may share their caste and class prejudices...” (Mody 1991, 105). Those prejudices may very well be the ones which contributed to adverse conditions for the audience—conditions which the communication campaign may be designed to reverse or eradicate (e.g., HIV/AIDS stigma).

As Johar, Holbrook and Stern (2001) have duly noted, creativity is appreciated in the marketing discipline, but rarely studied. Much of the literature surrounding the creative aspect of advertising revolves around consumers’ response to various forms (Stewart and Koslow 1989; McQuarrie and Mick 1992; Clow, Roy, and Hershey 2001), the interpersonal relationships among agency personnel and between client and agency (Thompson and Haytko 1997), or the motivational perspectives of a career in art direction or copywriting (Kover, James, and Sonner 1997; Young 2000). The call for scholars and practitioners to think more about the “creative spark, which drives much of advertising” remains virtually unanswered (Zinkham 1995). Consequently, it behooves marketers to gain a richer understanding of the lived experience of the creative personnel who bring these messages to fulfillment.

Method

The proposed study will take place in May 2006 and is in response to an initial round of research by a native graduate student, which dealt with three key issues: 1) assessing the baseline knowledge of key HIV/AIDS issues among the producers and recipients of the message, 2) determining the degree of experiential overlap between these two groups, and 3) gauging the effectiveness of message communication. It considered three main constituencies: 1) the producers and developers of the work (via 11 interviews), 2) the target audience (via a five-person focus group), and 3) the crafted messages themselves (via content analysis of 17 posters). No formal hypotheses were submitted. All activity took place between January and June 2003; however the communication artifacts were used island-wide between 1999 and 2003.

The results showed there was acceptable baseline knowledge of key HIV/AIDS issues among the producers and selected recipients of the message; however the degree of experiential overlap between these two groups was ambiguous as target audience participation was decidedly problematic. In a similar vein, the lack of a structured research instrument made the task of evaluating messages effectiveness difficult to ascertain. Before developing a subsequent round of research to address the gaps in the preliminary study and collect more statistically compelling data, the study has been reduced into smaller segments, the first being conversations with the producers.

Participants will be asked to describe the events that led up to involvement with this project per the guidelines put forth in Thompson, Locander, and Pollio (1990) for phenomenological interviewing. Interviews will be conversational in nature with the interviewee leading the exchange (both researchers will be present whenever feasible and appropriate). Rather than include explicit inquiry about the professional relationship with non-profits and public sector organizations or the impact of cultural heritage on their work, those lessons are expected to emerge from the data. The interview transcripts will be revisited using a deliberately iterative interpretative approach (Thompson 1997).

Current research objectives revolve around gaining a richer understanding of the following areas of inquiry 1) each participant’s personal journey in their career, 2) the knowledge of key HIV/AIDS issues among the producers, and 3) the process of negotiating form and content of the HIV/AIDS production project. This should help to develop a more theoretical understanding of the process used in message production and uncover any latent patterns in both the content and construction of the mediated communication.

Two frameworks will likely guide the retrieval of meaning from these narrative accounts. The first is the Social Adaptation of Thompson’s Hermeneutic Framework, which includes the following constructs: 1) perception of benefits; 2) consumer resistance; 3) countervailing consequences; and 4) countervailing socio-cultural forces (Rothschild and Andreasen 1998). The second is the UNAIDS/Penn State framework, which affirms five inter-related, behavior-shaping contextual domains—government policy, socio-economic status, culture, gender relations and spirituality (Airhihenbuwa, Bunmi, and Obregon 1999).

Findings/Implications

Preliminary findings from the first study suggest a possible relationship between “consumer resistance” (from the Thompson framework) and “gender relations” (from UNAIDS/Penn State framework), which may help explain, for example, why messages that feature a woman purchasing condoms lack credibility within the Caribbean context. Other issues such as the use of Jamaican patois (a national dialect of broken English), the challenge to solicit the insight of political influencers without obligation to physically represent them in posters, and the need to honor both legislative and cultural restrictions on the type of information shared (e.g., fear appeals or heavily rational, numbers-driven tactics are discouraged and likely will not be funded), exemplify the intersection of theory and practice within a social marketing context and offer tactical routes to improving message effectiveness. Nevertheless, it is anticipated that a richer understanding of the producer’s perspective will further illuminate the meaning of the preliminary findings.

SPECIAL SESSION SUMMARY

Understanding Reactions To Assortments: A Process Perspective

Kristin Diehl, University of Southern California, USA

SESSION OVERVIEW

More than 20 years of consumer research have demonstrated how changes in the assortment affect variety perceptions, satisfaction and choice. This session adds to our understanding of the psychological processes leading to these outcomes by revealing: 1) How variations in the structure and organization of assortments change psychological processes, and, 2) How these decision processes are linked to important outcomes such as assortment perceptions and WTP. Specifically, the papers focus on two mechanisms that underlie different reactions to assortments: similarity vs. dissimilarity processing and consumers' beliefs regarding their ability to preference match.

Poynor and Diehl investigate how different types of externally provided category structures (taxonomic or goal-based) impact the decision process. They demonstrate that taxonomic groupings cause consumers to focus on dissimilarities among items, while goal-based groupings increase the focus on similarities. As a result, participants selecting from goal-based groupings perceive the items in the assortment to be more similar and choose less expensive items from goal-based than from taxonomic sets.

Schlusser and White examine how removing items from a choice set affects opinions of the remaining items. Contrary to predictions based on reactance theory and halo effects, they show that consumers' reactions to available items depend on the reasons provided for the unavailability and on whether assortment characteristics highlight the similarities among items within the assortment. If similarities are focal, judgments of the remaining items are more favorable when unavailable items were sold out rather than discontinued, but the opposite is true when dissimilarities are focal. Further, choice process satisfaction mediates and individual differences in market knowledge moderates these effects.

Griffin and Broniarczyk investigate the effect of alignable versus nonalignable options on search effort and satisfaction. Nonalignable compared to alignable options trigger greater search. Initially such heightened search effort increases satisfaction because consumers feel they are more likely to find a good preference match. However, further search among nonalignable options makes necessary trade-offs salient, decreasing perceptions of preference match and reducing satisfaction.

These three papers focus on 1) similarity vs. dissimilarity processing and 2) consumers beliefs about preference match as drivers of consumers' reactions to assortments. Their findings demonstrate that 1) Similarity vs. dissimilarity-based processing alters consumers' reactions to assortments. Engaging in greater dissimilarity testing decreases perceived substitutability among items which affects perceptions of the assortment (P&D), leads to higher WTP (P&D) but also to more negative reactions to stock-outs (S&W). 2) Further, consumers' beliefs about their ability to preference match also affect reactions to assortments. How consumers react to stock-outs is affected by whether they believe they will be able to choose advantageously from the remaining items (S&W). In addition, consumers' beliefs about their ability to preference match determine whether an increase in search effort increases or decreases satisfaction (G& B).

These three papers investigate consumers' reactions to assortments from very different perspectives; however, their findings

converge on a few common psychological mechanisms that help improve our understanding of the psychological processes that drive substantive outcome reactions to assortment differences.

EXTENDED ABSTRACTS

“The Psychology of Category Design: The Impact of Goal-Derived Structures on Consumer Information Processing and Choice”

Cait Poynor, University of South Carolina

Kristin Diehl, University of Southern California

The enormous variety available in retail settings has alternately fascinated and frustrated both consumers and researchers (e.g. Iyengar and Lepper 2000, Schwartz 2004). Recent trends in retailing suggest that major retailers hope to manage such large assortments through reorganization rather than reduction of their stock (Anderson 2005). Our research investigates how different types of externally-provided categories (taxonomic or goal-derived) impact choice by prompting the consumer to adopt different information processing strategies. Particularly, we compare the information processing strategies adopted in taxonomic groupings, which are organized around shared attributes of the alternatives, to the strategies adopted in “goal-derived categories” (Medin and Barsalou 1981) which group items sharing benefits or occasions of use (Desai and Ratneshwar 2003). In one pilot study and two lab experiments, implicit and explicit measures provide evidence for the proposed shift in processing strategies, as well as effects on variety perceptions and prices paid.

Since taxonomic groups highlight structural similarities among options, we propose that consumers adopt an information processing strategy which facilitates discrimination among seemingly similar alternatives. Thus, we expect that consumers will accentuate existing differences and, in line with the classic model of contrast (Mussweiler 2003, Schwartz and Tversky 1980) will create both local and global contrast among these items when options are organized in taxonomic groups.

In goal-based groups, however, consumers face a different processing task: Goal-grouped items do not highlight structural similarities and may even be characterized by attribute dissimilarities. We expect that consumers will first determine a basis for comparison in goal-based groups, by engaging in similarity testing. That is, they will ask themselves, “In what way are these alternatives similar, and therefore, on what basis can I make my decision?” (Johnson 1989). With the identification of each additional basis of comparison, alternatives should become progressively *assimilated* to one another (Mussweiler 2003). As such, even if the underlying assortment from which choices are made is identical, inter-item as well as overall assortment similarity should be perceived as higher in goal-based groups (assimilation) but lower in taxonomic (contrast) groupings.

Prior research also demonstrates that as perceptions of similarity and product parity increase, individuals are less willing to pay higher prices. Therefore, we predict that as a consequence of the assimilative processing in goal-derived sets, participants will pay lower prices than will participants who make choices from taxonomic sets.

Pilot study In a pilot study, undergraduates imagined that they had a job interview and were shopping for a new pair of shoes. We then directed them to an actual online shoe retailer, Zappos.com, where they browsed the shoe selection organized either in terms of taxonomic identifiers (e.g., high heels, flats, sandals) or occasions of use (e.g., “The Office”, “Rodeo Drive”, “Country Club”). After browsing as long as they wished, participants chose their first and second choice of shoes. They then rated the variety of the website’s overall assortment and the similarity between their first and second choice shoes. Controlling for age and gender, participants who made their selections from the taxonomically-organized site reported significantly higher variety in the set as a whole, as well as less similarity between their first and second choice shoes, than did those who browsed the goal-derived sets. Since this pilot was undertaken in an ecologically valid yet noisy environment, where little control could be exerted over the actual similarities of products viewed, study 1 further investigates our predictions in a very controlled setting.

Study 1 In this study, students chose teas from a simulated online retailer. Participants were randomly assigned to one of three between-subjects conditions. Teas were organized either by taxonomic characteristics (Black, Green, Mint, and Rooibos), by the goal they help achieve (Energy-Boost, Stress-Relief, Cardio-Health, and Weight-Loss), or, for the control condition, grouped randomly into four pages (Page 1, Page 2, Page 3, Page 4). Importantly, *the same 32 teas* appeared in all conditions and were available to all participants.

After reading basic information about tea, participants browsed the site, selected at least 4 teas which interested them for consideration, and identified a first and second choice from their consideration set. They then rated the perceived similarity of items in the assortment and the perceived similarity of their first and second choice. We used two implicit measures to investigate the underlying decision processes. As such, participants were presented with their consideration set and asked to sort the set into two groups as they saw fit. Assimilation processes triggered by goal-derived groupings should create closer associations among options resulting in greater psychological cohesion. When assortment are organized along goal-derived categories it should therefore take longer to sort items and the proportion of items sorted into the two groups should deviate from a 50-50 split.

As predicted, assimilation processes in goal-derived groups are found both relative to taxonomically-organized sets and relative to the control group of randomly-organized alternatives. Participants in the goal-derived condition reported greater similarity between their first and second choice items as well as among all the items in the assortment, compared to participants who chose from taxonomic organizations and participants who chose from the randomly-ordered sets. In addition, analyses of the time taken to sort the individuals’ consideration sets and the balance of the sorted groups suggest that choosing from goal-derived sets results in higher levels of psychological cohesion among alternatives than choosing from taxonomically-grouped sets, supporting the proposed psychological process.

Study 2 Study 2 adapted the basic experimental paradigm used in Study 1, adding a within-subjects covariate trial, prices for each tea and an incentive compatible payment scheme. This adaptation allows us to examine the effect of external categorization on prices paid. In this study, all participants first selected a tea from a randomly-ordered set, providing us with an individual-level willingness-to-pay measure. They were then assigned to either the goal-derived or taxonomic condition. As anticipated, participants choosing from the taxonomic organizations chose options at a signifi-

cantly lower price than participants choosing from the goal-derived sets.

This research demonstrates that different external category structures can generate both theoretically interesting and managerially important effects. We demonstrate that taxonomic and goal-based organizations alter the way in which consumers process information, and thus that differences in category structures impact perceptions of inter-item similarity, change perceptions of assortment variety and prompt consumer to pick lower priced products. Future research may compare these findings to situations where preferences are held more strongly and in particular consider how other types of groupings, such as those based on brands, may impact consumers’ perceptions and choices.

“The Company They Keep: The Influence of Reasons for Option Limitation on Assortment Judgments”

Ann Schlosser, University of Washington

Tiffany White, University of Illinois

Prior research has demonstrated that adding alternatives to existing choice sets can influence judgments of original items in the set (e.g., Huber, Payne and Puto 1982; Simonson 1989). Receiving far less direct attention is the effect of removing alternatives from a set on judgments of the remaining items in the set (Zhang and Fitzsimmons 1999). Research has shown that compared to having all alternatives available to choose from, removing items from a choice set (option limitation) can negatively affect satisfaction with the choice process (Zhang and Fitzsimmons 1999) and can increase store-switching behavior (Fitzsimmons 2000; Broniarczyk, Hoyer and McAlister 1998). Yet, option limitation can have positive effects as well. For instance, option limitation can lead to higher decision satisfaction when the consideration set is large than small, presumably because it reduces the difficulty in making a choice by decreasing the number of alternatives that need to be compared (Fitzsimmons 2000). We argue that the effect of option limitation on assortment judgments also depends upon the reasons firms provide for item unavailability, namely whether unavailability is attributed to high demand (sold out) or low demand (discontinued), as well as characteristics of the assortment that highlight similarities between items in the assortment. Specifically, if the reasons for unavailability are favorable due to high demand (sold out), then judgments of the remaining items should be higher to the extent that the assortment is perceived as likely to contain other similar items. This can occur when the assortment is large or when the assortment is organized in a way that causes individuals to process the choice options in terms of their similarities rather than differences. However, the reverse should occur when the reasons for unavailability are less favorable due to low demand (discontinued).

Our predictions qualify those of reactance theory. Brehm’s (1966) framework suggests that when one’s freedom to choose is threatened (e.g., items from an assortment are no longer available to choose), individuals experience a strong motivation to restore that freedom, often by derogating the source of the restriction (Fitzsimmons and Lehmann 2004). Moreover, reactance is often greater to the extent that the removed item is preferred (Clee and Wicklund 1980). Hence, consumers may feel greater reactance when the reason for the removed item suggests that it would have been preferred (it was in high demand) than when it would not be preferred (it was in low demand). Consequently, judgments of the available items may be lower when the reason for option limitation suggests that the unavailable alternatives would have been preferred (sold out) than not preferred (discontinued).

Alternatively, responses to option limitation may exhibit a halo effect (Thorndike 1920). Specifically, the favorableness of the

reasons for option limitation may spill over to affect the judgments of the remaining items in the assortment. Existing research suggests individuals' general impression about a target causes them to judge the target similarly on other dimensions (Solomonson and Lance 1997). As a result, individuals' general impressions are relatively homogeneous across their evaluations. Likewise, the reasons for option limitation may influence individuals' general impressions of the assortment such that consumers' opinions of the remaining items in the set should reflect the favorability of the reason for option limitation. That is, judgments of the remaining items in an assortment should be higher when the reasons for option limitation are favorable than unfavorable (i.e., sold out vs. discontinued).

We test our predictions against these contrasting accounts in three experiments in which we vary the reasons for option limitation (i.e., sold out or discontinued) and assortment characteristics (i.e., assortment size and organization). In study 1, we reasoned that individuals would perceive greater similarity among items when the assortment size is large than small. In study 2, we held fixed assortment size and manipulated assortment organization, specifically the extent to which assortment items were organized in a manner that facilitated item-specific (i.e., attending to the differences between alternatives) or relational (i.e., attending to the similarities between alternatives) processing. Finally, in study 3, we tested an important moderator of these effects. Specifically, if our findings are indeed driven by consumers' intuitions about relative demand for sold out versus discontinued items, then our effects should hold only for those with relatively high versus low knowledge about market forces (e.g., the economic logic of supply and demand). Across these studies, we find that judgments of the available items depended not only on the reasons provided for option limitation but also upon factors influencing the likelihood that assortment items were similar. Specifically, when assortment was perceived as containing similar items, judgments were more positive when the unavailable items were labeled as sold out versus discontinued. However, when the assortment was perceived to contain *dissimilar* items, judgments were more favorable when unavailable items were discontinued versus sold out (study 3). Furthermore, we find that this interactive effect is mediated by participants' beliefs that they were able to choose the best option from the remaining items (study 2) and moderated by individual differences in market knowledge (study 3).

Theoretically, we contribute to the choice literature, which has examined the influence of adding items to a choice set on attitudes towards existing items in the set, but has devoted far less attention to understanding the impact of removing items from the choice set on evaluations of the existing choice items. We also contribute to the choice reduction literature by demonstrating that the influence of option limitation on judgments of the available assortment is moderated by the reasons for the reduction and whether other similar items are likely to exist in among the remaining alternatives.

“Search Paradox: The Role of Feature Alignability in the Rise and Fall of Satisfaction”

Jill Griffin, University of Evansville
Susan Broniarczyk, University of Texas at Austin

“Man is the only animal whose desires increase as they are fed; the only animal that is never satisfied.”

Henry George (1839-1897)

This research seeks to identify situations where people are compelled to search further in spite of diminishing satisfaction. Specifically, we examine the role feature alignability plays in

search quantity and search outcomes. A set of options can be considered alignable when it contains options that vary along a comparable feature. In contrast, a nonalignable set contains options that vary along non-comparable or unique features (Markman 1999; Gourville and Soman, 2005).

Searching among nonalignable options can increase learning about different features and benefits, whereas searching among alignable options provides information on just a single dimension. Consequently, it is argued that search among nonalignable options is more informative and engaging than is search among alignable options. Therefore, we expect greater search among nonalignable options than among alignable ones.

The impact of search on satisfaction is subject to a dual effect. Considering more options increases the chances of finding a close match to preferences (Baumol and Ide 1956). This is the basic argument for the cost-benefit tradeoff to search (Stigler 1961) where more effort leads to greater reward, in this case higher satisfaction. However, increased search can also increase desires for various features of a product. When physical product constraints or budget constraints require difficult tradeoffs to be made, an increase in desires can increase the psychological cost of choosing, decreasing satisfaction. We anticipate that both effects occur simultaneously. Which effect will dominate depends on the type and the number of options considered.

Regardless of alignability, we expect an initial increase in satisfaction from search as a person finds the feature or level of the feature that is most appealing. Nonalignable options are inherently more dissimilar than alignable ones, so we would expect a greater initial increase in satisfaction as the chance of finding a good match to personal preferences increases substantially with the first few nonalignable options searched.

As search continues, desires increase and the psychological cost of choosing begins to mount as tradeoffs must be made. When choosing among alignable options, a person receives some level of the alignable feature regardless of the choice, so the psychological cost of choice is not too great. In contrast, a choice among nonalignable options is inherently associated with feelings of loss as people pre-attach to various features of the options during search (Carmon, Wertenbroch, and Zeelenberg 2003) but cannot have them all. This would predict a greater decrease in satisfaction resulting from search among nonalignable than among alignable options.

The results of two studies support this dual effect of search on satisfaction for nonalignable but not for alignable options. Specifically, people experience an initial increase and then decline (inverted U shape) in satisfaction with continued search among nonalignable options, whereas satisfaction remains fairly flat for alignable options.

Study 1 is a mixed design: 2 (feature alignability) x 3 (number of options) x 2 (category). Feature alignability is a between-subjects factor with features being either alignable or nonalignable. Number of options is a between-subjects factor with participants viewing 3, 9, or 15 options in a category with negative attribute correlation. Category is a within-subjects factor including the categories of computers and mp3 players with order counterbalanced. Participants are directed to a website and instructed to examine options and select the one they would be most likely to purchase.

The results demonstrate that people are inclined to search further among nonalignable than among alignable options. Furthermore, alignability of options moderates the impact of search on desires congruency. An inverted U shape for satisfaction with respect to search is found for nonalignable options but not for

alignable options. Thus, we find evidence that people are more likely to continue searching even when choice satisfaction is declining as a result.

Study 2 extends Study 1 by examining free search where subjects can examine as many or as few options as they want. Additionally, we gain insight into the process underlying the effect of search on satisfaction by varying the timing of feature exposure. If the increase in desire resulting from search is due to feature exposure, we predict that exposure to features prior to search will negate the inverted U of satisfaction.

Participants in this study are assigned to one of three alignability conditions: alignable (A), nonalignable (NA), and nonalignable with feature pre-exposure (NAF). Participants are directed to a website containing 15 negatively correlated options. They search as few or as many options as they want and make a choice in the category of computers.

Corroborating Study 1, the results of Study 2 demonstrate that people search more when options are nonalignable than when they are alignable. Additionally, satisfaction initially increases and then declines as search progresses among nonalignable options. As predicted, there is no such inverted U shape for satisfaction when people search among alignable options or when they search among nonalignable options with prior exposure to features. Taken together, these analyses provide support for the idea that exposure to features during search among nonalignable options drives the inverted U for satisfaction.

In summary, the results of two studies demonstrate the paradox of search, indicating that people desire to continue expending resources in search among nonalignable options even when they begin to feel worse as a result. Our findings have a number of theoretical implications for search behavior as well as option alignability. There are also significant implications for consumers hoping to maximize satisfaction with their choices and for retailers trying to determine which products to offer and what type of information to provide.

ROUNDTABLE
How To Do (Better) Web-Based Research
Dan Goldstein, London Business School, UK

SUMMARY

Collecting data over the Internet seems like a solution to all an experimentalist's problems. Responses can be collected from the far corners of the world, from people in all walks of life. Experiments that would take months and cost thousands in person can now be carried out in days for a pittance. But ours is not an ideal world. Researchers wrestle with fickle software and participants who falsify identities, respond randomly, and worse. This roundtable gathers together seven active Web-based researchers to share tips, tricks, and long-run strategies for building, running, and maintaining an online laboratory.

The roundtable will be structured by the moderator opening seven different topics for discussion. During discussion, the seven panelists as well as members of the audience can share experiences and ask questions.

The first topic will be online lab construction, and the following questions will be opened for discussion. How have the panelists constructed their online labs? What percentage of software used is built and what percentage purchased? Which hosting companies are being used? What are the advantages and disadvantages of using various online survey companies? How are the issues of joining data and transferring responses to statistical packages being carried out?

The second topic is subject recruitment. What is the approximate size of the various panelists' pools? How were these participants recruited into the pool? How effective is advertising in building a pool? How effective is word of mouth? What is the impact of being listed? What strategies have been employed in reaching participants in other countries, of different age groups, and of different wealth levels?

Third is panel management. What percentage of emails bounce? What means are being used to clean dead entries from the database? How can a pool of participants be shared by many researchers in a department without causing conflict or ruining effects? How can one keep track of which participants have completed which studies?

Fourth comes payment. What means of payment are being used by the panelists? What are the pros and cons of direct payment, lotteries, or prizes? Are there types of studies that cannot have performance-based payment when carried out online? What means of direct payment are being employed? How best to pay participants in countries without online payment mechanisms? How can participants who wish to remain anonymous be paid?

Next comes an issue sure to get an emotional response: rule enforcement. How can we tell when participants are taking an experiment multiple times? How can we tell when participants aren't reading instructions? How can we tell when respondents are responding randomly? How can we prevent unauthorized participants from taking an experiment? How can we make sure participants take the desired path through the experiment? Is there a way to ask general knowledge questions online, where subjects have easy access to all the knowledge of the Internet at their fingertips? How can we prevent participants from sharing answers and making parts of the experiment public? What are the various kinds of "angry customers" and what is the best way to handle them?

Sixth is data cleaning. What methods can we employ for detecting random responses? What methods can we use to enforce the one-submission-per-person rule? What methods are being used

to clean data by response time? Should multiple responses per household be allowed? How can we treat incomplete surveys? At what point is a survey incomplete and at what point is it not started? Can we generate a priori rules for cleaning online data? What methods are most defensible from a journal's point of view?

Last and perhaps most importantly experimental integrity issues. How best to pseudo-randomly assign participants to conditions? How to organize and re-use blocks without compromising the flow of the participant experience? What processes of item-level randomization are being employed? Can accurate response-time data be best collected online? How should we be reporting response rates: based on emails, visits to the site, or some other measure? What techniques can be used to obtain consent and to keep data private?

There will be an opportunity at the end of the session for panelists and attendees to exchange information and discuss collaborative possibilities. A signup list will be circulated for attendees to easily exchange contact information.

SPECIAL SESSION SUMMARY

Using or Losing Self Control: Antecedents of Regulatory Strength and Regulatory Depletion

Minjung Koo, University of Chicago
Angela Y. Lee, Northwestern University

SESSION OVERVIEW

Recent research on self regulation suggests that the process of self control involves various motivational, affective, and cognitive mechanisms geared toward securing the unfettered pursuit of high priority goals (e.g., Gollwitzer 1990; Kuhl 1986; Mischel 1984; Trope and Fishbach 2000). In particular, research on the limited-resource model of self control depicts self-regulation as being governed by self-regulatory resources, which are a global (meaning that they aid in all types of self-regulation) but finite pool of energy that enables self-control. Acts of self-control consume self regulatory resources and may lead to subsequent self-regulation failure. The research discussed in this session contributes to the literature by examining some important antecedents of self control. All four papers explore distinct antecedents (regulatory orientation, emotional orientation, tradeoff difficulty, and exerting cognitive control) that lead to self control success or failure. Additionally, the last two papers show unique consequences of regulatory depletion (avoiding choices, increased passivity).

In the first paper, Koo, Labroo, and Lee examine the effects of two distinct motivational systems (prevention vs. promotion regulatory orientation) on self control. Across four studies, they show that a prevention (vs. promotion) orientation enhances self control. In particular, relative to those with a promotion orientation, participants with a prevention orientation were more likely to stay focused on their goal pursuit activities. They reported having more positive thoughts related to the goal and fewer positive thoughts related to the temptation; they also anticipated greater regret from goal failure. A thought listing task also showed that goal-related thoughts were more accessible and were listed earlier than temptation-related thoughts among the prevention- vs. promotion-oriented participants.

In the second paper, Eyal and Fishbach examine the effects of two distinct affect-based self regulatory systems on self control. The authors argue that one system involves low-level, hedonic affect (e.g., happiness, sadness) that cues the pursuit of short term goals whereas the second system involves high-level, self-conscious affect (e.g., pride, guilt) that cues the pursuit of long-term goals. They demonstrate that whether people adhere to a long-term goal over a short-term temptation may depend on the emotion that is made salient. In particular, participants primed with high- vs. low-level emotions persisted longer on a handgrip task and a verbal reasoning test.

In the third paper, Novemsky, Wang, Dhar and Baumeister examine the consequences of making choices on self control by investigating the mechanism underlying depletion in making choices. Across six studies, the authors demonstrate that regulatory depletion arises not because choosing per se is difficult but because consumers have to make difficult tradeoffs between alternatives. Interestingly, consumers seem to have insight into what their choices would be when they are depleted, but have little intuition as to the depleting nature of making choices.

Whereas most research on self control examines the disinhibitory effects of self-regulatory depletion, Vohs and Gailliot argue that depletion can also produce passivity. In the final paper, they demonstrate that controlling one's attention and suppressing distracters, as opposed to not controlling attention and responding naturally, causes subsequent depletion, which in turn reduces

participants' engagement in goal-directed behaviors, increases their passivity, and reduces their creativity. Across three studies, the authors find that participants who were depleted performed poorly as a golf instructor, were more tolerant of things going wrong, and less willing to participate in a creative task.

Taken together, the four papers provide a clear illustration of the big picture of self control. Specifically, the paper by Koo et al. investigates the motivational system that is associated with making better choices in light of temptations, and the research by Eyal and Fishbach examines the affective system that is associated with better self control. Whereas both papers examine how motivational and affective systems within the individual influence self control, the paper by Novemsky et al. contributes to the literature by examining task related characteristics that impair people's ability to self regulate. Across these three papers, disinhibitory behaviors are used to illustrate the consequence of a lack of self control. However, manifestation of lack of self control is not limited to disinhibitory behaviors. The paper by Vohs and Gailliot wraps up the session by showing passivity rather than disinhibition as a key characteristic of depletion.

EXTENDED ABSTRACTS

"Against the Odds: Prevention Focus Stands Firm in the Face of Temptations"

Minjung Koo, University of Chicago
Aparna A. Labroo, University of Chicago
Angela Y. Lee, Northwestern University

Regulatory focus theory (e.g., Higgins 1997) posits that the pursuit of higher order goals is marked predominantly by a desire for advancement and growth (promotion) or by a desire for safety and security (prevention). More recent studies showing high level construals being associated with better self control (Fujita, Trope, Liberman, and Levin-Sagi, in press) would suggest that people with a promotion focus (who tend to construe information at a high level) are more successful self-regulators. However, one could also argue that those with a prevention focus are more vigilant in their goal pursuit behaviors and thus have better self control, as demonstrated by increased task enjoyment in the presence of distractions (Freitas, Liberman, and Higgins 2002) and greater ability to suppress alternative goals (Shah, Friedman, and Kruglanski 2002). The current research tests these alternative predictions and investigates how regulatory orientation affects self control. We present evidence that supports the latter premise whereby prevention focus facilitates goal-compatible thoughts and behaviors and suppresses temptation-related thoughts and behaviors.

Experiment 1 demonstrates that participants primed with a prevention-focused academic goal that emphasizes duties and responsibilities indicate higher purchase intent for goal-compatible (professionally suited magazines) vs. goal-conflicting temptation targets (leisure magazines). The reverse was observed for those primed with a promotion-focused academic goal that emphasizes their hopes and aspirations. Experiment 2 demonstrates that participants on a diet evaluated a goal-compatible target (a health drink) presented in a prevention- vs. promotion-focused frame more favorably; whereas frame had no effect on those who were not on a diet. Experiment 3 replicates and extends the results of experi-

ments 1 and 2 by demonstrating that the effect of regulatory orientation on self control is mediated by increased positive goal-related thoughts. Undergraduate participants primed with a prevention (vs. promotion) focus using a mouse maze task also were more likely to stay focused on their goal (i.e., studying) rather than yield to temptation (i.e., taking a break with friends), even though they indicated that they would value taking the break more than promotion-primed participants. Furthermore, the results showed that positive goal-related thoughts mediated the effect of regulatory focus on choice. A thought listing task showed that goal-related thoughts were more accessible and came to mind sooner than temptation-related thoughts among the prevention- vs. promotion-oriented participants. In addition, prevention- versus promotion-oriented participants reported more regret in case of goal pursuit failure, but indicated no difference in how they felt if they were to forego the temptation. Finally, experiment 4 employed an actual choice measure and found that diet-primed prevention- vs. promotion-focused participants were more likely to choose the goal-compatible target (low fat pretzels) over the goal-conflicting temptation target (potato chips).

Taken together, these studies provide convergent evidence that self-regulatory focus influences self-control in that prevention focus leads to greater self control. People with a prevention orientation are more focused on the goal and less focused on temptations relative to those with a promotion orientation. Our results show that prevention-focused participants favored goal-related products more, have more positive goal-related thoughts, and express deeper regret in case of goal failure.

“Affect as a Cue for Self Control”

Tal Eyal, University of Chicago

Ayelet Fishbach, University of Chicago

Is the good feeling after having a rich and delicious chocolate cake the same as the good feeling after successfully restraining oneself from having fatty food while on a diet? Past research and theory on motivation and emotion commonly share the assumption that goal attainment is marked by positive affect and that part of the reason that people engage in goal related behavior is because they want to feel good (e.g., Carver & Scheier, 1990; Higgins, 1997). We believe that the role of affective processes in goal pursuit is more complex and propose that the relationship between positive affect and goal attainment depends on the type of goal that is being pursued. In particular, we focus on self-control dilemmas, posing a conflict between two goals; one that has short-term benefits and another that offers long-term benefits. We propose that the attainment of both short-term goals and long-term goals is associated with positive affect. However, the quality of this affect differs for these two types of goals such that short-term goals are associated with low-level affect (e.g., happiness) and long-term goals are associated with high-level affect (e.g., pride).

Emotion researchers typically identify affective responses with low-level, concrete processing and contrast them with cognitive responses, which are considered to be more abstract, high-level (Loewenstein, 1996; Metcalfe & Mischel, 1999). We suggest a different distinction between high vs. low level of emotions, according to which higher-level emotions are those that follow the attainment of long-term goals, whereas lower-level emotions are the outcome of the attainment of more immediate goals. We further suggest that because an association is established between specific affect and goals, affect becomes a cue for the pursuit of the corresponding goal, such that high-level affect motivates the pursuit of long-term goals and low-level affect motivates the pursuit of short-term temptations.

We present data in support of two predictions of our model regarding the role of affect in self control. The first prediction of our model is that high-level affect is associated with long-term goals and low-level affect is associated with more short-term goals or temptations. In support of this prediction, participants expected a chocolate cake (representing a short-term desire) to make them feel more happy than proud. At the same time, participants expected a vegetable salad (representing the means of a long-term goal) to make them feel more proud than happy (Study 1). The first prediction of our model also implies that the same action should lead to different affective experiences when considered from the near (making the temptation more salient) and from the distance (making the long-term goal more salient). In Study 2, participants with an accessible health goal who chose chocolate over baby carrots, reported feeling more happy than proud while eating the chocolate than while evaluating their choice later on. However, those who chose baby carrots over a chocolate bar reported feeling more proud than happy after a while than while having the carrots.

Finally, our model suggests that these two affective systems have motivational consequences for situations in which long term goals conflict with more specific, short term goals, like in self control dilemmas. We propose that since people associate actions with specific types of affect, this affect serves as a cue for engaging in an action that would result in the equivalent experience. Thus, we propose that low-level affective cues motivate succumbing to temptations whereas high-level affective cues motivate adhering to long term goals. Support for this prediction comes from two studies. In Study 3, participants with an accessible achievement goal were primed with either positive high level affective terms (e.g., pride, self-worth) or positive low level affective terms (e.g., happiness, pleasure) via a lexical decision task. We then measured the time they spent on completing a difficult verbal reasoning test. We found that participants who were primed with high-level affective terms exercised more self control by persisting longer on a difficult task than participants who were primed with low-level affective terms. Study 4 found similar results using a different self control measure. In this study participants with an accessible health goal were primed with positive high level affective terms or positive low level affective terms using the same lexical decision task as in Study 3. We then measured participants' ability to resist temptation by means of the number of chocolates they chose from a bowl of chocolates. Here, again, participants who were primed with high-level affect exerted more self control by taking less chocolate than those who were primed with low-level affect.

Taken together, our findings support the existence of two distinct affective systems in self regulation and demonstrate its implication to self control dilemmas. We show that low level, hedonic emotions are associated with short-term goals whereas high-level, self conscious emotions are associated with long-term goals. These associations have consequences for behavior such that high-level affect cues self control and low-level affect cues succumbing to temptations. We believe that the proposed model sheds light on the complex and unique functions of emotions as self regulatory feedback for goal pursuit.

“Self-control, Depletion and Choice”

Nathan Novemsky, Yale University

Jing Wang, Yale University

Ravi Dhar, Yale University

Roy Baumeister, Florida State University

Recent research by Baumeister and colleagues has revealed that individuals have a limited pool of resources available for exerting self-control (Baumeister 1998). One important task that

requires self control is choice. Baumeister and colleagues have shown that making choices can deplete one's self-control resources. We follow up this research by examining why choices are depleting and the effects of depletion in successive choices.

In our first study, we examine a real choice between a chocolate bar and a granola bar. We find that individual leaving the library are more likely to choose a chocolate bar (80%) over a granola bar than individuals entering the library (50%). We propose that this occurs because studying in the library requires self-control and therefore depletes self-control resources. When faced with a choice between a healthy and a tasty snack, choosing the healthy snack also requires self-control. Since those leaving the library have less self-control available when making the choice they are less likely to resist the chocolate bar.

The choice observed in study 1 could be the result of several differences between those entering and leaving the library. For example, those leaving the library could be more depleted of blood sugar and choosing the chocolate bar to quickly replace that blood sugar. In study 2, participants chose between high-brow and low-brow movies to see on a weekend that is several days away, a choice that is not relevant to immediate consumption. High-brow movies typically offer less immediate pleasure (or even some pain), but provide long-term benefits in the form of educational or cultural enrichment. Low-brow movies fall more into the temptation category because they are fun but forgettable (Read and Lowenstein, 1999). We expected that choosing a high-brow movie would require self-control and we found that participants were more likely to choose this type of movie when entering (72%) as compared to leaving the library (11%). This finding reveals that depletion can affect choices whose outcomes will only be experienced later (presumably after the current depleted state is dissipated). This study also suggests that study 1 was the result of depletion rather than some other immediate need that may have been more pronounced for those leaving the library.

In subsequent studies we further examine how one choice can affect subsequent choices through the depletion of self-control. In study 3, we have half of our participants make several choices between similar items (e.g. between two different pens, two different snacks). The remaining participants saw the same set of items, but instead of choosing, their task was to determine whether they had used each product in the last year. All participants then faced a choice among a set high-brow and low-brow movies, as in study 2. We found that many more participants chose a low-brow movie among those whose first task involved choice (40%) than among those whose first task did not require any choosing (10%).

In study 4, we investigated what aspect of choosing is more depleting of self-control resources. Again, we use our choice among movies to measure depletion. In this study, we tried to distinguish between tradeoff difficulty and choice difficulty. Choices can be difficult because the trade-offs are difficult (e.g. I want a cheap apartment, but I also want one near school—which am I going to give up if I can't have both?) or because the options are difficult to distinguish (e.g. all these apartments are very similar, making it difficult to differentiate and choose among them). We propose that only trade-offs lead to depletion, so if we construct two choices where one involves large trade-offs and the other involves very similar options, both may be equally difficult, but the former should be more depleting than the latter. Using this design, we found that small trade-off choices were rated as slightly more difficult than large trade-off choices. However, as predicted, following the large trade-off choices, 54% chose a low-brow movie, while only 39% chose a low-brow movie following the small trade-off choices. This design provides evidence that trade-offs are a depleting aspect of

choice, beyond any effect these trade-offs have on perceived choice difficulty. This is consistent with the notion that self-control involves giving up desirable things and accepting undesirable things. That is exactly what is involved in making trade-offs in choice.

Lastly, we investigated individuals' beliefs about depletion and choice. We described several of our studies and asked participants to intuit what would happen. We found that they could intuit that studying would lead to more depletion and they also predicted that more low-brow movies would be chosen after as opposed to before studying. However, when we described the choice versus ratings study (study 3 above), and asked participants who would be more depleted and who would choose more low-brow movies, we found that they did not predict any differences in depletion, nor any difference in preference for low-brow movies. That is, participants could intuit the effects of studying on depletion and subsequent choice, but they had no idea that choices could also deplete and thereby affect subsequent choices. If individuals were made aware of the interaction of successive choices through depletion, they might avoid making decisions about temptations following other choices and increase their ability to self-regulate in situations that require such regulation.

“A Loss of Self-regulatory Resources Makes People More Passive”

Kathleen D. Vohs, University of Minnesota

Matt Gailliot, Florida State University

The current research expands upon a model that portrays self-regulation as being governed by a set of finite resources. Self-regulatory resources are used when people modify, alter, or otherwise change their responses. The supply of self-regulatory resources is depleted after being taxed by a preceding act of self-control, the result of which is that ensuing acts of self-control are less successful. The results of over 60 published experiments support the self-regulatory resource model (see Vohs, Baumeister, and Tice, in press, for a review). Temporary depletion of self-regulatory resources has been shown to elicit a variety of disinhibited behaviors, such as impulsive spending, overeating among dieters, low emotional control, and narcissistic self-perceptions (see Vohs et al., in press). Hence, when people lack the ability to maintain control, they may behave disinhibitedly, which is to say that behaviors that otherwise would be regulated are released and emerge uncontrolled.

In the current research, we investigated whether depletion of self-regulatory resources may also lead people to become more passive. A look at research in this area hints of increased passivity after self-regulatory resource depletion. In one study, for instance, after participants made a series of choices, they were more likely to dazedly stare into space than were participants who did not make choices (Vohs et al., under review). Other research suggests that a loss of self-regulatory resources results in less variety seeking, relative to when people have a full complement of self-regulatory resources (Vohs and Kim 2006). In short, we hypothesized that depletion may result in passivity, a prediction that was supported in three experiments.

In Experiment 1, participants engaged in task that either did or did not require self-regulation; subsequently, they performed a physical task that involved learning to putt a golf ball. This formed the dependent measure of physical passivity. First, participants watched a six minute video (without sound) of a woman talking (modified from Gilbert, Krull, & Pelham, 1988). In the bottom corner of the screen, words (e.g., hair, hat, pulse) appeared individually for ten seconds each. Participants in the depletion condition were instructed to focus their attention only on the woman's face

and to resist looking at the words. If they happened to look at the words, they were to immediately re-focus attention to the woman. Participants in the no depletion condition were instructed to watch the video and were given no additional instructions. The physical activity task was adapted from Pryor (1987), and involved a confederate and the participant ostensibly learning how to putt a golf ball. The confederate and participant were told that one person would act as the instructor and the other as the learner, and then they completed a rigged drawing in which the participant was assigned the role of instructor. The participant was handed instructions on how to putt and asked to use this information to teach the confederate. They were reminded that the confederate was to follow all of the instructor's directions to the best of her ability. The experimenter left the room and for the next four minutes, participants instructed the confederate how to putt. Subsequently, participants and the confederate parted, and confederate (who was blind to depletion condition) rated the participant on eight traits indicative of passivity (*active, talkative, shy, socially skilled, sensitive, aggressive, hostile*). These traits were included among other filler items. Analyses showed that participants in the depletion condition were rated by the confederate as having been more passive than participants in the no depletion condition. Differences in passivity were not due to mood differences on the part of the participants, as measured by a commonly-used questionnaire.

A second experiment also used the attention control manipulation to deplete self-regulatory resources, similar to that described in Experiment 1. The dependent measure, however, measured passivity in a new way. After watching the video of the woman talking, participants completed mood questionnaires. Then the experimenter put in a new video, and told participants that they would be answering questions about it later. Instead of playing the video, however, the television only showed a blue screen. The dependent measure of passivity was the length of time before participants alerted the experimenter of the problematic video. Analyses showed a significant effect of prior engagement in self-control. Participants who had been depleted of their volitional resources were more passive (i.e., waited longer to alert the experimenter) than participants who had not been depleted of their resources. A third experiment manipulated emotion control demands and subsequently measured passivity in the form of a building task. Participants first watched a humorous video involving a Bill Cosby standup routine to which they were either instructed to suppress their emotions or watched naturally. The former condition has been found to deplete self-regulatory resources whereas the latter does not. Subsequently, participants were given a bucket of Legos with which to build a structure. There was a stipulation, however, and it was that they were only allowed to retrieve five blocks at a time from the bucket; participants could use as many blocks as they wanted, but would have to get up and walk over to the bucket to take another five (or fewer) blocks. The dependent measure was number of blocks used, and an ancillary criterion of passivity was the creativity of the structure, as rated by the experimenter and a second person. Results showed that participants who had earlier suppressed their emotions used fewer blocks in their creations than did participants who watched the video naturally. Furthermore, depleted participants' structures were rated as less creative, relative to structures built by nondepleted participants.

In sum, a loss of self-regulatory resources can lead to passivity. This insight provides a more nuanced approach to understanding self-regulatory resources and their role in controlled and uncontrolled behavior. Future research should work to illuminate under what conditions people behave passively versus disinhibitedly when lacking regulatory resources.

SPECIAL SESSION SUMMARY

Did You Know that Questioning Consumers Can Change Behavior?: New Research and Future Directions on the Question-Behavior Effect

Patti Williams, University of Pennsylvania, USA

David Sprott, Washington State University, USA

SESSION OVERVIEW

Asking consumers a question about their behavior has been demonstrated to change the performance of that behavior in the future. Sherman (1980) initially demonstrated this effect by using self-predictions to alter socially desirable and undesirable behaviors. Since that time, two sets of researchers have demonstrated the importance and nature of this *question-behavior effect*. While both sets of researchers have demonstrated the real-world importance of the question-behavior effect (most often by showing questions able to influence actual behaviors), each literature stream has generated a unique set of knowledge about the phenomenon.

One group of scholars—publishing research on the mere-measurement effect—employ scaled intention measures to influence consumer-related behaviors (e.g., Chandon, Morwitz, Reinartz, 2004; Dholakia & Morwitz, 2002; Morwitz & Fitzsimons, 2004; Morwitz, Johnson & Schmittlen, 1993; Williams, Fitzsimons, & Block, 2004). These researchers have demonstrated question-behavior effects with various actions, including: first time and repeat purchase of durable and non-durable goods, product choice, transactions with and defection from service providers, flossing, drug and alcohol consumption. These researchers have proposed and found support for an attitude accessibility explanation for observed findings such that the question makes attitudes accessible which in turn guide performance of behaviors in the future.

Other researchers—referring to their work as the self-prophecy effect—use self-predictions to affect behaviors with clear social norms (e.g., Greenwald, et al., 1987; Spangenberg, 1997; Spangenberg & Greenwald, 1999; Spangenberg, et al., 2003; Sprott, Spangenberg, & Fisher, 2003). These authors have demonstrated that a self-prediction can reduce the incidence of non-normative behaviors like cheating on an exam and increase the performance of normative behaviors like health club attendance, donating to a charity, recycling, voting and gender stereotyping. These researchers contend that the effects of self-prediction are due to cognitive dissonance generated by the question. In particular, these researchers contend that the self-prediction reminds a person of failures to perform and norms associated with the behavior. Inconsistency between prior behavior and social norms creates dissonance which in turn motivates behavior change.

While much has been learned about the question-behavior effect since Sherman's seminal work 25 years ago, there are many unanswered questions. The objective of the current special session is to address (with new and unpublished research) three research questions that have not been adequately addressed in the literature:

- (1) Do question-behavior effects always lead to positive outcomes for firms who question consumers about behavior?
- (2) What types of cognitive processes are activated when someone is presented with a question about future behavior?
- (3) Are there other theoretical mechanisms underlying the question-behavior effect in addition to attitude accessibility and cognitive dissonance?

SPECIAL SESSION SUMMARY

Rethinking Drama in Consumer Culture Research

Gülnur Tumbat, Oregon State University, USA
Markus Giesler, York University, Canada

SESSION OVERVIEW

Drama permeates consumer culture. Since Deighton (1992) pioneered the study of performance in consumption and marketing, consumer researchers have extensively explored the persuasive role of drama in advertising (e.g., Deighton, Romer, and McQueen 1989; Stern 1994; Escalas and Stern 2003) and services (e.g., Grove and Fisk 1992; Price, Arnould and Tierny 1998; John 1996; Moisisio and Arnould 2005). Consumer culture theorists in turn have developed the dramatic underpinnings of consumption practices and consumer lifestyle orientations. Celsi, Rose and Leigh (1993), for instance, have analyzed consumers' dramatic worldview in the context of skydiving. Likewise, Arnould and Price (1993) have portrayed white water rafting clients and guides as dramatic performers. Belk and Costa (1998, p. 234) in turn have portrayed the mountain man rendezvous as a "drama of living." Most recently, Holt and Thompson (2005) have illustrated how American middle-class men construct themselves dramatically as "men-of-action-heroes" in mundane and improvisational consumption domains.

While these prior elaborations are most relevant to our understanding of the dramatic underpinnings of consumption practices and consumer lifestyle orientations, they also suffer from a key theoretical oversight. Underlying these prior studies is a pervasive dramatic idealism that renders the performances of consumers and marketers as surprisingly playful, harmonious, and apolitical. Consequently, prior studies fail to recognize that social actors with competing dramatic motives sometimes struggle to negotiate, and resolve certain dramatic tensions, uncertainty, and risk. Perhaps this theoretical oversight stems from the fact that consumer culture theorists have too rashly adopted the marketing perspective on drama and performance. As Holt (2002, p. 70) observed, "academic marketing theorizes away conflicts between marketing and consumers." In this view, marketing "scripts, produces and directs performances *for* and *with* consumers" (Deighton 1992, p. 362, italics added). However, by accepting this marketing cohesion as the dramatic norm, consumer researchers have tended to overstate the playful dimensions of drama and overlook cultural conflict in dramatic consumption.

The purpose of our special session is to redress this theoretical imbalance. Specifically, we seek to contribute to extant consumer literatures on performance and drama by empirically specifying cultural conflict, tensions, and contradictions in dramatic consumption, by developing a conceptual understanding of these empirical instances, and by situating these findings within the broader marketing and performance literatures. We anticipate that our discussant, Eric Arnould, will help the audience to frame, question and debate important issues such as: What is the specific role of conflict in performance? How do certain cultural tensions translate into particular dramatic narratives, roles, and behaviors? How do consumers and producers dramatically construct or modify their personal and symbolic boundaries and social roles? What is the relationship between dramatic performance, cultural legitimacy, and social identity? The presentations are arranged as presenting current investigations on the dramaturgical performances focused on different research perspectives within CCT-perspectives that situate, challenge, and extend prior drama frameworks and knowledge.

First, Markus Giesler and Marius Luedicke develop and present empirical evidence for the process of marketplace drama. Based on a five-year ethnographic investigation on the war on music downloading including interviews, historical data, and cultural observation, they develop a marketplace drama as a series of antagonistic ritualistic performances among opposing groups of consumers and producers, through which their divergent ideological goals are attained and the normative patterns of social interaction in the marketplace are changed. In addition to showing that previous attempts to look at all marketplace performances in terms of purely theatrical, purely experiential, or self-oriented dimensions miss much of what impels consumers and producers to perform, they also extend fundamental Victor Turner's (1984) social drama theory by showing that no social drama can take place outside of the systems of meanings and interpretations that guide dramatic actors in particular ideological directions.

Building on experiential consumption, Gülnur Tumbat then explores and develops how risk taking and risk management in the case of dramatic leisure consumption and its commodification play a role in characterizing and further maintaining boundaries within and across groups of participants with competing motives. She argues that ideal notions of dramatic frameworks such as liminality and *communitas* have little value in explaining the essentially complex and divisive qualities of performances of marketers and consumers in contexts where stakes are high.

Finally, Risto Moisisio and Mariam Beruchashvili reexamine cultural contradictions as fuel for drama. Focusing on the relationship between performance and identity, his research looks at the performance of the griping ritual in the Weight Watchers brand community. They argue that griping, an underappreciated social ritual in consumer research literature, constructs a vulnerable self defined by traumatic experiences of stigma insinuated childhood that wound the self. Performance of the griping ritual constructs the vulnerable self in need of therapy and outside help.

The proposed session is a timely one with particular relevance to researchers interested in the relations of drama, performance, and consumer research. This session will help these researchers to consider the value of divergent perspectives on consumer performances and dramaturgical consumption. We believe that the presentations are, in themselves, exciting studies conducted by a diverse group of consumer researchers that merit further attention and that may inspire an increased interest in the complex interrelations between marketing, consumption, drama, and performance.

EXTENDED ABSTRACTS

"The War on Downloading: A Music Marketplace Drama in Four Acts"

Markus Giesler, York University

Marius Luedicke, York University

Although originally conceptualized in classic anthropological, sociological, and theatre studies as *performed cultural conflict* (e.g., Turner 1969; Goffman 1959; Schechner 1977), drama in consumer culture theory has been traditionally conceived of as a harmonious impression management exercise. Rooted in the marketing idea that the dramaturgical interests of producers and consumers align, this

dramatistic experiential view is underlying existing consumer culture theory on dramatic consumption (e.g., Arnould and Price 1993; Celsi, Rose and Leigh 1993; Belk and Costa 1998; Holt and Thompson 2004). Consequently, conflict as a driver of dramatic consumption has remained a rare topic in consumer research.

To redress this theoretical oversight, we advance the process of marketplace drama. A marketplace drama is defined as a series of antagonistic ritualistic performances between divergent groups of consumers and producers through which their conflicting ideological goals are attained and the patterns of power relationships in the marketplace are transformed. The empirical context of this research is the music marketplace. Using five years of ethnographic data, we explore and develop the dramatic social interactions between music downloaders and producers following the emergence of music downloading in 1999.

Our findings reveal multiple producer performances that idealize corporate music production and stigmatically link downloading with social categories of theft, crime, and defiance. Poised alongside these articulations are multiple downloader performances that demonize corporate music production and link downloading to cultural ideals of freedom and egalitarianism. In the music marketplace, antagonists' dramatic social interactions are permeated by these different cultural meanings and interpretations as well as by the need to promote or destabilize particular socially constructed systems of norms, values, beliefs, and definitions. Through their ritualistic performances, music downloaders and producers justify their particular ideological positions and locate their own source of cultural identity and power.

Conceptually, the findings of this ethnography have the potential to enrich our understanding of social drama, dramatic consumption and marketplace conflict. First, we show that previous attempts in consumer culture theory to look at all marketplace performances in terms of purely theatrical, purely experiential, or self-oriented dimensions miss much of what impels consumers and producers to perform. Second, we confirm, extend and situate extant literature on marketplace conflict. Thompson (2004, p. 173) has recently conceptualized consumer conflict as a "Sisyphian struggle against polymorphic power structures" between two groups of ideological stakeholder groups. We show that the cultural success of these standpoints is also very much driven, shaped, and constrained by dramatic considerations. Finally, we present a theoretical critique and extension of Victor Turner's classic social drama concept. Under the functionalist influence of Durkheim and Radcliffe-Brown, Turner has conceptualized social drama as a mechanism to sustain a social order and to secure solidarity among its members. However, we build the alternative case that no social drama takes place outside the systems of meanings and interpretations that guide dramatic actors in particular ideological directions. This alternative view accepts that there is no clear-cut distinction between where the drama begins and the "official social order" ends. Instead the marketplace serves as the central stage on which divergent groups of social actors engage in a dramatic interplay of structure and agency to legitimate their own ideological positions of identity and power. In summary, the consumption issues presented in this presentation provide an attractive theoretical platform for developing further theoretical linkages between dramatic performance, consumption, culture, and marketplace conflict.

"Four Ds of Risky Leisure: Drama, Divinity, Deservingness, and Deliverance"

Gülner Tumbat, Oregon State University

Few studies conducted about the so-called high-risk leisure activities in consumer behavior field used a dramatic approach to understand participants' experiences. Celsi, Rose, and Leigh (1993),

for instance, investigated the "dramatic and self-enhancing" activity of skydiving. According to the authors, the Western dramatic worldview through dramatic story lines and images of dramatic behaviors constitutes the socio-cultural context for participation. They reported the hedonic and transcendental benefits as self-realization, self-transformation, and *communitas* among some others. Arnould and Price (1993) reported similar benefits and called the river rafting experience as "extraordinary" and focused on the "magical" aspects and emotional content (Arnould, Price, and Otnes 1999). Although these studies provided valuable accounts of participation by using dramatic perspectives, they embraced a quasi-utopian idealism. In doing so, they neglected the economic, political, and structural dynamics that shape and drive the performances of marketers and consumers in such contexts. In order to address this oversight, I investigated the context of high-altitude mountaineering expeditions that are characterized by risk and stress elements.

Using data from ethnographic work at the Everest base camp in the Himalayas of Nepal and 23 in-depth interviews with high-altitude climbers and guides, I present evidence that ideal notions of dramatic frameworks such as liminality and *communitas* (Turner 1969) have little value in explaining the essentially complex and divisive qualities of performances of marketers and consumers in such experiences. The consumption of high-altitude climbing is not necessarily fun, play, and pleasure but rather a complex articulation of risk taking with a style, control, and empowerment through pushing one's limits and suffering in order to achieve or maintain status and boundaries. Furthermore, the same boundaries facilitate and shape the recognizing and negotiating of risk and uncertainty over both space and time. Furthermore, although it is from a perfect (and extreme) example of an extended service encounter, the data suggest that there are no boundary-open transactions among participants and that the experience does not transcend its commercial nature. There are four identified discourses in operation that account for these differing findings. Specifically, these are (i) discourses of deservingness (e.g., who deserve to climb here?), (ii) discourses of deliverance (e.g., how is a purchased experience made into something money can't buy?), (iii) discourses of divinity (e.g., what happens when the actors act like bricoleurs when it comes to include spirituality into yet another commercial experience?), and (iv) discourses of drama (e.g., how do clients as main actors negotiate risk with the service providers as the directors of their performance?).

The findings of this ethnography have the potential to enhance our understandings of social drama and consumer/marketer performance. I show that prior studies in consumer culture theory that look at high-risk leisure experiences in terms of hedonic and transformational dimensions do not capture the competitive, contradictory, and power dimensions involved in such performances. Building on and extending these studies, I present a critique of the constraining dramatic idealism underlying their theoretical considerations. In summary, my study shows that even in an extraordinary consumption context, the ideal notions of liminality and *communitas* are not achieved as statuses, roles, and boundaries are constantly maintained and seen necessary as a way of negotiating and managing risk.

"We Just Gripe'n Gripe...That's All We Do!": Performing the Griping Ritual in the Weight Watchers Brand Community"

Risto Moiso, University of Arizona

Mariam Beruchashvili, University of Arizona

In this presentation we report the findings from a study examining the performance of the griping ritual in the Weight

Watchers brand community. We extend the consumer culture theoretic (Arnould and Thompson 2005) understanding of the role that performance of ritual plays in brand communities by investigating the griping ritual in the Weight Watchers. As a form of negatively toned communication that enables members of a respective community to address a cultural problem through speech (Katriel 1991). The purpose of the griping ritual is to release frustration through expressive communication that manifests therapeutic qualities, coordinate blame, and to enforce solidarity (Katriel 1985).

To study the performance of the griping ritual, we use data collected over a two-year period focusing on the Weight Watchers brand community using observation and interviews. To triangulate across online and offline communities (Wallendorf and Belk 1989), we used a combination of online and offline observation to gain insight into the ritual aspects of the Weight Watchers members' collective communicative exchanges (e.g., Wallendorf and Arnould 1991) at Weight Watchers meetings. For the online community data, we collected data through the Weight Watchers online discussion boards (www.weightwatchers/community.com) (Kozinets 2002). We also conducted 30 interviews over two waves. In the first wave, we conducted 15 interviews with the Weight Watchers members. The purpose of the first wave of phenomenological interviews was to understand broader contours of weight loss experiences among the Weight Watchers members (Thompson, Locander, and Pollio 1989).

Our presentation highlights that the Weight Watchers brand community prospers because it harbors the performance of a social ritual of griping. Our results suggest that performances may be motivated by cultural contradictions. We show how the performance of the griping ritual enables Weight Watchers to counter cultural contradictions (Holt 2002) between the normalized thin body ideals pervading media (Richins 1991) and the overweight body images of dieters (Thompson and Haytko 1997, p. 32; Thompson and Hirschman 1995). Gripes enable Weight Watchers to construct a solution in the form of a vulnerable self, defined by traumatic experiences of stigma since childhood that wound the self. The performance of the griping ritual constructs the vulnerable self as powerless, lacking agency and suffering from addiction (Furedi 2004). Deploying the therapeutic vernacular as a cultural resource enables Weight Watchers to construct a self in need of outside help and support. Guided by our findings, we posit the Weight Watchers brand community is an opportune therapeutic institution and the facilitator of the griping ritual (Katriel 1985; Katriel and Philipsen 1981). We conclude that while cultural contradictions seem to fuel performance of a ritual as suggested by Holt (2002), Weight Watchers draw vigorously upon the therapeutic culture as a rich vernacular to develop solutions to the existential tensions they experience (Swidler 1986).

Currency of Search: Time Versus Money

Ritesh Saini, George Mason University, USA

Ashwani Monga, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Search is integral to consumption. Consumers search for the best products, the lowest prices, the most convenient locations and, in general, any information that can improve their consumption experience. Sometimes the currency of search is money (e.g., paying an agent to search for the best price) and sometimes it is time (e.g., spending time on websites to search for a specific product). In this research, we try to understand how search behavior varies depending on whether the currency of search is monetary or temporal.

In Stigler's (1961) seminal paper, search is analyzed as an "optimization under constraints" problem in which greater search leads to a higher likelihood of success, but involves greater costs as well. Following from this, the standard experimental paradigm is that of an individual performing a sequential search for a homogeneous good, the prices of which are assumed to be dispersed in the market with a known distribution function. Although each search has an associated cost, it can potentially lead to a better (lower) price. The overall finding from the experimental literature is that people rationally increase their search intensity when incentives to perform search are high (e.g., search costs are low). And if this were to translate to the real marketplace, one would expect to see the following: Price dispersion should be lower (reflecting high search behavior) when product prices are high (reflecting higher incentive to search). However, empirical data from naturalistic settings does not agree with this. Increase in the incentive to search does not reduce price dispersion (Carlson and Pescatrice 1980, Pratt, Wise, and Zeckhauser 1979). Furthermore, even though search costs are believed to be lower in the Internet era of "friction-free capitalism" (*The Economist*, 1997), the price dispersion in online markets is found to be comparable to that in offline markets (Brynjolfsson and Smith 2000, Schlotten and Smith 2002).

Although there could be numerous reasons for this discrepancy between the experimental and the real-world results, the current research focuses on one plausible explanation—the currency of search. Search experiments have traditionally employed a monetized value per unit search as a measure of search costs. In real-world settings, however, consumers rarely pay the costs of search in terms of money. More frequently than not, they spend time, rather than money, on activities such as searching within stores for the lowest price and scouring websites for product information. Could it be that people are less sensitive to search costs that are in terms of time (as in real-life settings) rather than money (as in experimental settings)? If it is so, that could explain why the relationship between search costs and search behavior emerges in experimental but not in real-world settings.

Relative to money, time is not as fungible or substitutable (Leclerc, Schmitt, and Dube 1995), is more ambiguous and, therefore, more prone to accommodation and rationalization (Okada and Hoch 2004), and is harder to account for, because accounting for time is not a routine activity for most people (Soman 2001). If time is indeed less concrete relative to money, consumers may be relatively less sensitive to changes in time versus money. Prior research seems to support this idea of differential sensitivity in that people have been found to be more sensitive to past investments of money than of time. This has been found in research related to sunk costs (Soman 2001) as well as in research related to satisfaction from an experience acquired by spending either time or money (Okada and Hoch 2004).

We propose that this general tendency of consumers to be less sensitive to time than to money ought to translate to search costs in the following manner. The extent of search done by a consumer is based on a tradeoff between the payoffs and the costs of increased search. Therefore, given fixed payoffs, search behavior ought to increase as the costs of search decrease. However, if the costs of search are in terms of time rather than money, people should be less sensitive to the costs. Consequently, a change in search costs should change search behavior less if those costs are that of time rather than money.

We test the above prediction in three experiments. In the first two experiments, we manipulate the currency (i.e. time vs. money) as well as the magnitude (i.e. high vs. low) of search costs and ask participants to indicate the extent to which they would like to search. The first experiment employs a moving company situation in which participants incur search costs in order to minimize their expenses on a moving company, and the second experiment employs a sequential-search experiment using a modified Bingo game in which participants incur search costs in order to maximize their payoffs. Both experiments support our prediction. Search behavior is more strongly influenced by changes in search costs that are in terms of money rather than time. A third experiment shows that this difference between time and money is not limited to search costs, but extends to search payoffs as well. Specifically, changes in the magnitude of search payoff have a greater impact when the currency of search is monetary rather than temporal.

How Do Low-Price Guarantees Deter Consumer Price Search? The Effects of Branded Variants and Search Costs

Hillbun (Dixon) Ho, University of Arizona, USA

EXTENDED ABSTRACT

Retailers establish their price-images through a variety of price signals like discount frequency and magnitude, reference prices, sale signs, "loss leader" items, and every day low price policies. Because consumers usually lack complete price information in the market, they tend to use salient and accessible price cues to make store price inferences (Alba et al. 1994; Bobinski et al. 1996; Simester 1995; Urbany et al. 1988). Retailers may thus capitalize on this consumer disposition by delivering signals of low store prices. In this paper, we focus on LPG signals because they are effective signals that influence consumers' price and value perceptions, store patronage intention, and search behavior.

Compared with other price signals, LPGs have a relatively short history in the retail market; research on its implications for consumer behavior is emerging but still scarce. Previous research has examined their impacts together with a number of market-level and individual-level variables including store image, store locations, consumer search cost and price knowledge, external reference prices, and selling price levels on consumers' perceptions and search behavior (Biswas et al. 2002; Srivastava and Lurie 2001; Srivastava and Lurie 2004; Lurie and Srivastava 2005). Nevertheless, our understanding of the effects of LPGs on consumer price search is still limited. Given that LPGs have been found to discourage consumers from shopping around (Srivastava and Lurie 2001), it is important to find out what factors would attenuate this behavioral tendency. Drawing on signaling theory and information economics, we provide theoretical explanations and develop hypotheses with respect to consumers' responses to LPGs when (1) individuals' search cost differs and when (2) branded variants are present or absent in the market.

Specifically, we argue that LPGs are non-credible signals of low store prices when there are branded variants in the market. As such, when consumers perceive a LPG signal to be credible due to the absence of branded variants, they lack motivation to do price search. In contrast, when a LPG signal is perceived as non-credible due to the presence of branded variants, consumers may tend to search more. However, the effect of branded variants on consumer price search is likely to be qualified by consumers' own search cost. Therefore, it is hypothesized that the number of stores searched is less when there is no branded variant (relative to its presence) in the market. This relationship is significant when consumers bear high search cost. When consumers bear low search cost, the difference in the number of stores searched between a market with branded variants and a market without branded variants should be less pronounced or even minimal. This is because when search cost is low, consumers can afford to search more stores even though there is no branded variant in the market and the LPG signal is credible.

Ninety undergraduate business students were recruited at a major university to participate in the experiment conducted in a computer lab. Subjects were randomly assigned to individual computers and instructed to use a program that simulated cross-store price search experience. The experiment was a 2 x 2 between-subjects factorial design that manipulated individuals' search cost (low versus high) and branded variants (absence versus presence) in the market. The 2 x 2 ANCOVA results showed that search cost ($M_{High\ Cost}=4.03$ and $M_{Low\ Cost}=5.24$; $F(1, 76)=6.6$, $p<.05$) and the interaction between search cost and branded variants significantly affected the number of stores searched ($F(1, 76)=7.90$,

$p<.01$). Simple effect analyses showed partial support for the hypotheses.

This study contributes to the extant literature on LPGs in a number of ways. First, it examines the implication of a specific market condition—branded variants—for consumers' price search when they receive LPG signals in the retail market. Second, it examines the interaction effect of branded variants and individual-level search cost on consumer price search. Since the presence of branded variants can reflect market-level search cost, the latter is operationalized in the experiment in a fashion independent of individual-level search cost. Our findings show that consumers' price search in response to the LPG is dependent on their search cost and whether branded variants are present or absent in the retail market.

Giving an “E-Human Touch” to E-Tailing: The Moderating Roles of Static Information Quantity and Consumption Motive in the Effectiveness of a Virtual Salesperson

Fang Wan, University of Manitoba, Canada

Subramanian Sivaramakrishnan, University of Manitoba, Canada

Zaiyong Tang, Louisiana Tech University, USA

EXTENDED ABSTRACT

An Ernst and Young study on barriers to online shopping found that the inability to talk to a salesperson and inadequacy of product information were among the most important reasons for not buying. Jupiter Research's study on online shopping behavior found that ninety percent of online shoppers wanted some sort of human interaction during the shopping process. According to an Accenture's survey of 25 top e-commerce sites, sixty-two percent of shoppers never complete their purchases due to a lack of real-time customer service. All these reports indicate that the lack of a salesperson and the consumer's inability to obtain additional information translate into lost sales for e-tailers (Raymond 2001).

Online marketers are increasingly addressing these two issues by utilizing virtual salespeople to provide product information in real time. These virtual salespeople play two roles—they provide information as well as a human touch to an otherwise impersonal online store. Although some e-tailers employ humans as virtual salespeople to assist online shoppers, others utilize more cost-effective artificial intelligence software that “chat” with the customer. For example, Coca-Cola uses “Hank” and IKEA uses “Anna”—virtual salespeople who provide online customer service. Nowadays, companies such as Kiwilogic (www.kiwilogic.com) and Oddcast (www.oddcast.com) market customized virtual salespeople that simulate human interactions.

Although virtual salespersons are increasingly adopted by e-tailers nowadays (Komiak, Wang, and Benbasat 2005), little is known about the effects virtual salespeople have on consumers' attitude toward the web site, product, and their likelihood of buying. In this paper, we examine the impact of a virtual salesperson (VS) on consumer response. We specifically examine whether the impact of the VS is moderated by the amount of static information available on the web site and consumer's consumption motive during the shopping process. We argue that when the web site has only limited static product information available, the VS can be rather useful for the consumer to obtain product information and can positively affect consumer attitude and purchase intention. On the other hand, the effectiveness of the VS as an information provider would diminish when the web site has sufficient static product information. We further propose that the “human touch” provided by the VS can positively impact consumer attitude when consumers have a hedonic consumption motive. However, when consumers have a utilitarian consumption motive, the VS can adversely impact consumer attitude and purchase intentions.

We examine our propositions in two experiments. Our results indicate that the impact of the virtual salesperson is moderated by the amount of static product information on the web site and the consumer's consumption motive. In study 1, we show that the virtual salesperson has a positive effect primarily when static product information on the web site is limited. In study 2, when detailed product information is readily available on the web site, the virtual salesperson proves detrimental when the consumer has a utilitarian consumption motive. Implications for online marketers are discussed.

The Benefits Leader Reversion Effect: How a Once Preferred Product Can Recapture Its Standing

Kurt A. Carlson, Duke University, USA
Margaret G. Meloy, Pennsylvania State University, USA
Daniel S. Lieb, Duke University, USA

EXTENDED ABSTRACT

The current work makes a qualitative distinction between preferences that result from learning about product prices versus those that result from learning about product benefits. In a binary choice setting, we posit that consumers who prefer one option (the "leader") over another, but who adopt a deeply discounted brand as their new leader, may also maintain a preference for their pre-price leader. That is, the original leader is more appealing in terms of benefits and remains so, even though the cheaper product is preferred overall net of price. We further posit that any benefits-oriented information processed after price will transport the consumer back to benefits space, causing the benefits leader to re-emerge as the overall leader. In two studies we find evidence of benefits leader reversion, even when the information after price objectively favors the cheaper brand.

A substantial body of research suggests that decision makers establish a cognitive element associated with whichever option emerges as preferred or leading during the choice process (Beckman and Kuhl 1984; Gerard 1967; Jecker 1964; Montgomery 1983; Russo, Meloy, and Medvec 1998; Svenson 1992). This article extends the work on predecisional cognitive elements by proposing and testing for the simultaneous existence of two different leaders. One of these leaders is the benefits leader, the option that is preferred based on the information overall, absent price. The other leader is the net-p leader (net of price leader). Under a specific set of conditions, one brand can be the net-p leader, while the other is maintained as the benefits leader. In a binary choice between two brands, this can occur when a slightly preferred brand is discovered to be substantially more expensive than the other brand. That is, the originally preferred brand is the benefits leader, while the cheaper brand becomes the net-p leader.

We expect that consumers who switch from a brand that has better benefits (benefits leader) to a cheaper brand (the net-p leader) will retain the benefits leader in memory. We further expect that this benefits leader will exert a gravitational pull on the predecisional processing of benefits-based information encountered after the price information. Specifically, we hypothesize that consumers who see additional non-price information about the choice options after price will revert to their benefits leader as their overall preferred option, even if the new information objectively favors the net-p leader. We examine these hypotheses in two studies.

In study 1, participants ($n=64$) made a choice between two resort hotels for spring break. The price attribute, which revealed one of the hotels was 20% cheaper than the other, was the fifth attribute in a six attribute sequence. Of the 64 participants, 18 exhibited a leadership pattern that qualified them for testing the benefits reversion hypothesis. Specifically, 18 participants switched to the cheaper hotel as a result of price. Twelve of these 18 participants (66.6%) switched back to their benefits leader after the last attribute, a proportion significantly greater than the normative proportion benchmark ($z=2.03, p<.05$). Importantly, these 18 participants were not more likely than other participants to exhibit leadership reversals before the price attribute.

Study 2 was designed to replicate study 1 and to test whether reversion to the benefits leader would occur even when the last attribute favored the cheaper hotel. To this end, we used the same stimuli from study 1, with one exception—the last attribute was

designed so that it diagnostically favored the cheaper brand. Our data revealed that 16 of the 50 participants in this study adopted the cheaper brand as their new leader after seeing the price attribute. As in study 1, a majority of these ($n=11$, or 68.8%) switched back to their benefits leader after the last attribute, even though this benefits based attribute favored the cheaper brand. This proportion was significantly greater than the normative benchmark for study 2 (28.3%; $z=3.59, p<.001$). Again, no individual differences in pre-price switching rates were found.

Two studies revealed that a majority of those who switched from their benefits leader to a cheaper option switched back to their benefits leader upon reading new non-price information. In study 2, a majority reverted back to their benefits leader even though the last attribute objectively favored the currently leading net-p leader (i.e., the cheaper option). These results have implications for pricing strategy, sales closing techniques, and the design of comparative advertising. They also have theoretical implications for the role of price as an attribute. Namely, most choice models of consumer behavior (e.g., conjoint analysis) do not afford unique status to price beyond suggesting that it should be given adequate weight to reflect its universal importance. Our findings suggest that price, as an attribute, should be treated as a unique entity.

The Brand Anchoring Effect: A Judgment Bias Resulting from Brand Awareness and Temporary Accessibility

Franz-Rudolf Esch, Justus Liebig University Giessen, Germany

Bernd H. Schmitt, Columbia Business School, USA

Joern Redler, Madeleine Mode, Germany

Tobias Langner, Justus Liebig University Giessen, Germany

EXTENDED ABSTRACT

Introduction

Anchoring refers to a biased judgment on a stimulus based on the initial assessment of another stimulus and the insufficient adjustment away from that initial assessment. Previous research indicates that anchoring seems to be a general phenomenon, underlying a wide variety of processing strategies (Epley and Gilovich 2001; Johnson and Puto 1987; Tversky and Kahnemann 1974). Every time when individuals form an impression or an image about a stimulus while another stimulus is present, these impressions may be subject to anchoring effects.

Consumers regularly form images about brands and compare brands to other brands. We therefore propose that there will be an anchoring effect in image impressions about brands—a phenomenon that we will refer to as “the brand anchoring effect.” The brand anchoring effect can be investigated, for example, in the context of co-branded identities (e.g., cellular phones offered by the brand alliance Sony Ericsson). We propose that in these co-branding cases, one constituent stimulus (Sony or Ericsson) may serve as an anchor and affect the image structure of the co-branded identity (Sony Ericsson) as a whole. We test the brand anchoring effect in three studies, identifying characteristics of the co-branded entities that lead to one of the constituent entities to become the anchor. We derive our hypotheses on the basis of the Selective Activation, Reconstruction, and Anchoring (SARA) model (Pohl, Eisenhauer, and Hardt 2003), which is specifically designed to explain anchoring effects, and the customer-based brand equity model (Keller 1993, 2003).

Theoretical Background

The SARA model assumes that when individuals are asked a question that requires a judgment (e.g., what is the brand personality of the co-branded identity?), they utilize available images about the “information units” in long term memory (such as an image of the brand associations of a constituent brand). Each judgment is associated with a number of images of the brands and the SARA model specifies which “information units” are chosen as an anchor. Specifically, the selection of the anchor and the direction of the judgment bias depend on distinct characteristics of internally represented brand knowledge. Once a brand has been selected as an anchor, it will bias the co-branded identity in such a way that its knowledge structure will be closer to the anchor brand than the other constituent brand.

Consistently with the SARA model, it has been shown in a wide range of domains, such as information integration theory (e.g., Fazio and Williams 1986), the accessibility-diagnostics framework (e.g., Feldman and Lynch 1988), brand alliances (e.g., Simonin and Ruth 1998), and in research on priming, that the accessibility of information has a strong influence on judgments. In the context of branding, Keller (1993) identifies brand awareness as one of the most important factors for retrieval of information about the brand. Thus, following the SARA model and the brand alliance study by Simonin and Ruth (1998), we predict that brands with a high level

of awareness in a co-branded identity are more likely to be anchors than those with low awareness.

Method

To test our hypothesis about the brand anchoring effect, we conducted three studies (each $n=80$) with fictitious brand alliances of existing brands from three different product categories. In studies 1 and 2, respondents evaluated the alliances and the constituent brands on Aaker's (1997) brand personality scale. We conclude that an anchoring effect was present or not, based on standard similarity measures (D , X , and q correlation) that compare the profiles of constituent brands with the brand alliance.

Study 1

In study 1, we tested two brand alliances that either consisted of two toothpaste brands with different levels of unaided awareness (high/low) or similar levels of awareness. The results support our assumption: The judgment of the brand alliance was based on the brands with the higher level of brand awareness. In contrast, in the similar-brand-awareness condition, none of the brands served as an anchor.

Study 2

Study 2 was designed to replicate the brand anchoring effect of high vs. low awareness for a new product category (chocolate). In addition, we tested whether or not we would observe anchoring effects for strong image brands (relative to weak image brands) when the awareness levels of both brands in the alliance are at comparable high levels.

Our results provided a replication of the brand anchoring effect of high (vs. low) awareness brands. However, when both alliance constituents have high awareness, independent of brand strength, none of the brands served as an anchor.

Study 3

In study 3, we addressed the key question of *how* brand awareness creates a brand anchoring effect. Following the SARA model, it is available information that provides retrieval cues, and therefore for awareness to produce anchoring effects, brand awareness should make information more available. Thus, we manipulated brand awareness and the availability resulting from it, rather than just measuring it (as in the previous two studies). Respondents were exposed to two different packaging designs for the brand alliance Milka Uncle Ben's, offering a crispy rice chocolate cereal. The package design either provided predominantly Milka related brand elements (e.g., color) or predominantly Uncle Ben's related design elements.

As expected, the profile in the Milka focused design was closer to Milka than Uncle Ben's whereas the profile of the Uncle Ben's focused design was closer to Uncle Ben's. These results confirmed that the packaging design made Milka brand-related information more available when the design first brought to mind Milka. In contrast, it made Uncle Ben's brand-related information more available when the design first brought to mind Uncle Ben's.

Conclusion

Taken together, the results of the three studies confirm our overall prediction: brand-related information, once made available, can result in a brand anchoring effect in the judgment of a co-branded entity. Brand-related information may be permanently more available in high awareness brands; alternatively, it can be made more available temporarily by presenting the co-branded entity in a particular way. Future research should examine possible moderators of the brand anchoring effect, such as brand name order in the alliance or product category fit, and how these factors influence the selection of the brand anchor.

Brands as Categories: Graded Structure and Its Determinants

Christopher Joiner, George Mason University, USA

ABSTRACT

As a result of many years of brand leveraging by marketers many brands now consist of multiple products sharing a single brand name. An outcome of this is that one of the ways that consumers' product information is likely to be organized is as brand categories.

Although these groups of related products are alternatively referred to as "umbrella brands," "brand portfolios," and "family brands," since it is the goal of this paper to investigate the nature of these groups as cognitive structures, the term brand categories is used. There are other possible organizations of consumer knowledge (e.g., by product categories, consideration sets, usage situations, etc.) however, the growing importance of brand categories to practitioners and academics alike suggests that brand organization is increasingly relevant. This research focuses on the structure of brand categories by specifically examining a number of alternative determinants of graded structure in two existing brand categories.

A series of surveys were used in order to collect individuals' perceptions of the two focal brand categories. Analysis of variance, factor, correlation, and regression analyses were all used to examine the internal structure of the brand categories. Analyses confirmed that brand categories do in fact possess graded structure as do the majority of other previously identified categories. The data suggests that all of the determinants of typicality that were examined (ideals, familiarity, frequency-of-instantiation, attribute structure, coherence) were highly correlated and closely related to overall typicality judgments. Further analyses suggested that both coherence and familiarity/frequency-of-instantiation were the best determinants of subjects' typicality ratings in the two brand categories examined here. The findings for the coherence measure were particularly interesting as this variable has rarely been empirically examined as a possible determinant of typicality judgments prior to this research. Significantly, this measure performed as well as other determinants that have been looked at in prior studies. Finally, as has been found in past research, the typicality of individual products in both brand categories was positively related to overall attitudes for the individual products. Theoretical and managerial implications of the findings are discussed.

It is now common for companies to have a series of products, more or less related, that are on the market under a single brand name. For example, Haagen-Dazs started out with a single product—premium ice-cream—but through a series of extensions and licensing agreements, now offer an array of products under the Haagen-Dazs brand name including frozen yogurt, sorbets, ice-cream bars, frozen yogurt bars, sorbet bars, and even liqueur. This market phenomenon suggests that one of the ways that consumers' product information is likely to be organized is as brand categories (e.g. Barone and Miniard, 2002; Boush and Loken, 1991; Boush et al., 1987; Cowley and Mitchell, 2003; Lee and Sternthal, 1999; Park, Milberg, and Lawson, 1991; Wanke, Bless, and Schwarz, 1998). Brand categories have also been labeled "umbrella brands," "brand portfolios," and "family brands". However, since it is the goal of this paper to investigate the nature of these groups of products as cognitive structures, the term brand categories will be used. Although there are other possible organizations of consumer knowledge (e.g., by product categories, consideration sets, usage situations, etc.) the growing importance of brand categories to practitioners and academics alike suggests that brand organization is in-

creasingly relevant. This research focuses on the structure of brand categories by specifically examining a number of alternative determinants of graded structure in two existing brand categories.

BRAND CATEGORY STRUCTURE

Cognitive structure is a hypothetical construct referring to the organization of concepts in memory. Structures in memory influence whether a particular piece of information will receive attention, and if so, the manner in which it will be encoded, organized, and subsequently retrieved. They also function as interpretive frameworks and thereby influence evaluations, judgments, predictions and inferences; and finally, overt behavior (Markus and Zajonc 1985).

Brand Category Graded Structure

A common characteristic of categories is their internal organization in a graded structure (Mervis and Rosch 1981). Graded structure means that a category consists of a continuum of category membership, ranging from typical (prototypical) members through unclear cases to prototypical nonmembers (Barsalou 1982). Typicality ratings predict performance in a wide variety of tasks, including categorization, remembering, naming, or reasoning about a concept's instances, with better performance associated with more typical instances (Barsalou 1992). Additionally, past research has suggested that an exemplar's typicality is related to overall attitudes towards the exemplar (Barsalou 1983, 1985; Loken and Ward 1990; Nedungadi and Hutchinson 1985) with more typical exemplars being more highly evaluated.

One of the important implications of graded structure, in the context of brand categories, is that typical instances of a category are used more often as cognitive reference points in comparisons (Mervis and Rosch 1981). This implies that if brand categories do possess the property of graded structure, the most typical products in the category may play a relatively larger role in how consumers think about the brand. Product categories have been shown to have graded structure with characteristics of both goal derived and taxonomic categories (Loken and Ward 1990) as have brand categories consisting of existing and hypothetical products (Boush 1988). In the context of brand categories, graded structure implies that some products are more representative of a brand name than are others (Boush and Loken 1991; Loken and John 1993).

Conceptually, it is possible that brand categories may be different from other types of categories with respect to graded structure. Boush (1993) noted that applying a common brand name to products differs from the way names are applied to objects in common taxonomic categories. Categorization of objects in common taxonomic categories frequently involves making the categorization decision ("Is it a member of category X?") after observing its characteristics. Unlike members of taxonomic categories, a branded product is categorized as a member of the brand category from the outset simply by being labeled with the brand name. When consumers see a branded product, they are essentially told that it is a member of an existing brand category. Other research has shown that how objects are grouped or organized together can influence which properties are used in judgments of the similarity of the objects (Tversky 1977). A specific grouping may determine the similarity of the objects in the group, rather than similarity judgments about the objects determining the grouping or classification. This suggests that grouping a set of products under a common brand

name may influence the selection of the particular properties that are attributed to the brand category (i.e., determine the dimensions of similarity that make the products cohere or fit, cf. MacInnis, Nakamoto and Mani 1992) and to some degree form the basis for categorization. As a result, because the products are by definition grouped together as “Brand X products,” all products sold under that brand name may be perceived as equally good, or typical, members of the brand category. Their organization under a common brand name may influence which properties are used to judge their similarity and select “common” features that individuals then use to “explain” the brand category. For example, because a wide range of products like athletic shoes, socks, t-shirts, hats, etc., are all sold and labeled as “Nike products,” consumers may attribute specific properties to the brand based on this grouping (e.g., “sportiness”) and view all of the products as highly similar on this dimension and therefore equally good examples of the Nike brand category.

However, it is more likely that brand categories have the property of graded structure with the typicality of products in a brand category determined by factors that have been identified as relevant to other categories (e.g., attribute-structure, ideals, coherence, familiarity).¹

In order to investigate the graded structure of categories, researchers have attempted to define some of the determinants of typicality. Frequently used measures that have been examined as possible determinants of global typicality ratings (e.g., Hampton and Gardiner 1983; Loken and Ward 1990) include: familiarity and frequency-of-instantiation (Barsalou 1985; Hampton and Gardiner 1983; Loken and Ward 1990; Martin and Stewart 2001; Read, Jones, and Miller 1990), attribute-structure (Loken and Ward 1987, 1990), ideals (Barsalou 1985; Martin and Stewart 2001; Read et al. 1990), coherence (Dawar and Anderson 1994). More recently, Viswanathan and Childers (1999) developed an alternative measure of product category gradedness based on fuzzy-set theory. A brief description of these measures is presented in the next section.

Determinants of Typicality

Familiarity. Past research has been mixed in finding that familiar exemplars are perceived as more typical than unfamiliar exemplars. Familiarity is measured in a category-free context in contrast to the frequency of instantiation measure described below. Barsalou (1985) found that familiarity was not a significant determinant of the graded structure of either taxonomic or goal-derived categories, Loken and Ward (1990) found that it was positively related to typicality for some product categories, while other researchers have found a significant positive relationship (e.g., Hampton and Gardiner 1983). Because of the unique characteristic of brand categories, familiarity may be an important determinant of their graded structure.

Frequency of Instantiation. Frequency of instantiation refers to a measure of the frequency with which people have experienced a particular exemplar as a member of a particular category, rather than a measure of the absolute frequency with which an exemplar is experienced and has been proposed as a more appropriate determinant of typicality than familiarity (Barsalou 1985). Exemplars that appear more frequently should have greater influence on the representation of the category and therefore typicality judg-

ments (Barsalou 1985). Research using this measure has found it to be a significant determinant of graded structure (Barsalou 1985; Loken and Ward 1990).

Ideals. Barsalou (1985) defined ideals as characteristics that exemplars should have if they are to best serve a goal associated with their category and found that they were an important determinant of graded structure in both common taxonomic and goal-derived categories. Loken and Ward (1990) demonstrated that ideals were a significant determinant of the graded structure of product categories (see also Read et al. 1990). Brand categories may also be structured by ideals since consumers may view a brand as a means to an end or associate it with a particular function, and typicality judgments may reflect the likelihood that a product will help achieve the consumption goal (cf. Broniarczyk and Alba 1994), as e.g., Lysol products and a “disinfectant” goal.

Attribute-Structure. The attribute-structure measure is based on the view that consumers judge the typicality of a product less by its family resemblance to other products and more by the degree to which the product has salient attributes related to the goals or uses of the category. The measure is assumed to encompass a more complete set of beliefs rather than a single ideal. Loken and Ward (1987, 1990) found that attribute-structure is particularly relevant to product categories in which graded structure was a function of salient beliefs about the member’s utility to consumers.

Coherence. Coherence, a measure used previously in brand extension research (Dawar and Anderson 1994), refers to how logical individual products are, and how much sense they make, as members of the brand category. This measure may be an important determinant of graded structure in the context of branded products. It attempts to assess consumers’ perception of the coherence (Lakoff 1987; Dawar and Anderson 1994; Medin and Wattenmaker 1987) of the brand category, or the extent to which the collection of products make sense under the brand name. This measure may account for consumers’ theories (cf. Murphy and Medin 1985) about why a group of products are sold under a particular brand name. The coherence measure focuses on “explanation” as a key variable in categorization decisions (Rips and Collins 1993). Because brand categories are essentially created and defined by marketers, coherence may be a particularly appropriate measure for accounting for consumers’ judgments about product typicality. Those products that make sense or are logical, given a consumer’s theory about what the brand means, may be viewed as the brand category’s most typical members.

Prior Consumer Research on Category Structure

Earlier research examined the determinants of typicality in product categories (Loken and Ward 1990, see also Viswanathan and Childers 1999) and demonstrated that new brand extensions vary in their typicality with respect to a brand category (e.g., Boush and Loken 1991; Loken and John 1993). Boush (1988) did measure the typicality of products in existing brand categories, however, it only examined a few (2-3) existing products in addition to a group of hypothetical products not sold by the brand. This research replicates and expands these results by considering the graded structure of existing products in real brand categories. In addition to confirming the existence of a graded structure for the exemplars within each brand category, it also addresses the ability of individual measures identified in previous work to predict global measures of typicality (cf. Loken and Ward 1990). Finally, because past research has demonstrated that an exemplar’s typicality is related to overall attitude towards the exemplar (Barsalou 1983, 1985; Loken and Ward 1990; Nedungadi and Hutchinson 1985), this relationship is examined as well.

¹In addition to research showing that different brand extensions vary in perceived typicality, some researchers have claimed that no categories have been discovered to date that do not have this property (Barsalou and Sewell 1985).

STUDY & EMPIRICAL RESULTS

All participants were undergraduate students enrolled in introductory marketing courses who participated as a class requirement. A series of pretests were conducted in order to develop the stimuli used in the main study.

Pretest 1. The first pretest was used to choose two existing brand categories that were familiar to participants and which consisted of a reasonable number of products currently sold in the local area under the brand name. A survey of local grocery, drug, and discount stores as well as of magazines, local newspapers, and *Consumer Reports*, was used to generate a list of eight potential brand categories. Thirty-nine respondents completed Pretest 1. Twenty of the respondents listed "as many of the specific products that you are aware of that are sold under the brand name" for four of the brand names. They then rated the typicality of the individual products for the other four brand names on an 11-point scale from "not at all typical" to "extremely typical." The other 19 respondents completed the same tasks for the brands in the opposite order. Finally, all respondents rated their familiarity with "products sold with the brand name" for each of the eight brand names on an 11-point scale from "never heard of them" to "extremely familiar". Based on the average number of products listed in the open-ended questions, the rated typicality of the individual products in the brand category, and the familiarity with the brand name, the Haagen-Dazs and Levi's brand categories were chosen. Each were familiar to most individuals and had a reasonable number of products (Haagen-Dazs=8; Levi's=12) that varied in perceived typicality.

Pretest 2. A second pretest was conducted to obtain a list of ideals and attribute beliefs, for each of the brand categories selected in Pretest 1. Ideals were selected by asking a sample of 29 participants to "list your goals or purposes for purchasing the following brand name". Two ideals for each category were chosen by taking the most frequently mentioned goals or purposes, mentioned by at least 34% of respondents (cf. Loken and Ward 1990).

This pretest sample also was used to develop the attribute dimensions used in the attribute-structure measure in the main study. Specifically, they were asked to list the "positive and negative attributes, qualities, or characteristics of this brand name that would increase (or decrease) your chances of purchasing one of its products." The most frequently mentioned attributes, mentioned by at least 39% of respondents, were used to form four belief statements for Haagen-Dazs and five for Levi's.

Graded Structure Measures and Data Collection Procedure. Four separate sets of respondents (total N=231) were used for the graded structure data collection. For each set of measures, the most typical individual product (based on Pretest 1 results) was presented first with the remaining products in the brand category presented in random order. This was done in order to anchor each person's judgments on the same prototypical product. Individuals were informed that all products in the survey were real products sold in the area.

The first set of 56 respondents provided global measures of typicality for each individual product in the two brand categories. Typicality was measured on two scales: typicality and representativeness. Subjects rated each product on a scale ranging from 0 (not at all typical of Brand X products) to 10 (extremely typical of Brand X products) and a scale ranging from 0 (very unrepresentative of Brand X products) to 10 (very representative of Brand X products). Instructions were adapted from Loken and Ward (1990) and Hampton and Gardiner (1983).

A second set of 56 respondents provided measures of familiarity and frequency of instantiation for the two brand categories. Familiarity was measured on scales ranging from 0 (not at all familiar) to 10 (extremely familiar). Instructions explained that:

"You should judge how familiar you are with the specific product not just with the brand name." The frequency of instantiation measure was adapted from the procedure used by Loken and Ward (1990). It was measured by asking the same respondents to rate how frequently they encountered each category member (product), in stores, advertisements, at a friend's, as a member, or example, of the category (made up of all the products sold under the brand name) on scales ranging from 0 (not at all frequently) to 10 (extremely frequently). Instructions noted the difference between this measure and the familiarity judgments. As in Loken and Ward (1990), respondents rated the two brand categories on both measures in order to increase the likelihood that they would discriminate between the two tasks.

The ideals and attribute-structure measures were completed by a third set of 58 respondents. Each rated (i) the extent to which category members fulfilled each ideal on scales ranging from 0 (very low amount) to 10 (very high amount), and (ii) the likelihood that each product possesses each attribute on scales ranging from 0 (extremely unlikely) to 10 (extremely likely). An attribute structure score for each individual product was computed by summing across the belief ratings for each subject.

A fourth set of 61 participants completed the coherence and attitude measures for the brand categories. Based on the definition described above, individuals were asked to decide "whether each product makes sense to you, or is logical, as a product of each brand name." Coherence was measured on two scales, the first ranging from 0 (makes no sense as a Brand X product) to 10 (makes a great deal of sense as a Brand X product), the second ranging from 0 (is very illogical as a Brand X product) to 10 (is very logical as a Brand X product). The same participants reported their attitude towards each product in the brand categories on three 0-10 evaluative semantic differential scales (unfavorable/favorable, very negative/very positive, poor/excellent).

All measures were averaged across individuals to provide an overall rating for each individual product. Each of the multiple item measures (typicality, coherence, attitude) were summed to form composite scales. The resulting scales (TYPIC, COHER, ATTIT) were assessed to ensure their reliability. For the 8 Haagen-Dazs products, the average coefficient alpha for the TYPIC measure was .89 (range: .798 to .960), for the 12 Levi's products, the average was .92 (range: .786 to .964). For the COHER measure, the average was .98 (range: .955 to .994) for the Haagen-Dazs products and .98 (range: .955 to .997) for Levi's. Finally, for the ATTIT scale, the average was .97 (range: .947 to .997) for the Haagen-Dazs products and .98 (range: .975 to .990) for the Levi's products.

Graded Structure Results

Analysis of the data focused on confirming that the brand categories do possess a graded structure (Barsalou 1983, 1985) and in determining which measures are the best determinants of this structure. The typicality ratings for the individual products in the two brand categories were analyzed in a one way repeated measure analysis of variance with the products as a within subjects factor. The results indicate that the individual products in both brand categories varied in subjects' perceptions of their typicality, with the products factor significant at $p=.000$ in both multivariate and univariate tests for both categories. Follow-up comparisons were conducted on the individual products in each category (see Table 1). The Haagen-Dazs brand category is characterized by a single prototypical product (ice cream), while jeans are clearly the prototypical product in the Levi's brand category. There was clear evidence of graded structure in both brand categories. The individual products represented a significant range of perceived typicality ratings.

TABLE 1
Individual Product Typicality Rating Means

Levi's			Haagen-Dazs	
jeans	9.29 ^a		ice cream	8.47 ^a
jean jacket	8.10 ^b		ice cream bar	7.58 ^b
jean shorts	7.82 ^{bc}		frozen yogurt	6.25 ^c
denim shirt	7.31 ^{cd}		frozen yogurt bar	5.89 ^c
jean vest	6.38 ^{cd}		sorbet and cream	5.68 ^c
t-shirt	5.69 ^{cd}		sorbet	5.56 ^c
flannel shirt	5.20 ^{fg}		sorbet bar	5.41 ^c
sweatshirt	5.15 ^{fg}		liqueur	2.55 ^d
belt	4.37 ^g			
socks	3.01 ^h			
polartec vest	2.59 ^h			
wallet	2.47 ^h			

Products sharing a superscript are not significantly different in pairwise comparisons ($p < .05$)

A series of correlation, factor, and regression analyses were conducted to investigate the relationships between the determinants, typicality, and attitude (cf. Loken and Ward 1990). Table 2 presents the correlation matrix between the typicality and attitude measures and the six potential determinant measures for the 20 products in the two brand categories. First, it is clear that all of the measures are highly related, with slightly higher correlations in the Levi's brand category. Although past research has found distinctions between the various determinants of typicality investigated in this study, for these stimuli all of the determinants appear to be highly related to perceived typicality. The measure with the lowest simple correlation with typicality was the attribute structure measure, and it was still a highly significant .832. Correlations between the various determinants were also high. For example, in this sample, measures of frequency-of-instantiation (FOI) and familiarity (FAMIL) are virtually indistinguishable ($r = .994$). Additionally, ratings of the two ideals measures were highly correlated ($r = .963$). To further examine these findings, a factor analysis (principal components, varimax rotation) was conducted. A single factor, accounting for 88.9% of the variance in the data, was extracted. All of the individual measures loaded on this factor with typicality and all factor loadings were above .89.

Although it was apparent that each of these measures was highly related to typicality in these brand categories, further analyses were conducted in order to examine their relative contributions. Because of the very high correlations between the FOI and FAMIL and two Ideals measures, each of these pairs was combined for the remaining analysis (FAMFOI and IDEALS). The four variables (COHER, FAMFOI, IDEALS, Attribute Structure) were entered in a regression with typicality as the dependent variable. The overall regression equation was highly significant ($F(4,15) = 217.24$, $R^2 = .983$, Standard Error = .295) and the two significant predictors were the COHER ($\beta = .524$) and FAMFOI ($\beta = .358$) measures.

Although these results should be interpreted with caution, there is some evidence that for these brand categories, the more an individual product makes sense, or is logical, as a member of the brand category, and the more familiar the product is, the more it is seen as a typical member of the brand category.

Finally, the simple correlation between TYPIC and ATTIT was a highly significant .879 (.862 and .954 in the Levi's and Haagen-Daz's brand categories respectively), replicating the relationship found for these two measures in past research (Barsalou 1983, 1985; Loken and Ward 1990; Nedungadi and Hutchinson 1985). In the two brand categories examined in this study, the typicality of a product is highly related to its evaluation.

GENERAL DISCUSSION

The results confirmed that brand categories do in fact possess graded structure as do most other previously identified categories. There were significant differences in the rated typicality of the individual products in both of the brand categories examined in this research. There were different patterns of typicality ratings for the products in the two brand categories, but it did not appear that there was a simple division between typical and less typical products. For example, Haagen-Dazs had an extremely prototypical product (ice cream) and a very atypical product (liqueur) with the remaining six products all viewed as moderately typical. The Levi's brand category consisted of products with a broader range of typicality ratings. Clearly, consumers judge certain products to be better examples of a brand category than others.

The data suggests that all of the determinants of typicality that were examined were closely related to typicality judgments. Further analyses suggested that both coherence and familiarity/frequency-of-instantiation were the best determinants of subjects' typicality ratings in the two brand categories examined here, however, these results must not be overstated given the high

TABLE 2
Correlations: Typicality, Attitude, and Individual Determinant Measures

Levi's (N=12 products)

	TYP	COH	FAM	FOI	IDLS1	IDLS2	ATST

* Correlations greater than .710 are significant at $p < .05$, two-tailed

correlations between all of the determinants examined and typicality. It appears that multiple determinants may influence consumers' perceptions of the typicality of products in a brand category.

The findings for the coherence measure were particularly interesting. Although this measure has been used previously in brand extension research (Dawar and Anderson 1994), and has its roots in the categorization literature in psychology (e.g., Lakoff 1987; Murphy and Medin 1985), it has never been empirically examined as a possible determinant of typicality judgments prior to this research. Significantly, this measure performed as well as other determinants that have been looked at in prior studies. The coherence measure seems particularly well-suited for studies of the graded structure of brand categories, capturing consumers' perceptions of how logical a product is, or how much sense it makes, as a member of a brand category. These judgments may be one of the best indicators of a products perceived typicality in categories which are essentially created and defined by marketers.

In the two brand categories examined here, the familiarity and frequency-of-instantiation (FOI) measures were virtually identical

($r = .994$). Chairs and firewood provide the classic example of when these two measures diverge. Most people are very familiar with chairs, but do not frequently encounter them as a member of the category firewood. It is likely that for many brand categories these two measures will be highly similar. In most situations, consumers will encounter a product as a member of the brand category. Sub-brands provide a likely exception to this generalization. Consumers may be highly familiar with Band-Aid bandages, or Nyquil medicine, but may not frequently encounter them as members of the Johnson & Johnson, or Vick's brand categories. In situations where there are multiple brand names associated with a product, and differences in the relative emphasis the names receive in marketing efforts, there may be differences between these two measures. Finally, as has been found in past research, the typicality of individual products in both brand categories was positively related to preferences (overall attitudes) for the individual products.

Developing knowledge of the relative importance of various predictors of typicality within brand categories is an important task that can be useful for brand managers in understanding consumers'

perceptions of their brands and products and for managing brand leveraging strategies. Many of the factors examined in this study may be differentially influenced by various marketing efforts, suggesting that marketers may be able to influence consumers' perceptions of the typicality of various products. This is particularly important since it was found that attitude and typicality are positively correlated in brand categories. Interestingly, the data suggest that there may be various ways for marketers to influence these perceptions. For example, a product's coherence may be affected by the effectiveness of marketing communications in convincing consumers that a product is a logical addition to the brand family. Alternatively, because familiarity/frequency of instantiation were also identified as important determinants, marketers may be able to pay less attention to the initial typicality of a new product they introduce to the brand category, instead focusing on increasing consumers' frequency of advertising exposure and product usage, which will in turn influence the product's perceived typicality (cf. Alba and Hutchinson 1987). The data suggests that marketers may be able to pursue multiple routes in influencing consumers' perceptions of the typicality of products in their brand categories.

It is possible that unlike in other types of categories (e.g., ad hoc, taxonomic) where a single, or small number of determinants account for observed typicality ratings, the typicality of individual products in brand categories are equally influenced by a wide range of factors.

Limitations

The results reported here should be interpreted in light of the fact that the research only examined two existing brand categories in a specific experimental context. The use of additional experimental paradigms and tools (e.g., reaction times) would be useful in furthering our understanding of brand category structure. It is very likely that brand categories of different sizes and composition may have characteristics that make them unique to some extent. Additionally, different contexts are likely to influence perceptions of graded structure and typicality (Barsalou 1982; Wanke, Bless and Schwarz 1998). Future research should expand the number and type of brand categories and contexts that are investigated, looking for any other important factors that may influence brand category graded structure.

After many years of pursuing brand extension strategies, many companies now have brand categories in their portfolios. It is critical for managers to understand how consumers' representations of these existing products interact and influence consumer behavior. Future research should continue to investigate brand category phenomena, acknowledging that an array of products often exist under a single brand name.

Which Fit Do Consumers Use in Composite Brand Extensions?

Roger Pruppers, Maastricht University, The Netherlands
Hans Ouwersloot, Maastricht University, The Netherlands
Niraj Dawar, University of Western Ontario, Canada

EXTENDED ABSTRACT

Theoretical Background

Composite Brand Extensions (CBEs) are a symmetrical co-branding arrangement where contributions of both parent brands are fully integrated (Ugla, 2004), such as SonyEricsson mobile phones and FujitsuSiemens computers. Several studies acknowledge that perceived similarity or “fit” is a core success factor for brand extensions (Aaker & Keller, 1990; Broniarczyk & Alba, 1994; Park, Milberg, & Lawson, 1991). In the Composite Brand Extension context, the role of fit may be markedly more complex. Consumers are not only confronted with an additional source of “product fit” (that between each of the parent brands and the extension product), but may also assess the fit between the two brands involved in the alliance (“brand fit”). Although several authors have suggested that different bases of fit play a role in a brand alliance context (e.g. Baumgarth, 2000; Simonin & Ruth, 1998; Ugla, 2004), little is known about the cognitive processes underlying the simultaneous evaluation of multiple fit cues.

The use of these cues is constrained by the principle of cognitive economy (e.g. Costley & Brucks, 1992; Garbarino & Edell, 1997; Park & Hastak, 1994), under which consumers are expected to exert as little cognitive effort as is necessary to accomplish a judgment task (Wyer & Srull, 1986). Therefore, they select cues that are most easily retrieved from memory, and most likely to carry the information required for the judgment task (Feldman & Lynch, 1988). Based on the accessibility-diagnostics framework, we propose a hierarchy of fit types in which the most accessible and diagnostic types of fit are given priority.

Hypotheses

Brand associations can be classified by their level of abstraction (Alba & Hutchinson, 1987; Keller, 1993). We conceptualize product fit as the association overlap between the current product categories of the parent brands and the extension product (Aaker & Keller, 1990). Brand fit on the other hand relates to the congruence between the parent brand concepts (Simonin & Ruth, 1998), such as “functional” or “prestigious” (Park et al., 1991). Cognitively, brand fit is at a higher level of abstraction than product fit. Consequently, it is both more accessible (Lynch Jr., Marmorstein, & Weigold, 1988) and more diagnostic (Menon & Raghuram, 2003) than product fit, as it provides richer, more generalizable information. We postulate that brand fit will have a stronger impact on CBE evaluations than product fit (Hypothesis 1).

Since we posit that the role of any given fit type in the evaluation process depends on its relative levels of accessibility and diagnosticity in comparison to other types of fit (Feldman & Lynch, 1988), we develop hypotheses for a three-way interaction between brand fit, product fit with parent brand A, and product fit with parent brand B. Brand fit and product fit provide complementary information, where brand fit explains the rationale behind the brands’ collaboration (Simonin & Ruth, 1998), and product fit explains why they jointly market the extension product. In line with the cognitive economy principle, we hypothesize that product fit with either parent brand will be sufficient for consumers to perceive the logic behind the alliance. The second product fit is then less diagnostic. Thus, when brand fit is present, the effect of a product fit will be

more pronounced when the other product fit is low than when it is high (Hypothesis 2a).

In the absence of brand fit information, consumers are expected to rely more extensively on product fit information. The second product fit thus becomes more diagnostic, leading to a hypothesis that is the reverse of hypothesis 2a: when brand fit is absent, the effect of a product fit will be more pronounced when the other product fit is high than when it is low (Hypothesis 2b). Together, Hypotheses 2a and 2b suggest a three-way interaction.

Method and Findings

The research design involved a 2*2*2 between-subjects factorial design, the factors being product fit A (high vs. low), product fit B (high vs. low) and brand fit (high vs. low). In line with previous research on brand alliances (e.g. Park, Jun, & Shocker, 1996; Simonin & Ruth, 1998), the stimuli consisted of existing brands and hypothetical (Composite) Brand Extensions. We conducted a series of pretests to develop and test the stimulus brands and products. In line with the research design, eight different scenarios were developed to represent the different combinations of the three fit types. Each scenario was evaluated by 30 respondents, with an effective sample size of 240. All hypotheses were analyzed by means of ANCOVA.

Our analyses support the hypotheses and reveal that brand fit occupies a central position in the evaluation process of Composite Brand Extensions. Although its main effect is more than twice as large as the effect of either product fit, brand fit is not a sufficient condition for favorable CBE evaluations. When the parent brands’ images match, product fit with either parent brand generates positive CBE evaluations. When brand fit is absent, the second product fit becomes more important. It can attenuate the negative consequences of lacking brand fit, yet it cannot fully compensate for them.

Our results generate further insight into consumer evaluation processes of brand alliances. They illustrate that consumers take multiple sources of perceived fit into account when evaluating Composite Brand Extensions. The respective role of these fit cues in the evaluation process appears to be determined by their relative levels of accessibility and diagnosticity. The central position of brand fit in this context illustrates the differences between the evaluations of simple and composite brand extensions, and emphasizes the importance of selecting an alliance partner with a congruent brand concept. Furthermore, our findings indicate that brands may gain access to unrelated markets by means of an alliance, provided they team up with a partner that has a brand concept that fits.

Corporate and Product Message Effects on a Product Portfolio

Daniel A. Sheinin, University of Rhode Island, USA

Gabriel J. Biehal, University of Maryland, USA

ABSTRACT

Based on a diagnosticity framework, we examine how corporate messages differentially transfer to consumers' judgments of multiple products in a company's portfolio compared with a product message. We find corporate messages influence the product portfolio, although the nature of their influence depends on message content. Corporate ability messages had stronger effects on product beliefs than corporate social responsibility messages. Both types of corporate messages had a greater influence on unknown products in the portfolio than known products, and product messages only influenced that product not other unknown products in the portfolio.

Me, Myself, and My Choices. The Influence of Self-Awareness on Preference-Behavior Consistency

Caroline Goukens, K.U.Leuven, Belgium
Siegfried Dewitte, K.U.Leuven, Belgium
Luk Warlop, K.U.Leuven, Belgium

EXTENDED ABSTRACT

For a long time consumers have been assumed to be rational decision makers with well-defined preferences. Experimental research, however, suggests that consumers often construct their preferences as needed to make decisions (Bettman, Luce, and Payne 1998). Consumers' tendency to sometimes switch away from their favorite choice options (Ratner, Kahn, and Kahneman 1999), as well as the subtle influence of task and context factors (e.g. Huber, Payne, and Puto 1982), lead to inconsistencies in consumers' choices.

Public self-awareness, often induced by the presence of an audience or video camera, has recently received attention by consumer behavior researchers, most notably by Ariely and Levav (2000) and Ratner and Kahn (2002). They found that people display more variety in their choices when their behavior is public because choosing variety is consistent with societal expectations. Private self-awareness on the other hand, although it has stimulated a lot of research in social psychology, received little attention in consumer behavior literature. In this research we examined to what extent private self-awareness can play a role in consumer decision making. As previous research in social psychology has shown that a self-attentive person becomes more conscious of his/her attitudes and beliefs (Gibbons 1990), we expected private self-awareness to reduce preference-behavior inconsistency during choice making.

In a first study (n=99), we manipulated private self-awareness by placing a mirror in front of the participants. We asked high self-aware (Mirror condition) versus low self-aware participants (No Mirror condition) to choose five frozen meals from a set of eight. Attitude-behavior consistency was operationalized as the consistency between these choices and previously measured personal liking ratings. Consistent with the prediction that high self-awareness increases attitude-behavior consistency, we found that participants in the Mirror condition stuck more to their favorite meals than participants in the No Mirror condition. Thus, high self-aware participants behave in a more consistent manner with their personal preferences than low self-aware participants.

A follow-up study (n=159) confirmed the crucial role of private self-awareness in choice making. Fenigstein and Levine's (1984) story-writing task was used to manipulate self-awareness. We compared the extent to which high self-aware versus low self-aware are susceptible to context effects (i.e. context and attraction effect). As difficulties in determining product preferences is an underlying condition for context effects to occur, we expected private self-awareness to moderate context effects. That is, when consumers have difficulty determining product preferences, a search for reasons increases the likelihood that decision makers will prefer a compromise or an asymmetrically dominating option (Simonson 1989). Thus, this bias arises not because people are simplifying, but rather because they are making too many compensatory comparisons (Dhar, Nowlis, and Sherman 2000). As consumers with articulated attribute preferences are characterized by a less comparative processing (Chernev 2003), and as private self-awareness increases the awareness of personal preferences, we expected self-awareness to decrease context effects. The results of the second study confirm this reasoning: When participants are highly self-aware, they are less likely to choose a compromise or an asymmetrically dominating option than when they are not self-aware. We

suggest that because of an increased awareness of one's personal preferences, high self-aware participants engage less in comparative processing and, therefore, are less susceptible to context effects.

In sum, the two studies reported in this paper provide strong evidence that private self-awareness can have a major impact on people's preference-behavior consistency. In the first study, we provide evidence for this conjecture: By increasing self-awareness, people are able to behave in a way that is more consistent with their personal preferences. In a follow-up study, we show that this increased preference-behavior consistency makes it more difficult for context effects to intrude: When participants are self-aware they are less likely to choose a compromise or an asymmetrically dominating option than when they are not self-aware. Both studies strongly support the view that when consumers are in a state of high self-awareness, they encounter fewer problems in determining their preferences.

Our findings also point to the practical power of private self-awareness: On the one hand, by increasing self-awareness (e.g. by placing a mirror), consumers are able to make choice decisions that match their personal preferences better, which, afterwards, might result in higher choice satisfaction. On the other hand, marketers need to understand that the advantage of certain sales tactics (f.e. creating compromise products), can disappear with self-attentive consumers. In addition, it will be harder to push a consumer towards a certain product in such conditions. Thus, certain selling environments might be more likely to benefit from selling strategies which draw attention away from the self. In general, the present research implies that marketers ought to consider the side effects of their store arrangement (e.g. mirrors) or their sales talk (e.g. small talks) on self-awareness, as these might have major implications on their sales strategies.

Who Chose the Forgone Alternative?: The Effects of Social Comparison on Regret

Karen L. Page, University of Pittsburgh, USA
Vikas Mittal, University of Pittsburgh, USA
J. Jeffrey Inman, University of Pittsburgh, USA

EXTENDED ABSTRACT

Previous regret literature has focused on individual comparisons to any alternative that was not selected (Inman, Dyer, and Jia 1997; Tsiros 1998), yet findings suggest that social comparisons play an important role in feelings and decisions (Hoelzl and Loewenstein 2005; Kumar 2004). This paper draws on research in social psychology regarding evaluations in group settings (Beach et al. 1998; Brewer and Weber 1994; Brown et al. 1992; Tesser 1988) to consider the effect of social comparisons on regret. Specifically, we examine the effects of group identity and closeness to others on regret.

The prior regret literature has demonstrated that regret occurs from comparison to forgone alternatives. How is this affected when comparisons are made to in-group members versus out-group members or to a significant other versus a stranger? Kumar (2004) finds that the valence of the decision maker's relationship with an other and the proximity of the other moderate the effect that the decision of the other impacts one's likelihood to take action. Specifically, purchase likelihood is less when a referent other in close proximity took advantage of a previous opportunity. These results indicate that social comparison to a close other can negatively impact purchase likelihood. Yet, social comparison to a close other may have positive effects on our decisions (Hoelzl and Loewenstein 2005).

Larrick (1993), drawing on social psychology literature, argues that decision-makers are concerned not only with outcomes, but also with maintaining a positive self-image. This research on group identity has found that, at the group level, a success by an in-group member leads to a positive evaluation, or minimal regret, through association with the group member and reflection upon their positive performance (Brewer and Weber 1994; Brown et al. 1992; Tesser 1988). Thus, when individuals make comparisons to the choice of an in-group member (someone who is a member of their group), reflection occurs. This reflection effect (Brewer and Weber 1994; Tesser and Campbell 1982) predicts that regret will be decreased when a group member chooses a highly satisfying alternative. In contrast, when individuals make comparisons to the choice of an out-group member (someone who is not a member of their own group), an upward comparison, or a comparison to a forgone alternative perceived to be better, is expected to increase regret.

These predictions are tested via a 2 (closeness: significant other vs. stranger) X 2 (outcome: better vs. worse) between-subjects design with MBA students (N=183). After reading a scenario about the outcome of their entrée choice at a banquet, participants indicated their regret for their dining experience. The results indicate that the interaction of closeness and outcome is significant ($p < .01$), as predicted. Examining the simple effects, we find that for participants in the better outcome condition, regret is greater among those comparing their entrée against that of a significant other than that of a stranger (3.04 vs. 2.44; $t = 2.32$, $p < .05$). For participants in the worse outcome condition, regret is less among those in the significant other condition than those in the stranger condition (3.16 vs. 3.60; $t = -1.70$, $p < .10$).

A second study further examines this effect of social comparison on regret by considering the effect of individual differences in social comparisons (Lennox and Wolfe 1984). It is hypothesized that regret for individuals who are susceptible to social comparison

information should be influenced by the interaction of the other's outcome and one's own outcome. When individuals perceive they did worse than a stranger, regret should be significantly more when one has low satisfaction with their own entrée than when they have high satisfaction with their own entrée. In contrast, for individuals who are low in social comparison and perceive they did worse than a stranger, regret should not differ between high and low satisfaction because their regret is not influenced by the other individual's better performance.

These effects are examined in a field study with restaurant customers, greatly enhancing the generalizability of these findings. A total of 215 customers at a casual dining American restaurant were surveyed about their entrée choice, their satisfaction and regret with entrée, their comparisons to entrées ordered by individuals seated at other tables, and their attention to social comparison information (ATSCI) tendencies. A significant three-way interaction among satisfaction, perception of own entrée, and ATSCI is found ($b = 0.36$, $p < .05$). In further analysis, results show that for low ATSCI individuals, the two-way interaction of satisfaction x perception of own entrée is not significant ($F_{1, 113} = 0.35$, ns), as expected. In contrast, for high ATSCI individuals, the two-way interaction of satisfaction x perception of own entrée is significant ($F_{1, 100} = 4.98$, $p < .05$), such that when a high ATSCI individual perceives their entrée to be worse, regret is significantly greater when there is low satisfaction with own entrée than when there is high satisfaction with own entrée ($M = 4.13$ vs. 2.10 ; $t = 3.46$, $p < .01$). When a low ATSCI individual perceives their entrée to be worse, regret does not differ between high and low satisfaction ($M = 2.84$ vs. 2.44 ; $t = 0.65$, ns).

The joint results of these studies indicate that it is not only *who* chose the forgone alternative, but also one's individual susceptibility to social comparisons that impacts regret. These two studies use different measures (imagined vs. real regret) and methods (between-subjects and survey) to indicate robust findings that make significant contributions to the regret literature by recognizing that regret is impacted by the social aspects of comparisons, which is consistent with previous findings on the effects of social comparisons. Since individuals frequently make social comparisons, these results have broad implications for understanding the regret consumers experience.

To Hold Me Is To Love Me: The Role of Touch in the Endowment Effect

Suzanne Shu, Southern Methodist University, USA

Joann Peck, University of Wisconsin-Madison, USA

EXTENDED ABSTRACT

How does touch influence the valuation of an object? Twenty-five years of research has shown that consumers place a higher valuation on an item once they have taken ownership of it, a finding commonly known as the endowment effect (Thaler 1980, Knetsch and Sinden 1984, Kahneman, Knetsch, and Thaler 1990). The effect has been replicated in a variety of settings and with a variety of endowed objects, including lottery tickets, mugs, pens, and chocolate bars (Knetsch and Sinden 1984, Kahneman et al 1990, Franciosi et al 1996, Johnson et al 1993). One feature of nearly all endowment effect experiments is that the buyers and sellers have the opportunity to physically hold the item being traded. But how does this physical contact with the item affect the endowed consumer's valuation and sense of ownership? Can aspects of the physical features of the item, such as how much fun it is to touch and hold, influence valuation? And how might individual differences in sense of touch interact with these physical features?

The basic finding of the endowment effect is that individuals value an item higher when it is in their possession than when it is not. In the typical experiment, half of the subjects receive an item (e.g., a mug) and are told that it is theirs to sell or keep (sellers), while half do not get an item (buyers). Solicitation of selling prices and buying prices then show a significant discrepancy; sellers often require at least twice as much as buyers are willing to pay, consistent with loss aversion (Kahneman and Tversky 1979). Additional work on the endowment effect has considered ways to moderate the effect by focusing participants' attention on certain aspects of the decision process, such as focusing on other uses for the money (Johnson, Haeubl, and Keinan 2004). Length of ownership also moderates the effect, with shorter ownership reducing (but not eliminating) it and longer ownership increasing it (Strahilevitz and Loewenstein 1998). Other recent work has looked at the role of affect, finding that endowed items can be contaminated by negative emotions such as sadness, reducing the seller's valuation (Lerner, Small, and Loewenstein 2004).

The three studies presented in this paper extend research on moderating influences on the endowment effect by demonstrating the importance of physical touch in participants' valuation of endowed objects. Based on recent research on the consumers' use of haptic (touch) information (Peck and Childers 2003a, 2003b), we propose three hypotheses relating valuation of endowed objects and feelings of ownership to whether or not individuals can touch the item (H1), whether or not the object itself is fun-to-touch (H2), and individual differences in touch preferences (H3). Study 1 examines differences in the endowment effect for a "fun-to-touch" item when participants are either able to touch the item or not, and also considers individual differences in preferences for touch. Studies 2 and 3 test the theory with a not fun-to-touch item, again considering individual differences; we then provide a direct comparison of the Study 3 results to the Study 1 results to explicitly test how the type of object influences the effect. In addition to measuring valuation of the endowed objects, we also consider participants' sense of ownership to understand how this interacts with the touch variables.

All three studies follow the basic procedure of the traditional endowment effect study, starting with an induced value market and using Becker, DeGroot, and Marshak (1964) elicitation procedures. In Study 1, we give 271 undergraduates a slinky, pretested as being

fun-to-touch. Participants are divided into buyer (chooser) and seller roles, and also split according to whether they can actually touch the slinky itself or only examine it through its packaging. We also administer the Need for Touch (NFT) scale at the end of the study to assess individual differences. A significant endowment effect is found in both conditions; however, sellers who can touch the item value it even more than sellers who can only touch the packaging. No difference is found between choosers in the two touch conditions. We also find that individual differences in sellers' (but not choosers') scores on the Autotelic NFT scale, which focuses on the sensory enjoyment associated with touch, affect valuation, as predicted.

Studies 2 and 3 allow us to further investigate how the haptic features of the object itself influence valuation. Both studies use pretested "not fun-to-touch" objects: for Study 2, a keychain, and for Study 3, a package of mini-tape. In both cases we find no effect of either the touch/no touch condition or individual differences in Autotelic NFT on sellers' (or choosers') valuations and feelings of ownership for the objects. In Study 3, we specifically chose an item that is pretested to have objective valuation similar to the slinkies used in Study 1, allowing us to do a more direct comparison of the data from both studies. We find that endowed sellers who can touch the object feel more ownership when it is fun-to-touch (the slinky) than when it is not (the mini-tape), demonstrating that the touch characteristics of the object itself have an effect. We also found in Study 3 that individuals who score high on an Instrumental NFT scale reported higher valuation and psychological ownership of the mini-tape, which we did not predict.

How does touch influence the valuation of an object? Results of our studies suggest that for endowed items that are fun-to-touch (a slinky), and for individuals who touch because they find it fun, the ability to touch leads to higher valuation and more psychological ownership. This effect of touch on endowed items does not occur for familiar items that are not fun-to-touch, such as the keychains and mini-tape in our Studies 2 and 3. Thus, the combination of ability to touch, an item's touch characteristics, and the individual preferences for touch of the individual lead to specific, predictable differences in object valuation.

Scope Insensitivity in the Service of the Rational Self: The “Mere Token” Effect

Oleg Urminsky, Columbia University, USA

Ran Kivetz, Columbia University, USA

EXTENDED ABSTRACT

Difficult choices are pervasive throughout decision making. In this paper, we specifically explore decisions evoking intrapersonal choice conflict (e.g. Ainsle 1975, Thaler and Shefrin 1984, Bazerman et al 1998) where the implicit tradeoffs require the decision maker to sacrifice either one internal goal or the other. We argue that such conflicts, involving incompatible goals, are not readily resolved by a cognitive process of calibrating compensatory tradeoffs but instead involve a search for justifications external to the tradeoff in order to ameliorate the emotional conflict experienced (Janis and Mann 1977; Luce, Bettman and Payne 1997). In our intrapersonal conflict framework, we propose that justifications primarily affect decision through their presence or absence rather than degree, and the resolution of intrapersonal choice conflict is fundamentally scope insensitive (Hsee and Rottenstreich 2004) to the magnitude of the justification. On the other hand, the effect of justification is highly sensitive to the level of intrapersonal conflict, with justifications becoming largely irrelevant in choices involving little conflict. Our framework suggests that a “mere token” justification can often resolve choice conflict and significantly alter the choices made. In a series of studies, we propose and demonstrate a new mechanism for resolving choice conflict, dubbed the mere token effect, in which adding a small common element to both choice options systematically shifts preferences by making it easier to choose the less tempting but higher valued option.

First, we investigate the mere token effect in the context of intertemporal choice, a context widely used to represent self-control conflict. In the base condition, we consider a choice between two outcomes, involving a tradeoff between the timing and magnitude of gains, such as choosing between:

- (a) \$400 in one week, and (b) \$1000 in one year.

We find that in such choices between a sooner-smaller reward and a later-larger reward, the addition of a mere token amount to both options (experimental condition shown below) systematically alters consumer preference.

- (b) \$100 in 3 days and \$400 in one week, (b) \$100 in 3 days and \$1000 in one year.

In a series of studies we had subjects make a single choice, either with or without the mere token (manipulated between subjects), and we demonstrate that the addition of the mere token to both options significantly increases choices of the later-larger reward. We argue that this effect occurs because the immediate mere token amount reduces the intrapersonal conflict by providing token gratification to the desire for immediacy. This common reward effect represents a violation of the principle of separable additivity in discounting, which underlies both exponential and hyperbolic discounting (e.g. Loewenstein and Prelec 1992). In further support of our framework, we show that the choice scenario with the mere token is seen as inducing less emotional conflict and that the mere token effect is scope insensitive to the size of the token amount.

In a series of additional studies, we provide further evidence that the mere token effect operates by reducing intrapersonal choice conflict. We show that increasing psychological distance of both options (by making rewards uncertain) and therefore reducing the intrapersonal choice conflict debiases the common reward effect.

Further, we show that the mere token effect is enhanced when the choice options represent a starker contrast, consistent with the intrapersonal choice conflict model but inconsistent with preference uncertainty and in violation of utility-based models of decision making. We go on to show an “illusory” mere token effect, in which the value of the mere token is deducted from the choice options, thus demonstrating the mere token effect while holding total valuations constant between the base and experimental conditions.

Lastly, in a parallel series of studies, we extend the mere token effect and the related findings discussed above to the more general domain of risky choice. Consumers made choices between a smaller lottery reward with a higher probability of winning and larger lottery reward with a lower probability of winning. Those who made a choice between the two options bundled with a small certain mere token amount were more likely to choose the larger-riskier lottery than those whose choice options did not include the mere token. This effect was shown to be scope insensitive to mere token size and to be moderated by manipulating the degree of intrapersonal choice conflict. We demonstrate that our findings are inconsistent with risky choice models (Savage 1954, Tversky and Kahneman 1992) but consistent with our intrapersonal conflict framework. In closing, we contrast our finding with the literature on choice deferral and discuss the broader implications of both the mere token effect and, more generally, of scope insensitive justification and intrapersonal choice conflict.

A Structural Look At Consumer Innovativeness and Self-Congruence In New Product Purchases

Kelly O. Cowart, Florida State University, USA

Gavin L. Fox, Florida State University, USA

Andrew E. Wilson, Florida State University, USA

EXTENDED ABSTRACT

Conceptualization

While consumer perceptions and responses to product launches have been studied extensively, a major gap remains. Specifically, there is a need for a larger nomological network of innovativeness. A key contribution of this study is to help marketers leverage the relationship between innovativeness and product/image self-congruence. This research expands on a set of disjointed concepts by empirically testing a model that considers the effects of several independent variables on behavioral intentions.

Bagozzi (1982) extended the theory of reasoned action (Ajzen and Fishbein 1980; Fishbein and Ajzen 1975) by considering the role of cognitive and affective self-regulatory mechanisms in determining behavioral intentions. Our proposed model is inspired by this work. A consumer's evaluation of a new product can be seen as what Bagozzi refers to as an "outcome-desire unit," defined as "an event that happens to one, that one produces, or that one can take steps to influence in the future (Bagozzi 1992, p. 187)." Consumers' appraisals of new products may be shaped in part by individual difference traits such as innovativeness, as well as more situational states such as self-congruence and perceived risk. This process may lead to an emotional reaction, represented in our model by satisfaction, which in turn may lead to a coping response, represented in our model by behavioral intentions. Beginning with this essential framework, the relationships in the model were constructed based upon a review of the literature on each of the constructs.

Innovativeness refers to the tendency of some individuals to adopt new products early. Consumer innovators are valuable resources to firms introducing new products, as they perform essential roles in innovation diffusion. Researchers have also shown direct links between consumer innovativeness and behavioral intentions across several domains.

Interaction between a product-user image and a consumer's self-concept can result in a subjective experience termed self-congruence (Sirgy, et al. 1997). Through the consumption process, consumers utilize brands to project images of themselves to others (Chang 2005). Within this framework, purchase intentions for new products should also depend directly on self-image congruence. Innovativeness may play a role in a consumer's construction of self-concept.

Perceived risk is consistently linked with behavioral intentions (Howard & Sheth 1969). Low perceived risk should promote behavioral intentions. Innate innovativeness is a tendency to make risky and innovative decisions (Midgley and Dowling 1978). Park et al. (2005) suggest that higher risk is associated with lower purchase intentions. Innovators must be less risk averse to purchase new products.

Satisfaction is an affective state. Self-congruence can regulate satisfaction such that consistent messages can cause positive emotion (Markus and Wurf 1987). Satisfaction can also impact consumer behavior (Park et al. 2005) and aspects of product encounters can impact satisfaction. Consistent with Schwartz's (1990) findings, people who are satisfied should evaluate new products more favorably than those who are dissatisfied. Satisfaction is also recognized as a key driver of behavioral intentions (Zeithaml,

Berry, and Parasuraman 1996). Satisfaction can also alter perceived risk. Johnson and Tversky (1983) reported that positive affect may reduce perceived risk, whereas negative affect can elicit the opposite reaction. New products, though inherently riskier, have been shown to elevate affect and decrease perceptions of risk (Park et al. 2005).

- H1: Innovativeness positively affects behavioral intentions for new products.
- H2: Self-congruence with a product positively affects behavioral intentions for new products.
- H3: Innovativeness positively affects perceived self-congruence in the context of new product purchases.
- H4: For new product purchases, innovativeness negatively affects perceived risk.
- H5: For new product purchases, perceived risk negatively affects behavioral intentions.
- H6: In new product purchases, self-congruence positively affects satisfaction.
- H7: In new product purchases, satisfaction positively affects behavioral intentions.
- H8: Satisfaction negatively affects perceived risk for new product purchases.

Method

Students were asked to describe their purchase behavior for home electronics (342), new music releases (213), and electronic handheld devices (191). Online surveys were used. Respondents' names were checked across samples to ensure independence of the individual observations. Duplicates and respondents who incorrectly answered a quality check were purged. The three samples were combined, yielding a total of 741 respondents. The sample was 57% female with a median age of 21. Seventy-three percent of the sample was Caucasian, 12% African-American, 9% Hispanic-American, and 4% Asian-American.

Existing scales were adapted to measure innovativeness, self-congruence, perceived risk, satisfaction and behavioral intentions in the two new product consumption settings. All measures utilized a seven-point Likert or semantic-differential scale. The final model consisted of three items from Sirgy et al.'s (1997) self-image congruence scale, two items from Parasuraman, Zeithaml, and Malhotra's (2005) behavioral intentions scale, three items from Goldsmith and Hofacker's (1991) domain specific innovativeness scale, two items from Heijden et al.'s (2003) risk perception scale and three items from Zhu et al.'s (2002) consumer satisfaction scale.

The psychometric properties of the five constructs were evaluated using confirmatory factor analysis (CFA) in accordance with Anderson and Gerbing (1992). Results of the combined CFA indicate excellent measurement fit and establishment of convergent and discriminant validity in accordance with Fornell and Larcker (1981).

Major Findings

This study's objective was to clarify the relationships among innovativeness, self-congruence, satisfaction, perceived risk and

behavioral intentions. The results provided strong support for the proposed model. Results were robust across three industries. All hypotheses were supported, indicating that the research model best described the nomological network surrounding consumer innovativeness and behavioral intentions for new products. Innovativeness affects perceptions of perceived risk and self-congruence and it also directly impacts behavioral intentions. Findings indicate that there is considerably more confluence among the variables than indicated by existing literature.

The relationship between innovativeness and self-congruence suggests innovativeness is part of a consumer's self-concept. New products can play an important role in the construction of self-image and can be used to define one's innovative personality aspects. Findings suggest that innovators' tendencies to diffuse innovation can be leveraged by focusing more on the image creation aspects of new products than utilitarian aspects. Managers can improve results by carefully managing the relationship between their respective brands and images of being modern, unique, and expert.

The Effect of Uniqueness on Word-Of-Mouth Agency: The Moderating Roles of Product Category and Availability

Amar Cheema, Washington University in St. Louis, USA
Andrew M. Kaikati, University of Minnesota, USA

EXTENDED ABSTRACT

Increasing consumer skepticism of the advertising industry and fragmentation of television audiences has decreased the effectiveness of traditional mass media advertising. Consequently, companies are relying more on WOM communication and other non-traditional communication approaches to increase their return on Marketing investment (Court, Gordon, and Perrey 2005). There is increasing reliance on “brand ambassadors,” or agents, who are affiliated with, but typically not paid by, firms, to engage in positive WOM. Companies often pay agencies that enlist consumers to serve as volunteer WOM agents. The present research focuses on this growing phenomenon.

While a significant body of research has studied the outcomes of WOM in the context of persuasive communication, less is known about the causes of WOM agency, that is, why consumers choose to become WOM agents. We explore the *social* benefits and costs associated with a consumer’s decision to become a WOM agent. While being a WOM agent may be attractive for market mavens (Feick and Price 1987), it may hurt consumers who are high in their need for uniqueness (Lynn and Harris 1997) by decreasing the uniqueness of their possessions. Additionally, this social cost of decreased uniqueness may vary across products. We expect that the detrimental effect of WOM agency (in terms of decreased uniqueness of consumed products) is greater for publicly consumed luxury products than for privately consumed luxury products (Bourne 1957). Furthermore, we expect that uniqueness affects WOM agency when a public luxury product is available, but not when it is unavailable.

Effect of Need for Uniqueness (NFU)

Informing other consumers about a product increases their likelihood of adopting that product and decreases its uniqueness. High need for uniqueness (NFU) individuals desire rare products which provide differentiation from other people. For fear that others will get the same product, consumers may choose not to tell others about it. Unique product choices may attract other people who are also high in NFU (Fisher and Price 1992), and high NFU individuals may feel threatened if others become similar to them (Tian, Bearden and Hunter 2001).

Moderating Role of Product Category

This detrimental effect of NFU on WOM agency may, however, vary across product categories. Peer influence on product-level decisions is stronger for publicly consumed than privately consumed products (Bearden and Etzel 1982; Childers and Rao 1992; Tian et al 2001). Furthermore, factors which increase adoption of a conspicuous product will decrease the value of a product for high NFU individuals (Amaldoss and Jain 2005). Thus, we expect that while high NFU consumers will be *less likely* to engage in word of mouth for public products than for private products, they will be as willing as low NFU individuals to endorse a private product. In contrast, low NFU individuals will be equally likely to promote public and private products.

Availability Moderates Role of NFU on WOM Agency for Public Luxury Products

Commodity theory posits that anything that is useful to a person, conveyable to another person, and potentially possessable will be valued when its availability is limited (Brock 1968). Need for uniqueness is one explanation of *why* unavailability leads to increased desirability (Lynn 1992b). Brock (1968) refers to the potential time delay in acquiring a product as one of the drivers of availability. We predict that the detrimental effect of WOM agency for high NFU consumers will disappear if the public luxury product is not yet available in the market. That is, when the product is not yet available for purchase, the WOM agent does not decrease the uniqueness of the product by talking about the product with acquaintances.

Empirical Results

In study 1, we measure NFU and demonstrate its effect on WOM agency for public and private luxury products, while controlling for market mavenism. Respondents read a scenario in which they receive an email from a company to join a program as a WOM agent. A specific product in need of WOM promotion is described in the email. Approximately half the respondents read about the public product (Apple iPod Shuffle digital music player), while the remaining respondents read about the private product (Apple Monitune monitor/TV). Pretests confirm that while both these products are perceived to be luxury products, the Shuffle is perceived to be a more publicly used product than the Monitune. All respondents then rate how likely they are to join the program. The results indicate that the attenuating effect of NFU is more *negative* for public luxuries than for private luxuries.

In study 2, we replicate the uniqueness effect of study 1, using a prime to manipulate NFU between subjects (Aaker and Lee 2001). Respondents first evaluate an advertisement for Welch’s Grape Fruit Juice, which either focuses on an individual or on a group. They then read a scenario similar to study 1. Results indicate that among respondents who see the public product, those exposed to an individual prime (high NFU) are less likely to purchase than those exposed to a group prime. However, among respondents who see the private product, the prime does not have a significant effect.

In Study 3, we demonstrate how availability level moderates the effect of NFU on WOM agency for public luxury products. We present consumers with a public luxury product (a Siemens cell phone) and manipulate whether this product is presently available in the market or will be available in six months. Results indicate that when the product is available, high NFU respondents are significantly less likely to become WOM agents than low NFU respondents. However, when the product is not available, high NFU respondents are as likely to become WOM agents as low NFU respondents.

Conclusion

These results indicate that there is a cost of WOM for consumers who are high in NFU, and this cost is exacerbated for a) public

versus private products, and b) available versus unavailable products. The results suggest that high NFU consumers may be more successful as WOM agents when promoting private luxury products and/or when promoting products that are yet to be launched in the marketplace.

Personality Characteristics of Market Mavens

Vito Brancaleone, La Trobe University, Australia

John Gountas, La Trobe University, Australia

ABSTRACT

A number of papers have been published investigating the demographic, motivational and psychological characteristics of the maven, but none has attempted an in-depth investigation of their personality traits. This paper tests the relationships between the characteristics of market mavens with Extraversion-Introversion and four personality orientations or traits that have been developed recently. The findings suggest that it is possible to anchor the construct of market mavens within a broader personality theory. The research found strong relationships between market mavens, physical/sensing personality orientation and extraversion.

EARLY ADOPTERS (INNOVATORS)

In general, all consumers are the targets of marketing communications, although some consumers are more valuable to businesses and industries than others (Feick and Price, 1987; Goldsmith, Flynn, Goldsmith, 2003). An examination of the marketing literature has revealed that three types of consumers are especially valuable to businesses and the marketplace. These are known as reference groups and can be grouped into the early adopters (innovators), opinion leaders and market mavens. Their value to businesses and industries originates from their affinity to share knowledge about the marketplace, products and services.

The first of the reference groups, early adopters (also known as innovators) tend to be associated with usually a bell shape type of normal distribution, which is characterised as product or category specific as opposed to being interested in all product categories across the board (Rogers, 1995). Studies of early adopters/innovators have found that early adopters tend to be better educated, younger ages, upwardly mobile and come from the higher socioeconomic status relative to others in the social system, who usually can afford to take the risks and have the money too (Engel, Blackwell and Miniard, 1995). In comparison to other social groups, early adopters are more likely to adopt a new product or service comparatively earlier than other groups of consumers (Clark and Goldsmith, 2005) and are more likely to disregard the risks associated with new products or services (Engel et al., 1995). Numerous studies have shown that early adopters are heavy users of commercial, professional and interpersonal information sources (Goldsmith, Flynn, and Goldsmith, 2003; Fisher and Price, 1992; Mahajan and Muller, 1990). These studies also showed that early adopters tend to be more likely to share information they have gathered about a specific product or service with other members of their local reference groups.

OPINION LEADERS

Like early adopters, opinion leaders are an attractive target for marketers as they have been shown to be effective facilitators for spreading information specific to a product or service (Chan and Misra, 1990; Clark and Goldsmith, 2005; Feick and Price 1987; Goldsmith et al, 2003). There has been a lot of debate as to what are the general characteristics of the opinion leaders (Marshall and Gitosudarmo, 1995). A number of studies have sought to identify differences between opinion leaders and early adopters. These differences include opinion leader's characteristics that relate to levels of sociability, such as gregariousness (extraversion); of outer-directed personality traits (Marshall and Gitosudarmo, 1995);

their degree of innovativeness, positive attitudes to change and demographic characteristics such as youth, higher education and income (Marshall and Gitosudarmo, 1995). Innovativeness is usually tempered by social respectability or need for trustworthiness, which is not always present in the early adopters/innovators. However, opinion leaders, like early adopters, are high information seekers (Clark and Goldsmith, 2005) and use large amounts of commercial, professional and interpersonal sources of information regarding a specific product or category of interest. Opinion leaders regularly share their knowledge with other people. A few studies have shown that opinion leaders may be sought after and consulted about new products or services, by other consumers, because they are usually perceived as more knowledgeable with regards to high involvement purchases (Christiansen and Tsiourtis, 1998).

MARKET MAVENS

The conceptualisation of the third reference group has been credited to the study by Feick and Price (1987). Feick and Price (1987: 85) defined market mavens as "individuals who have information about many kinds of products, places to shop, and other facets of marketing, and initiate discussions with consumers and respond to requests from consumers for marketplace information".

Feick and Price (1987) demonstrated that although market mavens have similar demographic characteristics as opinion leaders and early adopters/innovators, they differ from the opinion leaders and early adopters/purchasers on the higher levels of general knowledge about the marketplace and product marketing mix (product, prices, distribution, promotions) characteristics. Mavens have been shown to have a broader array of information about different types of products, including durable, non-durables, services and store types (Feick and Price, 1987). This contrasts with the opinion leaders and early adopters who are more knowledgeable and want to share information about a specific range of products within a product category or specific market environment characteristics. Market mavens collect and retain information about a wider range of issues such as product quality, prices, sales, availability, store personnel characteristics and other features that may be relevant to themselves and to other consumers. The media habits of market mavens differ from those of early adopters and opinion leaders. Market mavens are more likely to read retail magazines, direct mail advertisements and discuss retail store image attributes more freely than non-mavens (Higie, Feick and Price, 1987) and to be heavy users of coupons, grocery lists and budgeting tactics (Price and Feick, 1988).

Although demographically similar to opinion leaders and early adopters, market mavens are more likely to be female, marginally lower educated than non-mavens and more likely to come from certain sub cultural groups (Feick and Price, 1987). Market mavens have been shown to be more accurate in their evaluation of service quality than early adopters and opinion leaders (Engelland, Hopkins, and Larson, 2001), but early adopters and opinion leaders are more likely to be influential with a specific market or product category. In contrast, market mavens can be seen to be a source of general or non-specific marketplace information. This trait makes mavens an attractive target market to retailers and other large industries that produce and/or sell a wide range of durable and fmcg products. Market mavens are more likely to

encourage spread of information through word-of-mouth or viral marketing across a wide range of product categories (Clark and Goldsmith, 2005; Goldsmith et al., 2003; Price et al., 1987).

A large number of studies have focused on identifying the general media consumption, communications and demographic characteristics, but little is known about the market maven's motivational and psychological characteristics (Walsh, Gwinner and Swanson, 2004). Knowing that mavens watch more television and read more magazines than non-mavens, without knowing the reasons or motivational and psychological characteristics of the market maven, leaves the question of how to target effectively, build a relationship and communicate in a meaningful way with market mavens relatively unanswered.

MOTIVATIONAL CHARACTERISTICS AND PREFERENCES OF MARKET MAVENS

A number of studies have endeavoured to identify some of the motivational and psychological characteristics of the market mavens (Clark and Goldsmith, 2005; Engelland et al., 2001; Goldsmith et al., 2003; Walsh et al., 2004). Motives arouse and direct consumer behaviour and therefore market mavens would be targeted more accurately if their motives were better understood (Walsh et al., 2004). Identifying and understanding the motivations behind the actions of the market maven is particularly important to businesses wishing to highlight their product/service attributes and provide relevant information to market mavens. Price and Feick (1987) noted that compared to other groups of consumers, market mavens would be differentially motivated from other groups of innovators and early adopters. Walsh et al (2004) identified some of these unique motivational factors for mavenism. They found that market mavens were motivated to share their information with other consumers for a number of reasons, which include; an obligation to share information; a strong desire to help others; and an intrinsic pleasure in sharing information with others. Clarke and Goldsmith (2005) suggest that market mavens conform to social norms and can be susceptible to normative influences. Therefore cultural and sub cultural or social class norms, values and attitudes are likely to influence and be influenced by market mavens. Clarke and Goldsmith (2005) clarify this result by explaining that although mavens are information leaders, they do have socially normative boundaries, which are used appropriately and skilfully. However, the maven's socially normative behavioural considerations are moderated by the personality trait of high self-esteem and social respect or prestige/status. The literature review has identified no study that attempts to anchor the market maven characteristics within a general personality theory. The ad hoc type of description of the market maven's personality without any reference to their overall personality characteristics without an explanation of what kind of person is a market maven, seems to be a relevant research issue that is very useful for theoretical and model building purposes as well as for marketing practitioners. By expanding our understanding of the broader market maven's personality traits or characteristics, researchers and marketing practitioners would be able to differentiate more clearly market mavens from other groups of innovators/early adopters in terms of their psychographic characteristics and styles of decision making.

PERSONALITY CHARACTERISTICS AS PREDICTOR VARIABLES OF CONSUMER BEHAVIOUR

Albanese (1993) suggests that although all consumers have a personality it is hard to understand how it affects behavioural

decisions. Efforts to utilise personality theory as a single predictor item with consumer behaviour have produced unconvincing results in general (Kassarjian and Sheffet, 1991). However, it is difficult to generalise about the effectiveness of personality in relation to predicting consumer's behaviour and decision making process, because researchers have used a variety of competing theories, definitions, methodologies, and instruments measuring different personality characteristics, in a wider range of appropriate and inappropriate marketing applications (Pervin, 1997; Plummer, 2000). It is very difficult to provide a clear-cut assessment of whether personality as a single or general global construct is a good predictor of behaviour without any other relevant information about the consumers, for example, demographic characteristics, attitudes, motives and values. The degree of construct specificity affects the level of relationships with consumer's behaviour. Personality is considered to be very general construct, attitudes tends to be more of an intermediate level, and specific traits are more closely related with specific context and behavioural aspects of consumer's nature. Therefore, predictive validity of consumer's behaviour varies according to the type of construct (broad, intermediate or specific) and the type of context the trait is hypothesised to be relevant and used for (Nakanishi, 1972; Kassarjian and Sheffet, 1991).

The degree of construct generality is bound to have an effect on the level of predictive power. Gountas and Mavondo (2005) found strong correlations between personality and behaviour using global personality preferences/traits, as well as more specific traits like self-efficacy (Bandura, 1982). Integrating personality characteristics (general as well as more specific behavioural context related traits) with motivation, available resources, and external opportunities, (Gountas, 2004; Gountas and Mavondo, 2005) achieved stronger levels of relationships between personality and consumer's behaviour (actual and intended behavior). Personality constructs can be very useful predictors of consumer behaviour if they are developed appropriately for specific consumer behaviour purposes, and if they include other important influences such as social, external factors, demographics, and overall market conditions (Kassarjian and Sheffet, 1991). There is a tremendous range of consumer decisions, varying from high involvement to low/trivial level of importance, and therefore it is appropriate to consider carefully the usage of existing off the shelf personality instruments with all kinds of consumption decisions and behaviour studies.

Kassarjian and Sheffet (1991) suggested that consumer researchers should avoid using ad hoc personality items, especially if they are single personality traits but always endeavour to use well-validated and reliable personality instruments, which have high reliability scores. They suggest that personality instruments should be embedded in a well-developed theory of personality and to consider personality as one of a number of variables moderating or influencing consumer's choices and behaviour.

The literature review identified a number of personality traits and theories being used as predictor or explanatory variables of innovators/early adopters and market mavens, but none has attempted to use the Myers-Briggs Type Indicator (MBTI) or any new Jungian personality type of theories (Briggs-Myers and McCaulley, 1989; Jung, 1921/1971). This study uses a new personality theory that has its foundations in the broad Jungian personality typology and takes into consideration the MBTI and other Neo-Jungian ideas. The new personality theory (Gountas, 2003) has been developed over a number of years, has been tested, and retested with representative samples of consumers. The validity and reliability

scores are above the expected standards and therefore the instrument is robust and appropriate for applied consumer research purposes.

THE FOUR PERSONALITY ORIENTATIONS

The new four personality orientations/mega traits attempt to identify distinctive consumer approaches towards processing information and viewing the world from different perspectives. The conceptual foundations of the new theory are a synthesis of the original Jungian (1921/71) and post Jungian personality types postulations (Briggs-Myers, and McCaulley, 1989) based on the four functions or human faculties (thinking, intuitive, feeling and sensing). The new model (Gountas, 2003) departs from the original eight predetermined Jungian personality types which included the four functions, the two additional attitudes or extraversion and introversions and the arbitrary notions of two groups of organising functions that of perceptive and judgement. The new model hypothesises that there are four broad but different approaches/functions regarding consumer's behavior and postulates that each orientation has a different valence and intensity of preferences.

The theoretical model put forward by Zajonc and Markus (1982) of the existence of two distinctive preferences that of cognitive and affective with regards to a wide range of behaviours and actual decision making, has been extended and adapted to form the feeling and thinking orientations of the new personality orientations model. Cacioppo's and Petty's concept that individuals have different Needs for Cognition (Cacioppo and Petty, 1982) has been integrated and adapted to fit in to the overall construct of Thinking/Logical that Jung has put forward too. The Jungian and post or Neo-Jungian function of sensing has been synthesised and adapted with the trait of materialism (Moschis, and Churchill, 1978; Richins, 1987; Richins, and Dawson, 1992) to form the Physical or Somatic/Materialistic orientation. The labels of the four personality orientations in the new model are thinking/logical, imaginative, physical/sensing, and feeling/emotion/action. The core characteristics of each orientation are briefly summarised in order to provide an idea of what are the main differences between the four personality orientations/functions. Each orientation or trait is hypothesised to manifest in all consumers in varying degrees, therefore there is no single one orientation or complete lack of other orientations that exert influence on the consumer's range of preferences and styles of decision-making.

The thinking/logical orientation/function is characterised by a higher level of interest and focus on generating new ideas and understanding the way things or certain phenomenon operate. There is a higher need for cognitive type of processing information; a need to know how and why certain products are more appropriate; and evaluate objectively the differences between products based on accurate factual information and guided by evaluative criteria. The thinking orientation enjoys thinking/ideation, is inclined to form logical connections between ideas, and uses effortful cognitive processing strategies to make sense of any obscure or abstract concepts (Cacioppo and Petty, 1982). Decision-making is likely to be based on the careful cognitive and logical examination of facts and other sources of information related to a product purchase. Consumers with higher scores on the thinking trait rely on principles to guide their reasoning of cause and effect and tend to be impersonal in their relationships (Moss, 1989; Gountas, 2003). Thinking/logical orientation traits are related with a strong interest in creating new knowledge, generating new ideas and constructing new understanding of how the world works (Pervin, 1997; Gountas, 2003). Consumers with an overall higher tendency towards the thinking orientation may show all or some of the characteristics

hypothesised in the thinking/logical construct. Some of these characteristics, construct facets, of the thinking/logical orientation are: interest in analysing information, maintaining objectivity in decision making, using well founded intellectual principles to guide thinking process, value justice and fairness, tend to use critical and deliberate thinking, which can appear emotionless or blunt and less concerned for feelings (Briggs-Myers and McCaulley, 1989; Gountas, 2003).

Consumers/individuals with higher score on the imaginative trait/orientation have a heightened sense of awareness of the unconscious perception (Jung 1921/71; Pervin, 1997). They tend to rely on visual type of learning stimuli, using diagrams and pictures to store information and identify differences between product attributes. They are more likely to interpret and adapt to the word around them using imaginative process of thinking and visualisation techniques to make sense of what and how to do things. Their main sources of information are not logically organised but they are guided by creative and need to understand the non-visible aspects of the world. They are able to use and perceive subconscious images and sensing of what has happened (past events) and what might happen in the future (Jung, 1921/71; Gountas, 2003). Although information is gathered by the five senses, the same as all other personality orientations, at very high speed, not in a particular organised manner, and therefore input tends to be generic, blurred on the details and interested to identify the creative and interesting or unusual qualities of the information material (Moss, 1989). Imaginative consumers tend to prefer unconventional approaches and products, like more abstract and creative types of communication and better at constructing theories and 'hunches' through imaginative processes. The imaginative consumer can visualise patterns and make sense of event with minimal information. They prefer complexity rather simple reality. The facets or sub constructs of the imaginative orientation/trait are a stronger tendency to visualise, to construct and manipulate images, are more inclined to value idealism, reflection, creativity, imagination, tolerance for the unusual and unconventional process of decision making.

The physical/sensing consumers value physical comforts, material possessions and enjoy more the physical world just for its own sake. They experience more pleasure from the physical or material goods and the tangible attributes of products. They rely heavily on the input of their five senses (sight, smell, hear, touch and taste) as well as their instinctive earthy/physical body reactions to tell them what is appropriate for them (Jung, 1921/71; Gountas, 2003). The physical/sensing person is more likely to appreciate the details and real as opposed to the imagined or cognitive interpretations of a situation (Moss, 1989). They tend to focus on the immediate physical experiences and often show an acute ability to see very accurately material characteristics (colour, texture, and three-dimensional aspects). They can understand the material world very well and enjoy transforming and creating new material artefacts. The facets or sub constructs of the physical/sensing orientation/trait are physical realism, acute powers of material observation and understanding, memory for details, practical, down to earth and enjoyment of physical pleasures, achievements and comforts (Briggs-Myers and McCaulley, 1989; Moss, 1989; Gountas, 2003).

The feeling/action orientation/trait is characterised by a higher level of energy drive and achieving the best possible feelings. They tend to prefer experiential input to construct their understanding of the world and who they are as individuals. They focus on the enhancement of self-identity and self-esteem and therefore strive to achieve goals that are socially sanctioned and approved. They evaluate events, products and experiential benefits in subjective terms and whether they are likely to enhance their own sense of

worth, social and self-respect, social acceptance, status and individuality. They enjoy emotional experiences, understand their own emotional states and those of others and are capable of transforming and creating new emotional/feeling states (Briggs-Myers and McCaulley, 1989; Gountas, 2003). Feeling/action oriented consumers tend to evaluate products based on their social symbolism, status and emotional appeal. They are able to evaluate consumption interactions in terms of negative or positive feeling/emotion outcomes based on their own subjective and perceived social evaluation of a service or product (Gountas, 2003; Pervin, 1997). The evaluation process is based on the perceived subjective level of significance or potential to enhance and add status, and feelings of success, importance and power for the individual. Feeling/action orientation consumers rely more and are more interested in the understanding of the personal as well as group values and therefore they are more subjective in their interpretations and construction of reality is more heuristic and based on actual experiential evidence. The feeling/action orientation/trait facets or sub constructs are: higher concern for the human emotional and feeling aspects, experiential sources of information, a need for affiliation, status, social respect and achievement, understanding emotions and able to transform and create new emotions, preference to evaluate products in terms of emotional benefits and social symbolism (Gountas, 2003).

The constructs of extraversion and introversion (E-I) have been considered relevant to include as free standing personality characteristics (Costa, and McCrae, 1992; McCrae and Costa, 1997) in addition to the four general personality constructs in order to be able to provide a more comprehensive understanding of the market maven's characteristics. The E-I construct is composed of the sub constructs or facets of sociability, gregariousness, assertiveness, activity, excitement and positive social interactions. They are hypothesised to be relevant personality aspects that may influence decisions and behaviours of market mavens concerning the product category context of food consumption in restaurants.

RESEARCH HYPOTHESES

The specific industry we want to test the relationships between market mavens and the four personality orientations is the restaurant and hospitality industry. The hospitality industry relies heavily on its diners to 'experience' the whole product of the restaurant, including the food, service, atmosphere and the company of others. Market mavens play a critical role in the diner's experience, by providing information and opinions about restaurants; market mavens are able to determine, inadvertently, which restaurants will be patronised by the consumers.

Market mavens are expected to be more knowledgeable about food and restaurant outlets and to produce the highest or stronger positive relationship with the physical/material orientation/trait. All other personality orientations/traits are expected to produce lower (than the physical/material orientation) but positive relationships with market mavens. Eating and dining out in restaurants is a social activity and therefore we expect that second highest correlations with market mavens to be the feeling/action orientation/traits followed by thinking/logical and last the imaginative orientation/trait dominant consumers.

H1: there is a stronger positive relationship between market mavens and physical/material orientation; followed by feeling, thinking and imaginative orientations in order of significance.

The trait of extraversion is expected to influence the strength of the relationships between market mavens and all four personality orientations, but the physical/material orientation is hypothesised to produce the highest regression score followed by feeling, thinking and imaginative orientations.

H2: there is a higher and positive relationship between extraversion and market mavens, and a lower negative correlation between introversion and market mavens.

METHODOLOGY

Exploratory qualitative and quantitative research was conducted to refine the research instrument and the survey method. The questionnaire instrument performed well and researchers decided to use a self-completion survey method within a specific restaurant as the most appropriate venue for the intended sampling method.

Participants. A random sample of dinners throughout the weekdays was selected and two hundred and three (N=203) responses were collected. The demographic characteristics included all ages (18-65+), from all educational and income levels and with an equal proportion of male-female gender participants (male=48.3%, female=51.7%). The findings were factor analysed and then hierarchical regression analysis was carried out to determine the degree of correlations between the hypothesised constructs of market mavens, personality orientations/traits and E-I traits.

Instruments. The researchers used existing scales that are embedded in well developed personality theories, with small adaptations to suit the hospitality environment; five items for market mavens (Feick and Prices, 1987), six items in total for extraversion-introversion (Briggs-Myers and McCaulley, 1989), and an adapted version (twenty four items in total) of the four personality orientations/traits (Gountas, 2003).

INDEPENDENT AND DEPENDENT VARIABLES

The four personality orientations/traits and the individual traits of Extraversion-Introversion were hypothesised to be the independent variables because they are the overall personality characteristics that influence many other aspects such as market mavenism, attitudes and motives. Market mavenism is hypothesised to be the dependent variable because it is a second order type of personality characteristic.

ANALYSIS AND RESULTS

The reliability analysis produced acceptable Cronbach alpha scores: Market Maven ($\alpha=.88$), Thinking orientation/trait ($\alpha=.72$), Feeling orientation ($\alpha=.71$), Physical/sensing orientation ($\alpha=.64$), Imaginative orientation ($\alpha=.74$), Extraversion ($\alpha=.69$), and Introversion ($\alpha=.69$). Bivariate correlations between the market maven composite construct and a number of demographic variables revealed that there are some interesting and significant relationships at the .01-.05 (2-tailed) level. For example mavens are more likely to frequent restaurants (.286**), if they have achieved a degree level of education (.631**), are aged 26-35 years old (.351*), with an average income of 35-45,000 dollars (.440*), having professional status (.258*), and are equal proportions of males and females (.286**).

The actual regression analysis results (see table 1) suggest that the physical/sensing orientation/trait is the best predictor with the highest score ($r=0.474***$), followed by the thinking trait ($r=0.463***$), feeling trait ($r=.408***$) and imaginative ($r=0.205***$).

TABLE 1
Regression analysis

	Model 1	Model 2	Model 3	Model 4	Model 5	Model 6	Model 7
	Beta (standardised coefficients)						
Dependent variable: Market Mavens							
Independent variables:							
1. Thinking orientation/trait	0.463***						0.242*
2. Feeling orientation/trait		0.408***					0.048
3. Physical/Sensing orientation/trait			0.474***				0.307***
4. Imaginative orientation/trait				0.205**			-0.109
5. Extraversion (Sociability)					0.242**		0.125*
6. Introversion						-0.124	-0.148*
7. All Psychological characteristics (1-6)							
<i>r</i>	0.463	0.408	0.474	0.205	0.242	0.124	0.551
<i>r</i> ² (<i>r</i> Square)	0.214	0.166	0.224	0.042	0.059	0.015	0.304
F value	54.771***	40.09***	58.167***	8.859**	12.508***	3.156	14.244***
(***) <i>p</i> <.001; ** <i>p</i> <.01, and * <i>p</i> <.05)							

Hypothesis 1 is largely supported because all of these regressions are positive and the order of magnitude of relationships is as predicted except one (feeling) is not the second highest correlated orientation as hypothesised.

Hypothesis 2 is also supported because the regression scores between extraversion and mavens is significant, positive and larger ($r=0.242^{***}$) than the introversion trait correlation (-0.124).

When all the independent variables are entered into the regression analysis, the strongest predictor of the maven trait is the physical/sensing orientation/trait followed by the thinking and extraversion (see table 1).

DISCUSSION OF RESULTS

The results support the findings by Price and Feick (1988) that market mavens have a higher level of interest and influence on services and store types. The research findings support the hypothesis that mavens are more likely to frequent restaurants. Mavens are likely to be well educated, with average incomes with no significant difference between males or females; they tend to have higher levels of education (college degree level) and are mostly professional people. The most significant predictor item that distinguishes mavens from other market segments is their preference for the physical (food) type of enjoyment. Mavens patronise restaurants for the sheer interest in good food physical comforts rather than for social prestige, status or to escape from everyday life. However, they are sociable and interested in activities that have a social flavour and therefore they tend to be extraverts rather than introverts. Mavens are more likely to evaluate logically which restaurant to patronise and weigh up the different options based on real accurate market facts as opposed to emotional or imaginative considerations. Restaurant outlets need to target and promote their service products and services based on the core benefits (physical pleasure, comfort and luxury type of atmosphere) and provide enough physical evidence to support their promotional communication claims to persuade their prospective customers.

CONCLUSIONS

In this paper we have examined some of the market maven's personality characteristics, namely their four major personality

orientations/traits and extraversion-Introversion. Understanding some of the core personality characteristics of mavens, would enable marketers to identify more clearly the preferences and motives of their most influential consumers. This is an important aspect for academic researchers and marketers because market mavens and early adopters/innovators are usually the key drivers of market demand for new and existing products and services. Consumption patterns change and often they are driven by small groups of consumers (mavens and innovators) who are usually more interested in many product categories and in communicating their knowledge to other consumers.

Does Word-of-Mouth Change with the Passing of Time?

Anat Toder-Alon, Boston University, USA

Frédéric F. Brunel, Boston University, USA

EXTENDED ABSTRACT

Over several decades, sustained consumer research on word-of-mouth (WOM) has produced a substantial body of knowledge about this consumer phenomenon, its components and some of its processes. However, most of this previous research has treated WOM interaction as a static and mostly dyadic event, and has not fully investigated the content of the actual WOM exchange. Even though this focused research perspective has led to significant advances, it also seems problematic in our current hyper-connected social and business environments, where WOM can be performed not only by close contacts, but also within large groups of virtual strangers who may never physically meet and who are only connected through some computer mediated community. The growth of online communities has created borderless virtual spaces where geographically dispersed consumers can become participants in informational exchanges. Although the importance of this phenomenon is undeniable, much remains to be learned with respect to the relationship dynamics and WOM communication dynamics in these communities. This basic acknowledgement underscores the importance of studying WOM not just from a dyadic (source-seeker) perspective, but instead as a group activity that is achieved through group communication practices. As such, we seek to understand how WOM exchanges are affected by the social nature of the groups or communities in which they take place. In particular, we seek to extend our knowledge of how the dynamics of community development and community relationship building can influence WOM exchanges in general and WOM rhetoric in particular.

In this netnography (Kozinets 2002), we analyzed text data from the discourse of bulletin boards hosted at BabyCenter.com—a website for new and expectant parents. Our unit of analysis was the verbatim thread transcript, which was operationalized as a post with all of the replies. The complete text of all messages of one bulletin board was captured for a nine month period. The threads were concerned with WOM talk (661 threads) or interpersonal relationships within the community (used for contextual grounding of the data).

Our analysis followed an ethnomethodology program (Garfinkel, 1996). From this analysis, we develop a typology of WOM interaction genres and show that they change over the community lifespan. Our findings confirm that the levels of social connection and the interaction communicative functions are the main factors that distinguish different WOM genres. This conceptualization assumes that linkages between messages (i.e., between WOM initiation and WOM responses, and between WOM responses themselves) vary from loosely connected messages to tightly connected bonds, and that simultaneously these messages can serve instrumental (task-oriented) or socio-emotional functions. When a group WOM conversation stems from interactions between individual members who are focused on their own personal identity, the overall WOM genre is disconnected. Group members act or react in a non-coordinated way, with no notions of mutual sharing or collective concepts incorporated into the interaction. In this genre of WOM, interactions are pseudo-dyadic despite their group setting, and WOM advice giving/seeking roles and practices are static throughout the WOM episode, with generally a limited potential repertoire of WOM rhetorical methods. There are two main genres of disconnected WOM, and they differ based on the function of the overall interaction. In the disconnected instru-

mental WOM genre, consumers' intentions within these WOM episodes may be viewed through efforts to achieve private instrumental goals (i.e., task-oriented). In this genre of WOM, initiators typically provide no detail about their situation or problem, and focus solely on the potential solution. Also, the requested response is framed as paradigmatic and object-oriented. Correspondingly, the WOM responses are typically non-personal and paradigmatic. Alternatively, in the disconnected experiential WOM genre, WOM initiators typically provide background information for their problem and situation, and frame the requested response as narratives, thereby inviting personal and experiential accounts. Correspondingly, responses are often self-referential anecdotal stories.

By contrast, when participants to group WOM interactions develop a group identity and orient their actions toward the group, we found that the WOM genres are connected (or even multidirectional). In these WOM genres, group members jointly construct mutual understandings and shared volitional commitments to perform group actions and consciously come to see their actions in this way. Collective concepts such as group objectives, we-intentions, and social identity are central variables in this genre of WOM interactions. The WOM genres associated with this connected orientation definitely stem from 'real' group interactions (as opposed to pseudo-dyads) and can lead to indirect outcomes in the WOM exchanges, with others besides the initiator also being influenced. Further, in these connected WOM genres, the rhetorical repertoires appear more diverse and richer, and there is general fluidity between advice seeking and advice giving roles, with members often switching roles during an interaction. There are two main genres of connected WOM, and they differ based on the function of the overall interaction. In the connected instrumental WOM genre, participants' communicative practices focus on instrumental goals. WOM initiations are typically framed in solution-oriented terms and the requested response is typically framed in object and paradigmatic terms. Corresponding responses also follow a non-personal and paradigmatic focus. Further, in this genre of WOM exchange, it seems that even though we have a true group discussion, the nature and dynamics of the exchanges are limited to achieving basic informational exchanges and basic alignment of the group goals. In contrast, in the other connected genre: multidirectional communal WOM, we found that the interaction mechanisms were more complex and sophisticated, fully leveraging the potentials that group discussions offer. In this genre, we found that the WOM discussions exhibited a wide range of collaborative conversation practices such as: tag-teams, agreements and debates. In order to fully leverage the group resources, in this WOM genre, WOM initiators typically provide detailed background information for their problem and situation, generally providing a full diagnostic. Further they frame the requested response as narratives, inviting personal and experiential accounts. Since members are closely collaborating, in this communal connected WOM genre, responses are often recipient-referential anecdotal stories, utilizing narrative tools, often co-produced and revised through multiple messages. To conclude, it seems that in this WOM genre, something far more important than the exchange of information motivates participants to invest such amounts of time and energy

As a whole, this study shows that the methods used in seeking and providing WOM advice or more broadly engaging in some aspect of a WOM communicative practice can reveal the context in

which they are occurring, demarcate group membership and individuals' social identity orientation, indicate purposes of interaction, and define participants' motivations in a particular episode.

SPECIAL SESSION SUMMARY
Health Marketing: How Consumers Cope

Lisa E. Bolton, University of Pennsylvania, USA

SESSION OVERVIEW

The objective of this special session is to address an important problem in health care—how to encourage consumers to engage in health-protective behaviors and to comply with medication or treatment regimes. Such research is part of a larger literature on how consumers respond to health communication messages and how to promote active coping strategies among consumers in the health domain.

Each project offers a unique yet complementary perspective on these issues. Specifically:

- 1) “How Does Drug And Supplement Marketing Affect A Healthy Lifestyle?” investigates the effects of remedy marketing on a healthy lifestyle. It finds that drugs (versus supplements) serve as get-out-of-jail-free cards that reduce healthy lifestyle intentions among consumers within the problem domain. The authors attribute their results to reduced motivation and efficacy to engage in health-protective behaviors that constitute a healthy lifestyle.
- 2) “Getting Emotional about Health” examines the effectiveness of health messages that present consequences for the self or family. Its premise is that emotions point to the stakes of a disease, and health consequences have two crucial types of stakes: for self and for family. It finds that, when individuals are primed with a positive (negative) emotion, the compatibility between the referent and the emotion fosters (hinders) message processing.
- 3) “Fact, Fear, or Regret: Getting People to Cope Actively” investigates how the negative emotions of fear and regret as compared to a factual appeal differentially affect coping processes and behaviors. Specifically, a regret appeal evokes a state of responsibility and triggers action-oriented coping (e.g., use of a remedy). In contrast, a fear appeal dampens feelings of responsibility and triggers denial coping. In factual appeals, coping is driven by individual trait coping styles.

Together, these projects examine consumer and message factors that influence the effectiveness of health marketing and, more specifically, adaptive coping (i.e., avoiding risky behavior and starting/maintaining health-protective behavior). In large part, prior research in health communications has been focused on cognitions (e.g., examining consumer response to risk-avoidance communications). Departing from this tradition, the present research emphasizes the roles of motivation and emotion and also extends its investigation to remedy messages (i.e., for products that promise to manage/reduce risk). On the one hand, then, each project offers a “new” perspective by introducing and examining factors in ways that have not previously been addressed in the literature (e.g., discrete emotions, referent appeals, remedy labeling). On the other hand, each project also points to the “age-old” challenge of designing effective health communications—the myriad ways that consumer characteristics influence message processing. For this reason, our discussant Joel B. Cohen from the University of Florida (who has been chosen for his unique breadth and depth of experience in this area) will focus specifically on the advantages and disadvantages of each perspective within a broader context. Doing so is fundamental to any effort to understand and integrate the diverse findings in the health marketing literature—and, ultimately,

to improve our understanding of consumer health behavior and, in turn, consumer welfare.

EXTENDED ABSTRACTS

“How Does Drug And Supplement Marketing Affect A Healthy Lifestyle?”

Lisa E. Bolton, Americus Reed II, Kevin G. Volpp and Katrina Armstrong

A variety of health care products or remedies purport to aid consumers in adopting or maintaining a healthy lifestyle. Although the *intended* objective of remedies is to reduce health risks, recent research suggests that remedy marketing may have *unintended* consequences (i.e., boomerang effects) that undermine risk-avoidance by consumers (Bolton, Cohen, and Bloom 2006). Within the health domain, there are many risky behaviors (e.g., high-fat eating, a sedentary lifestyle, smoking, excessive drinking) that are attractive to consumers and yet increase disease risk (e.g., heart disease, stroke, cancer, liver disease). The present research investigates whether the boomerang effect on healthy lifestyle intentions extend to both drugs and supplements as remedies.

On the surface, there may seem little reason to expect differences. For consumers within the problem domain, both drugs and supplements may be perceived as remedies that reduce risk and thereby undermine risk avoidance via a healthy lifestyle. In contrast, however, we investigate whether consumer react differentially to drug versus supplement marketing. Specifically, we propose that drug marketing may be *more* likely to boomerang than supplement marketing for two reasons. First, by increasing the salience of thoughts about poor health, a drug may lead consumers to classify their problem as one of poor health. This low self-image may reduce self-efficacy about enacting complementary health-protective behaviors and living a healthy lifestyle (Bandura 1986) inasmuch as a sick person feels less empowered to take responsibility for their own health outcomes and instead may look to external aid and treatment. Second, drugs—by reducing the salience and perceived importance of other complementary health-protective behaviors—may persuade consumers that drugs alone are sufficient to reduce risk. If so, then consumers will be less motivated to engage in complementary health-protective behaviors. With supplements, additional protective behaviors that contribute to a healthy lifestyle will still be seen as important to protect one’s health—indeed, the name itself serves as a reminder. Based on these two psychological mechanisms, we hypothesize that:

- H1: Drugs (compared to supplements) will decrease intentions to engage in healthy lifestyle practices (i.e., a boomerang effect).
- H2: Drugs (compared to supplements) will a) reduce perceptions of health and perceived efficacy; and, b) reduce perceived importance of, and motivation to engage in, complementary health-protective behaviors that constitute a healthy lifestyle.
- H3: Motivation and efficacy will mediate the effects of drug and supplement marketing on healthy lifestyle intentions.
- H4: A combined intervention (designed to increase motivation *and* efficacy to engage in health-protective behaviors) will increase healthy lifestyle intentions for a drug

remedy (versus no intervention or a single-mechanism intervention).

In a set of laboratory and field experiments, we investigate the effects of drug and supplement remedies (e.g. fat-fighting pills, anti-cholesterol products) on intentions to live a healthy lifestyle.

In experiment 1, a drug (versus supplement) undermined healthy lifestyle intentions. In experiment 2, healthy lifestyle intentions declined for a drug (versus supplement) as effectiveness increased. In experiment 3, drugs were associated with poorer health and reduced importance of healthy lifestyle practices than supplements; cognitive schema about drugs and supplements were shown to influence such judgments. In experiment 4, a consumer taking a drug (OTC or prescription) versus a supplement or no product was perceived as engaging to a lesser extent in healthy lifestyle practices. A drug also led to lower perceptions of health, efficacy, ability, and motivation to engage in healthy lifestyle behaviors. In experiment 5, a drug reduced efficacy and motivation to engage in health-protective behaviors and, in turn undermined healthy lifestyle intentions. When accompanied by a combined intervention that increased efficacy and motivation, the drug no longer boomeranged. Finally, in experiment 6, a combined intervention accompanying a drug remedy that targeted efficacy and motivation increased healthy lifestyle intentions; single-component interventions targeting motivation or efficacy alone did not.

These findings support our hypotheses and are significant for five reasons: 1) our research proposes a boundary condition in the health domain for the boomerang effect of remedies demonstrated in previous research, namely the type of product (supplement versus drug); 2) identifying products as supplements (or supplemental in nature) could serve as a corrective technique by reminding consumers that their use should accompany a healthy lifestyle; 3) from a health care perspective, corrective interventions that target motivation and efficacy as mediating psychological mechanisms can ‘undo’ the drug boomerang and promote healthy lifestyle practices; 4) from a consumer welfare perspective, the proliferation of supplement marketing may in fact be less harmful to a healthy lifestyle than similar drug marketing that undermines other health-protective behaviors; and 5) from a public policy perspective, the marketing activities of companies promoting drugs and supplements may merit attention to ensure that information is prominently displayed to reinforce healthy lifestyle practices. More generally, these findings add to the growing debate over the regulation of drug and supplement markets, the role of direct-to-consumer advertising, and de-marketing efforts to reduce risky consumption. Specifically, our research suggests that drugs boomerang on consumers by undermining their motivation and efficacy to engage in health-protective behaviors. Thus, consumers “tune out” other health-protective behaviors that contribute to a healthy lifestyle. In contrast, supplements remind consumers to “turn on” complementary protective behaviors as part of a healthy lifestyle package. Thus, drug marketing—and even supplement marketing—should be treated with caution—lest such products seduce consumers into treating them as get-out-of-jail-free cards.

“Getting Emotional About Health”

Nidhi Agrawal, Geeta Menon and Jennifer L. Aaker

It is well documented that people’s self-perceptions are often self-enhancing, even in the face of adverse reality. People tend to underestimate the likelihood of contracting a disease (i.e., “unrealistic optimism” or “self-positivity bias”), raising concerns regarding the effectiveness of health-related advertising. Extant research has focused largely on the role of moderating factors that increase self-risk perceptions, thereby heightening health awareness and

disease prevention (e.g., Luce and Kahn 1999; Raghurir and Menon 1998). We build on this base of research but focus on a different set of phenomenon.

Our premise is that emotions point to the stakes of a disease, and health consequences have two crucial types of stakes: for self and for family. Therefore, to understand the effectiveness of health messages that present consequences for the self or family, one needs to take into consideration the role of emotions—both as a provider of resources and of information. Important research questions we address pertain to: (a) the role of discrete emotions in fostering the acceptance of vulnerability or leading to the rejection of vulnerability, (b) how discrete emotions and message characteristics interact to influence message effectiveness, and (c) delineating the process by which these effects occur. To address these gaps, we conducted four experiments that examine the role of four strategically-chosen discrete emotions (happiness, peacefulness, sadness, agitation) in influencing message effectiveness, with a particular focus on how the emotions interact with health messages focused on the consequences of an illness for self or family. We show that when primed with a discrete positive (negative) emotion, the compatibility between the message referent and the discrete emotion fosters (hinders) the processing of health information. Further, this effect occurs due to an increase in the negative emotional state in compatible situations while processing disease-related information.

We argue that discrete emotions, varying on the dimensions of valence and self/other-relatedness, can influence the processing of health messages featuring the two distinct referent groups. While the valence of the emotion (e.g., positive, in the case of happiness) becomes a source for the acceptance or rejection of a message that presents a relevant health threat, the self/other-relatedness dimension of the same emotion (e.g., self-relatedness of happiness) forms the basis of compatibility with the message referent (e.g., self). Thus, this research integrates recent work on moods as antecedent states influencing the resources to process the message (e.g., Keller, Lipkus, and Rimer 2003) with research suggesting that discrete emotions may be appraised on distinct dimensions (e.g., Lerner and Keltner 2000).

We prime happiness and peacefulness (experiment 1), sadness and agitation (experiment 2). The results show that under happy emotional states, self-referent health appeals are more effective than family-referent appeals, whereas the converse occurred for peaceful emotional states. And under negative emotional states like sadness (vs. agitation), the compatible self-referent health appeals were less effective than family-referent appeals. Together, these findings suggest that compatibility between message referent and self/other relatedness dimension of the emotion impacts message effectiveness—an effect that is critically dependent on valence of the emotion. In experiment 3, we expand the set of message effectiveness measures, and enhance external validity by embedding the message in a more realistic domain where a magazine primes the emotions that then foster or hinder the processing of health related information. Here too, we demonstrate that a compatible message referent leads to greater message effectiveness, but only for positive emotional states when there are resources to deal with such emotionally aversive messages. Negative emotions appear to encourage a mood repair motive, discouraging consumers from accepting the messages presented by a compatible appeal. We also demonstrated that the interactive effect of emotional valence and compatibility on message effectiveness is mediated through depth and quality of processing of information, thereby providing evidence for the process that we posit. Finally, experiment 4 demonstrates that emotional deterioration underlies the effects observed in experiments 1-3.

Our results have implications for the literature on emotions, compatibility effects, and health communications. Our findings speak to (a) examining compatibility effects between message characteristics and individual factors, and (b) positing specific cognitive-based mechanisms underlying the effects including elaboration likelihood, experienced fluency, or perceptions that a persuasive message “just feels right.” We add to this literature in three ways. First, we show that compatibility can occur not simply between a primed construct and message characteristics, but also between one dimension of an incidental discrete emotion and message characteristics. Second, we extend this emotion-based compatibility finding by demonstrating its dependence on the valence of the emotion such that positive emotions foster compatibility effects, but negative emotions make compatible appeals less persuasive. Extant research on compatibility effects has found only argument strength as a moderator of the persuasiveness of compatible messages (Petty and Wegener 1998). Our findings introduce valence of emotion as another such moderator.

“Fact, Fear, or Regret: Getting People to Cope Actively”

Kirsten Grasshof, Barbara Kahn and Mary Frances Luce

Negative emotions are commonly used in advertisements promoting everything from mammogram screening to cat food. Negative emotions vary in important ways, perhaps most notably in the action tendency or coping response they generate. For example, fearful people will tend to flee dangers while angry people approach them. Some negative emotions make people feel incapable of managing the situation themselves so they escape while others make people feel capable and responsible so they act.

Lazarus (1991) suggested that people cognitively appraise a situation on several different appraisal dimensions (e.g., valence) and that these cognitive appraisals give rise to different emotions. When negative emotions are experienced, people generally use coping strategies to mitigate them. Recent research has begun to investigate how specific emotions and or specific appraisals prompt various coping strategies. For example using a recall task, Folkman and Lazarus (1988) found that appraisals of responsibility lead to action-facilitative-coping (e.g. “I thought about what steps to take”). Conversely, feelings of threat and a lack of efficacy led to avoidance coping (Duhachek 2005). These results support the hypothesis that links emotions that evoke strong (weak) feelings of responsibility, for example regret (fear), with active (avoidance) coping strategies. However, despite strong theoretical support and some recent experimental support, research that directly examines the link between emotions, coping, and behavior is still scant and riddled with prevalent inconsistencies and null effects (Skinner et al. 2003).

The present research investigates how the emotions of fear and regret as compared to a factual appeal differentially affect coping processes and the resulting impact on behaviors. In this research instead of asking participants to indicate how they cope with an emotional event we actually observe the coping process by watching how they navigate through various Internet sites, allowing us to measure coping patterns and times. This format of using internet links that are reflective of coping strategies is congruent with the way many consumers process emotionally charged decisions from deciding what brand of car to purchase to considering different types of medical treatments.

In study 1, participants were exposed to messages pretested to evoke fear or regret, each compared to a more factual control message regarding Chlamydia. They were then given the opportunity to explore several Internet links as much (or little) as they desired. The available links were designed to reflect active coping

strategies (1. how to use condoms, a step by step guide to proper condom use, 2. purchasing condoms, a site that sold discounted condoms), information seeking strategies (3. advantages and disadvantages to condom use, 4. ask Alice, a peer generated site discussing condoms) or denial strategies (5. a joke site). The links that were explored and time spent per link and overall were recorded.

The results indicated no significant differences in the overall time spent coping. However, the relative mix of action oriented versus denial coping varied. Participants in the fear condition spent a significantly smaller portion of time actively coping than either those in the regret or factual condition. Furthermore, the fear participants spent a significantly larger portion of time exploring the denial (joke) link. The results support our hypothesis that participants exposed to a fear message are less likely to cope actively and more likely to engage in denial coping than regret or factual participants. We also found preliminary support for our hypothesis that participants in the regret condition would cope more actively than those in the factual condition. Finally, coping tendencies appeared to be moderated by individual coping styles in the factual condition, and thus in the absence of a specific emotional theme to direct coping strategies.

In a second study we find that the differences between regret and fear coping are exacerbated in an emotional versus a deliberative mind set. We also find that the actual decision to purchase condoms is predicted by the results in the emotional condition. This is consistent with our expectation that a condom serves as a visceral cue evoking emotional reactions and coping tendencies.

In summary, using real time measures of coping we find the theorized differences between the high responsibility emotion of regret and the low responsibility emotion of fear. This suggests that when a state of responsibility is evoked through an emotional appeal (specifically a regret appeal), action oriented coping can be triggered. However, when feelings of responsibility are dampened through a fear appeal, denial coping is triggered.

SPECIAL SESSION SUMMARY

Negativity Biases in Consumer Preferences, Choice, and Outcome Perception

Carey K. Morewedge, Princeton University, USA

SESSION OVERVIEW

Much research on evaluation has focused attention on the role of preferences. For example, how preferences increase for the things we choose and receive (Festinger, 1957; Kahneman, Knetch, & Thaler, 1990). Whether our preferences reflect the immediate, prospective, or retrospective pleasure experiences or objects will bring (Kahneman, 1999). And whether we are too focused on what we prefer in the short term and do not account for decisions' long term ramifications (Mischel & Shoda, 1995). Research, however, has also demonstrated that negative events have a profound impact upon our lives, and that much of life is spent attempting to avoid them (Baumeister et al. 2000; Denrell, 2005; Kahneman & Tversky, 1979; Rozin & Royzman, 1999). The research we present focuses on what we dislike, and how our distastes influence decisions. It demonstrates why the unpleasant aspects of our decisions and their outcomes also deserve serious consideration.

Hsee first presents research on negativity bias in the judgment of alternatives. Whether evaluating penguins, politicians, or peers, his findings suggest that people are more likely to agree on what they dislike than what they like. In other words, there is greater consensus across individuals on what is bad than on what is good. Second, Kramer, Maimaran and Simonson examine the relative ease of assessing options' strengths and weaknesses. They find that the peculiar attractiveness of compromise (utilitarian) options may be due to their superior resistance to criticism relative to risky (or hedonic) options, rather than to differences in the benefits they confer. Third, Morewedge presents research suggesting that negative outcomes appear specially intended to perceivers. He finds that people are more likely to attribute negative outcomes to the intentions of other people rather than to non-intentional causes (i.e., computer programs and chance), whereas people are more likely to ascribe positive outcomes to non-intentional causes rather than to the intentions of other humans. Finally, Dan Ariely will critique these papers, discuss how they relate to other existing research, and point out potential implications.

ABSTRACTS

“Do People Agree More On Who is Pretty or On Who is Ugly?”

Christopher K. Hsee, The University of Chicago

This research explores two general questions: whether people agree more on what they like or on what they dislike, and whether people err more when predicting what others like or predicting what others dislike. We find that in general people agree more on what they dislike yet err more when predicting what others like. We explore the underlying reasons of these effects and identify situations where the reverse effects may emerge.

“De gustibus non est disputandum? The Impact of the Nature of the Chosen Option in Positive and Negative Contexts”

Thomas Kramer, City University of New York

Michal Maimaran, Stanford University

Itamar Simonson, Stanford University

Given that consumers often criticize others' choices or seek to defend their own, it is surprising that academic research provides

such little empirical evidence on the impact that the specific nature of the chosen option has on both choice criticism and choice defense. That is, we currently know very little about whether consumers' sensitivity to the choice type (e.g., virtue vs. vice, or compromise vs. non-compromise) differs between criticizing others and responding to others' criticism. Presumably, criticism of choice and response to criticism are two sides of the same coin: the option that is easier to criticize should be harder to defend. For example, if it is easier to criticize a choice of a cake over an apple, then choice of the cake should also be harder to defend.

However, we propose that the two actions are asymmetric with respect to the impact of the nature of the chosen option. In particular, we hypothesize that in the relatively negative context of criticizing choices, consumers tend to focus more generally on shared norms, whereas in the relatively positive context of defending choices, they focus more on the particular product attributes of the chosen option. Thus, the *nature* of the chosen option will have a larger impact when criticizing choices than when defending these choices.

Specifically, in order to respond to criticism of their choices, consumers can generate reasons justifying their choice based on the sovereignty of their idiosyncratic preferences (e.g., Shafir, Simonson, and Tversky 1993; Simonson 1989). Since tastes or preferences are highly subjective, choice options *irrespective* of their nature can be defended by reliance on the options' attributes matching these particular values. In contrast, the particular nature of others' choices is likely to play a relatively greater role in negative contexts of criticism. Since subjective tastes are difficult to argue (“de gustibus non est disputandum”), criticizing consumers for their choices may involve shared norms regarding which choices are the appropriate ones to make. For example, when choosing between a vice (e.g., a chocolate brownie) and a virtue (e.g., a fruit salad), it is common knowledge that one *should* choose the salad in order to maintain better health. Similarly, when choosing between a compromise and a non-compromise option, most individuals assume that choosing the compromise option is safer and minimizes losses, making it the ‘right’ option to choose.

Thus, consumers are likely to base their criticism on known norms and shared rules, so that the nature of the option being criticized is likely to play a bigger role. Specifically, it is more difficult to criticize the choice of conventional options, those that are easier-to-justify (e.g., the compromise option; Simonson, 1989), or ‘sure-thing’ options (Simonson, Kramer, and Young, 2004). Conversely, unconventional options (such as non-compromise or risky gambles) are more easily criticized. Therefore, we hypothesize and test in a series of studies that, whereas the choice of an option makes a large difference when forming criticism, the ability to respond to criticism is rather insensitive to the nature of the option one chooses.

In Study 1, participants were randomly assigned to one of two conditions: in the ‘criticism’ condition they read about other students' choices between (1) vices and virtues (e.g., a brownie and an apple), (2) hedonic and utilitarian options (e.g., a candy bar and a calling card), (3) compromise and non-compromise options, and (4) ‘sure-thing’ (e.g., \$25 for sure) and risky gambles (e.g., a 20% chance to receive \$250). Subjects were then asked to rate how easy it would be for them to criticize another student for his choice of

each option. In the ‘respond’ condition, participants rated how easy it would be for them to respond to criticism had they themselves chosen each option.

Across the various problems, we find an interaction between the task (criticize vs. respond) and the type of option. Specifically, participants reported that it would be significantly easier to criticize the choice of the non-compromise, the hedonic option, the vice and the gamble than the choice of the compromise, utilitarian option, virtue and the sure-thing, respectively. In contrast, the differences in ease of responding to choosing one option or the other (e.g., the vice or the virtue) were much smaller and not significant.

In Study 2, we (1) generalized the findings to additional choice contexts as well as replicated the previous results, (2) examined whether the effect also appears in a within-subject design, and (3) ruled out the possibility that the results of Study 1 are due to differences in difficulty of evaluating the ease of criticizing versus the ease of responding. In addition to the two between-subjects conditions, we included two within-subjects conditions in which participants rated both the ease of criticizing others’ choice and the ease of responding to others’ criticism (order counterbalanced; no order effects were found). All participants evaluated choices of (1) compromise versus non-compromise options (2) sure-thing versus risky gambles, and (3) dominating versus dominated options. Finally, participants rated the ease of completing the criticizing versus responding to criticism task.

As hypothesized, we found bigger differences in ease of criticizing each option (compromise vs. non-compromise, dominating vs. dominated and sure-thing vs. risky option) than in ease of responding to criticism for choosing each option. Specifically, criticizing the choice of ‘non-conventional’ options was judged to be significantly easier than criticizing the choice of ‘conventional’ options. Finally, the two tasks were equally difficult (in both the within and between designs) suggesting that the difference in difficulty of tasks cannot account for our results.

A third study (currently underway) seeks to provide direct support for our proposition that negative contexts of criticizing choices versus relatively positive contexts of defending choices affect the degree to which consumers focus more generally on shared norms versus on the particular product attributes of the chosen option. In particular, a ‘choice criticism’ group is presented with several problem types (e.g., hedonic vs. utilitarian options; compromise vs. non-compromise) and indicates in an open-ended format the reasons they could give for criticizing choice each of the options. Similarly, a separate ‘choice defense’ group is presented with the same problem types and indicates in an open-ended format the reasons they could give for defending choice of each of the options. Additionally, a third group of subjects will be recruited to evaluate the persuasiveness and effectiveness of the reasons for criticizing choices of the options (from group 1) and for defending choices of the options (from group 2).

“Negativity Bias in the Perception of External Agency”

Carey K. Morewedge, Princeton University

People seem apt to believe that machines have a “mind of their own” when they malfunction, and that referees were responsible for their team’s loss. Yet, when machines work well or their team is winning, the state of affairs is seldom attributed to the intentions of an external agent. This discrepancy reflects a general asymmetry in the way people ascribe intentional agency. Four experiments, employing ultimatum games and gambles, demonstrate that negative outcomes more often prompt one to infer the presence and influence of external intentional agents than do neutral and positive outcomes.

SPECIAL SESSION SUMMARY

Current Methodological Concerns for the Behavioral Researcher

Joachim Vosgerau, Carnegie Mellon, USA

SESSION OVERVIEW

In the past 40 years, statistical methods have become increasingly sophisticated. New methods allow behavioral researchers to more efficiently reveal increasingly complex patterns of causal relationships. In this session, advancements in three prominent statistical analysis techniques are presented: Mediation analysis, mean-centering of variables, and measurement analysis. The first paper presents a method for uncovering mediation that is more efficient (in terms of statistical power and accuracy) than traditional mediation analyses. The second paper demonstrates the advantages and disadvantages of mean-centering and its consequences for the interpretation of ANOVA and moderated regression. And the third paper introduces a new measurement analysis for panel data that allows discerning trait and state components. Overall, the session covers a broad range of methodological concerns that are equally important to the experimental researcher as to the researcher working with field data and surveys.

An important aspect of the session is its appeal to a diverse group of researchers. This is one reason we believe that the session will attract a wide variety of conference attendees. In his role as the discussant Joel Huber will conclude the session by briefly commenting on the papers presented, and will highlight methodology questions that are worthy of future investigation. He will then draw the audience to discuss issues raised by the session.

EXTENDED ABSTRACTS

“A Meditation on Mediation”

Dawn Iacobucci, Wharton

Mediation is frequently of interest to social science researchers. A theoretical premise posits an intervening variable, M , some indicative measure of the process through which an independent variable, X , is thought to impact a dependent variable, Y . The researcher seeks to assess the extent to which the effect of the independent variable on the dependent variable is direct or indirect via the mediating factor.

For example, X might be a trait, M , a general attitude, and Y , a specific response judgment. Whatever the theoretical content, tests of mediation seem particularly appealing to behavioral researchers attempting to track processes. For example, in the *Journal of Consumer Research* and the *Journal of Consumer Psychology* mediation tests are reported in approximately one quarter of the published articles.

Without question, the most popular means of testing for mediation is the procedure offered by Baron and Kenny (*JPSP*, 1986). Using their approach, the researcher fits three regression models to assess the links between X and M , X and Y , and the combination of X and M predicting Y .

We begin this paper by challenging the unquestioned and overly frequently use of mediation assessments (acrwebsite.org/topic.asp?artid=337). Yet, for the researcher determined to test for mediations, we demonstrate that structural equations models (SEM) are the superior tool for the mediation testing. The regression technique never surpasses SEM. This result is true even in the simplest of data scenarios, and clearly the SEM analytical framework allows us to consider a variety of data scenarios with greater sophistication.

First is the scenario in which a researcher has multiple indicators of the X , M , and/or Y constructs—a scenario prefigured by Baron and Kenny, but not addressed fully in their article. They acknowledge that, like any regression, their basic approach makes no particular allowances for measurement error, which is simply subsumed into the overall error term, contributing to the lack of fit.

To compare the analytical approaches, we created a series of Monte Carlo simulation studies to investigate and compare the regression vs. SEM methodologies in terms of superiority in identifying mediation structures. We varied the strength of the mediated vs. direct effects in the population, and the sample size in the data.

Even in the simplest of data scenarios—the classic case of only three constructs and only one measure per construct—the choice between regression and SEMs matters, and structural equations modeling is the superior technology. The SEM results work to the researcher's benefit, in being more likely to detect existing patterns of mediation, being truer to the known population structural characteristics, and in being statistically more defensible, given the elegance of the simultaneous estimation. Fitting components of models simultaneously (i.e., via SEM) is always statistically superior to doing so in a piece-meal fashion, e.g., to statistically control for and partial out other relationships.

In Study 2, we demonstrate that when multi-item scales are aggregated and their means imputed into regressions, the use of a structural equations model is again superior to the regressions. There is no circumstance in which a structural equation is outperformed by the regressions.

Taking means over multiple items (e.g., $\{X_1, X_2, X_3\}$ to \bar{X}) to simplify analyses is commonplace, but doing so does not use the data to their full advantage as would allowing the representation of the items in a measurement model. In Study 3, we compare multiple items for X , M , and Y as used in SEM vs. their aggregate means. We classified the results into the categories of “no,” “partial,” and “full” mediation and conclude that the results for the mean analysis are not as clear as the results from the full SEM treatment of the multi-item data. When there is “no” or “partial” mediation, means are more likely to overstate the extent of mediation.

Complementary to the concern of measurement issues is the substantive concern over the interrelationship among the focal constructs. We examine the logic and statistics underlying the scenario in which the X , M , and Y constructs are embedded in a richer nomological network that contains additional antecedent and/or consequential constructs. This broader nomological network is encouraged by philosophers of science and methodologists to offer the richest view of the phenomena and their explanations. The addition of at least one more construct, Q , is necessary even if the researcher cares more about X , M , and Y than Q .

The principal statistical purpose of the additional construct is to yield sufficient degrees of freedom to accurately test the mediation links. The mediation model, which posits three links among three constructs, is “just identified,” meaning the directionality of the effects, from X to M vs. M to X is empirically indeterminate (i.e., the fit statistics are perfect, e.g., CFI=1.00; rmse=0.00, and indistinguishable).

Theory should help differentiate the meaningfulness of these alternative models, yet competing models are rarely mentioned,

much less frequently tested. Further, rivals can be conceptually equally plausible. For example, if X =affect, M =cognition, and Y =behavior, there exist supporters of theories which pose $X \rightarrow M \rightarrow Y$, $M \rightarrow X \rightarrow Y$ or $Y \rightarrow M \rightarrow X$, etc. (Breckler, *PsychBull*, 1990).

The regression techniques are no different from the structural equations models in offering no solution to the issue of using all the available degrees of freedom in the decomposition of the variance (the parameter estimates are equivalent). The use of multi-item scales offers no solution to this problem either—additional degrees of freedom are illusory, contributing to the measurement model accuracy, but not to the critical structural model. Ideally, the X , M , Y mediation would be tested in the presence of at least one additional construct, Q , whose role is to serve as an antecedent to X , or a consequence of X , M , or Y .

In the final part of this paper, we extend the SEM models to consider moderated mediation. SAS code is provided for all scenarios.

“Mean-Centering and the Interpretation of ANOVA and Moderated Regression”

*Joachim Vosgerau, Carnegie Mellon
Hubert Gatignon, INSEAD*

ANOVA is the most prominent statistical analysis in experimental behavioral research. When an interaction of a continuous variable and a categorical variable is hypothesized, it is common practice to dichotomize the continuous scores and analyze the data with an ANOVA. For example, if a researcher wants to test the interaction of familiarity with a product class and gender on the size of the consideration set, the researcher might dichotomize familiarity scores into unfamiliar (score=0) and familiar (score>0), and analyze the data with ANOVA. This practice prevails although dichotomizing continuous variables bears negative consequences such as diminishing statistical power (Irwin and McClelland 2003 *JMR*). The reluctance to analyze data with moderated regression seems to result from the difficulties in interpreting moderated regression results.

Indeed, moderated regression and ANOVA can yield seemingly different effects when applied to the same data. We demonstrate that these differences occur because in ANOVA main effects are estimated at their means, and interaction effects are restricted to be symmetric cross-over effects relative to the means. In contrast, in moderated regression constant effects are estimated at zero, and no specific pattern of interaction is imposed.

In order to make moderated regression and ANOVA effects comparable, some researchers have argued to mean-center variables in moderated regression. We show that mean-centering yields effects that are statistically equivalent to effects from raw variables, but it restricts interaction effects to be symmetric relative to the means of the variables. As a consequence, constant effects in moderated regressions are no longer constant but depend on the specific range of the variables. For example, assume the researcher hypothesizes an interaction of familiarity and gender, such that female consumers who are familiar with the product class include more products in their consideration set than female consumers who are less familiar with the product class. For male consumers no differences with respect to product familiarity are expected. The researcher analyzes the raw data with a moderated regression and finds a significant interaction. In this raw-data analysis, the effect for gender is constant, whether a sample with familiarity scores from 0 to 3 is used or a sample with familiarity scores from 3 to 6. But if the researcher mean-centered familiarity scores, the effect for gender would depend on the specific sample. That is, the researcher would find a different gender effect with the sample of 0 to 3 familiarity scores than with the sample with 3 to 6 scores.

The same problem is shown to hold for main effects in ANOVA. If the researcher dichotomized familiarity scores and analyzed the data with ANOVA, the main effect for gender would depend on the range of the familiarity scores. This undesirable property of range-dependence of main effects in ANOVA is a result of ANOVA constraining interaction effects to be symmetric cross-over effects relative to the mean.

Another interpretational problem with ANOVA concerns the way main effects are estimated. Main effects in ANOVA, as constant effects in mean-centered moderated regression, are computed as the effect when the other variable is at its mean. So, the main effect for familiarity (unfamiliar vs. familiar) is estimated at the mean of gender (female vs. male). But what is the mean of female and male? It clearly makes no sense to talk about the mean of gender. And thus it makes no sense to interpret the main effect of product familiarity that is estimated at the mean of gender. Concluding, in the presence of interaction effects, ANOVA main effects have to be interpreted with caution. Main effects depend on the specific range in which the independent variables are manipulated or measured.

Mean-centering in moderated regression, although it is shown to lead to the undesirable property of range dependence of the constant effects, can nonetheless be beneficial. Mean-centering does not reduce multicollinearity (as some researchers and statistical textbooks claim), but it can help to overcome the arbitrary origin problem of interval scales such as Likert scales. Interval scales have no defined zero point, adding an arbitrary constant to an interval scale does not change its meaning. But adding an arbitrary constant to a continuous variable in a moderated regression changes the effect of the other variable in the moderated regression. So, in moderated regression with an interval scale focal variable, the constant effect of the moderator variable is non-interpretable because of the arbitrary origin of the focal variable. The arbitrary origin of interval scale variables can be eliminated by mean-centering. Mean-centered scores only include deviations from the variable mean, and thus arbitrary constants that are added to the raw variable drop out. However, because mean-centering also changes moderation to a symmetric cross-over interaction effect, caution has to be taken about which variables to mean-center in a moderated regression. We show that when the moderator variable is interval scale, mean-centering this variable allows for interpreting the focal variable's effect as its effect when the moderator is at its mean (the interpretation of the moderator variable's constant effect is not affected by the mean-centering transformation). But when the focal variable is interval scale, mean-centering does not help (as it would change the constant effect of the moderator variable to an effect that varies with the focal variable). In this case, the constant effect of the moderator variable should not be interpreted (the focal variable's effect would not be affected by the mean-centering transformation).

“An Extended Paradigm for Measurement Analysis of Marketing Constructs Applicable to Panel Data”

*Hans Baumgartner, Penn State University
Jan-Benedict E.M. Steenkamp, University of Northern Carolina*

Although the measurement of marketing and consumer behavior constructs has greatly improved in recent years, we believe that several topics have received insufficient attention in the literature. First, in many areas of research it is necessary to draw a clear distinction between the trait and state aspects of a construct. Although the distinction between states (transitory characteristics of individuals that change with circumstances and over time) and traits (relatively stable dispositions) has led to valuable insights in many areas of behavioral research (e.g., enduring vs. situational

involvement), these two components are not treated separately in conventional measurement models.

Second, measure specificity and other sources of systematic but non-construct-related variation in observed responses are usually confounded with random measurement error in standard measurement analyses. Treating all sources of non-substantive variation as an undifferentiated amalgam of measurement error (a) gives the misleading impression that the causes of measurement error are unknown and unknowable; (b) makes it impossible to get insights into the relative importance of the different sources of error or take ameliorative action; and (c) may lead to improper assessments of reliability and cause other problems as well (e.g., when correlations are corrected for attenuation, the correction may be inappropriate).

Third, the means of observed and latent variables are generally not considered explicitly in measurement analyses because all variables are defined as deviations from their means. This is problematic if item or scale means are to be compared across groups of respondents or over time because the comparisons are only meaningful if certain assumptions of measurement invariance are satisfied.

To overcome these problems, we propose an integrative procedure for conducting measurement analysis that (a) distinguishes temporary and stable components of variance in constructs corresponding to their state and trait aspects; (b) separates systematic sources of non-construct variance from random measurement error; and (c) takes into account the means of the observed variables.

With regard to the first point, we propose a second-order factor specification that enables a sophisticated investigation of the stable and transient components of a construct and avoids the problems associated with assessments of stability via test-retest correlations. For example, the procedure allows researchers to determine what proportion of the variation in a construct is due to states or traits.

With regard to the second point, we propose a new classification of measurement error along two dimensions. The first dimension distinguishes between three types of error depending on how many items are affected: (a) measurement error that is specific to a single item within a scale; (b) measurement error that affects a subset of items within a scale; and (c) measurement error that impacts all the items in a scale. The second dimension distinguishes between sources of error that are restricted to a given occasion of measurement (transient) and those that are consistent over time (stable). We show how the resulting six sources of error (stable scale-wide error, transient scale-wide error, stable item-subset error, transient item-subset error, stable item-specific error, and transient item-specific or random error) can be modeled using a factor-analytic specification and discuss the implications of the model for measurement analysis.

With regard to the third point, the proposed procedure incorporates the item and scale means into the measurement analysis, makes assessments of measurement invariance an explicit component of the scale validation process, and ultimately leads to cross-sectional and longitudinal comparisons of means (as well as relationships between constructs) that are methodologically justified.

An extended application of the model to the constructs of brand loyalty and deal proneness is presented to illustrate the benefits of the proposed procedure. We found that about one quarter of the total variance was systematic (nonrandom) measurement error, most of it stable over time. Moreover, scale reliability using the conventional procedure (such as Cronbach's alpha) was substantially overestimated. This result is probably not unique to the present context because the sources of systematic error will also be present in other scales. In addition, we found that ignoring system-

atic measurement error had a very substantial biasing effect on the results, since the correlation between the substantive constructs of brand loyalty and deal proneness was underestimated by a factor of almost 3 (-.25 versus -.70). In general, the direction of the bias depends on the sign of the true correlation. Measurement errors are typically positively correlated. If the true correlation between two constructs is negative, it will be underestimated, as in our illustration. If the true correlation is positive, it will be overestimated.

ROUNDTABLE

The Question-Behavior Effect: Current and Future Research

David Sprott, Washington State University, USA

SUMMARY

Asking someone a question about a behavior changes the ultimate performance of that behavior in the future. This *question-behavior effect* was initially demonstrated by Sherman (1980) using self-predictions to influence both socially desirable (making a donation to a charity) and undesirable (singing over the telephone) behaviors. Since that time, two primary groups of researchers have consistently demonstrated the question-behavior effect and have elucidated (at least some of) the theoretical mechanisms underlying the effect.

One group of scholars (who have published research on the mere-measurement effect) have used scaled intention and satisfaction questions to influence most often non-normative consumer-related behaviors (e.g., Chandon, Morwitz, Reinartz, 2004; Dholakia & Morwitz, 2002; Morwitz & Fitzsimons, 2004; Morwitz, Johnson & Schmittlen, 1993; Williams, Fitzsimons, & Block, 2004). These researchers have shown such questions to influence a wide-variety of actions (e.g., first time and repeat purchase of durable and non-durable goods, product choice, transactions with and defection from service providers, flossing, drug and alcohol consumption). The theoretical mechanism expected to underlie these effects is one based on attitude accessibility, whereby the question makes attitudes accessible which guide future performance of focal behaviors.

Another group of researchers (referring to their findings as the self-prophecy effect) have employed dichotomous self-predictions to influence behaviors with clear norms associated with the behavior (e.g., Greenwald, et al., 1987; Spangenberg, 1997; Spangenberg & Greenwald, 1999; Spangenberg, et al., 2003; Sprott, Spangenberg, & Fisher, 2003). In various settings, these researchers have shown that self-predictions can reduce the incidence of non-normative behavior (e.g., cheating on an exam) and increase the rate of normative behavior (e.g., recycling, health club attendance, donating to a charity, gender stereotyping, voting). In contrast to an accessibility perspective, these authors suggest that self-predictions are effective due to the motivation associated with cognitive dissonance. It is argued that the question simultaneously reminds people of prior failures to perform the behavior and norms associated with the target action; any discrepancy between what people have done and what they know they should do produces dissonance, which in turn motivates behavior change.

Both streams of research have demonstrated the importance of the question-behavior effect by reporting findings for real behavior. For example, Spangenberg (1997) found self-predictions to increase health-club attendance rates up to 6 months after the prediction. Similarly, Morwitz et al. (1993) showed that an intention measure influenced car purchase rates up to 6 months after the question was asked. Clearly, the question-behavior effect has significant implications for businesses measuring future behaviors and for organizations that may use questions to alter future behavior. As noted previously, research on the theoretical mechanisms underlying observed effects has documented at least two processes including attitude accessibility and cognitive dissonance. Both mechanisms have received considerable theoretical support in the literature including research demonstrating significant moderators of observed effects. For example, Morwitz and Fitzsimons (2004) demonstrated that prior brand attitudes influenced the magnitude of the question-behavior effect and Sprott, et al. (2003) found that self-

predictions were more effective for those with high (vs. low) social norms. These findings respectively support the attitude accessibility and dissonance interpretations.

Although much has been learned about the question-behavior effect since its introduction over 25 years ago, there is much left to be studied. Research on the theoretical mechanisms driving these effects should continue. Clearly attitude accessibility and cognitive dissonance are likely to underlie at least a portion of the reported findings, still future investigators should examine potential alternate theoretical processes related to these effects that have yet to be explored (e.g., implementation intentions). Other promising areas of research include investigations on the wording of the question and how such changes in wording may influence the magnitude of the effect. Prior research suggests that relatively simple (and outwardly benign) changes to the wording of intention measures can have differential effects in the theory of reasoned action (e.g., Sheppard, Hartwick and Warshaw 1988), similar effects may be possible regarding the question-behavior effect. As noted previously, question-behavior effects have been observed for up to six months after completing the question; such effects are hard to be accounted for via attitude accessibility and cognitive dissonance. Future research therefore needs to investigate further the nature of such long terms effects and the processes by which such effects manifest. Finally, research needs to investigate additional moderators of question behavior effects—most promising moderators would be those that help to clarify the processes underlying the effect.

The purpose of this roundtable is to bring together researchers interested in this area and to discuss unpublished findings and directions for future research. As can be seen from the list of references and those who have committed to attending this roundtable, a fairly substantial number of consumer researchers have investigated (or are at least interested in) the phenomenon. This roundtable is the first of its kind at ACR, although ACR has been the venue for many informal discussions of this topic over the years. Having a formal roundtable is hoped to take these discussions to a new level and stimulate future research into the question-behavior effect.

SPECIAL SESSION SUMMARY

Possessions and Identity: Shifting Identities, Shifting Relationships

Jonah Berger, Stanford University, USA

SESSION OVERVIEW

Identities and relationships with possessions often shift, but we know relatively little about how such shifts influence the way consumers choose and relate to possessions. Research has shown that consumers choose products that match their self-concept (e.g., Sirgy, 1982), and delineated different consumer-product relationships (e.g. Fournier, 1998), but identities and relationships are often not static. Even if one assumes that preferences are influenced by identities, certain identities may be salient at one time, but not others, and the particular identity expressed by choosing a product may change. Similarly, consumers' relationship with products may shift over time. Some research has begun to examine the effects of identity salience (e.g., Kleine, Kleine, & Kernan, 1993; Reed, 2005) and shifting product relationships (e.g., Aaker, Fournier, and Brassel, 2004), but many important questions remain. How might these shifts influence the way consumers react to and choose products, as well as consumer satisfaction and well-being?

This session examines the consequences of shifting identities and product relationships. What happens when consumers choose a product when one identity is salient, but have to live with the consequences of their choice when a contrasting identity is evoked? How do consumers react when other social groups adopt a product that they had used to signal their identity? What happens when consumers lose special possessions and what factors moderate this threat to psychological security? How do shifts in salient identities change consumers' attitudes towards and relationships with products? The session examines these, and related questions, as it attempts to deepen our understanding of the consequences of shifting identities and product relationships.

Overview of Topics/Issues

The paper presented by LeBoeuf and Belyavsky examines how shifts in identity salience over time influence consumers' satisfaction with choice. We often make choices while one identity is salient, but must live with those choices while a contrasting identity is evoked. They find that the match between these different identities moderates satisfaction with choice, and that mismatches may lead consumers to undo or "revoke" previous choices.

Ferraro, Escalas, and Bettman explore how identity impacts the way consumers respond to the loss of a special possession. To protect themselves from future pain, consumers generally become less attached to possessions after a loss. The magnitude of lowered attachment, however, depends on attachment style, and consumers are less able to distance themselves from possessions closely tied to their identities.

Research by Machin examines how shifts in the set of identities that are applicable to a person may lead to shifts in product relationships. Certain products may seem antithetical to a consumer's identity at one point in time, but as life course events shift the centrality of different aspects of the self, the same product may later be embraced.

Finally, the research presented by Berger and Heath investigates how people react when products that once signaled their identity are co-opted by out-group members. Products can signal identity, but if out-group members adopt them, the identity they signal may change. The studies illustrate that to avoid signaling undesired identities, people may abandon products that are adopted by other social groups.

Taken together, these papers highlight not only that identity influences consumers' choice of, and relationship with possessions, but also how these choices and relationships are sensitive to shifts.

We thus expand the view of the identity possession link from a static, "one moment in time" perspective to a dynamic, interactive, and fluid process. Given the breadth of issues addressed in these papers, it is expected that the session will be of interest to a wide audience, including researchers interested in identity, decision making, and relationships, as well as consumer satisfaction and well-being.

EXTENDED ABSTRACTS

"I Wasn't Myself When I Chose That: Identity-Salience Fluctuations and Post-Choice (Dis)Satisfaction"

Robyn A. LeBoeuf, University of Florida

Julia Belyavsky, University of Florida

People hold numerous social identities reflecting their group memberships and social roles. For example, a woman may be a lawyer, a mother, an American, a Democrat, and so on. The salience of these identities fluctuates in response to environmental cues; recent research has revealed that consumer preferences also fluctuate to align with the momentarily salient identity (LeBoeuf, Shafir, and Belyavsky 2007; see also Forehand, Deshpande, and Reed 2002; Reed 2004). Thus, contrary to normative assumptions that each person holds a fairly consistent preference ordering, people may instead express any one of several (potentially conflicting) preferences, depending on which identity happens, at the moment of choice, to be salient.

This paper investigates consequences of these identity-congruent choices. Although identity salience is inherently fluid, choices, once made, tend to be fixed. Thus, a decision maker may make a choice congruent with a currently salient identity and may be bound to that choice even when another, potentially conflicting, identity arises. For example, a woman may subscribe to a fashion magazine while a feminine identity is salient, but may then view that decision disdainfully if the magazine arrives at work where an occupational identity is salient. This research addresses such issues.

We first identified a set of preferences that would be affected by identity-salience manipulations for our participants (University of Florida business majors). Pre-testing revealed that two potent identities for these participants were the relatively scholarly, serious business-student identity and the relatively social, frivolous University-of-Florida-student identity. We elicited the business identity for approximately one-half of our sample by asking students to evaluate extra-curricular business activities, business courses, and business graduate programs. We elicited the university identity for the remaining participants by asking them to evaluate socializing-oriented extracurricular activities, student-friendly restaurants, and university sports teams. Students then participated in an ostensibly unrelated "consumer preference" study, choosing one of four movies, one of two prizes, one of four books, one of four magazines, and one of four small gifts. Choices were constructed so that half of the alternatives in each choice set were congruent with the serious business identity (e.g., *BusinessWeek*, *Fortune*), but the others (e.g., *Cosmopolitan*, *People*) were congruent with the sociable university identity. Across the five choices, those for whom

the business identity was evoked selected reliably more serious, business-congruent alternatives than did those for whom the university identity was evoked. Thus, preferences indeed assimilated to the salient identities.

Next, we sought to establish that identity-salience fluctuations have implications beyond the moment of purchase, in that they also impact satisfaction with prior choices. As such, a new sample of participants completed the above-described procedure, making choices while either the university-student or the business-student identity was salient. Participants then completed a 15-minute filler task, after which we evoked either the same identity as before or the contrasting identity. To evoke the business identity in this second stage, participants evaluated issues relating to business education and listed positive aspects of being a business major. To elicit the university identity, students evaluated campus issues and listed positive aspects of being at the university. Finally, participants were told that we were interested in their *current* feelings about their prior choices. For each choice, participants were shown the set of previously available alternatives and were reminded which they chose. They were asked to rate their satisfaction with each prior choice and to rate their likelihood of making a similar choice again in the future. We averaged these ratings for each choice; a 2 (first identity) x 2 (second identity) x 5 (item) ANOVA revealed a reliable first identity x second identity interaction. Those who chose under a salient university identity later expressed more dissatisfaction with their choices when a business-student identity was evoked, compared to when the university identity was again evoked. Conversely, those who initially chose under the business identity were more dissatisfied when the university, instead of business, identity was later evoked.

Thus, people view their prior choices more favorably when the “experiencing” and “choosing” identities match. We next explored whether these effects on post-choice satisfaction could lead to actual reversals of prior decisions. We recruited a new sample who completed the first elicitation, choice, filler task, and second elicitation procedures, as described above. In the final part of the study, participants were given the opportunity to “switch” from their original choices and select different items. For each choice, we showed participants the previously available alternatives, reminding them of their choice and asking them to indicate which alternative they *now* preferred. We coded whether, for each item, participants made a “congruent” second choice, a “more serious” second choice (compared to the first), or a “more frivolous” second choice. Across the five items, those for whom the business student had first been elicited were more likely to switch to a more frivolous option when the university student was evoked than when the business student was re-evoked. Similarly, those for whom the university student was first elicited were more likely to switch to something more serious when the business, instead of university, identity was later evoked. A follow-up study replicated these results using different identities and different choices, thus establishing the generality of these effects. Thus, when the self who must “live with” the choice differs from the one who made the choice, people not only demonstrate dissatisfaction with the prior choice, but may even desire to switch to an option more congruent with the currently (although temporarily) salient identity.

Preferences assimilate to the salient identity. This paper shows that identity-salience fluctuations impact not only choices, but also retrospective evaluations of choices. Such findings may shed light on why consumers occasionally “undo” prior decisions (by, for example, cancelling subscriptions or returning items to stores). This work, while expanding our understanding of identity salience, provides a new perspective on temporal inconsistency, suggesting that people may come to regret choices, and to act inconsistently

with commitments, not always because of calculated hypocrisy, but because identities dormant during choice may become prominent post-choice, giving the decision maker a new, potentially contradictory, set of values.

“Attachment Style, Psychological Security, and Consumer Response to Special Possession Loss”

Rosellina Ferraro, University of Maryland

Jennifer Escalas, Vanderbilt University

James R. Bettman, Duke University

The objects we own often take on special meaning arising from the use of possessions to satisfy psychological needs (e.g., Belk 1988). Consumers use special possessions to create personal identity, act as symbols of personal accomplishment, provide self-esteem, assert individuality, present themselves to others, and help them through life transitions. Possessions can also serve a social purpose, providing linkages to other people, integrating one into one’s family, community, cultural group, and society in general. Furthermore, possessions may represent who we were in the past and who we want to be in the future.

Belk (1988) identifies three primary reasons for using possessions to extend self: they give us a sense of security, so we feel anchored in the world; they are instrumental to knowing who we are; and they increase status. In our research, we focus on the notion that special possessions provide consumers with psychological security. We believe that when special possessions are lost, psychological security is threatened. We explore how consumers cope with such security threats arising from the loss of a special possession, both generally, in terms of thoughts, feelings, and potential actions, and specifically, regarding how the loss of one possession affects the extent to which consumers are attached to remaining possessions.

Hart, Shaver, and Goldenberg (2005) posit a tripartite model of psychological security in which people are able to buffer themselves from apprehension and anxiety through enhanced self-esteem, strong cultural beliefs, and important relationships. They suggest that threats to one component of the system can trigger compensatory responses from the other two components. In our research, we build on this theory to suggest that possessions can reflect these three different sources of security (self-esteem, cultural beliefs, and important relationships) and thereby serve as buffering mechanisms from anxiety. Therefore, the loss of a special possession linked to one of these important components of the psychological security system is seen as a threat to that security source and should trigger compensatory action from one or both of the other components. We examine what happens to the value we place on special possessions in one important domain when a special possession in one of the other important domains is lost or stolen and cannot be replaced. Will people compensate by increasing the value they place on other special possessions or devalue those remaining possessions?

We expect that the impact of a possession loss is dependent on people’s possession attachment tendency. Attachment tendency is conceptualized as the extent to which an individual uses possessions to define and communicate their sense of self. People high on attachment tendency tend to derive part of their identity from possessions. They feel that possessions are central to their identity and allow them to achieve a desired identity. We expect that the effect of losing a possession in one critical domain affects the subsequent importance people attach to other special possessions and that this effect will be moderated by attachment tendency. People low on attachment tendency, those who do not use possessions as a communication vehicle for the self, will compensate differently than people high on attachment tendency.

We conducted two studies to examine the effects of possession loss on attachment to other possessions. American participants drawn from an international Internet survey panel were asked to list three special possessions, one that was reflective of an important relationship, one that was reflective of a personal achievement, and one that was reflective of their cultural worldview. To capture attachment tendency, we measured how much the participants initially valued each of these possessions adapting items from Sivasdas and Venkatesh (1995) extended self-scale. We also measured the importance people placed on each of the three possessions. We then asked participants to imagine that the possession reflecting cultural worldview was stolen or lost and could not be replaced and took additional measures of how much value the participants placed on the two remaining possessions.

We found that attachment to the self-esteem and relationship possessions decreased after loss of the cultural worldview possession, with the extent of this decrease moderated by attachment tendency. Importance placed on the remaining two possessions decreased. The extent of this decrease, however, was moderated by attachment tendency. Participants high on attachment tendency exhibited less of a decrease than participants with low attachment tendencies. This result suggests that individuals who tend not to use possessions to define and communicate the self devalue their remaining possessions more so than do those individuals who do use possessions for this function.

In Study 2, we compared responses to losing a special possession to those of two well-known threats to psychological security: a threat to one's world view and mortality salience (where one's death is made salient). This study examined whether the loss of a special possession results in a unique pattern of coping, or whether different security threats lead to similar coping mechanisms. This study was almost identical to Study 1 except that two additional conditions were added, one threatening participants' cultural worldview and the other making mortality salient. The results in the worldview possession loss condition replicate the results of Study 1. Responses to worldview threats and mortality salience mirror those of worldview possession loss.

Our results indicate that after a possession linked to an important aspect of self is lost or stolen, the importance that people place on other special possessions decreases. This suggests that people may be seeking to protect themselves from the possibility of further possession loss in the future by devaluing their remaining possessions. However, the extent of the devaluation is moderated by the overall importance of the possession to self-identity. People high on attachment tendency do not devalue the two other possessions as much as do people low on attachment tendency. People high on attachment tendency rely on their possessions to define and communicate who they are. Thus, the extent to which they can devalue their possessions is limited. Our results also indicate that responses to two other specific types of psychological security threats are consistent with the threat of worldview possession loss.

"Identity Shifts and the Decision to Consume"

Jane Machin, Virginia Tech

This research examines how shifts in the gender identity of women trying to conceive influence their decision to avoid or to purchase over-the-counter fertility aids. Past research on the relationship between womanhood and motherhood has focused on one of three different groups of women: women who already have children (e.g., Leifer, 1980), women who are pregnant (e.g., Lederman, 1993) or women who are child-free (e.g. McMahon, 1998). How the process of trying to conceive influences gender and motherhood identities has not been addressed. This represents an important gap since the point at which a woman takes active steps

to try for a baby is often the first time she has seriously addressed what motherhood means to her. It is also important to consider how this relationship changes the longer she has to wait to conceive since identification with a motherhood role is a gradual process (McMahon, 1998). Furthermore, there is no research on how the consumption of over-the-counter fertility aids influences women's identity. As these aids are available over the counter and are relatively cheap they represent a viable fertility aid for many more women than new reproductive technologies.

Using a grounded approach, results from a series of qualitative focus group interviews, together with a textual analysis of home ovulation test cartons are presented (Auerbach and Silverstein 2003). The focus groups were conducted among women at different stages in the process of trying to conceive. The theoretical foundation used to interpret the data is based on symbolic interactionism (e.g. Solomon, 1983) and social identity theory (Tajfel & Turner, 1979). It also draws from the literature on female gender and motherhood identities (e.g. Skevington & Baker, 1993) to address the following research questions: (a) what is the gender and motherhood identity for women who are trying to conceive (b) how do these identities shift as the length of time trying increases and (c) how does the shifting identity influence their decision to consume (or not) home ovulation tests. The following is a brief summary of the main findings.

When women first decide to try for a baby, the motherhood identity is not a particularly salient or central aspect of their overall gender identity. Being a working woman, a wife, or a daughter is far more important to their concept of womanhood. They are not yet ready to adopt fully the motherhood identity: in fact, the motherhood identity is viewed rather negatively and as lower status than their current gender identity. These women are aware of home ovulation tests and freely concede the functional benefits of such aids. However ovulation tests also symbolize artificial conception and the desperate mother-to-be who cannot conceive naturally, images that are incongruent with their current gender identity. Avoiding the purchase and use of such fertility aids strengthens their identity both as a woman able to conceive naturally and as a woman whose life is not limited solely to children.

As the length of time women try to conceive progresses, however, motherhood becomes more central to their overall gender identity, making the consumption of home ovulation tests more acceptable: these women become very aware that they are in a low status social group ("infertile women") and they adopt behaviors to address this situation. This primarily consists of reinterpreting negative characteristics in a positive manner, including making comparisons to a new (lower) status group: they now view themselves as women who really want children—motherhood is now seen as a positive identity—and anything that helps them achieve that identity is also viewed positively. Home ovulation tests, symbolizing women who really want children, help to reinforce the motherhood image: by doing everything they can to have children they are fulfilling their socially expected feminine role.

The research also provides support for the idea that purchase avoidance can be a successful identity reinforcing strategy. Achieving congruence between self identity and product identity has been highlighted as an important driver for consumption: consumers are more likely to choose products, brands or stores whose image is highly congruent with their own identity (e.g. Sirgy, 1982; Belk, 1988). The key motivation in this process is assumed to be one of approach: consumers actively choose particular brands, products, services or stores in order to maintain or reinforce a particular identity (e.g. Kleine, Kleine & Allen 1995). In some circumstances however it seems likely that the main motivation is actually avoidance: consumers actively choose to *avoid* consuming particular

brands, products, services or stores in order to maintain or reinforce a particular identity (e.g. Wilk, 1997).

“Don’t Confuse Me with Them: Identity-Signaling and Product Abandonment”

Jonah Berger, *Stanford University*
Chip Heath, *Stanford University*

Cultural tastes (e.g. products, attitudes, and behaviors) can signal identity, but the particular identity they signal may shift based on the identity of the people that hold them. Tastes communicate aspects of people (e.g., what type of person they are) to others and can act as signals within the social communication system (e.g., Levy, 1959). People probably assume that a Harley Davidson rider is tough or prefers beer over wine. But just as tastes often gain such meaning through their association with similar types of individuals, their meaning can shift over time if they are adopted by outsiders. If suburban accountants start riding Harleys in an attempt to seem tough, the meaning of the taste may change and signal different characteristics altogether (i.e., wannabe tough guys).

The paper examines the consequences of shifts in the meaning of cultural tastes. We suggest that when outsiders start to adopt a taste, original taste holders may diverge and abandon the taste to avoid signaling undesired identities. The jocks, for instance, may stop saying a catchphrase once it is adopted by the geeks. Further, we suggest the cost of misidentification will lead people to be more likely to diverge from others that are dissimilar. The more dissimilar out-group adopters are to the current taste holders, the more costly it should be for people to be misidentified as members of the wrong social group. Snowboarders might not want people to think they are akin to skiers, but they probably prefer that mistake to being thought of as akin to golfers.

In our initial experiment, we first examined whether people would actually abandon a real possession that was adopted by an out-group with which they do not want to be confused. Before they became popular, we sold yellow Livestrong wristbands¹ to members of a campus dorm (Target dorm). Separate experimenters then measured the number of dorm members who wore the wristband before and after the same wristbands also were sold to the “geeky” Academic Focus dorm next door. As predicted, almost one-third of Target dorm members abandoned the taste once it was adopted by the geeks. Further, a control dorm on the other side of campus did not show such a significant decline in wristband wearing, allowing us to rule out boredom with the wristband as an alternative explanation. This study provides preliminary evidence that people may abandon products to avoid undesired identity inferences.

The next study examined our prediction that people should be more likely to diverge from social groups that are dissimilar. Students were asked how they would change their use of a catchphrase they and their friend liked saying if it was adopted by various social groups (e.g., business executives, janitors, and suburban teenagers). Separate groups of participants rated the social groups on similarity, liking, or demographic status. As predicted, people reported that they would decrease their use of the phrase if it was adopted by other social groups. Further, while people said they would diverge more from disliked groups, even controlling for liking and relative status, people were more likely to diverge from social groups that were dissimilar.

A follow up study found that divergence from dissimilar groups was mediated by concerns of misidentification. Each par-

ticipant rated how much they would diverge from each social group, perceived similarity, and desire to avoid being confused as a member. As predicted, people diverged more, and preferred not to be confused with, social groups that were dissimilar. Further, desire to avoid confusion mediated the relationship between similarity and divergence.

If identity-signaling is driving divergence then people should care the most about who they share their tastes with in certain domains, i.e., those that others use to infer identity (e.g. hairstyles and music tastes as opposed to dish soap or DVD players). A final study tests this possibility by investigating whether out-group similarity has a greater influence on divergence in identity-related domains. Student participants were given 10 different taste domains (e.g., music tastes, DVD player, and hairstyles) which varied in how much others used them to infer identity (as rated in a pre-test). In a between-subjects design, they were asked to imagine that members of another social group (i.e. Business executives, inner city teens, or Princeton students) had started to copy their tastes in a particular domain (e.g., Princeton students had started adopting their favorite type of music). They then indicated what percentage of the other group would have to adopt the taste for them to abandon it (e.g., would they abandon if 10% of Princeton students had adopted? 50%? Never?). These particular social groups were chosen because they were previously rated as equivalently liked but varied in similarity to the subject population. Results indicated that as predicted, people said they would abandon tastes that were adopted by other social groups. Further, both out-group similarity and the identity-relatedness of the domain influenced the abandonment threshold. Participants required the presence of fewer dissimilar others to abandon a taste, and the abandonment threshold was lower in domains used to communicate identity. Finally, there was a similarity x domain interaction; the similarity of the adopting group only influenced abandonment in domains that people use to communicate identity.

The identity signaled by a possession can shift over time based on the identity of the set of people that hold it. This paper illustrates that to avoid communicating undesired identities, people may abandon tastes that are adopted by other social groups.

SPECIAL SESSION SUMMARY

Gazing into the Crystal Ball: How Thinking about the Future Impacts the Present and Relates to Faulty Memories of the Past

Rebecca K. Ratner, University of Maryland, USA

SESSION OVERVIEW

Consumers' decisions are often based on a prediction about future emotional states. For example, the decision to book a spa vacation could depend on whether a person thinks that he or she will need a break from work. Recent research suggests that consumers' affective forecasts are often erroneous. The papers in this session examine mechanisms that underlie affective forecasts, including how thinking about the future impacts present experiences, processes by which individuals anticipate how they will feel about a future event after a certain amount of time has elapsed, reasons why affective forecasting errors persist over time, and ways in which people's forecasts about the future can be impacted by erroneous memories of the past.

The first paper (Meyvis and Nelson) examines how taking the future into account influences consumers' current real-time experience. The results suggest that although people believe that they will savor upcoming positive experiences and dread upcoming negative experiences, they actually enjoy the present less when anticipating positive experience and enjoy the present more when anticipating negative experiences.

The second paper (Ebert and Gilbert) distinguishes two psychological processes that underlie forecasts about the future: *forward-looking* ("How will I feel right when the semester ends, and how will I feel one month after that point?") and *backward-looking* ("How will I feel mid-June, and how will my well-being at that point be influenced by the fact that I finished the semester one month before?"). Results suggest that the order in which people consider these two points in time impacts the judgments they make. "Backcasting" (the apparent default strategy) is more likely to lead people to use information about both the impacting event and the future state than does forecasting.

The third paper (Ratner, Meyvis, and Levav) investigates why affective forecasting errors persist over time despite disconfirming evidence. The authors suggest that people's memories of their initial forecasts are biased by their present experience, and as a result people do not realize that they made a forecasting error. They therefore do not perceive a need to adjust their forecasting strategies in the future.

The fourth paper (Novemsky, Wang, and Dhar) suggests that consumers incorrectly anticipate the decreasing trend of enjoyment from owning a product for products they have not yet experienced. After a short period of experience, consumers overpredict their adaptation to the same product, perhaps because they overpredict their frequency of usage of the product and underweight the interruption to adaptation from intervening experiences.

Collectively, the papers in this session investigate how people form affective forecasts based on an integration of their present affective state and what they recall from their past experiences and predictions. These papers offer a more dynamic view of affective forecasts than is typically discussed in the literature in that they focus more on process than simply documenting the misforecasting phenomenon.

EXTENDED ABSTRACTS

"Contrasting Against the Future: The Unexpected Effects of Expectation"

Tom Meyvis, New York University

Leif Nelson, New York University

Although consumers are unaware of many of the context effects that have been documented in empirical studies, they do have an intuitive understanding of contrast effects. In fact, they tend to generalize contrast effects to domains in which they actually do not occur. In particular, consumers believe that they contrast hedonic experiences to other experiences that preceded them (e.g., that a regular meal will taste better when it follows a bad meal than when it follows a great meal). However, previous empirical research has not been able to find strong evidence of these hedonic contrast effects (e.g., Novemsky & Ratner 2003). Does this imply that there is no such thing as hedonic contrast effects?

In this project, we examine the effect of *anticipated* experiences on people's enjoyment of their current experience and we observe a data pattern opposite to what has been observed for the effect of *preceding* experiences. Although people do not forecast that future experiences will have a contrasting influence on current experiences, this is exactly what we find. Three studies indicate that negative experiences become more negative when consumers anticipate a pleasant experience and positive experiences become more positive when consumers anticipate an unpleasant experience.

Of course, this is not the first research to suggest that people's current affective state may be influenced by the anticipation of future experiences. However, previous research has focused on *intuitions* about the effects of anticipation rather than the actual *experience* of anticipation (Loewenstein 1987, Lovallo & Kahneman 2000). Interestingly, people do not seem to intuit contrast effects, but instead expect that the anticipation of an unpleasant event will make them feel bad (dread), whereas the anticipation of a pleasant event will make them feel good (savoring). Consistent with these intuitions, people prefer sequences that improve over time (in contrast to sequences that start out with the best experience), are willing to pay more for a delayed positive hedonic event (a kiss with their favorite movie star) than for the same immediate event, and are willing to pay more to avoid a delayed negative event (a 110 volt shock) than for an immediate negative event (Loewenstein 1987). While we do expect such dread and savoring effects to occur in some actual experiences, our research indicates that many experiences reflect contrast effects instead.

Our first study examined the effect of an anticipated pleasant sound experience on participants' experience of the preceding negative sound experience. Participants listened to 60 seconds of sound while continuously indicating how irritating the sound was at each moment. Approximately half of the participants were asked to listen to a vacuum cleaner for 60 seconds, the others were asked to listen to the vacuum cleaner for 50 seconds, followed by 10 seconds of pleasant piano music (Glenn Gould's rendition of the Goldberg Variations). Real-time (and retrospective) irritation ratings show that anticipating the pleasant music made the experience of the preceding vacuum noise significantly more irritating.

The second study varied the valence of the anticipated experience. Participants were asked to listen to the noise of a vacuum cleaner for 50 seconds and either expected that this would be followed by 10 seconds of pleasant piano music (as in the study 1) or 10 seconds of an annoying drilling sound. As expected, real-time ratings revealed that participants perceived the vacuum noise as more irritating when they anticipated the piano music than when they anticipated the drilling sound. Furthermore, when they anticipated the piano music, the vacuum noise became *more* irritating over time (as they got closer to the piano music), whereas when they anticipated the drilling sound, the vacuum noise became *less* irritating over time (as they got closer to the drilling sound). The retrospective measures provide further convergent evidence. Participants who anticipated the piano music rather than the drilling noise, evaluated the vacuum noise as more irritating, were more likely to prefer to switch to another annoying sound, and were willing to pay more to avoid the vacuum sound. These last two measures also provide evidence against a re-scaling explanation.

In the third study, we examined whether the opposite effect would occur for positive experiences: do positive experiences become more enjoyable when you anticipate that it will be followed by a negative experience? We asked 151 participants to listen to a pop song. Half of the participants were asked to listen to 60 seconds of the song, whereas the other half of the participants were asked to listen to 50 seconds of the song, followed by 10 seconds of annoying guitar feedback. Participants who expected the annoying guitar feedback provided more favorable real-time ratings of the song and were willing to pay more for a concert by that artist.

Although the observed pattern is consistent with the existence of prospective hedonic contrast (i.e., contrasting your current affective experience to an anticipated experience), we are still considering some plausible alternative accounts. In the negative domain, it is possible that the anticipation of more favorable future experiences prevents us from activating our psychological immune mechanisms (e.g., adaptation) which mitigate the unpleasantness of the current experience (Gilbert et al. 2004). In the positive domain, on the other hand, the expectation of a negative change may encourage consumers to extract more positively utility from their current experience. We are currently running studies to distinguish between these explanations and prospective hedonic contrast.

“Forecasting and Backcasting: Predicting the Impact of Events on the Future”

Jane E. J. Ebert, University of Minnesota

Daniel T. Gilbert, Harvard University

Consumer research has begun increasingly to explore the effects of anticipated affect on decision-making, i.e., affect that consumers expect to feel in the future post-choice (see MacInnis, Patrick, and Park (2005) for a recent review). While this research has shown that consumers can spontaneously use hedonic predictions in consumption decisions, and are influenced by their hedonic predictions in both the choices they make and how they feel about their consumption experiences, little attention has so far been paid to understanding how and when hedonic predictions are made and how they may be altered or induced. This is especially surprising given the potential importance of hedonic predictions for a broad range of consumer behavior (such as consumer preference, behavioral intentions, consumer satisfaction, brand loyalty and repeat purchase) and the now well-established finding that people are not very good at making hedonic predictions. The present research examined and compared two methods, forecasting and backcasting, by which consumers may predict their feelings in the future following a hedonic consumption event, such as a baseball game or a jewelry purchase.

How often have we heard that “time heals all wounds” or “someday this will all be but a distant memory”? Both of these adages help us recognize that events will have less impact in the future than we might otherwise believe, but they also represent two different ways of thinking about the hedonic impact of an event. The first adage reminds us that our present feelings will decrease with the passage of time, whereas the second adage assures us that our future states will be relatively uninfluenced by the events that precede them. For example, if I want to understand how I will feel on my birthday next month if I see the Red Sox lose today, “time heals all wounds” encourages me to forecast my future feelings by first considering my response to this event (“I’ll be very unhappy if the Red Sox lose today”) and then correcting for the passing of time and circumstances (“...but I’ll probably feel better on my birthday by the time it rolls around next month”). On the other hand, “someday this will be but a distant memory” encourages me to backcast my future feelings by first considering my usual feelings in a future state (“I’m going to be so happy at my birthday party next month”) and then correcting for the occurrence of the event and for the passing of time (“...and if the Red Sox lose today it shouldn’t make much difference by then”).

Forecasting and backcasting are logically identical methods for consumers to predict their future hedonic states after an impacting consumption event: in both cases a consumer ends by making the same prediction, of his or her feelings in a particular future state given the occurrence of an earlier consumption event (e.g., “How will I feel on my birthday if the Red Sox lose today?”), and in both cases the person has and can use precisely the same information. Nonetheless, the two methods reverse the order in which information about feelings in a future state (i.e., how I usually expect to feel on my birthday) and information about the impacting consumption event (i.e., the Red Sox loss) are considered, and although the order of information makes no logical difference in a computation such as this, decades of research has shown that the order in which information is considered can make a large psychological difference.

In four experiments we determine (a) whether backcasters and forecasters make different predictions about the impact of events on their future feelings, (b) whether they consider different kinds of information when making these predictions, and (c) whether predictors who are not guided spontaneously may use forecasting or backcasting to make such predictions.

In studies 1 and 2, respondents were guided to make forecasts, backcasts, or were unguided, and we measured how much impact they thought an event would have on their future feelings (addressing a and c above). In studies 3 and 4, we examined the kinds of information that forecasters and backcasters (and, in study 3, unguided respondents) used (addressing b and c above). In study 3, respondents rated the extent to which they considered the impacting event, their future state, and the elapsed time, and in study 4, we manipulated information about the impacting event, their future state, and the elapsed time. These two studies tell us whether forecasters and backcasters use information about their futures differently in their predictions, and provide us with some evidence on how forecasters and backcasters combine this information to make their predictions.

The data across four studies consistently supported three conclusions. First, backcasters and forecasters make different predictions from the same information. Specifically, backcasters’ future impact predictions are more strongly influenced by the nature of the impacting event and their usual feelings in a future state than are forecasters’ predictions. Second, backcasters and forecasters consider different kinds of information. Specifically, backcasters consider the nature of the impacting event and the

future state more than forecasters do. Third, when people are not guided to use one or other of these methods, they tend to make predictions and consider information as backcasters do. A simple primacy or recency explanation is insufficient to explain these findings.

**“Why We Don’t Learn to Accurately Forecast Our Feelings:
How the Misremembering of Our Predictions Blinds Us to
Our Past Forecasting Errors”**

Rebecca K. Ratner, University of Maryland

Tom Meyvis, New York University

Jonathan Levav, Columbia University

Why do people persist in making erroneous affective forecasts (e.g., Gilbert, Pinel, Wilson, Blumberg and Wheatley, 1998; Novemsky & Ratner, 2003)? We present the results of several studies that suggest that this persistence is partly caused by people’s biased recollections of their initial predictions. Individuals who experienced a negative event (e.g., Kerry supporters following the 2004 presidential election and Philadelphia Eagles fans following the 2005 Super Bowl) were less upset than they had predicted and misremembered this prediction as less extreme than it actually was, thus obscuring the fact that they had made a forecasting error. Similarly, individuals who experienced a positive event (e.g., UNC students following their men’s basketball team’s appearance in the Final Four) also recalled having made less extreme predictions than they had originally indicated. Interestingly, although participants’ memories were inaccurate for affective forecasts relating to the Final Four, their forecasts about winning the championship were quite accurate. This suggests that people’s memories for their affective forecasts may be better for unusual, extremely positive events than for unresolved, more emotionally-ambiguous events. Furthermore, even when individuals were able to accurately recall their affective forecasts, they did not spontaneously bring these to mind, and thus did not learn from the discrepancy between their affective forecasts and their actual experience unless prompted to do so.

We find that when we confront people with the fact that their initial forecast was wrong, they make less extreme predictions in a similar situation in the future. After a real-time experience that disconfirmed their initial affective forecast (i.e., not experiencing as strong context effects as participants’ expected when eating liked and disliked jellybeans, following Novemsky and Ratner 2003), people misremembered their initial affective forecasts as having been less extreme than they actually were. Respondents who were reminded of these actual, extreme initial forecasts showed more learning (i.e., made less extreme predictions for a similar, future set of experiences) than those who were not reminded of what their initial predictions had been. This indicates that learning is indeed impeded when people do not realize that their initial affective forecasts did not match their real-time experience.

In another study, we extend our investigation to the planning fallacy and find that students also misremember predicted completion times for class assignments as less optimistic than they actually were. Furthermore, students who were asked to *recall* their predicted completion times *before* making a second prediction, made less optimistic second predictions than those who were *reminded* of their prior predictions or those who only *recalled* their prior predictions *afterwards*. In fact, those students who made the largest recall errors tended to make the least optimistic second predictions. This suggests that people may sometimes perceive their prior predictions as more diagnostic than their prior behavior, leading them to anchor on their recalled prior predictions when formulating a prediction for a new, similar task. Note that this is consistent with previous theorizing that the persistence of the planning fallacy is in

part caused by people perceiving their past failures as nondiagnostic for their present predictions—since they ascribe these failures to idiosyncratic obstacles that were specific to that past situation.

In sum, these studies indicate that one of the reasons for the persistence of forecasting errors is people’s tendency to systematically misremember their predictions. We often recall our predictions as being closer to the actual outcome than they in fact were. This recall error creates the illusion that we did in fact accurately predict the outcome (or that our misprediction was less severe than it actually was), thus reducing the perceived need to learn. However, these studies also suggest some boundary conditions for this phenomenon. First, we do not always misremember our predictions. For instance, predictions regarding exceptional events tend to be recalled more accurately. Second, even when we systematically misremember our prediction, this may sometimes facilitate, rather than impede learning. For instance, when we use our recalled prior prediction as an anchor for our future predictions, recalling this prediction as being closer to reality will provide a more realistic anchor, and thus a more appropriate basis for our future predictions. Together, these results indicate that a systematic bias in memory for past predictions contributes to the persistence of forecasting errors.

“How Predictions Differ from Actual Adaptation to Durable Products”

Jing Wang, Yale University

Nathan Novemsky, Yale University

Ravi Dhar, Yale University

Many consumer purchases involve items for which consumption extends over a long period of time and decisions to purchase such products depend critically on predictions about how the experience with these products will unfold over time. For example, the decision to purchase a sunroof in a new car depends on whether one believes that it will provide little enjoyment after 6 months. Are consumers able to accurately predict this at the time of purchase? Clearly the ability to predict enjoyment with a product over time is important for many decisions. Failures in predictions of how utility from a product unfolds over time can result in repeated dissatisfaction with purchases or lack of repeat purchase of worthwhile items.

There is a growing body of research on predictions about how consumers will feel in the future in particular circumstances or following particular events. This research has examined many possible influences, including the weather, various health conditions, being denied tenure, having your favorite candidate win an election, etc. For example, Schkade and Kahneman (1998) found that individuals overpredicted the effect that weather would have on their well-being, thinking that Californians would be happier than Midwesterners. One key mechanism for this and many other mispredictions seems to be a focusing illusion (Schkade and Kahneman 1998) whereby individuals focus disproportionately on, and thus exaggerate the importance of, things that would change in the future while ignoring things that would remain the same when making predictions about overall happiness in the future. In actual experiences, individuals pay less attention to any one particular circumstance because they are busy fulfilling the demands of everyday life. A second explanation for misprediction of future happiness is that people may fail to appreciate the speed and extent to which they will emotionally adapt to changes in life circumstances (Gilbert et al., 1998; Loewenstein & Frederick, 1997). In light of these two major explanations for the gap between predicted and experienced happiness, past research has shown that drawing attention to focusing illusions or emotional adaptation might improve the quality of hedonic prediction about long-term emotional impact of certain events (Ubel, Loewenstein, and Jepson, 2005).

The present research differs from this existing affective forecasting research in one important way: the present studies examine happiness with a particular product over time rather than general happiness or well-being. Our measures of predictions and experiences are focused exclusively on the target item, and therefore are not subject to the documented effect of overweighting one event or dimension in considering total well-being.

Our first study examines how predicted enjoyment compares to actual enjoyment for a durable hedonic product. Participants were either given the product to take home (experience condition) or presented with a picture and detailed description of the same product (non-experience condition). Participants assigned to the experience condition either reported their current enjoyment after 1 day or 7 days with the product. Participants in the non-experience condition made predictions about enjoyment after either 1 day or 7 days with the product. We found a substantial reduction in actual experienced enjoyment with the product over time, and yet participants failed to anticipate this downward trend in future enjoyment without a first-hand experience with the product. This failure in predicting adaptation prior to experience with the target product might help explain why intuitive knowledge or past experience of adaptation often fails to curb the desires for new products, especially novel hedonic products, that consumers have yet to experience.

In our second study, we examined how predicted enjoyment compares to actual enjoyment for consumers who have gained some experience with a product. All participants in this study were given a product to keep and were assigned to either a 1-day or 7-day condition. One-day participants were asked to report their current enjoyment after one day with the product and to predict how they would feel about the product on day 7. Seven-day participants were asked to report their current enjoyment on day 7. The hedonic measure again shows that enjoyment is declining over time. Interestingly however, after owning the product for one day, participants largely overpredicted adaptation to the product, i.e., 1-day participants anticipated their enjoyment of the product to be much lower on day 7 than what the 7-day participants actually experienced. It is possible that once participants get to experience a product, they focus too much attention on how they are going to use or play with the product, overpredicting the usage frequency when making predictions about their future enjoyment and hence conclude that its novelty will wear off sooner than it does.

In study 3, we borrowed a defocusing manipulation from Wilson and colleagues (Wilson et al. 2000) to examine whether accuracy of hedonic prediction for a target product can be improved by drawing attention to various daily activities. We used a similar design to our study 2 with the addition of a 1-day defocusing condition. Before making predictions about their future enjoyment of the target product on day 7, participants assigned to this condition first completed a "Diary Study" where they were asked to estimate the number of hours they would spend on 10 activities during a typical week of a year (e.g., going to class, socializing with friends, studying, eating meals). We replicated the study 2 findings that participants in the 1-day control condition predicted their enjoyment of the target item to be much lower on day 7 than what the 7-day participants actually experienced. However, participants who were first asked to reflect on daily activities they would typically be engaged in made predictions that are roughly on par with the actual experienced enjoyment of the item on day 7.

In summary, we find that consumers' enjoyment of durable hedonic products often declines over time. Predictions sometimes fail to accurately represent these trends. Specifically, consumers fail to predict adaptation for products that they have not yet

experienced. Once they gain experience with the product, consumers tend to overpredict the degree of adaptation by focusing disproportional attention on their use of the target item.

How Cue Congruity Affects Consumer Perceptions

Anne L. Roggeveen, Babson College, USA

Dhruv Grewal, Babson College, USA

EXTENDED ABSTRACT

Consumers are exposed to a barrage of information cues about and from retailers. These cues can be categorized as being either high-scope or low-scope. A high-scope cue is one that is enduring such as a retail reputation. Whereas a low-scope cue is more easily changed such as a retailer offering or not offering a price matching guarantee (PMG) (Purohit and Srivastava 2001). The focus of this research is how consumers use the low-scope cue in forming evaluations as a function of the congruity with and valence of the high-scope cue.

Previous research offers conflicting evidence as to the use of high and low-scope cues in evaluations. Purohit and Srivastava (2001) demonstrate that high-scope cues are used in evaluations regardless of the valence of other cues, but low-scope cues are used only when the valence of the high-scope cue is positive. In contrast, research into the impact of PMGs (a low-scope cue) demonstrates that a low-scope cue is only used when a retailer is not price-competitive (a negative high-scope cue) (Biswas et al. 2002; Lurie and Srivastava 2005). Thus, one research stream indicates that the low-scope cue will be used when the high-scope cue is positive, and the other indicates that it will only be used when the high-scope cue is negative.

This research seeks to resolve the apparent discrepancy by understanding how the level of congruity between the high and low-scope cues impacts evaluations. Consider, for example, the association between the type of retailer reputation and a PMG. A PMG is more congruent with a retailer with a reputation based on price; and less with a retailer with a reputation based on service. Previous research has shown that the level of congruity between a stimulus (e.g., the low scope cue) and an evoked schemas (e.g., schema based on the high-scope cue) influences both processing and evaluation of the stimulus (Campbell and Goodstein 2001, Mandler 1982, Meyers-Levy and Tybout 1989). Thus, we expect that the level of congruity between the cues will impact when the PMG is considered diagnostic and hence used in evaluations. Cue diagnosticity and level of congruency serve as underlying frameworks for this research.

Considering the impact of both congruence and the valence of the high-scope cue, we expect that when the low-scope cue (PMG) is congruent with the high scope cue (price reputation), the low scope cue will not impact evaluations of the retailer if the high-scope cue is positive, but will if the high-scope cue is negative. The reasoning for this follows from the fact that if the two cues are congruent they both evoke a schema related to price resulting in consumers viewing the PMG as relevant additional information to update their existing schema. If the high-scope cue is positive (retailer is price competitive), the low-scope congruent cue (PMG) is not necessary to further improve perceptions. But if the high-scope cue is negative (retailer is not price competitive), the low-scope congruent cue (PMG) will enhance consumer evaluations of the retailer. The PMG partially offsets the negative impression caused by the high-scope cue because it is congruent, and hence, relevant information to that evoked schema. Thus, we hypothesize:

H₁: When the high and low-scope cues are congruent (PMG provided and retailer's reputation based on price competitiveness) there will be an interaction such that:

- *The low-scope PMG cue enhances perceptions about the retailer when the high-scope reputation cue is negative.*
- *The low-scope PMG cue has no impact on perceptions about the retailer when the high-scope reputation cue is positive.*

If the two cues are moderately incongruent they evoke different schemas related to the retailer. Cues which are moderately incongruent can both still indicate positive information. For example a retailer that provides excellent service can also offer competitive prices. If the high-scope cue is positive (excellent service reputation), consumers will consider other information about the retailer even if it is not related to the high-scope cue. Thus, the low-scope moderately incongruent cue is expected to impact evaluations when the high-scope cue is positive.

But if the high-scope cue is negative (poor service reputation), impressions of the retailer will be more heavily influenced by the negative information (Ahluwalia 2002; Skowronski and Carlston 1987). A moderately incongruent cue is not directly associated with and hence relevant to the schema evoked by the high-scope cue and is unlikely to offset the negative impact of the high-scope cue. Thus, we expect that:

H_{1b}: When the high and low-scope cues are moderately incongruent (PMG offered and retailer's reputation is not based on price) there will be an interaction such that:

- *The low-scope PMG cue enhances perceptions about the retailer when the high-scope reputation cue is positive.*
- *The low-scope PMG cue has no impact on perceptions about the retailer when the high-scope reputation cue is negative.*

These hypotheses are tested in three experiments. Experiment 1 uses a retailer with a reputation based on price, and experiment 2 uses retailer with a reputation based on service. Hence, the PMG is congruent with reputation in experiment 1 and is moderately incongruent with reputation in experiment 2. Finally, experiment 3 provides evidence to support the congruency and process arguments used in the development of hypotheses 1 and 2.

Experiment 1 utilized a 2 x 2 between subjects design which manipulated reputation of the retailer (positive/negative) and the presence of a PMG (present/absent). The retailer's reputation was based on price. Experiment 2 utilized the same design but the retailer's reputation was based on service. Finally experiment 3 utilized a 2 x 2 between subjects design in which the valence of the retailer's reputation (positive/negative) and the type of retailer's

reputation (service/price) were manipulated. Results support the hypotheses.

Cue Competition, Attention Shifting, and the Highlighting Effect

Marcus Cunha, University of Washington, USA

Juliano Laran, University of Florida, USA

EXTENDED ABSTRACT

Researchers have invested considerable effort into understanding how consumers learn associations between product attributes and product benefits (Janiszewski and van Osselaer 2000; Keller 1993; van Osselaer and Alba 2000; van Osselaer and Janiszewski 2001). One of the more commonly studied consumer-learning phenomena is cue competition (van Osselaer and Alba 2000; van Osselaer and Janiszewski 2001). Cue competition occurs when learning of an association between a predictive cue (e.g., product attribute) and an outcome (e.g., brand name) interferes with the learning about a second cue. For instance, a consumer shopping for a pain reliever may learn early in the process that a certain brand has a rapid release property and is gentle to the stomach. Later on, this consumer may learn that another brand of pain reliever has the same rapid release property (i.e., a common attribute) and has anti-inflammatory properties (i.e., a unique attribute). Recent research on associative learning and cue interaction (Kruschke 2001a; Kruschke, Kappenman and Hetrick 2005; Medin and Edelson 1988) shows that the association between the redundant cue and the first outcome (first brand) is stronger than the association between this cue and the second outcome (e.g., second brand). This phenomenon has been labeled the *highlighting effect*. In this paper, we use Attentional Theory (Kruschke 1996, 2001a, 2001b) to explore the marketing implications of the highlighting effect. The Attentional Theory account of the highlighting effect predicts that people will shift attention from common attributes toward unique attributes when learning associations of a second brand to preserve the association between the common attribute and the first brand learned. An implication of the attention shifting account is that the order of learning and the value of the predictive cues can have a strong impact on consumer preference for products with equally valued attributes.

In three experiments, respondents were trained to associate attributes to two different brands. Both brands were associated with one imperfect predictor (*I*) and one perfect predictor (*PC* or *PR*). The first brand offered attributes *I* and *PE* (brand b(*E*)) and the second brand offered attributes *I* and *PL* (brand b(*L*)). After the learning phase, respondents were tested with products offering attributes *I* or *PE*/*PL*. In line with Attentional Theory, we predicted that a product offering attribute *I* only should be more frequently associated with b(*E*). Conversely, a product offering attributes *PE*/*PL* should be more frequently associated with b(*L*). The first experiment provides compelling support to this prediction. The second experiment shows that the strength of association between attributes and brands learned at different points in time has a direct impact on product preferences. When attribute *I* has a higher value than attributes *PE* and *PL*, b(*E*) receives a higher evaluation than b(*L*) since the first brand becomes more strongly associated with attribute *I* than the second brand, which is expected to have stronger association with *PL*. Finally, the third experiment provides further evidence for Attentional Theory and rules out explanations based on mere-exposure and primacy effects for the results of the second experiment. By manipulating the value of attribute *I* to be either larger or smaller than the value of *PE* and *PL*, we show that brand name repetition or primacy is unlikely to drive the results of the second experiment. In addition, we show that, depending on the relative value of the attributes *I*, *PE* and *PL*, reversals in brand preferences can be obtained as predicted by Attentional Theory.

Even though the highlighting effect seems to represent an irrational learning behavior, it can be considered a drawback of a rational attention-shifting process. In evolutionary terms, it is important to protect and accelerate learning through attention shifts. An organism that does not protect the learning of a previous negative episode will have a high chance of experiencing this episode again. For example, the protection of the learning that a certain type of food is associated with poisoning or that a type of sound indicates the presence of a predator is a crucial survival skill. Thus, in the greater scheme, attention shifting is indeed a rational process.

Do You or Someone You Know? When does Prior Experience Mitigate Unrealistic Optimism and Pessimism in Risk Perception

Ying-Ching Lin, National Dong Hwa University, Taiwan
Priya Raghurir, University of California, Berkeley, USA

EXTENDED ABSTRACT

Most individuals believe that their chances of experiencing negative events are lower than those of other people (Self<Other). This is the robust “unrealistic optimism” bias (Weinstein 1980, Raghurir and Menon 1998) though “realism” has been documented for depressives (Keller, Lipkus, and Rimer 2002). The absolute levels of perceived risk moderate the extent of self-other differences, such that unrealistic optimism is associated with those who are optimistic in absolute terms, but “unrealistic pessimism” (Self>Other) has been shown for those who are pessimistic in absolute terms (Lin, Lin, and Raghurir 2003). Gender moderates these effects, such that, when given base rate information, optimists remain unrealistically optimistic irrespective of gender, while pessimistic men become realistic, and pessimistic women remain unrealistically pessimistic (Lin and Raghurir 2005).

This paper demonstrates the moderating role of experience for these biases. We replicate the effect that optimists are unrealistically optimistic irrespective of gender, but show that the pattern for pessimists is only valid for those who do not have experience with a cancer/depression victim. For those without experience, pessimistic men show realism, and pessimistic women show unrealistic pessimism. However, experience flips the manner in which gender and experience interact for pessimists. For people who know a cancer/ depression victim, pessimistic women become realistic, and pessimistic men remain unrealistically pessimistic. We argue that these results suggest that one of the underlying reasons for self-other differences are biased processing of information about base-rates or exemplars due to cultural differences (Hofstede 1990), where men have been shown to have a more independent self-construal and women a more interdependent one (Sedikides, Gaertner, and Toguchi 2003). Women, who have experience in interacting with others due to their interdependent self-construal should be able to use information regarding an exemplar to become realistic, while men, who culturally have more of a independent self-construal, when faced with an exemplar of a disease due to experience with another person imagine themselves in that position leading to their being unrealistically pessimistic. Two studies test this prediction.

Method

Participants. Study participants were undergraduate students in Taiwan (n=152 in Study 1, and n=385 in Study 2).

Procedure. Participants estimated the likelihood of getting a disease (cancer in Study 1; and depression in Study 2) using a 0 to 100 scale for themselves and the average undergraduate student.

Design: Both studies used a 2 (target: self / other) x 2 (male/ female) x 2 (experience/ not) x 2 (optimist vs. pessimist) mixed design, with the target factor manipulated within-subjects, and the remaining factors measured between subjects. Experience was measured by asking respondents whether they knew a person who had cancer/ depression. Optimism was defined in terms of a median split (Median=20 in study 1 and Median=38.6 in study 2) of people’s self-estimates. Respondents who reported a likelihood of more than the median were categorized as “pessimists,” whereas the remaining participants were categorized as “optimists.”

Results

Study 1: A 2x2x2x2 ANOVA on risk estimates for cancer, revealed a two-way interaction between target and optimism ($F(1, 144)=37.653, p<0.001$), a three-way interaction between target, experience and gender ($F(1, 144)=9.94, p<0.002$); and an overall four-way interaction ($F(1, 144)=5.104, p<0.05$). Means are shown in Table 1.

The pattern of means show that optimists show self-positivity irrespective of gender and experience. However, gender and experience interact for pessimists: male pessimists without experience show realism, as do female pessimists who have experience; while pessimistic females without experience and pessimistic males with experience show unrealistic pessimism.

Study 2: A similar analysis on risk estimates of depression showed a main effect of target ($F(1, 377)=16.67, p<0.001$) which interacted with experience, optimism and gender ($F(1, 377)=4.05, 189.11, 8.71$, respectively, $p<0.05$) while both the three-way interaction between target, experience and optimism and the overall four-way interactions were significant ($F(1, 377)=4.05$, and $8.15, p<0.05$). Means are provided in Table 2 and replicate the patterns found in Study 1.

Discussion

Results of two studies showed that optimists demonstrate unrealistic optimism irrespective of experience, while pessimists are either realistic or unrealistically pessimistic as a function of their gender and experience. Pessimistic males who did not know any one with cancer/ depression were more realistic about their risk-estimate, but pessimistic males who knew a depression victim showed unrealistic pessimism. On the other hand, pessimistic females without experience show unrealistic pessimism, while those who know a person who has cancer/ is depressed are more realistic.

The fact that pessimist females who know a cancer/ depression victim become more realistic can be explained by the fact that females tend to have closer, intimate relationships with others’ than men (Shek 1995), therefore, when they know a depression victim, they are more likely to have specific knowledge of depression. It implies that their beliefs about their own chances may reflect greater realism rather than positivity or negativity bias. Pessimistic males, with a more independent self-construal, may instead focus on the many reasons they could get a disease once they have been exposed to an exemplar.

The Moderating Effects of Past Experience on Behavioral Intentions

Blair Kidwell, University of Kentucky, USA

Robert D. Jewell, Kent State University, USA

EXTENDED ABSTRACT

Despite the growing body of research on the positive association (i.e., main effect) of past behavior on intention, key questions remain as to whether specific components (i.e., predictors) of intentions are enhanced or diminished when past behavior is included as a moderator in behavioral intention models (cf. Orbell, Hodgkins & Sheeran, 1997). Further, little is known about how past behavior might induce changes in people's deliberative and heuristic processing of information within these models (cf. Wood, Tam & Witt, 2005). For example, it is possible that people with very little experience may be motivated to engage cognitive resources such as considering their evaluations of salient beliefs when making a decision. In contrast, those with extensive experience may be less motivated to process cognitive information, relying instead on heuristic information such as their past success performing the behavior (i.e., confidence in their ability) and their perceptions of how easy or difficult behavioral performance will be (i.e., external facilitators of behavior). These possibilities are investigated in this research.

We make predictions that the level of past behavior will change the nature of the relationship between attitude and intent at low levels of past behavior, and between internal and external control at high levels of past behavior. Thus, the purpose of study one is to test the predicted moderating effects of past experience on attitude and perceived internal and external control with respect to behavioral intent.

Study One. In study one, hypothesis 1 was supported indicating that past behavior accounted for a significant amount of variance beyond the effects of attitude, subjective norm, external and internal control. This is consistent with other research indicating the explanatory power of past behavior within the framework of the TPB. Further, it was shown that for participants with low levels of past experience, attitude was predictive of intention while internal and external control were not, in support of hypothesis 2. At higher levels of past behavior, internal control and external control were predictive of intention while attitude was not, in support of hypotheses 3 and 4. These findings support our theoretical model that past behavior can have a moderating effect on the other variables within the TPB. More importantly, we provide a framework for establishing the rationale as to why such moderating effects occur. Specifically, our framework suggests that those with lower levels of past behavior are more likely to engage cognitive resources when formulating a behavioral intent than those with higher levels of past behavior and thus, when past behavior is low, attitude is the primary driver of behavioral intent. Additionally, these findings support the view that when past behavior is higher individuals are more likely to utilize less cognitively demanding inputs such as perceived control. Despite this support of the influence of past experience on decision making within the TPB, further direct evidence is needed to assess the boundary conditions under which past experience can influence a consumer's likelihood to engage cognitive resources to assist in the deliberative processing of information. Study 2 seeks to address this issue.

Study Two. In our conceptual model, different levels of past behavior result in differential levels of cognitive processing. Thus, study two examines the processes related to past behavior in an experimental paradigm in which the extent of cognitive processing

of information is explicitly considered. We argue that when past behavior is low, individuals will be more likely to engage cognitive resources to access additional information to make up for their lack of actual experience. Thus, we predicted that if low past-behavior participants are likely to engage cognitive resources, they should demonstrate discrimination between strong and weak message arguments. Conversely, when past behavior is high, individuals will be unlikely engage additional cognitive resources because of the small gap between their perceived level of personal resources and the threshold-level of personal resources believed to be necessary to form a behavioral intent. Thus, we predicted that if high past-behavior participants are unmotivated to engage cognitive resources, they should demonstrate little discrimination between strong and weak message arguments.

Findings in study 2 suggest that those in the low past-behavior condition engaged in greater elaboration of the issue-relevant arguments contained in the message than those in the high past-behavior condition, as evidenced by their discrimination between the argument quality of the message. That is, participants with low levels of past behavior were more motivated to engage cognitive resources to the processing of the issue-relevant components of the message than those in the high past-behavior condition. These findings are generally supportive of our theoretical model and more specifically are supportive of hypotheses five and six.

These findings have important implications for both marketers and consumer educational interventions for the prevention of debt. Our research demonstrates that, based on the nature of the interactions, it would be useful for researchers to segment the target population based on experience as suggested in past research (e.g., Beale & Manstead, 1991). For marketers, communications focusing on engaging cognitions of consumers may be quite effective for inexperienced consumers since their attitudes are typically formed through beliefs about the advantages of credit cards (e.g., build credit history, precaution for emergencies, etc.) and reducing disadvantages (e.g., risk of future debt, damaged FICA score, etc.). Thus, marketing campaigns could highlight these salient cognitions and provide positive consequences that are likely to strengthen intention through a favorable attitude (Fishbein & Ajzen, 1975).

Marketers could also target experienced consumers with communications about the ease with which products and services, such as credit cards, can be acquired and the conveniences that they offer, in order to increase the consumer's external control. Also, for experienced consumers, communicating information that builds confidence in their ability to acquire a given product or service can be effective. For example, increased perceptions of one's ability to select the best product might be based on past successes and favorable outcomes associated with a particular brand.

The Role of Fictionality on Gender Differences in Responses to Emotional Melodramatic Entertainment

Jennifer J. Argo, University of Alberta, Canada
Rui (Juliet) Zhu, University of British Columbia, Canada
Darren W. Dahl, University of British Columbia, Canada

EXTENDED ABSTRACT

Characterized by its heart-tugging, emotional plot, melodrama is a subtype of dramatic entertainment that appeals to the heightened emotions of audiences and readers of all ages. Often labelled “chick-flicks,” “tearjerkers,” or “human interest stories,” emotional melodramas appear in a wide range of entertainment formats (e.g., movies, short stories). In general, the target audience for emotionally melodramatic entertainment has primarily been female consumers. For example, The Oprah Winfrey Show which regularly features stories of tragedy, personal weakness and devastation, attracts approximately 50 million US viewers, among whom women outnumber men in the audience by a ratio of 19 to 1 (http://www2.oprah.com/presents/2005/20anniv/tows/tows_trivia.jhtml). Given this prevalent belief, the purpose of the present research is to understand and test for gender differences in evaluations of melodramatic entertainment. We use as our context of investigation emotionally melodramatic short stories. Further, we extend this literature by identifying the role of one characteristic inherent in melodramatic entertainment—its level of fictionality—on the activation of these gender differences. Finally, the present research seeks to explore underlying processes and tests the impact of the credibility of the fictionality communication source in influencing gender and the level of fictionality on consumers’ evaluations of melodramas.

Gender research has consistently found that females are more emotional and emotionally expressive than males (e.g., Allen and Haccoun 1976). The existence of these gender differences has been attributed to gender-specific norms regarding the “rules of emotions” that are developed through socialization (Birnbaum 1983). For little boys, the norm that they should be emotionally strong and refrain from emotional experiences is socialized by discouraging them from displaying soft emotions (e.g., “big boys don’t cry”; Birnbaum and Croll 1984; Timmers, Fischer and Manstead 2003). In contrast, such restrictive norms do not apply to females and in fact, society encourages women to seek and express their emotions (Timmers et al. 2003). Given the existence of these norms for emotional expression, we expect that females in general will respond more favorably to emotional melodramatic entertainment than males.

However, we expect that this predicted effect will be moderated by an important factor inherent in such melodramas, its level of fictionality. Defined here as the extent to which the story line for a melodrama reflects a real-life event (i.e., low in fictionality) versus a fictitious account (i.e., high in fictionality), the level of fictionality in melodramatic entertainment is expected to either attenuate or magnify gender differences in evaluations of such entertainment. Melodramatic entertainment that is high in fictionality is safe because it is not real or binding, permanently beneficial or harmful (Izod 2000). This is in stark contrast to reality where social rules and norms must be adhered to if one is to avoid the penalties imposed by society for deviating behaviors. Given that fiction presents a context where rules and norms are relaxed and there may be minimal social ramifications for eliciting emotions, we expect that males will feel safe to become involved in a melodramatic story, experience and express their emotions, and consequently evaluate the story more favorably. In contrast, when a melodra-

matic story is factual, the rules of society (i.e., gender norms about emotional responses) cannot be freely discarded without potential negative consequences. Thus, in this situation, we expect males to react consistently with gender norms, such that they will be less involved in an emotionally melodramatic story and thus evaluate the story less favorably. The opposite pattern is expected for females as developmental psychology suggests that they have a preference for reality which begins to become apparent at a young age. In particular, while little boys are prone to play fantasy themes and devise make-believe toys (e.g., Marshall 1961), little girls generally replicate reality by playing a domestic or teacher role (McLoyd 1983; Nicolopoulou 1997). Furthermore, these developmental findings for the preferences towards reality are reflected in adulthood (e.g., Elkin and Handel 1972). Thus, we expect that females will respond more favorably to melodramatic entertainment that is low in fictionality (i.e., based on reality). This should be the case because melodramatic stories that are high in realism are more salient and vivid, thus increasing involvement with the story and consequently eliciting more favorable evaluations. Finally, the predicted pattern of effects for both genders is only expected to arise when information about the level of fictionality is provided by a high (vs. low) credible source.

Three studies examined the impact of level of fictionality on gender differences in consumers’ evaluations of emotional melodramatic entertainment. The first two studies found that males formed more favorable evaluations of a melodramatic story when they were explicitly told that the story was make-believe (i.e., high in fictionality) versus real (i.e., low in fictionality). In the make-believe condition, males temporarily relaxed their gender emotion stereotypes, which led to increased emotion expression, and consequently more favorable evaluations. Females, on the other hand, evaluated the melodramatic story more favorably when they were told it was based on a real occurrence (i.e., low in fictionality). Mediation analysis demonstrates that as implied in the theorizing for both genders, higher involvement was shown to lead to more favorable evaluations of a melodramatic story. The third study extends on the first two studies by examining the role of source credibility on individuals’ evaluations of a melodramatic story. The interaction effects between gender and level of fictionality only held when the source of the fictionality communication was high in credibility. When source credibility was low, the differences in responses to fictionality were attenuated for both genders.

This research makes three important contributions. First, it advances our understanding of gender differences in evaluations of melodramatic entertainment by identifying an important factor (i.e., level of fictionality) which moderates these differences. Second, it explores underlying processes (e.g., involvement) for the observed effects. Finally, it investigates a boundary condition (i.e., source credibility) for the impact of fictionality and gender on evaluations of melodramas.

Love and Consumption in Poor Families Headed By Lone Mothers

Kathy Hamilton, University of Strathclyde, Scotland
Miriam Catterall, Queen's University, Belfast

INTRODUCTION

In the US, 32.3 million people are classified as poor, representing some 12% of the total population (Hill 2002a). In the UK, the General Consumer Council (2001) estimated that between 13 and 14 million people live in poverty. Lone parents, mainly lone mothers, account for a significant percentage of the poverty population (Field 1996). One in four families in the UK is headed by a lone parent and 62% of these families live on or below the poverty line (Gingerbread 2003). Despite their prevalence, low-income families and their consumption decisions are neglected in consumer research generally, and in family consumer research in particular. There is only a very small stream of research that focuses on the poorer consumer, mainly located within the sub-fields of macromarketing (Hill and Stephens 1997) and marketing and public policy (Andreassen 1993). Similarly, in family consumer research Ahuja and Stinson (1993) called for more attention to the fastest growing family type in the US, the female-headed single parent family.

In addition to bearing the burden for ensuring the family's financial survival, lone mothers are often stigmatized by other members of society. The tendency to view lone mothers as a homogeneous group facilitates the social construction of lone motherhood as a social problem (Kanji 2004). Yet Edin and Lein's (1997, 159) study of single mothers, many of them in extreme poverty, found "*surprising resilience and creativity in building strategies to help their children overcome poor life conditions.*" The study of lone mother headed families reported here supports this finding in the context of consumer decision making. Lone mothers try to ensure that their children are protected from the realities of living on a meager budget. In doing so, they either suppress their own needs and desires or place them on hold. Children may also contribute to the family coping effort directly through earned income or, indirectly by withholding their desires for consumer goods. Thus, by their actions lone mothers and their children demonstrate the potential strength of love influence on family decision making.

The paper begins with a review of literature on the poor as consumers and then goes on to consider decision making in family consumer behavior research. The methodology is then discussed with details of sampling, data collection and interpretation methods employed in the study. The study findings are presented and the subsequent discussion considers the significance of love as a driver of consumer decision making in families. Finally, the implications of the findings for family consumer research are discussed.

LITERATURE REVIEW

Most studies with low-income consumers consider how they cope with poverty with an emphasis on how finance and other resources are accessed. There is little information regarding decisions on resource allocation within low-income families. Even in disciplines where poverty is a more vibrant research topic, there is a tendency to analyze poverty in terms of the financial circumstances of families and take little or no account of the distribution of expenditure within families (Millar and Glendinning 1992).

Low-income consumers often show great skills in exploiting their environments to exert some control within their lives and adapt to the financial realities with which they are faced (Hill and Stephens 1997). For example, the poor often turn to alternative sites

of acquisition for many essential household goods (Williams and Windebank 2001). People on limited incomes patronize car boot sales more frequently than other consumers (Stone, Horne and Hibbert 1996). Gregson, Crewe and Brooks (2002) found that charity shopping is often a necessity for impoverished consumers even though this involves a lot of time and effort to find adequate, good quality products.

Lone mothers frequently borrow money even though this compromises their independence (Edin and Lein 1997). Usually, they rely on cash help from members of their personal networks, such as absent fathers, boyfriends, relatives and friends. In the financial sector, credit unions and mail order credit (Ford and Rowlingson 1996) are important sources of credit, as are doorstep lenders and pawnbrokers. However, as financial circumstances worsen, households tend to move away from credit towards a more liquid form of budgeting (Ford and Rowlingson 1996).

Illicit income can be generated from legal activities in the form of informal work such as babysitting, or from illegal activities such as prostitution or selling drugs (Hill and Stephens 1997). Fryer (2005) found that men typically attempt to maximize income through illicit activity whereas women try to reduce expenditure through careful budgeting and economizing, exploitation of special offers, reduction in expectations of life, creative activities (for example, buying and restoring old furniture) and cultivation of social support. Social support from family and close friends, and from sources including churches and other non-profit associations, is an important resource asset for low-income consumers (Lee, Ozanne and Hill 1999).

The plurality of family structures has not been greatly recognized within the consumer research literature (Ekström 2004). Despite the changes in family structure, consumer researchers have largely neglected the issue of how alternative family forms influence consumer behavior (Rindfleisch, Burroughs and Denton 1997). Thus, little is known about the consumption patterns of lone parent families. Bates and Gentry (1994) studied stem families resulting from divorce and found that children are accorded "adult status" earlier. Ahuja and Stinson (1993), in their study of lone mother headed families, found that children's influence in this family type varies according to demographic characteristics of the family, the mother's sex role orientation, product type and stage in the decision making process. However, Geuens, Mast and De Pelsmacker (2002) found that contemporary family structures, such as single parent families and smaller families, have only a minor impact on children's influence on decision making. Studies of family consumer decision making have tended to consider abstract concepts, such as influence and power, rather than focusing on the tangible consumer behaviors of family members (Hall et al. 1995), such as how resources are spent and distributed within the family. Since family decisions are made within a private and intimate setting, it can be difficult for researchers to access this information.

METHODOLOGY

In line with other consumer researchers (Darley and Johnson 1985), this study adopted a relative perspective on poverty and defined low-income consumers as lacking the resources necessary to participate in the normal customs of their society. However, to aid the selection of families for the study, the results of the Poverty and Social Exclusion Survey of Britain (Gordon et al. 2000) were

used as a guideline. This survey indicated that the income after tax needed each week to escape overall poverty averaged £239 for all households. Most of the families in the study were on incomes under £200 per week.

Purposeful sampling was used for this project, which involves the selection of information-rich cases that are used to provide in-depth information that is relevant to the purpose of the research. The study involved twenty-four female lone parent headed families. Families were selected from urban areas and all but three of the mothers were unemployed, one was employed full-time and two were in part-time jobs. Employed mothers were working in low-paid jobs. The interviews began in March 2004 and continued until May 2005.

In-depth interviews were held with the families. As poverty can affect the whole family unit, a family approach was adopted in that all households included at least one child under the age of 18. In 16 families, the mother was interviewed alone and in 8 families it was possible to arrange an interview with the mother and her children (aged 11 to 18). Family methodologies have not been widely used in consumer research (Ekström 2004). Poverty is often experienced within the social context of the family and as such, responses to poverty may be collaborative in nature. The interviewing of multiple family members permits a deeper understanding of the family dynamics in terms of each person's role and influence in consumption decisions. Given the private and personal nature of the research, interviews were carried out in respondents' homes to ensure a familiar and comfortable environment.

Hermeneutics was used to interpret the data. This is an iterative process, "in which a 'part' of the qualitative data (or text) is interpreted and reinterpreted in relation to the developing sense of the 'whole'" (Thompson, Pollio and Locander 1994, 433). These iterations allow a holistic understanding to develop over time, as initial understandings are modified as new information emerges. First, each individual interview was interpreted. Secondly, separate interviews were related to each other and common patterns identified.

FINDINGS

The study findings are presented under 3 sub-headings relating to ensuring children fit in, the price of fitting in and support from children.

Ensuring Children Fit In

Many mothers in the study aimed to minimize the negative consequences of poverty for their children. Fear of social difference affected almost all the mothers, highlighting the strong social pressure they are under to ensure that their children do not stand out as being different from other children. Within the consumer society there is a large emphasis on designer brand names that have high brand awareness among children, even those younger than school age. One way that this is manifested is through the purchase of brand name clothing and footwear and many mothers felt pressurized into ensuring that their children had access to socially acceptable clothing.

Jackie: "Actually nearly all his friends wear brand name shoes so I wouldn't make my child stand out" (23, one child).

Lorraine: "It seems to be that it's the done thing to dress your kids in brand name clothing, I have to do it now; she has reached that age. For years I avoided brand names, but I was never going to make her stand out from the rest of them" (43, three children).

Sarah: "If I buy them cheap stuff they won't wear them, they're

only going to be laughed at in the street, you buy stuff for the kids so as they're not going to be bullied" (46, six children).

Previous research also suggests that it is not uncommon for children in low-income families to own branded clothing and they consider that if someone is wearing expensive-looking brand names they could not be poor (Elliott and Leonard 2004). However, this desire for brand name clothing can place families under financial stress. Some mothers turn towards credit in order to obtain the desired products.

Eva: "I have to shop from catalogues sometimes because you can pay it off. There's times I just couldn't go to the town and spend £30 or £40, I mean some of these Reeboks and all that Sarah [12 year old daughter] would want, I mean I couldn't take £35 out of my money, I can't do it" (45, three children).

Low-income consumers may be accused of acting irrationally because they spend their limited incomes on branded goods that may be deemed as luxuries rather than necessities. In some family interviews teenagers admitted that their peers would tease them if they did not wear the "right" clothes. The purchase of brand name clothing and footwear may be aimed at maintaining visible consumption whilst reducing expenditure in other less visible areas, such as food consumed within the home. Some parents commented that if they have to reduce expenditure it is food that is the most flexible.

Eva: "You have to pay your bills; you can't have no electric or no heating. You'd have to cut back, maybe instead of having a full dinner, you'd have maybe beans and toast or egg and chips instead of egg sausage and chips" (45, three children).

The Price of Fitting In

The majority of the mothers said that obtaining what their children need and want is their main priority and consequently, even everyday family consumption is structured around the children. To illustrate, several mothers organize their own diet around their children's preferences with comments such as "I tend to buy what they eat and I would sort of skimp on my own stuff" and "I eat kids' food, I don't eat adult's food, I just eat what they're eating." As one lone mother described, this situation is also found with money allocated to clothing, "he [2 year-old son] gets a lot of my shopping money, he gets a lot of clothes. I can't afford to buy clothes for me and him."

Many parents in the study suppress their own needs to provide for their children. Indeed, some parents even implied that their lives were on hold as all their energy was aimed at caring for their children. Some parents choose to delay fulfilling their own ambitions and place their own desires secondary to those of their children.

Julie: "My lifestyle is very very budgeted, very sacrificing. It can be quite stressful... it amazes me how I can find the money to pay for some of the bills that I have like Holly's [5 year-old daughter] school bills... because she wants to be involved in loads of stuff for her school which costs a fortune" (24, one child).

While many families have to endure sacrifices in other areas to afford to buy the branded goods their children desire, others turn to unreported income. Janet is a 38-year-old lone mother with 3 children. Although she is receiving welfare payments, she supple-

ments this income with an unreported job in the local fast food outlet for which she receives cash-in-hand payment. Janet describes her experiences of benefit fraud as follows.

"It's very hard and dangerous too. I've already been caught. You have to pay them back; I'll be paying £20 a month back until I'm 84 or something."

This illicit work provides benefits over and above financial ones, such as the opportunity for social interaction and improving feelings of self-worth. As Janet states, *"it's good because you're meeting people and you're not stuck in the house."* However, the overriding reason for such work is the extra income it generates. Although Janet mentions the benefits of illicit income, she also implies that this is not a problem-free option. The stress and constant worry of being reported creates an emotional strain: *"I hate my life like this, looking over your shoulder all the time"* but *"I just want to be able to give the kids a bit more."*

Kochuyt (2004) discusses how exclusion from the marketplace can be countered by the inclusive effects of the family unit which is made into a back-up institution to fill the gaps created by the failures of the market and the insufficient safety nets of the welfare state. The subordination of individual needs to family needs demonstrates that the way in which resources are allocated amongst family members is unequal. As Kochuyt (2004, 145) suggests *"By imposing an 'artificial lack' of resources upon themselves, the parents create an 'artificial affluence' for their kids."* One reason for the prioritization of children's wants and needs is that mothers view their children as part of their extended self (Belk 1988). If mothers are judged based on their children, it follows that the well-being and appearance of children can be seen as an extension of concern about their individual identities. By providing children with increased possessions and opportunities, parents aim to prevent the reproduction of poverty in the next generation.

Support from Children

Previous research suggests that children employ pre-meditated and well thought-out strategies to persuade parents to meet their consumption desires (Palan and Wilkes 1997). Often this involves overt influence attempts such as bargaining or repeated entreaty (Daly and Leonard 2002). This study demonstrates that the process of low-income children's influence does not necessarily result from overt direct persuasion strategies. Indeed, many of the children had an awareness of their family's financial situation and consequently curtailed demands for increased possessions. Rossiter (1978) pointed out the need to distinguish between direct influence and indirect influence whereby the former represents an active role based directly on the decision maker's own needs and the latter represents a passive role in which the decision maker takes another family member's needs indirectly into account. This study demonstrates how more passive forms of influence can be as powerful as overt persuasion tactics.

In some families, children play an active role in coping with financial constraints and are effective in contributing to the family's united coping effort. Take the example of Melissa, a mother to five children (all below the age of 7) who has faced extreme financial difficulties resulting in personal bankruptcy. Due perhaps to the severity of their financial circumstances, Melissa explained that her 6 and 7 year-old daughters understand the value of money. The following extract demonstrates how 7 year-old Debbie contributes to the coping effort.

"I had no money at all and the girls were eating rice for breakfast and they were eating meatballs and crap food. And

I said, "look Debbie, whenever my money comes I will give you a fiver and you can go down to the shop and you can buy whatever you want," and she went down to the Co-op and brought up a pack of Variety [Breakfast] Cereal and two liters of milk and came back and put it all in bowls for everyone, God love her."

Melissa's guilt over not being able to provide her children with good quality food encourages her to give her daughter money out of the limited budget. Given the extreme financial difficulty, this may appear irrational to outsiders. However, Melissa feels that this is an appropriate course of action in the circumstances. Additionally, in this case, the money is ultimately allocated to collective family consumption. Debbie understands the importance of necessities and uses her own pocket money in such a way as to benefit all members of the family. Additionally, although the pressure to display socially acceptable clothing does not escape Debbie, she rationalizes these choices by curtailing demands in other areas.

"When they were getting their uniforms, we went out to get trainers and Debbie kept saying "no mummy it's ok, no mummy it's ok" and we came home that night and she said "you know what I would really want, do you remember those trainers with the big thick soles, they were Reebok mummy, could I not have them? I'll not get black shoes, I'll just get my trainers, I'll just get them."

Melissa's financial situation is worse than the difficulties faced by many of the other families in the study. However, the evidence suggests that other young children are also capable of understanding financial constraints. Some children attempt to make a direct financial contribution to the household taking the form of both withdrawing money from savings accounts and contributing money earned from part-time employment. Sarah, mother to six children, (four under the age of 18) described how her 11 year-old daughter withdrew half of her savings from her credit union account to help the family.

"One day I was stuck, she went and took, she only had a tenner and she went and took a fiver out of it for me."

Teenage children who earn money from part-time employment can help the family both directly and indirectly. This is consistent with previous research that highlights children's resourcefulness in attempting to improve their family's situation by accessing part-time work (Ridge 2002). Some teenagers contribute directly to the household bills, for example, one informant described how her 16 year-old daughter contributes money towards the electricity bill. Similarly, in another family consisting of a lone mother with three children, the two older children had full time jobs meaning that all bills were split three ways. As well as direct financial contributions towards the maintenance of the household, teenagers with part-time employment also indirectly reduce the pressure placed on parents. In an interview with Janet and Pamela, a mother and her 16 year-old daughter, Pamela described how she is able to buy her own clothes with the money earned through her part-time job. Pamela now has her own income source and as a result is placing fewer demands on her mother.

In some families, especially those with older children, mothers expect their children to participate in the coping process. This does not always require a financial contribution but rather an understanding of the family's financial situation and the limitations that this entails. One way in which mothers achieve this is through open family communication to keep children informed of financial

circumstances. In an interview with Maria and her 17 year-old son, Ryan, Maria mentioned that both Ryan and her other children are “*made very aware of what we’ve got and what we haven’t got.*” As a result Ryan maintained that he does not place unrealistic demands on his mother, relieving pressure at special times such as Christmas. This is supported in the sociology literature as Daly and Leonard (2002) found that some children curtailed their demands for brand name clothes or alternatively sourced clothes with prices that fell within their families’ means.

The strategies can be categorized into those that involve a direct financial contribution to the household and those that indirectly alleviate financial pressure due to the reduced demands placed on parents.

DISCUSSION

Previous family consumer research suggests that children influence the consumption choices of products for which they are the end user such as toys and breakfast cereals (Lackman and Lanasa 1993). This study shows how limited financial resources may actually increase children’s influence. These low-income children are at the centre of consumer decision making within the family, not only in relation to products that are used by them, but also in relation to products for other family members. As in this study, Kochuyt’s (2004) research with low-income families in Belgium also found that parents place children’s needs first, making considerable sacrifices in the process.

However, there is evidence in the study reported here that sacrifices for others are not confined to parents alone. There were many instances where children, though not all of them, put family needs above their own personal needs. This suggests that the family as a consuming unit provides a protective capsule against the risks of poverty by acting in a collaborative manner such that the available resources are distributed within the family on the basis of need. Of course, it could be argued that ‘need’ is perhaps an inappropriate term in this context. Many of the buying decisions in this study may appear irrational to more affluent consumers.

The poor are often accused of acting irrationally because they spend their limited incomes on products that society deems as unnecessary. Given their financial situation, it is assumed that the poor would be cautious shoppers and, consequently, actions that are not aimed at minimizing expenditure can be viewed as irrational. For example, Alwitt and Donley (1996) found that poor consumers prefer nationally branded goods and do not use generic or store brands any more than other shoppers. In this study, it may seem irrational to spend £40 on a pair of branded training shoes for a child, who may shortly outgrow them, when family financial resources are so meager. Furthermore, in order to buy these trainers, savings may be made by serving ‘*crap food*’ to the family and spending less of their resources on what is identified as essential products required for a healthy life (Firat and Dholakia 1998). Andreasen (1993) argued that people act rationally given their own circumstances. In this study one of the overriding aims of buying expensive branded goods and services is the protection of children in terms of potential stigmatization, social difference or bullying from peers, a rational decision given the circumstances.

Thus, current categories such as rational and irrational decisions and discretionary and non-discretionary spending need to be revisited when considering the behavior of poor consumers, as do hierarchy of needs frameworks that suggest consumers meet basic needs for food and shelter before buying the more discretionary ‘social’ goods, such as branded trainers. For low-income consumers spending on branded clothing and footwear is non-discretionary whereas with food spending, in terms of quantity and quality at least, there is some discretion. This suggests new categories for

low-income families of visible and invisible goods placed, perhaps, at either end of a continuum. Spending on visible goods and services will be towards the non-discretionary pole for it is through them that poor consumers present themselves to the world, giving added meaning to conspicuous consumption. Their lack is an indicator of poverty and the associated stigma and shame. By contrast, there is some discretion in invisible spending, which applies to goods and services consumed in the privacy of the home.

Findings demonstrate that both mothers and their children place the needs of other family members before their own needs, suggesting that love can be a driver of consumer decision making. Park, Tansuhaj and Kolbe (1991, 723) note that family consumer research has given little attention to emotions including love, affection, sympathy, intimacy, anger and guilt in consumer behavior. It seems also that family researchers in other disciplines give little attention to love. According to Bahr and Bahr (2001, 1234): “*The naming of love and sacrifice as essential concepts, even root metaphors, strikes the modern student of families as quaint, for neither term plays much part in today’s family theory.*” Certainly, it is difficult to find many instances in consumer research where love is theorized as a driver of consumer decision making.

Miller (1998) suggests shopping is not an individualistic act and that objects can be the means of creating or enhancing relationships of love between subjects. Belk and Coon (1993, 413) examine agapic love in the context of romantic love and gift giving but suggest that it may also apply to “*brotherly love, spiritual love, and parental or familial love,*” and also to non-gift purchases. Agapic love means that the giver is willing to make sacrifices and do anything for the recipient. More specific to impoverished consumers, Hill (2002b, 20) recognizes the potential of love driven behavior to improve the lives of the poor. Other-centered love involves behavior, “*designed to support and advance the quality of life of loved ones.*” He argues that other-centered love stems from individuals who believe that giving to others is an extension of their concern for their own families. It can also come from individuals outside the community who bring new resources to help alleviate poverty.

One of the difficulties in attributing love to consumer decision making is the slippage between terms such as other-centered, caring, self-sacrifice, altruism, emotion, agape and love, which, though not synonyms, could all be used to offer at least a partial description of behavior that places others’ needs before one’s own. Additionally, the “deconstruction” of many of these terms means that there is caution surrounding their use. For instance, self-sacrifice can have distinctly negative connotations when applied to the family. Feminist scholars argue that when sacrifice is employed in this context, it tends to be women who are expected to do the sacrificing—mothers with their children, daughters with elderly parents, and so on (Bahr and Bahr 2001). Similarly buyer behavior, like economics, rational choice theory and psychology, has difficulty in accepting ‘genuine’ altruistic or other-centered behavior since it is assumed that self-interest underpins action (Monroe 1994), perhaps more so in an era when it is widely accepted that consumers are increasingly individualistic.

CONCLUSION

Contributions from this research are evident on a number of levels. First, poverty impacts on the family as a whole and, it follows, that responses to it have the potential to be more collaborative in nature. Parents often restrict or minimize their personal needs to satisfy children and children may suppress their desires and use their ‘own’ financial resources to buy items for other family members. Such collaborative consumption demonstrates the importance of using the family as a unit of analysis. Secondly, it

questions assumptions about the poor and the seeming irrationality of their buying decisions. It suggests that a new category of visible and non-visible goods and services may help explain some seemingly irrational buying decisions by poor consumers. Thirdly, it questions the predominant model of consumer decision making that assumes self-interest and suggests that love may be more of a driver of such decisions than current theory suggests. There are opportunities for further explication and development of love and terms used as synonyms in the consumer buying context. Finally, findings from this study may not be exclusive to low-income families. Regardless of income or marital status, mothers may suppress their own needs and desires, or place them on hold, until their children are older.

The Use of Seeker and Sentry Persuasion Management Strategies by Heterosexual Male Shoppers

Linda Tuncay, Loyola University Chicago, USA

Cele C. Otnes, University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

Interpersonal influence has often been examined in terms of how marketing agents and other individuals persuade consumers. For example, past research has explored how the influence of salespeople (Crosby, Evans, and Cowles 1990) or strangers (McGrath and Otnes 1995) can shape consumers' experiences. However, recent research has examined how consumers respond to and manage persuasion attempts by others in the shopping environment. Kirmani and Campbell (2004) develop a typology of 15 consumer response strategies in managing marketing persuasion interactions. However, little research has examined how male shoppers manage marketing interactions, especially in a domain where they may be particularly vulnerable to influence. This study examines the response strategies of men who are avid consumers of fashion and grooming products—a domain in which most men do not have a lot of experience and knowledge. Unlike the Kirmani and Campbell (2004) study of both college students and individuals between the ages of 30-74, this study is more narrowly focused on younger male consumers in urban areas, such as Chicago, IL and New York City, NY. Collage construction, in-depth interviews, and shopping trips with consumers were utilized in order to gain a holistic picture of how men engage in consumption and how they manage their interactions with influencers that guide this type of consumption. A comparison to the Kirmani and Campbell (2004) typology is offered in order to understand how men rely on and resist interpersonal influences. The findings suggest that informants did use some of the seeker strategies detailed by Kirmani and Campbell (2004), such as Ask, Accept Assistance, Establish Personal Connections, Direct, and Test. Men asked for advice and guidance, particularly from women, in their pursuit of creating an ideal masculine identity. Informants often turn to women due to their perceived expertise in the domain of physical appearance. In addition, several informants accept the assistance of salespeople in their consumption of grooming and fashion goods. Informants in this study also establish personal connections with others, such as friendly behavior and loyal patronage, in the pursuit of their consumption goals. Moreover, men direct others to their consumption needs in order to successfully construct their desired identity. While the Kirmani and Campbell (2004) proved useful in some of the strategies that the male consumers in this study employed, other strategies emerged as well. The three new strategies identified include: Monitoring influence attempts, Hiring surrogate consumers, and Acquiescing to others' influences. For example, informants monitor and observe how others use goods and services in order to determine if they want to portray the same image as those individuals. Other men hire professionals, such as personal shoppers, to aid in the shopping process of fashion goods. Men also give into others' influence and suggestions in order to reach their desired identity goals. Moreover, some of the strategies detailed by Kirmani and Campbell (2004) as sentry strategies, or those behaviors which aid in warding off unwanted influence, actually manifest themselves in a different manner with our informants. Specifically, informants use strategies such as Deceive, Prepare, and Enlisting Companions to assist in the pursuit of their identity goals rather than to ward off an unwelcome persuasion attempt. For example, men did engage in deception, or withheld information about their consumption behavior, not to fend off persuasion agents, but because this type of

consumption fell beyond the traditional boundaries of heterosexual masculine consumption, and they did not want to be ridiculed in their social circles. Informants also engage in preparation through conducting extensive research on goods in order to build up expertise, to ensure that they were purchasing quality goods, and to avoid crossing the boundary into perceived homosexual consumption. The men in this study also enlist companions for advice and guidance in the shopping process rather than to assist in warding off persuasion attempts. Thus, in this segment of consumers who are relatively inexperienced and vulnerable, seeker strategies prevailed. The finding that sentry strategies are not salient in this study reflects the fluidity of the seeker/sentry typology among certain segments of consumers. Finally, this research reveals the importance of females in the consumption process of fashion and grooming products by heterosexual men. We offer a discussion of possible drivers of this dependence on female others. This study enhances our understanding in a neglected domain of male shopping and consumption behavior, as well as extends the work on consumer response strategies to interpersonal influence. In addition, it provides managers with the tools to more effectively understand how interpersonal influence both aids in and deters men in the consumption of fashion and grooming products.

Children's Conceptualizations of Sales

Wendy A. Boland, University of Arizona, USA
Lance-Michael Erickson, University of Arizona, USA

EXTENDED ABSTRACT

A growing body of evidence suggests that children, at a very young age, understand the sequence of events involved in a shopping trip (Berti and Bombi 1998, Peracchio 1992, Karsten 1996). Children frequently accompany their parents to retail stores and amass a good deal of knowledge about aspects of shopping such as store layouts, product offerings, and exchanging money for goods (McNeal 1992). One particular aspect of the shopping experience that has not been studied much is children's understanding of a sale. Retailers routinely use sales to encourage customers to make a purchase, drive traffic to their store, etc. They also communicate sales to customers in a variety of ways, including purely semantic cues such as "clearance" or in ways that indicate the amount of the price reduction such as take "30% off." The aim of this paper is to broaden our understanding of how children conceptualize sales. Explicitly, we propose that the concept of a sale is established relatively early in the consumer socialization process, and that the manner in which sales are communicated has differential effects on children's understanding of the sale and its impact on the transaction.

Three exploratory studies demonstrate that children have an understanding that sales lower the regular price of items. In our first study, participants were asked to look at a three picture series of a mother and son shopping for bicycles and write a story about what they thought was going on in the pictures. We find that younger children (first and second grade) evaluated the pictures by focusing on the perceptual features of the situation (e.g. people are shopping, bikes are blue), while older children (fifth grade) make statements about the price of the bikes, both comparing the price of one bike to the other bike in the picture and making judgments about whether or not they feel the prices shown are reasonable given the product.

Two follow-up studies also involved picture sequences. In one, children were shown a picture of a display of pudding snacks with the sign "Clearance Savings" placed above it, and were asked to describe what that meant. Most of the participants indicated that this meant that the products were "on sale" or "cost less money," and some also mentioned that stores do this when they are trying to get rid of something they have too much of. In another picture sequence, children saw a display of pudding snacks with the sign "We Sell For Less" and a price sign of "\$2.74" placed above it. Children were asked to estimate the regular price of the pudding snacks. Although there was considerable variance in the price estimates, 85% of the participants indicated a regular price that was greater than \$2.74, demonstrating some understanding that the sale price must be lower. These three studies provide support for the notion that children by the age of 7 or 8 have at least a rudimentary knowledge of what the term "sale" means, why retailers might engage in them, and that sale prices are lower than regular prices.

We also hypothesize that the manner in which a sale is communicated will have differential effects on children's estimates of dependent variables such as the absolute price of the item, the relative prices of items, the likelihood that the child will purchase it, and the likelihood that they could convince a parent to purchase it. We expect these effects to vary by age group. We conduct two experiments with second and fifth grade children. The first study was a between-subject design where we manipulate the description of a sale using four verbal cues: "sale," "clearance," "save," and "special". Although we expected younger children to be less

accurate than the older children, we have no evidence of a difference between the groups. But, when analyzing the responses by word condition, we find an association between the term used and accuracy. The results indicate that the term "special" resulted in significantly less accuracy than any of the other three terms ("sale," "save," "clearance"), supporting our prediction that the framing of the communication of the sale can impact children's understanding.

In the second study we use two different numeric cues to denote sales: dollar-off cue (e.g. "take \$2 off") and percentage-off cue (e.g. "take 10% off). Unlike the first study, we find a significant association between age and ability to identify the least expensive item in both the dollar-off and percent-off conditions, where younger children are less accurate than older children. Additionally, in the dollar-off condition we find a significant association between age and accuracy of the estimates of sale prices. Moreover, we find that all the errors in sale prices were conceptual rather than computational. We conducted a similar analysis of the percent-off condition and again find a significant association of age and accuracy. Explicitly, none of the second graders were able to derive the correct new price of the item at either store, whereas 50% of the fifth graders were able to compute the sale price correctly. Further analysis shows that while the fifth grade errors were more computational in nature, the second grade errors were almost entirely conceptual in nature.

Our research demonstrates that young children seem to understand the concept that a sale reduces the regular price of a product. Furthermore, young children have a basic understanding of why a retailer may institute a sale, although the level of sophistication in understanding sales increases with age. Our results also suggest that children's understanding is susceptible to the manner in which the sale is communicated. Also, when sales are presented in either dollar-off or percent-off terms we find that younger children are more likely than older children to make conceptual errors, and that a percent-off cue proves to be difficult computationally for older children.

Individuality, Relatedness, or None of the Above? How Thinking Concretely Can Impair the Activation of Self-Relevant Goals

Carlos Torelli, University of Illinois at Urbana–Champaign, USA

EXTENDED ABSTRACT

People often have two different perceptions of their relationship to others. That is, one may have a conception of oneself as either as separate from other persons (i.e., an independent self-concept) or as connected to others (i.e., an interdependent self-concept, Markus and Kitayama 1991). These two self-concepts are associated with distinct knowledge representations that can coexist in memory and that can be brought to mind (i.e., primed) at different times, depending on the situation (Trafimow, Triandis, and Goto 1991). Abundant research has shown how these alternative self-concepts affect persuasion (e.g., Agrawal and Maheswaran 2005), judgments (e.g., Mandel 2003), and choices (e.g., Briley, Morris, and Simonson 2000). Frequently, researchers rely on a motivational explanation for their findings arguing that the activation of the distinct motivations associated with the temporary accessibility of these two self-concepts (i.e., independence vs. relatedness, Markus and Kitayama 1991) lead individuals to make judgments and take actions instrumental for these motivations (see Kim and Drolet 2003; Torelli 2006). However, recent research that shows that a temporarily accessible self-concept can be more likely to influence judgments under certain conditions (see Agrawal and Maheswaran 2005; Torelli 2006) suggests that there are situations that facilitate (or inhibit) the activation of the high-level motivations associated with a given self-concept. In this research, we study the impact of people's mindsets on the activation of the distinct motivations associated with the temporary accessibility of an independent and an interdependent self-concept.

Mindsets are general cognitive orientations that facilitate a given task (Gollwitzer 1996) and that can have an impact on motivation-related variables (Freitas, Gollwitzer, and Trope 2004). In particular, abstract and concrete mindsets have been found to affect the types of goals one attends to in a situation (Freitas et al. 2004). An abstract mindset facilitates individual's focus on the high-level, abstract aims of a situation, whereas a concrete mindset facilitates the focus on the low-level, concrete aspects and experiences of the same situation. As cognitive operations, mindsets are subject to activation (Bargh and Chartrand 2000). Once activated, there is increased likelihood that these operations will be used in upcoming tasks to interpret new information (Freitas et al. 2004; Higgins 1996). Thus, the activation of a particular mindset (i.e., mindset priming) can affect the level of abstraction at which an individual constructs a situation in a subsequent task.

Priming a given self-concept can increase both its accessibility in memory and that of its associated motivations and cognitions (Trafimow et al. 1991). A vital part of these activated mental representations are goals-means associations that can guide individual's future behavior (Markus and Nurius 1986). These goals-means associations are conceptualized as goal hierarchies that include a fundamental goal, close to the core sense of self, at the top of the hierarchy that is served by a larger number of concrete activities, or means (Carver 1996; Shah, Kruglanski, and Friedman 2003). Thus, priming independent or interdependent self-concepts can bring to mind distinct goal hierarchies with goals of independence and competition at the top of the hierarchy (as in the case of the independent self-concept), or with overarching goals of relatedness to others (for the interdependent self-concept).

Distinct goal hierarchies brought to mind by a temporarily accessible self-concept would make more likely the activation of their corresponding high-level goals when individuals are in an

abstract mindset. In this context, the more abstract goal activated by a higher-level identity would be upper in the goal hierarchy (Carver and Scheier 1999) and closer to the channeling out of fundamental, self-relevant motivations (Levy, Freitas, and Salovey 2002; McClelland, Koestner, and Weinberger 1989). In contrast, individuals in a concrete mindset would focus on goals at the lower-level of the hierarchy and/or concrete experiences from the situation, which would take them away from bringing to mind high-level goals linked to the self, regardless of the accessible self-concept. We then hypothesize the following:

- H1:* Individual's mindset would moderate the goals brought to mind after being primed with a given self-concept:
- H1a:* Upon the activation of an abstract mindset, individuals primed with independence (interdependence) would be more likely to bring to mind independence (relatedness) goals than their counterparts primed with interdependence (independence).
- H1b:* Upon the activation of a concrete mindset, individuals primed with independence and interdependence would focus on concrete goals, and they would not differ in terms of the independence and relatedness goals they bring to mind.

Four experiments provided empirical support for these hypotheses using varied operationalizations of goal activation. In experiment 1, participants listed their thoughts related to performing specific tasks. In experiment 2, we assessed the goals participants spontaneously projected onto a hypothetical consumer. In experiment 3, participants made inferences about the traits of a hypothetical user of a product. Finally, in experiment 4, we assessed the subordination of feasibility to desirability information. Overall, the findings support the notion that priming one's interdependent self activates a motivation to relate to others and priming one's independent self activates a motivation to be independent and seek personal achievements. However, these motivations are more likely to be brought to mind when individuals are in an abstract mindset. When individuals are in a concrete mindset, they are more likely to focus on concrete processes and experiences of the situation, which inhibits their focus on the high-level motivations linked to the temporarily accessible self-concept.

A key contribution of this research is showing the importance of mindsets as cognitive processes that can interact with people's self-representations and impact the way in which individuals interpret consumer situations, which adds to the growing view of human actions that integrates motivation and cognition into synergistic frameworks with more explanatory power (Sorrentino 2003). Findings from this research can help to understand the impact of self-concept on people's actions under the presence of factors that can affect the level of abstraction used by individuals to interpret their actions. We discuss in the paper some of these factors like temporal distance, level of personal agency, and level of familiarity. We also derive some implications from our findings in the areas of persuasion, self-regulation, and decision-making.

The Dilution Model: How Additional Goals Undermine the Perceived Effectiveness of a Common Means

Ying Zhang, University of Chicago, USA
Ayelet Fishbach, University of Chicago, USA
Arie W. Kruglanski, University of Maryland, USA

EXTENDED ABSTRACT

Goals are attained through various means (i.e., an object, an action, or a place) connected to it by functional associations. For example, one may go to a café to get coffee and to get lunch. A question that arises is how learning that this café shop serves sandwich in addition to coffee would influence one's judgment of the coffee that it serves, and the subsequent decision to buy coffee here when sandwich is not desired. More generally, this article considers the question of how adding more goals to a given means affects the individuals' motivation to employ it when only one of these goals is activated.

Based on the goal systems theory (Kruglanski et al. 2002), we propose a dilution model of goal pursuit, and suggest that the perceived effectiveness of a given means to goal attainment, and the resulting motivation to pursue it, are determined by the strength of the association between the means and the goal, with stronger associations leading to higher perceived instrumentality. Because an efficient means is likely to be used a great deal, and hence come to be strongly associated with the goal, individuals may assume that the opposite direction of causality also holds and that a greater association of a means to a goal attest to greater efficacy.

According to this model, the associative strength between a goal and a means, and the resulting motivation to pursue the means, are determined by several factors. *First*, it depends on the number and frequency of instances in which the two entities (the goal and the means) have appeared together in the past. A stronger association between a means and a goal is expected if they have appeared together frequently. *Second*, the means-goal associative strength may depend on the uniqueness of the association, that is, on the number of additional means related to the goal or the number of additional goals related to the means. According to a spreading activation model (Anderson 1983; Anderson and Bower 1973), as the number of associations attached to a mental construct increases, each association becomes weaker, as demonstrated by a lower retrieval rate of the target when the central construct is activated. Similarly, it is plausible to hypothesize that adding more goals to a given means dilutes the means-goal association, and this dilution might reduce the perceived effectiveness of the means with respect to the goal. *Third*, the strength of the means-goal association may further depend on the extent to which the goals simultaneously connected to certain means *differ* from each other. The more distinctively different goals are believed to be, the stronger their tendency to undermine each others' association with the common means. When a single means is assumed to satisfy multiple distinctive goals, it might therefore be seen as less effective in satisfying each of these goals, because of the weakened degree of association between the means and each goal.

The aforementioned predictions were tested in four experimental studies. Specifically, Study 1 tested the general hypothesis that an increase in goal number decreases the perceived effectiveness of the means for any specific goal attainment. This study found that when participants listed one goal that certain means satisfied, the means were judged to be more effective for the attainment of the original goal than when they listed three goals that the means satisfied. Study 2 tested whether perceived goal distinctiveness moderates the degree of the dilution effect, and illustrated that, for

the same two goals, participants who elaborated on how the two goals were similar perceived the means to be more effective for serving both goals than participants who elaborated on how the two goals were different. This study demonstrated that the dilution of means-goal associative strength depends on the distinctiveness between goals. Study 3 manipulated the strength of the association between the means and one goal, and tested whether the change in associative strength between the means with one goal impact the perceived effectiveness of the means for an alternative goal connected with the means. In this study, strengthening means-goal association subliminally by pair them together in a sequential prime task made participants believe the means was more effective for serving this goal, but was less effective in satisfying an alternative goal that was also served by the means. Finally, Study 4 used a behavioral measure and examined whether the dilution-induced changes in perceived effectiveness correspond to changes in preference for certain means in actual choice. This study found that when a single means served two (vs. one) goals, it was less likely to be chosen as a means for an activated goal than when it served this activated goal only.

Taken together, these studies provided empirical evidence for a dilution model of goal pursuit, whereby adding goals to a single means reduces the perception of its instrumentality with respect to the original goal. Several specific hypotheses followed from the model were tested in the current research: First, adding more goals to a single means renders this means less instrumental for the attainment of each individual goal. Second, the degree of reduction in instrumentality depends on the perceived distinctiveness of the goals connected to a single means, with more distinctive goals having greater impact on the perceived effectiveness of means. Third, the degree of reduction in instrumentality is directly related to the reduction in associative strength between a goal and a means. Fourth, means that are associated with multiple goals are less likely to be chosen and pursued in the course of self-regulation toward any particular goal.

Hungry for Money: The Desire for Caloric Resources Increases The Desire for Financial Resources and Vice Versa

Barbara Briers, HEC Paris, France
Mario Pandelaere, K.U.Leuven, Belgium
Siegfried Dewitte, K.U.Leuven, Belgium
Luk Warlop, K.U.Leuven, Belgium

EXTENDED ABSTRACT

One of the strongest motivations for people living in modern societies is the desire to obtain money. Notwithstanding the cultural dominance of money, for most of mankind's history 'resources' have connoted food rather than money (Diamond 1997). Collecting or producing enough food to survive has always been man's main challenge. It seems reasonable then to consider that people's desire for money is a modern derivative of their evolved desire for food.

The canonical economic model assumes that the utility from money is indirect, and is only valued for the goods or services it can procure (e.g. Camerer, Loewenstein, and Prelec 2005). While food is generally considered as a primary reinforcer, money can be consumed only indirectly. As a consequence, standard economics consider the desire for food and the desire to obtain money as two different strivings. However, some neurological evidence suggests that the relationship between money and food might be more entangled than most economists would predict. The orbitofrontal cortex, for example, is known to be activated by monetary rewards (Breiter, Aharon, Kahneman, Dale, and Shizgal 2001), as well as food rewards (O'Doherty, Deichmann, Critchley, and Dolan 2002). The overlap in neural activation suggests a common pathway to the processing of money and food rewards, which may have major implications for the standard economical perspective on the utility for money.

Some behavioral evidence is consistent with the proposed entangled relation between financial and caloric resources. Nelson and Morrison (2005) found that men who either feel poor or hungry prefer heavier women than men who feel rich or satiated. They suggested that preference for women's body weight is determined by people's individual experience of resource scarcity. This is consistent with the finding that in cultures with scarce resources, heavier women are preferred to slim women (e.g. Pettijohn and Jungeberg 2004). As male financial and caloric deprivation appears both related to perceived ideal female body weight, we suggest that cues signaling scarcity in one domain might also motivate people to acquire or maintain resources in the other domain. Thus, we claim that people are less likely to sacrifice money when they desire food and eat more when they desire money. Three studies tested this hypothesis.

In Study 1, we manipulated hunger and measured participants' willingness to donate to charity. The participants received a donation scenario and a taste test. To fill in the taste test, all participants had to eat a big piece of cake. In the hunger condition, the donation scenario preceded the taste test. In the satiated condition, the order was reversed. The results showed that hungry participants were less likely to donate to charity than satiated participants. To rule out reciprocity (for receiving the cake) as an alternative explanation, we manipulated the desire to eat food by means of an olfactory food cue in Study 2. Participants had to play a 'give some game' in a room that either was or was not scented with freshly baked brownies. Exposure to an olfactory food cue is known to increase craving, liking, and the desire to eat the cued food (e.g., Federoff, Polivy, and Herman 2003). Like Study 1, Study 2 revealed that desire for food made consumers more likely to hold on to their money. Finally, in

Study 3, we tested the inverse relationship. We manipulated participant's 'desire for money' by inducing lottery-winning fantasies (the manipulation was pretested relying on Bruner and Goodman's 'size of coins' (1947), which reflects participants' desire for money) and measured the amount of candy eaten in a subsequent taste test. Respondents in the high-desire-for-money condition consumed more candy than respondents in the low-desire-for-money condition, but only for unrestrained participants.

In sum, three studies demonstrate a symmetric association between the incentive value of food and money. To our knowledge, we are the first to test the psychological link between money and food empirically. Part of our contribution therefore exists in providing support to evolutionary psychologists' assumption that findings involving money are informative about findings involving food and vice versa. Our results may further provide a partial explanation for Nelson and Morrison's (2005) finding that financial and caloric deprivation appears both related to perceived ideal female body weight. The preference of lower income men for heavier women, as well as the acceptability of a larger body size for lower income women for example, might be interesting social phenomena that can be well predicted from our findings. In addition, our findings might yield an alternative explanation for (at least part of) the findings of Nisbett and Kanouse (1969) that food deprivation differently affects obese and nonobese shoppers (see also Steinberg and Yalch 1978). Normal weight shoppers tend to purchase more when deprived than overweight shoppers. Perhaps, obese persons are not that sensitive to internal hunger cues as nonobese people because they possess more caloric resources. Considering our findings, we might predict that obese people would be more likely to donate to charity than nonobese people. Further research is needed to address this question. Finally, common intuition suggests that we should not negotiate on an empty stomach or that hungry consumers are less cooperative and thus, probably, are less likely to agree with a sales pitch or, in the context of fund raising, less inclined to donate some money. Our findings indeed imply that we should not ask people to donate before an upcoming meal or at the entrance of a bakery.

An avenue for future research is to investigate the overlap in neurological activation due to 'desire for money' on the one hand, and to 'desire for food' on the other hand. The emerging evidence that both reward systems share a brain region (e.g. Breiter et al. 2001; O'Doherty et al. 2002) raises the question to what extent this region is involved in the processing of *all* kinds of rewards (Montague and Berns 2002; Wilson and Daly 2004). The idea that many rewards are processed similarly in the brain has important implications for economics, which assumes that the marginal utility of money depends on what money buys.

Does Silence Matter? Effect of Time Taken to Respond on Bargaining Outcomes & Evaluations

Shweta S. Oza, University of Maryland, USA
Joydeep Srivastava, University of Maryland, USA

EXTENDED ABSTRACT

Bargaining, the decision making process through which buyers and sellers establish terms of trade, is a fundamental phenomenon in inter-firm exchange behavior (Perdue and Summers 1991). Extant research on bargaining can be categorized as either examining the influence of contextual factors or negotiator related factors on bargaining outcomes and evaluations (Neale and Northcraft 1991). While a relatively large literature examines the influence of contextual factors (e.g., Kim, Pinkley and Fragale 2005; Pinkley, Neale and Bennett 1994) and negotiator's cognitions (e.g., Bazerman 1983; Thompson 1991) on bargaining outcomes, relatively few studies have examined the influence of negotiator interaction process factors on bargaining outcomes and evaluations (e.g. Galinsky, et al. 2002).

This paper examines how negotiator interaction process factor (hence forth also mentioned as 'process factor') that emerges from within the bargaining environment, such as the time taken to respond to an offer, affects bargaining evaluations and outcomes. Moreover, the influence of contextual factors and negotiator related factors on bargaining outcomes and evaluations has been studied in isolation. Thorough understanding of human behavior in social settings, however, is gained tremendously when, in addition to the main effects, the interactions between several predictors are taken into consideration (Beersma and De Dreu, 2002). Behavioral negotiation theory (Neale and Northcraft 1991) posits that bargaining outcomes are a product of the interaction of contextual and negotiator related factors (which includes interaction process between the negotiators). Accordingly, we examine how an interaction process factor such as time taken to respond to an offer, that emerges from within the bargaining environment affects bargaining outcomes and evaluations in presence of contextual factor such as opponent role.

Study 1 examines evaluations of bargaining outcomes as a function of time taken to respond when an offer is either accepted or rejected, and traces the relationship between bargaining evaluations and inferences about opponents' bargaining position (e.g., reservation price). Study 1 demonstrates that the time taken by an opponent to respond to an offer affects bargaining evaluations in both positive and negative domains (i.e., when the first offer is accepted and rejected, respectively).

Study 2 tests the condition under which time taken to respond to an offer does and does not influence bargaining evaluations. Study 2 shows that evaluations of bargaining outcomes were perceived to be superior in the delayed versus the immediate acceptance condition only when the bargaining opponent was an individual bargaining on his behalf. In contrast, time taken to accept the offer had no impact when the opponent was a salesperson.

Overall, this research examines the influence of an interaction process factor that may emerge from within the bargaining environment on bargaining outcomes and their evaluations and highlights the interaction between a negotiator interaction process factor such as time taken to respond to an offer and a contextual factor such as opponent's role. Together, our results suggests that silence does matter in bargaining setup, but does not always influence bargaining outcomes and evaluations as consumers do have mechanisms

by which they guard falling prey to opponent's silence as can be seen in the results of study 2.

SPECIAL SESSION SUMMARY

Challenges and Extensions to Standard Beliefs in Branding Research

Kelly Goldsmith, Yale University, USA
Tom Meyvis, New York University, USA

SESSION OVERVIEW

The three papers in this session share a common concern that existing work on brand equity and brand extensions has been overly narrow in both its conceptual focus and its methodological approach. As we will argue, these limitations matter since incorporating new dimensions of brand equity and introducing greater variation in experimental methodology will challenge some of our prevailing beliefs about the nature of brand equity and the ease with which it can be extended. At a general level, these three papers aim to broaden our conceptualization of brand equity and encourage researchers to question some commonly endorsed branding strategies. At a more specific level, these papers attempt to answer three questions: How can we reliably and meaningfully measure the concept of brand experience? Can widespread concerns about brand dilution be addressed by small changes in branding strategies? And lastly, has prior brand extension research overestimated the importance of fit and underestimated the importance of quality?

In the first paper, Zarantonello, Schmitt, and Brakus address the nascent area of brand experience—a concept that has gained popularity in marketing practice, but has not received as much attention in academic branding research. To fill this void, the authors propose a conceptualization of brand experience based on the theory of mind modularity and develop a reliable and meaningful scale of brand experience consistent with this framework.

In the second paper, Sood, and Keller not only challenge common concerns about the diluting effect of low quality brand extensions on the equity of the parent brand, but also deviate from the commonly used methodology in brand extension research by having participants actually experience the extension products. In a series of experiments, they demonstrate that brand name structure influences the processing style that consumers employ when evaluating brand extensions, and that this processing style in turn leads to differences in extension evaluations and dilution effects.

Lastly, the paper by Meyvis, Goldsmith, and Dhar presents a series of studies which test the effect of consumers' mindset on their response to brand extensions and, in doing so, highlight important limitations of the methodology used in prior brand extension research. The authors demonstrate that the hypothetical, abstract mindset that is common in most brand extension research tends to overly emphasize the fit between the brand and the extension category. In contrast, when consumers are in a more concrete mindset (as is common in a regular shopping environment), they focus more on factors that promise concrete rewards, such as the quality of the parent brand.

These three papers investigate consumers' perceptions of brands from multiple theoretical perspectives and employ a variety of methods to uncover the processes behind consumers' brand experiences and brand extension preferences. In addition, the session also raises issues of ecological validity in consumer research, specifically in research on branding. C. Whan Park, who has contributed widely to branding research, will lead a discussion aimed at facilitating a broader understanding of brand experience and brand extension preference construction that we anticipate will be insightful and engaging.

EXTENDED ABSTRACTS

“Development of the Brand Experience Scale”

Lia Zarantonello, IULM University

Bernd H. Schmitt, Columbia Business School

Josko J. Brakus, University of Rochester

The topic of “experiential branding” has attracted great attention from marketing practitioners, and several trade books have appeared in the market (Andersson and Andersson 2006; Pine and Gilmore 1999; Schmitt 1999, 2003; Shaw and Ivens 2002; Smith and Wheeler 2002). However, little conceptual and empirical work has been done on that topic. One major reason may be the lack of a brand experience scale, compared to other brand related areas where scales exist, e.g., the Brand Personality Scale (Aaker 1997) or the Centrality of Visual Product Aesthetics Scale (Bloch, Brunel, and Arnold 2003).

Here we present our research to develop a theory-based reliable and valid brand experience scale. Drawing on the theory of mind modularity (Fodor 1983; Pinker 1997; Plotkin 1998; Tooby and Cosmides 2000) and an experience categorization by Dewey (Dewey 1922; 1925; see also Dubé and LeBel 2003), we propose that consumer experiences with a brand arise when consumers are exposed to brands and pay attention to the experiential aspects of brand executions. Experiential cues appear as colors, typefaces, emoticons, smiley faces, word games and the like, on brand communications such as print and TV advertising, packaging, in events and stores, on web sites and mobile electronic communications and, at times, on the product as such. We propose that brand experiences consist of five types: sensory, affective, social, bodily, and intellectual. Empirically, we develop a scale that measures each facet of experience and show that different brands can be differentiated on these experience factors.

Item Generation

We first generated items that cover the five facets of experience. An extensive literature review and search for concepts was undertaken. For sensory items we examined research related to aesthetics (Arnheim 1974; Berlyne 1974; Bloch, Brunel, and Arnold 2003; Feibleman 1945; Postrel 2003; Schmitt and Simonson 1997). For affective items we reviewed the literature on affect and emotions in consumer behavior (Cohen and Areni 1998; Edell and Burke 1987; Holbrook and Batra 1987; Richins 1997) and on the psychology of emotions (e.g. Izard 1978; Plutchik and Kellerman 1989). We covered intellectual experiences using Guilford's (1956) intelligence research, and we also looked at creative thinking and applications of creative thinking in advertising (Smith and Yang 2004; Torrance 1987). For consumer bodily experiences, we reviewed the literature on physical/ behavioral and lifestyles aspects (e.g. Brehm and Kassin 1990; Helman and De Chernatony 1999; Richins 1983; Solomon 2004). Finally, for consumers' social experiences, we reviewed the literature on brand communities (Cova and Cova 2002; McAlexander, Schouten and Koenig 2002; Muniz and O'Guinn 2001).

After initial face-validity screening and empirical screening by an expert panel of consumer researchers and experience consultants, who rated on a Likert scale the degree to which the items referred to brand experiences, a set of 125 applicable items was

retained: 24 sensory, 29 affective, 26 intellectual, 23 bodily, and 23 social items. Of these items, about one third were presented as negatively worded.

Next, a sample of 30 university students participated in a study on brand experiences. After explaining the concept of brand experience to the students, we asked them to evaluate to which extent the 125 items were descriptive of their experiences with brands, using a 7-point scale (1="not at all descriptive", 7="extremely descriptive"). Additional open ended questions were asked to assess the quality of the items. We retained items with a mean value greater than 4.0 and with a standard deviation smaller than 2.00. A total of 83 items was left: 23 (7 negative) for sensory, 13 (7 negative) for affective, 10 (8 negative) for intellectual, 18 (7 negative) for bodily and 19 (7 negative) for social experiences.

Brand Selection

Next, 68 university students were asked to think of three distinct product categories. They were also asked to pick one brand for each product category that they believed was marketed in an experiential fashion and one that they believed was not marketed in an experiential fashion.

Brands with the highest rating were retained for a total of 21 brands: 16 experiential (Abercrombie & Fitch, Apple, Barnes & Noble, BMW, Coca Cola, Jet Blue, McDonald's, Nike, Reebok, Sony, Starbucks, Target, Tiffany, Virgin, W Hotels, Whole Foods) and 5 non-experiential (Dell, Gristedes, IBM, Poland Spring, Wal-Mart).

The 21 brands were then randomly split into five groups, and to assess internal consistency, one brand (Apple) was included in each of them.

Factor Analysis

293 students from three universities completed a questionnaire on brand experiences, by judging to which extent the 83 items described their experiences with the 5 brands listed. To reduce primacy and recency effects, five different versions of questionnaire were prepared. After excluding 4 items which were not properly understood by more than 10% of participants, a factor analysis using Varimax rotation resulted in a nine factor solution using the eigenvalues > 1 criterion, but only the first five factors were significant based on scree plot. The first factor contained mostly intellectual items, the second included affective and social items, the third included sensory items, the fourth comprised bodily items, and the fifth included sensory items again. We also conducted another exploratory factor analysis by restricting the number of factors to 4. Results showed that sensory items grouped together, and that the other three factors contained respectively intellectual, bodily, and a combination of affective and social items. The total variance explained was 62%. For each factor, those items with a loading greater than .7 were retained, for a total of 19 items (6 sense, 5 feel/relate, 6 think, 2 act). Each factor (i.e., subscale of the Brand Experience Scale) had a high or acceptable coefficient alpha (think: .93, sense: .92, feel/relate: .92, act: .78).

The mean values of the 83 items for each of the 21 brands were then calculated. All the "experiential brands" had higher mean values (Abercrombie & Fitch: 3.70; Apple: 4.96; Barnes & Noble: 4.19; BMW: 4.92; Coca Cola: 3.93; Jet Blue: 4.20; McDonald's: 4.06; Nike: 4.61; Reebok: 3.52; Sony: 4.18; Starbucks: 4.32; Target: 3.73; Tiffany: 4.44; Virgin: 3.95; W Hotels: 3.74; Whole Foods: 4.74) than all the "non-experiential brands" (Dell: 3.48; Gristedes: 3.10; IBM: 3.25; Poland Spring: 3.47; Wal-Mart: 3.22). Moreover, the Apple means were highly consistent (all means ranged from 4.81 to 5.03).

Confirmative Factor Analyses

We then worked on a shorter version of the scale, which consisted of 12 items. As sensory items we had "I find this brand interesting in a sensory way", "This brand makes a strong impression on my visual sense or other senses", and "This brand does not appeal to my senses". Emotions were addressed with items such as "This brand induces feelings and sentiments", "I do not have strong emotions for this brand", and "This brand is an emotional brand". The intellectual sphere was investigated with the items "This brand stimulates my curiosity and problem solving", "I engage in a lot of thinking when I encounter this brand", and "This brand does not make me think". Finally, as behavioral items we had "I engage in physical actions and behaviors when I use this brand", "This brand results in bodily experiences", and "This brand is not action oriented".

We also prepared another series of brands and we divided them randomly in 6 groups of five brands each (Adidas, American Express, Ben & Jerry, Blackberry, Calvin Klein, Clinique, Crate & Barrell, Dannon, Disney, Ferrari, Gatorade, Gillette Mach3, Hallmark, Harley Davidson, Hershey's, iPod, L'Oreal, La Prairie, Lego, Motorola, Nokia, Prada, Puma, Samsung, Starbucks, Sudoku, Toys'r'us, Tropicana, Viagra, Victoria's Secret).

Then, we asked 193 students from Columbia University to evaluate to which extent they agreed the items were descriptive of their experience with the brands listed, by using a 7-point Likert scale (1="strongly disagree", 7="strongly agree"). Exploratory factor analysis revealed three factors with eigenvalues greater than one. The three factors explained 67.17% of variance. After the Varimax rotation was applied, a clean factor structure emerged. Three "sense" and three "feel/relate" items loaded on one factor (with one loading equal to .59, another equal to .63, and the rest greater than .72); three "act" items loaded on the second factor (all loadings greater than .72); finally, three "think" items loaded on the third factor (all loadings greater than .75).

We then ran another exploratory factor analysis on the six "sense" and "feel/relate" items that loaded on the first factor in the analysis above. After we applied the Varimax rotation, this subsequent analysis revealed two "nested" factors—the "sense" factor (all loadings greater than .72) and the "feel/relate" factor (all loadings greater than .69). These two factors explained 74.3% of variance generated by these six items only.

Consequently, it seemed that the best model was the three factor model: "act" items loading on one factor, "think" items loading on another factor, and the two "nested" factors within the third factor—"sense" and "feel/relate".

After we analyzed a number of models, the confirmatory factor analyses confirmed that the best models were the one that emerged in the exploratory analysis (the three factors plus two "nested" factors; see above) and the conceptually similar four-factor model: sense, feel/relate, act, and think. Its GFI was equal to .92 and CFI to .92; the lower bound of the 90% confidence interval of the RMSEA estimate was .08 indicating borderline reasonable fit. Since it is easier to implement the four factor "non-nested" model as a measurement tool, we decided to further work with that model.

Current Work

We are now testing both the divergent and predictive validity of the Brand Experience Scale. More specifically, the fourth study aims at showing that our scale measures a construct different from that measured by other scales, i.e. the Brand Personality Scale. The fifth study wants to demonstrate the impact that the brand experience has on brand loyalty, brand attitude, customer delight, and customer satisfaction.

"The Effects of Brand Name Structure and Product Experience on Brand Extension Evaluations and Parent Brand Dilution"

Sanjay Sood, *University of California, Los Angeles*
Kevin L. Keller, *Dartmouth College*

The structure of the name used to launch a brand extension has become an increasingly important topic in academic research. For example, Park, Jun and Shocker (1998) showed that the type of co-brand name significantly influences extension evaluations. More recently, Desai and Keller (2002) showed that the type of ingredient brand name significantly influences the acceptance of extensions. In this research, we examine a naming structure known as sub-branding, where new products are introduced by combining the parent brand name with an individual brand name (e.g., Quencher by Tropicana cola). We propose that traditional family branding (e.g., Tropicana cola) invokes categorical processing of brand extensions whereas sub-branding results invokes a more piecemeal processing of brand extensions (Sujan and Bettman 1989). As a result, the traditional brand extension effects of category similarity found in past research are more appropriate for family branding than for sub-branding strategies.

More importantly, the type of information processing invoked by the brand extension has direct implications regarding the potential for brand dilution. Past research has found mixed results on brand dilution, sometimes finding consistent dilution and other times not finding any dilution at all, while keeping a family

branding strategy constant (Keller and Aaker 1992; Milberg et al. 1997; Loken and Roedder John 1993; Roedder John, Loken, and Joiner 1998; Romeo 1990). One limitation of this past research is the exclusion of direct experience with the extension. We propose that the compelling, vivid nature of a negative product experience with an extension is more likely to dilute brand equity than simply informing consumers about negative extension performance as in past research. We find that dilution does consistently occur when consumers have a negative extension experience, but only with family branded extensions in similar categories. Interestingly, sub-branding shields the parent brand from dilution, apparently by invoking a piecemeal processing strategy that sends a signal to consumers that the extension is different from the parent brand.

In the first experiment we measure brand extension attitudes and response latencies to provide initial support for the category vs. piecemeal processing models. Respondents were asked to evaluate several brand extensions in a survey administered on a computer. The experiment involved a 2 (similarity: similar or dissimilar) x 2 (name: family or sub-brand) mixed design. Some respondents in the similar (dissimilar) condition evaluated a new cola from Pepsi (Tropicana) as family named extensions; other respondents evaluated these same new products with a sub-brand name (e.g., Quencher by Pepsi). Consistent with our prediction, there was an interaction between similarity and name such that similar family branded extensions were evaluated higher than dissimilar family branded extensions, but there was no difference for sub-branded extension evaluations. In addition, family branded extensions were evaluated more quickly, consistent with category-based processing whereas sub-branded extensions were evaluated more slowly, consistent with piecemeal processing.

In the second study we added product experience to the experiment to form a 2 (similarity: similar or dissimilar) x 2 (name: family or sub-brand) x 2 (experience: favorable or unfavorable) design. Respondents were given the same brand extensions along with a trial taste test for each new product. Some of the new products provided a favorable experience in that the sample was either actual Pepsi or Tropicana. Others in the unfavorable experience condition tasted a diluted version of the drink. This experiment replicated the evaluations of the first study with experience in the favorable experience conditions. That is, family branded extensions were influenced by similarity and sub-branded extensions were not, even though everyone had tasted exactly the same drinks. The results also showed significant parent brand dilution but only for similar family branded extensions. Interestingly, sub-branding eliminated any dilution effects.

The remaining experiments investigate boundary conditions of these effects. Experiment 3 contrasts direct experience via product trial with indirect experience via Consumer Reports. We find that direct experience has a much larger effect on evaluations, even when the Consumer Reports evaluations are in conflict with the product trial experience. Experiment 4 investigates the structure of the sub-brand name. We change the dominance and prominence of the elements in the sub-brand name by changing the order of the elements and the diagnosticity of the individual name. We find that the individual component has to be dominant and meaningful in order for sub-branding to have the most beneficial impact on extension evaluations and dilution effects.

Collectively, our studies provide evidence that brand name structure can invoke different types of information processing strategies and therefore influence both extension evaluations and dilution effects. Specifically, the sub-branding results suggest that slight changes to the extension name structure can result in large changes in consumer responses. Whereas family branding consistently resulted in similar extensions being evaluated higher than

dissimilar extensions, even in the presence of product ratings, sub-branding neutralized these category similarity effects due to the induction of piecemeal (vs. category-based) processing. In terms of dilution effects, sub-branding evidently sends a credible signal to consumers that helps diffuse negative attributions and separates the locus of the extension's failure from the parent brand. In addition, experience was found to guide evaluations more than product ratings, presumably because the self-generated information related to the former led to greater perceptions of diagnosticity. Finally, the results also indicate that dilution effects can be avoided if consumers are provided with some rationale, either via sub-branding or external information, as to why an extension may perform poorly.

“Beyond Survival of the Fittest: The Influence of Mindsets on Consumers’ Response to Brand Extensions”

Tom Meyvis, New York University

Kelly Goldsmith, Yale University

Ravi Dhar, Yale University

Treating their brands as assets, many businesses have attempted to leverage their brand equity by using established brand names to launch new products as brand extensions. Previous research on brand extensions has identified the *fit* between the brand and the extension as an important determinant of a positive consumer response to the new extensions. Regardless of how it has been conceptualized, be it as overlapping category associations, compatible skills (Aaker and Keller 1990), or overlapping benefit associations (Broniarczyk and Alba, 1994), researchers have argued that a good fit between the brand and the extension category is a necessary condition for favorable consumer reactions. However, some recent work (Klink and Smith 2001) suggests that the impoverished presentation of extension information in past brand extension research has led to an overestimation of the importance of fit.

In the current research, we propose that the relative importance of fit will depend on the *mindset* that the decision maker adopts. In most brand extension studies, participants are asked to provide separate evaluations of hypothetical extensions. We argue that this encourages participants to adopt an *abstract*, hypothetical mindset as opposed to a more *concrete*, pragmatic mindset. As research on psychological distance (e.g., Liberman, Trope, & Stephan 2005) has suggested, decision makers who adopt a more hypothetical mindset are more likely to be guided by abstract principles. We therefore propose that participants who are asked to evaluate hypothetical extensions will rely on their lay beliefs and their general principles about how the marketplace should be structured, rather than concrete quality concerns that would drive their actual purchase decisions. In other words, those participants may adopt a more abstract perspective and overstate their sensitivity to the fit between the brand and the extension. Conversely, shifting people's perspective from an abstract to a more concrete mindset should reduce the impact of general principles such as fit and increase the impact of factors that promise concrete rewards, such as brand quality.

Consistent with this proposition, results from five experiments indicate that when the decision context is made more concrete, people's preferences shift from extensions of high fit, low quality brands to extensions of low fit, high quality brands. In a first study, participants were presented with hypothetical extensions to the same product category of a high fit, low quality brand (e.g., ShopRite cottage cheese) and a low fit, high quality brand (e.g., Haagen Dazs cottage cheese). In the *separate evaluation* condition, participants were asked to separately evaluate each extension (every participant rated both ShopRite and Haagen Dazs, but they were separated by other products); in the *joint evaluation* condition,

participants also evaluated each extension, but the two extensions to the same category were presented adjacently; and in the *choice* condition, participants chose between the two brand extensions in each category. Consistent with previous findings in the literature, participants in the separate evaluation condition rated the high fit (low quality) extensions more favorably than the low fit (high quality) extensions. However, when participants made choices between extensions in the same category, or when they jointly evaluated these extensions, they preferred the low fit (high quality) extensions instead. We propose that the comparisons between brands in the same category resulted in more concrete product representations (and increased similarity to regular purchase behavior) and reduced reliance on abstract principles such as fit, in favor of the immediate benefits associated with brand quality. The reduced reliance on fit was supported by results from a second study that replicated the separate evaluation and choice conditions, but also asked participants to list the thoughts they relied on for their decision. As expected, people in the separate evaluation condition were significantly more likely to mention fit-related thoughts than were people in the choice condition.

To further test the effect of inducing a more concrete mindset, we conducted a third study in which all participants made a choice between a high fit, low quality extension (e.g., CVS deodorant) and a low fit, high quality extension (e.g., Nike deodorant). For half the participants, we increased the ease of imagining the extensions by providing a picture of the product. The picture showed a typical product in that category and was identical for both extensions. Even though the picture did not convey any additional information, providing the picture significantly increased participants' preference for the low fit, high quality extension. A fourth study replicated this effect and also asked participants to list their thoughts when choosing between the extensions. As expected, participants who had been provided with pictures were significantly more likely to mention quality-related thoughts (very few participants mentioned fit-related thoughts in either condition). Finally, in a fifth study, participants were again asked to choose between the same extensions as in studies 3 and 4, but no pictures were shown. Instead, for half the participants, the choice context was made more concrete by asking them to think about the extensions before making a choice. Similar to the picture effect, thinking about the extensions before choosing increased the preference for the low fit, high quality brand. Together, these last three studies indicate that as the decision context becomes more concrete (by making the extensions easier to imagine), the benefits offered by high-quality brands become more persuasive, and violations of general principles become less problematic.

These findings illustrate the malleability of consumers' evaluative response to brand extensions and provide further support for Klink and Smith's (2001) contention that previous brand extension research has overstated the importance of fit. However, this work also highlights a concern in consumer research in general, and in branding research in particular. When asking people how they would decide in hypothetical situations, we implicitly encourage them to adopt an abstract, hypothetical mindset that may increase their reliance on abstract principles and lay theories. This is of particular importance to researchers who study consumers' reactions to changes in brand strategies, as they are at risk of measuring consumers' lay beliefs about the decisions that managers ought to make rather than how they would react as consumers in the marketplace. To reduce this risk, researchers can encourage participants to adopt the concrete mindset that is common in typical purchase situations by facilitating the concrete representation of the choice options.

Development of the Brand Experience Scale

Lia Zarantonello, IULM University, Italy
Bernd H. Schmitt, Columbia University, USA
Joskő J. Brakus, University of Rochester, USA

EXTENDED ABSTRACT

The topic of “experiential branding” has attracted great attention from marketing practitioners, and several trade books have appeared in the market (Andersson and Andersson 2006; Pine and Gilmore 1999; Schmitt 1999, 2003; Shaw and Ivens 2002; Smith and Wheeler 2002). However, little conceptual and empirical work has been done on that topic. One major reason may be the lack of a brand experience scale, compared to other brand related areas where scales exist, e.g., the Brand Personality Scale (Aaker 1997) or the Centrality of Visual Product Aesthetics Scale (Bloch, Brunel, and Arnold 2003).

Here we present our research to develop a theory-based reliable and valid brand experience scale. Drawing on the theory of mind modularity (Fodor 1983; Pinker 1997; Plotkin 1998; Tooby and Cosmides 2000) and an experience categorization by Dewey (Dewey 1922; 1925; see also Dubé and LeBel 2003), we propose that consumer experiences with a brand arise when consumers are exposed to brands and pay attention to the experiential aspects of brands executions. Experiential cues appear as colors, typefaces, emoticons, smiley faces, word games and the like, on brand communications such as print and TV advertising, packaging, in events and stores, on web sites and mobile electronic communications and, at times, on the product as such. We propose that brand experiences consist of five types: sensory, affective, social, bodily, and intellectual. Empirically, we develop a scale that measures each facet of experience and show that different brands can be differentiated on these experience factors.

Item Generation

We first generated items that cover the five facets of experience. An extensive literature review and search for concepts was undertaken. For sensory items we examined research related to aesthetics (Arnheim 1974; Berlyne 1974; Bloch, Brunel, and Arnold 2003; Feibleman 1945; Postrel 2003; Schmitt and Simonson 1997). For affective items we reviewed the literature on affect and emotions in consumer behavior (Cohen and Areni 1998; Edell and Burke 1987; Holbrook and Batra 1987; Richins 1997) and on the psychology of emotions (e.g. Izard 1978; Plutchik and Kellerman 1989). We covered intellectual experiences using Guilford’s (1956) intelligence research, and we also looked at creative thinking and applications of creative thinking in advertising (Smith and Yang 2004; Torrance 1987). For consumer bodily experiences, we reviewed the literature on physical/ behavioral and lifestyles aspects (e.g. Brehm and Kassin 1990; Helman and De Chernatony 1999; Richins 1983; Solomon 2004). Finally, for consumers’ social experiences, we reviewed the literature on brand communities (Cova and Cova 2002; McAlexander, Schouten and Koenig 2002; Muniz and O’Guinn 2001).

After initial face-validity screening and empirical screening by an expert panel of consumer researchers and experience consultants, who rated on a Likert scale the degree to which the items referred to brand experiences, a set of 125 applicable items was retained: 24 sensory, 29 affective, 26 intellectual, 23 bodily, and 23 social items. Of these items, about one third were presented as negatively worded.

Next, a sample of 30 university students participated in a study on brand experiences. After explaining the concept of brand experience to the students, we asked them to evaluate to which extent the

125 items were descriptive of their experiences with brands, using a 7-point scale (1=“not at all descriptive,” 7=“extremely descriptive”). Additional open ended questions were asked to assess the quality of the items. We retained items with a mean value greater than 4.0 and with a standard deviation smaller than 2.00. A total of 83 items was left: 23 (7 negative) for sensory, 13 (7 negative) for affective, 10 (8 negative) for intellectual, 18 (7 negative) for bodily and 19 (7 negative) for social experiences.

Brand Selection

Next, 68 university students were asked to think of three distinct product categories. They were also asked to pick one brand for each product category that they believed was marketed in an experiential fashion and one that they believed was not marketed in an experiential fashion.

Brands with the highest rating were retained for a total of 21 brands: 16 experiential (Abercrombie & Fitch, Apple, Barnes & Noble, BMW, Coca Cola, Jet Blue, McDonald’s, Nike, Reebok, Sony, Starbucks, Target, Tiffany, Virgin, W Hotels, Whole Foods) and 5 non-experiential (Dell, Gristedes, IBM, Poland Spring, Wal-Mart).

The 21 brands were then randomly split into five groups, and to assess internal consistency, one brand (Apple) was included in each of them.

Factor Analysis

293 students from three universities completed a questionnaire on brand experiences, by judging to which extent the 83 items described their experiences with the 5 brands listed. To reduce primacy and recency effects, five different versions of questionnaire were prepared. After excluding 4 items which were not properly understood by more than 10% of participants, a factor analysis using Varimax rotation resulted in a nine factor solution using the eigenvalues > 1 criterion, but only the first five factors were significant based on scree plot. The first factor contained mostly intellectual items, the second included affective and social items, the third included sensory items, the fourth comprised bodily items, and the fifth included sensory items again. We also conducted another exploratory factor analysis by restricting the number of factors to 4. Results showed that sensory items grouped together, and that the other three factors contained respectively intellectual, bodily, and a combination of affective and social items. The total variance explained was 62.06%. For each factor, those items with a loading greater than .7 were retained, for a total of 19 items (6 sense, 5 feel/relate, 6 think, 2 act). Each factor (i.e., subscale of the Brand Experience Scale) had a high or acceptable coefficient alpha (think: .93, sense: .92, feel/relate: .92, act: .78).

The mean values of the 83 items for each of the 21 brands were then calculated. All the “experiential brands” had higher mean values (Abercrombie & Fitch: 3.70; Apple: 4.96; Barnes & Noble: 4.19; BMW: 4.92; Coca Cola: 3.93; Jet Blue: 4.20; McDonald’s: 4.06; Nike: 4.61; Reebok: 3.52; Sony: 4.18; Starbucks: 4.32; Target: 3.73; Tiffany: 4.44; Virgin: 3.95; W Hotels: 3.74; Whole Foods: 4.74) than all the “non-experiential brands” (Dell: 3.48; Gristedes: 3.10; IBM: 3.25; Poland Spring: 3.47; Wal-Mart: 3.22). Moreover, the Apple means were highly consistent (all means ranged from 4.81 to 5.03).

Confirmative Factor Analyses

We then worked on a shorter version of the scale, which consisted of 12 items. As sensory items we had "I find this brand interesting in a sensory way," "This brand makes a strong impression on my visual sense or other senses," and "This brand does not appeal to my senses". Emotions were addressed with items such as "This brand induces feelings and sentiments," "I do not have strong emotions for this brand," and "This brand is an emotional brand". The intellectual sphere was investigated with the items "This brand stimulates my curiosity and problem solving," "I engage in a lot of thinking when I encounter this brand," and "This brand does not make me think". Finally, as behavioral items we had "I engage in physical actions and behaviors when I use this brand," "This brand results in bodily experiences," and "This brand is not action oriented".

We also prepared another series of brands and we divided them randomly in 6 groups of five brands each (Adidas, American Express, Ben & Jerry, BlackBerry, Calvin Klein, Clinique, Crate & Barrell, Dannon, Disney, Ferrari, Gatorade, Gillette Mach3, Hallmark, Harley Davidson, Hershey's, iPod, L'Oreal, La Prairie, Lego, Motorola, Nokia, Prada, Puma, Samsung, Starbucks, Sudoku, Toys'r'us, Tropicana, Viagra, Victoria's Secret).

Then, we asked 193 students from Columbia University to evaluate to which extent they agreed the items were descriptive of their experience with the brands listed, by using a 7-point Likert scale (1="strongly disagree," 7="strongly agree"). Exploratory factor analysis revealed three factors with eigenvalues greater than one. The three factors explained 67.17% of variance. After the Varimax rotation was applied, a clean factor structure emerged. Three "sense" and three "feel/relate" items loaded on one factor (with one loading equal to .59, another equal to .63, and the rest greater than .72); three "act" items loaded on the second factor (all loadings greater than .72); finally, three "think" items loaded on the third factor (all loadings greater than .75).

We then ran another exploratory factor analysis on the six "sense" and "feel/relate" items that loaded on the first factor in the analysis above. After we applied the Varimax rotation, this subsequent analysis revealed two "nested" factors—the "sense" factor (all loadings greater than .72) and the "feel/relate" factor (all loadings greater than .69). These two factors explained 74.3% of variance generated by these six items only.

Consequently, it seemed that the best model was the three factor model: "act" items loading on one factor, "think" items loading on another factor, and the two "nested" factors within the third factor—"sense" and "feel/relate".

After we analyzed a number of models, the confirmatory factor analyses confirmed that the best models were the one that emerged in the exploratory analysis (the three factors plus two "nested" factors; see above) and the conceptually similar four-factor model: sense, feel/relate, act, and think. Its GFI was equal to .92 and CFI to .92; the lower bound of the 90% confidence interval of the RMSEA estimate was .08 indicating borderline reasonable fit. Since it is easier to implement the four factor "non-nested" model as a measurement tool, we decided to further work with that model.

Current Work

We are now testing both the divergent and predictive validity of the Brand Experience Scale. More specifically, the next study aims at showing that our scale measures a construct different from that measured by other scales, i.e. the Brand Personality Scale. Another study wants to demonstrate the impact that the brand experience has on brand loyalty, brand attitude, customer delight, and customer satisfaction.

SPECIAL SESSION SUMMARY

Automatic Heart and Automatic Mind: Nonconscious Affective and Cognitive Influences on Consumer Behavior

Michal Maimaran, Stanford University, USA
S. Christian Wheeler, Stanford University, USA

SESSION OVERVIEW

The importance of nonconscious processes in determining consumer behavior is gaining increased attention among consumer behavior researchers, but the range of effects of subtle influences on cognition and behavior has yet to be determined. Moreover, less is known about how and when these processes can influence and interact with the emotional and cognitive components that serve as inputs to consumer behavior. The present session seeks to provide an integrative look at nonconscious affective and cognitive effects on choice decisions by examining the main and interactive effects of emotional and cognitive components on automatic behavior.

The first paper, by *Zemack-Rugar and Bettman*, provides evidence that specific emotion constructs can be activated through subliminal priming procedures. The authors show that specific, equally valenced emotions (guilt and sadness) can be subliminally primed, remain inaccessible to conscious awareness, but yet affect indulgence and helping behavior. Moreover, in their third and fourth studies they use a delay paradigm to find that it is the motivational component, and not the semantic emotion-related component, that drives behavior. Hence, this paper shows that specific emotions can be nonconsciously activated by subliminal priming and affect important consumer behaviors.

The second paper, by *Maimaran and Wheeler*, examines activation of cognitive constructs by priming stimuli and shows that active automatic construction processes can lead even novel and impoverished priming stimuli to exert significant effects on construct accessibility and choice. Specifically, they show that participants spontaneously extract higher order cognitive constructs (e.g., uniqueness) upon incidental exposure to novel arrays of shapes (e.g., one square among five circles). More important, they show that such stimuli can also significantly affect fundamental choice propensities such as seeking uniqueness and variety. Hence, this paper shows that higher order cognitive constructs can be activated by very primitive visual stimuli and exert congruent effects on choice.

The third and fourth papers examine how emotional and cognitive processes can moderate nonconsciously instigated processes. The third paper, by *Fishbach and Labroo*, shows that mood can significantly affect nonconscious goal pursuit. Because positive mood signals to approach accessible goals, individuals in positive moods should be more likely to adhere to subtly primed goals, regardless of their content. Because negative mood signals to avoid accessible goals, individuals in negative moods should be less likely to adhere to subtly primed goals. Using a variety of dependent variables, the authors show that positive-mood individuals are more likely to pursue both subtly activated self-improvement and mood-management goals than negative-mood individuals.

In the fourth paper, *Wood, Poynor, and Chartrand* present a new individual difference scale of priming susceptibility. Using a range of individual difference variables, they show that individuals with dispositional propensities to attend to the environment and engage in associative processing exhibit larger effects of primes on their behavior. These various individual difference variables are distilled into a single Susceptibility to Priming scale that has great

potential utility for both consumer behavior researchers as well as advertising practitioners. Additionally, the isolation of these two factors lends additional insight into the critical processes responsible for prime-to-behavior effects.

EXTENDED ABSTRACTS

“Effects of Specific, Nonconscious Emotion Primes on Behavior”

Yael Zemack-Rugar, Virginia Tech
James R. Bettman, Duke University
Gavan J. Fitzsimons, Duke University

Research in nonconscious emotion priming has been limited to showing effects of positively versus negatively valenced affect. Such research has utilized two methods, subliminally priming participants with positively or negatively valenced words (Chartrand et al., 2006) and subliminally priming participants with pictures of people with positive versus negative facial expressions (Winkielman et al., 2005).

We introduce a new paradigm of nonconscious *emotion* priming that goes beyond valence and demonstrates novel effects. Although specific, equally valenced, *conscious* emotions lead to different behaviors (Lerner & Keltner, 2000), it has not been shown that these effects extend to nonconsciously primed emotions. We show that specific, equally valenced emotions (guilt and sadness) can be subliminally primed, remain inaccessible to conscious awareness, and still differentially affect behavior. We prime emotions by subliminally flashing emotion adjectives. Individuals report no differences in their consciously experienced emotion across the prime conditions, yet behave consistently with the specific emotion primed. We argue that two interrelated processes underlie these effects: nonconscious activation of emotion-constructs and nonconscious activation of emotion-regulation goals (Chartrand & Bargh, 2002).

First, subliminal emotion priming nonconsciously activates emotion-constructs associated with each emotion type (Lazarus, 1991; Lerner & Keltner, 2000). Subsequently, activation of these negative emotion constructs leads to automatic and nonconscious activation of emotion-regulation goals (Bargh & Chartrand, 1999; Erber, 1996; Larsen, 2000).

Such emotion-regulation goals are pursued differently by sad versus guilty individuals. Individuals feeling sad find an unpleasant helping task unappealing for emotion-regulation (Isen & Simmonds, 1978), whereas individuals feeling guilty may find such a task appealing and useful (Bybee, 1998; Tangney & Dearing, 2002). Similarly, individuals feeling guilty find indulging unappealing for emotion regulation (Tangney & Dearing, 2002; Bybee, 1998) whereas individuals feeling sad find indulgence helpful (Rehm & Plakosh, 1975). Hence, guilt-primed individuals are expected to show reduced indulgence and increased helping compared to sadness-primed individuals.

However, emotion-regulation goals are also pursued differently based on individual coping characteristics, such as guilt-proneness (Morris & Reilly, 1987; Tangney et al., 1992). Specifically, individuals feeling guilty and high in guilt-proneness typi-

cally respond to guilt with reduced indulgence or increased helping. Thus, an automatic emotion-behavior link is formed between guilt and these behaviors for high guilt-prone people (Bargh & Chartrand, 1999). However, individuals feeling guilty and low in guilt-proneness do not tend to cope via reduced indulgence and enhanced helping, and therefore will not have such an automatic emotion-behavior link. Thus, we predict that individuals primed with guilt and high in guilt proneness will show less indulgence and more helping than guilt-primed, low guilt-proneness or sadness-primed participants, despite a lack of differences in conscious, reported emotion.

In study 1 participants are subliminally primed with either four sad words or four guilty words using Chartrand and Bargh's priming paradigm (1996). Then, an enhanced PANAS scale including the word primes and additional guilt adjectives (previously shown to differentiate conscious guilt and sadness; Zemack-Rugar, 2006) is administered. Next, participants complete a "consumer survey" and indicate how much of a \$50 coupon (which they may win) they would like to allocate to either school supplies or a CD/DVD (pretests show CD/DVDs are considered an indulgence); dollars allotted to the CD/DVD is the main dependent variable. Finally, participants complete the TOSCA measure of guilt-proneness (Tangney et al., 1992).

As expected, participants primed with guilty words and high in guilt-proneness show lower levels of indulgence than all other participants. Additionally, a hanging neutral control condition indicates that the reduction in indulgence is absolute. Importantly, participants in the sad, guilty, and neutral conditions report equal conscious levels of positive, negative, and guilt-specific emotions. Despite lack of conscious awareness of the prime or the activation of the emotion construct, participants behave in accordance with the prime they received and their individual coping characteristics.

In study 2 participants complete the same subliminal priming procedure, followed by an option to participate in an unpleasant helping task for charity. The amount of time allotted (0-20 minutes) is the main dependent variable. As predicted, participants primed with guilty words and high in guilt-proneness allot more time to the helping task than all other participants. A hanging control condition reveals that this increase in helping is absolute. As in study 1, participants in all conditions report equal positive, negative, and guilt-specific emotions.

The findings of studies 1 and 2 may have been generated by two possible mechanisms. One mechanism is semantic or ideomotoric (Prinz, 1990); certain emotions are semantically linked to certain behaviors, so that verbal activation of those emotions can lead to enactment of linked behaviors. Alternatively, the emotion-behavior link may be motivational, with activation of a negative emotion-construct leading to activation of an emotion-regulation goal (Morris & Reilly, 1987; Bargh & Chartrand, 1999). To examine whether the effects are goal-driven, an established dissociation paradigm is utilized (Bargh et al., 2001; Dunn & Kirsner, 1988) by adding a 5-minute time delay between the emotion prime and the behavior of interest. If behavior is semantically driven, effects should fade with delay (Anderson, 1983); however, if behavior is goal-driven, performance should not fade over time (Atkinson & Birch, 1970).

In a pretest we demonstrate that performance on a semantic task (word-search with prime-related words) diminishes over time, whereas performance on a goal-driven behavior (indulgence) does not. In studies 3 and 4 we add a 5-minute time delay and replicate our prior findings. This persistence of the behavioral effects after a 5-minute time delay suggests that the effects are driven by an emotion-regulation goal.

"Circles, Squares, and Choice: Graphical Priming Effects on Uniqueness and Variety Seeking"

Michal Maimaran, Stanford University

S. Christian Wheeler, Stanford University

Research on human information processing shows that people are adept at disambiguating ambiguous stimuli and making generalizations from limited information (e.g., Higgins, 1996; Schank & Abelson, 1977). These processes can occur spontaneously, without the intention or awareness of the perceiver (e.g., Uleman, Newman, & Moscovitz, 1996). In this paper, we test the limits and implications of these processes by examining whether people will extract higher-order constructs from impoverished stimuli that have no inherent meaning, such as arrays of geometrical shapes, and whether exposure to such arrays will systematically affect consumers' choices without their awareness or intention.

Specifically, we propose that individuals spontaneously and unintentionally extract abstract concepts from simple arrays of shapes, such as OOOOXO.¹ Being primed with these types of arrays, we argue, can lead to activation of abstract concepts (in the above example, the concept of uniqueness), making them more accessible. We further propose that the activation of such constructs can affect consumer choice in a manner congruent with the activated construct. In contrast to most prior research on priming and automatic behavior, which has employed words (e.g., Bargh, Chen, & Burros, 1996) or pictures or objects with inherent meaning or existing associations as the priming stimuli (e.g., Kay, Wheeler, Bargh & Ross 2004; Aarts & Dijksterhuis 2003), our paradigm uses novel arrays of shapes without any inherent meaning or preconditioned associations.

We conducted three studies in which we found effects on cognitive accessibility of uniqueness concepts, preference for uniqueness, and preference for variety seeking. We initially focused on these concepts because of their importance and centrality to consumer behavior. Nevertheless, we believe our findings can be generalized to other concepts, such as cooperation and defection in strategic situations. More generally, these arrays can be used in very mundane situations, such as logo selection by brands, to subtly convey various concepts.

In Study 1, we presented participants with either "uniqueness" arrays (e.g., OOOOXO) or "homogeneity" arrays (e.g., OOOOOO). These and subsequent arrays were pretested to ensure that they conveyed the appropriate concepts. During the priming procedure, participants were instructed to count the number of circles and squares in each stimulus array. The presentation of arrays was combined with a lexical decision task, in which participants were asked to identify as quickly as possible whether a string of letters is a real word or not. As hypothesized, we found that participants shown uniqueness arrays were faster in recognizing "uniqueness" words (e.g., 'unique', 'single') than either "homogeneity" words (e.g., 'similar', 'uniform') or "neutral" words (e.g., 'review', 'thirsty'), indicating a greater accessibility of the uniqueness concept. Importantly, in all studies, careful debriefing revealed that no participants consciously perceived any pattern to the stimulus arrays or believed that exposure to the arrays affected their behavior.

In Study 2, participants were presented with either "uniqueness" arrays or "homogeneity" arrays and were asked to count shapes as in Study 1. As compensation, participants were given the opportunity to select one from a set of milk chocolates. As hypoth-

¹Throughout this abstract, 'O' represents a circle, 'X' a square and 'V' a triangle

esized, those shown uniqueness arrays were significantly more likely to choose the unique chocolate (a milk Hershey's kiss wrapped in a different color) than those shown homogeneity arrays.

In the third study, we extended our examination to variety seeking. We presented participants with either "variety" arrays (e.g., OVOXOVXO) or "homogeneity" arrays (see above). As compensation, participants were offered a choice of three chocolates. As hypothesized, those shown variety arrays were significantly more likely to exhibit variety seeking in their choices (i.e., choose three different types of chocolates) than those shown homogeneity arrays.

Taken together, these studies show that individuals spontaneously extract meaning from ambiguous stimuli and their behavior unintentionally follows in kind. These studies reflect two key themes in the study of human perception and behavior: that individuals extract concepts beyond those inherent in the stimuli they encounter and that individuals' behavior is driven by factors of which they are unaware. That these studies used impoverished stimuli for which individuals had no prior associations illustrates the pervasiveness of these tendencies and suggests that the applicability of these broad principles to consumer behavior processes may be greater than suggested by prior research and theorizing.

"Be Better or Be Merry: How Mood Affects Self-Control"

Ayelet Fishbach, University of Chicago

Aparna A. Labroo, University of Chicago

Are happy (vs. unhappy) consumers more or less likely to read an emotionally disturbing charity appeal and donate money toward the advocated cause? Are happy (vs. unhappy) consumers more or less likely to attend to an ad appeal that warns them about the adverse effects of caffeine consumption and advises them to change their wayward ways? Such issues that involve motivating consumers to incur short term pains for long term gains are often at the helm of public policy planning, and whereas the literature suggests that consumer moods will affect self control and adherence to goals, the evidence on what the effect will be and what the underlying process may be is mixed. On the one hand, the literature on mood indicates that happy individuals are more likely than neutral or unhappy individuals to seek positive and avoid negative stimuli, which suggests that they would be less likely to engage in unpleasant tasks involving self control. On the other hand, the literature also reports that happy (vs. unhappy) individuals seek out negative information when it is self relevant, which suggests that at least on some occasions they may be more likely to engage in self control.

The current investigation addresses this controversy from a perspective of recent research on goal priming. Since the pursuit of many long-term consumer goals requires overcoming conflicting short-term motives (e.g., Loewenstein, 1996; Metcalfe & Mischel, 1999), contextual primes for an overriding goal are often not sufficient to promote goal-congruent actions. Under these conditions, happy (vs. neutral) individuals are better able to pursue primed long-term goals because positive mood is a signal to approach any accessible goal, whereas unhappy (vs. neutral) individuals are more likely to deter from pursuing primed long-term goals since negative mood is a signal to avoid an accessible goal. Importantly however, happy (vs. unhappy) individuals are expected to demonstrate increased self-control only when the higher order long-term goal is primed. Since positive mood serves as a booster, facilitating adherence to *any* primed goal, happy individuals are further expected to adhere to a contextually primed short-term goals such as maintaining their positive mood, whereas unhappy individuals would deter from such goal. As a result, happy individuals work harder on a task that serves an accessible long-term goal of self-improvement, but abstain from this task when primed with an incompatible mood-management goal. On the other

hand, unhappy individuals deter from a task that serves an accessible long-term goal of self-improvement, which they are more likely to pursue when primed with an incompatible mood-management goal.

Four studies tested whether happy (vs. neutral and unhappy) individuals adhere to accessible goals regardless of their content (self-improvement or mood maintenance). These studies manipulated participants' mood (happy, neutral, and unhappy) and accessible goal (self-improvement vs. mood maintenance) and measured for performance on self-control tasks. Study 1 indicated that happy (vs. unhappy) individuals with an accessible self-improvement goal donated more to a charity campaign that involved exposure to negatively valenced emotionally draining materials; however, they withheld their donations (compared to unhappy individuals) when their accessible goal referred to mood-management. Study 2 expanded these findings to performance on a difficult and challenging creativity test depicted to be a valid indicator of future professional success. It finds that individuals in a happy mood with a salient self-improvement goal performed better on the test compared with unhappy individuals, but happy mood led to lower test performance among participants whose accessible goal referred to mood-management. Study 3 indicates that a positive mood further facilitates physical endurance, as measured by persistence on squeezing a handgrip described to participants as an indicator of future healthiness, but only when the task was compatible with a primed self-improvement goal. When the task was incompatible with a primed goal of mood-management, happy individuals did not express greater physical endurance than others. Finally, Study 4 examines the effect of mood on recalling negative information and it finds that happy individuals spent more time than others recalling the health consequences of caffeine consumption and that they ended up recalling more information—but only to the extent that they were primed with self-improvement rather than mood-management goal.

By addressing the effect of moods on adhering to accessible goals, this research integrates two lines of research of the relationships between mood and self-regulation: research on mood as the ultimate goal of self-regulation (e.g., Diener, 2000; Gilbert et al., 1998; Kahneman, 2000) and research on mood as a resource for self-regulation (e.g., Aspinwall, 1998; Leith & Baumeister, 1996; Raghunathan & Trope, 2002). We propose that when people experience mild positive mood, they are more likely to adhere to contextual goal primes. Under these conditions, when the mood-management goal is accessible, positive mood discourages choice of actions that undermine this goal. However, when the accessible goal refers to self-improvement, positive mood improves performance and hence it serves as a resource for self-regulation. Task performance thus depends upon whichever goal is more salient because of contextual primes. Happy individuals are better able to regulate either of these accessible goals.

"Individual Susceptibility to Priming Effects"

Stacy L. Wood, University of South Carolina

Catherine Poynor, University of South Carolina

Tanya Chartrand, Duke University

New research in priming suggests that our old beliefs about the inefficacy of subliminal advertising may need to be qualified (Bargh 2004). Researchers have demonstrated, in diverse paradigms, how people may respond to concepts that they have been exposed to below conscious awareness. Although priming effects are robust across reported studies, within-study variance suggests that some individuals are more impacted by the primes to which they are exposed. The purpose of this research is to test this concept and identify the characteristics that would contribute to individual differences in susceptibility to priming (STP). While priming

researchers may benefit from an STP scale as a useful covariate, consumer behaviorists are likely to be interested in the concept of STP due to its implications for advertising efficacy. If advertisers use priming to make salient those goals, ideas, or evaluative criteria that are most advantageous to the company, which consumers are most likely to be vulnerable to this nonconscious influence?

Hypothesis. We posit that people who are confident, socially poised, creative, and thoughtful are those who are most susceptible to priming. Stated broadly, one may interpret this as counterintuitive because of an expectation that those consumers who would be most at risk from subliminal advertising (or any form of manipulative advertising) are those who are characteristically vulnerable due to lower than average capabilities in cognition or communication. Yet, the mechanisms by which priming work suggest the opposite. Priming works through a spreading activation process in which a prime (e.g., a concept like “luxury”) automatically activates related nodes without the conscious control of the individual. Thus, primes require 1) physical (but not necessarily aware) exposure and 2) associative processing. This suggests two paths to priming susceptibility. First, individuals who are confident and socially poised may be more likely to exhibit an “approach” attitude to the environment and thus may naturally attend most to their immediate environment—this promotes physical exposure to a prime. Second, individuals with high need for cognition and creative or association-based thought (e.g., imaginative or interdependent thinkers) may favor thought processes that facilitate the spreading activation of primes.

Study Protocol. To test this hypothesis, we measured a population ($n=112$) on eight different trait scales that tapped into attentional or associative factors (Self Esteem, Need for Cognition, Self Monitoring [Attention to Emotion and Ability to Modulate], Action-Orientation, Imaginativeness, Interdependence, and Closemindedness) prior to their attendance at a research session. At the later session, participants engaged in several unrelated tasks, one of which was a priming study. Procedures similar to those used by Chartrand and Bargh (1996) were used to prime memory goals. Participants were randomly assigned to either the memory-prime or no-prime exposure condition. After the prime exposure, participants were directed to an ostensibly unrelated task in which a computer program self-guided participants through a product evaluation task. Participants received information about a new type of sports drink and were asked to read this information carefully. The screen then displayed 11 statements about the drink. After the 11 statements had been displayed, participants were given a questionnaire that asked them to recall as many statements as possible about the sports drink. Thus, priming effects would be demonstrated by primed participants recalling more words than unprimed participants.

Results and Discussion. Two coders, both blind to the study hypothesis, counted the number of discrete thought units correctly listed in participants’ free recall. Participants in the memory prime condition recalled significantly more words ($M=9.91$) than those who received no prime ($M=8.54$; $F(1,108)=5.16$, $p=.025$). We then considered each individual difference scale separately to assess its impact on priming efficacy. A median split for each scale created two groups who scored either higher than or lower than the median. Five of the eight traits had a material influence on the priming effect as indicated by significant Prime x High/Low [scale median split] interactions. These traits included two attention-oriented tendencies (Self-Esteem and Attention to Emotion) and three associative tendencies (Action-orientation, Imagination, and Closemindedness).

A post-hoc formative scale to measure STP was constructed by selecting representative items from each of the scales. We selected the two items that had the highest item-to-total correlation

within each respective scale. This 16 item scale showed remarkable reliability (Cronbach’s $\alpha=.672$) despite its amalgamation from several distinct constructs. We then divided the participants into two groups based on a median split of the STP scale (median=77). As expected, the Prime x High/Low STP interaction is significant ($F(1,104)=6.14$, $p=.008$, one-tailed). Those who scored high on the STP scale showed a significantly stronger priming effect; primed participants recalled more words ($M=10.89$) than unprimed participants ($M=7.79$). This simple contrast is significant ($F(1,46)=11.09$, $p=.002$). For those low in STP, the prime did not have an effect on the number of words recalled ($M_{\text{prime}}=9.08$; $M_{\text{no prime}}=9.03$; $p>.95$). This protocol was repeated in a second study that examined a different type of priming task (achievement goal).

Overall, we demonstrate that people are differently susceptible to priming influences. This finding, and the development of a short-form STP scale, offer interesting implications for psychology, consumer behavior, public policy, and advertising and would generate an interactive and insightful discussion within the ACR forum.

ROUNDTABLE SUMMARY

Exploring the Co-Evolution of Possession Constellations, Self, and Identity: Part Two—Mundane Consumption

Robert E. Kleine, III, Ohio Northern University, USA

Twenty eight scholars gathered at Exploring the Co-Evolution of Possession Constellations, Self, and Identity, a 2005 ACR roundtable session, to discuss the intersection of possession constellations (Solomon and Assael 1987), self, and identity. The quantity of participants, and quality of the discussion, demonstrates that this theme provides a common thread linking seemingly diverse topics in consumer research. Representative topics thus linked include: self-extension (Belk 1988), possession attachment (Ball and Tasaki 1992; Kleine, Kleine, and Allen 1995; Wallendorf and Arnould 1988), possession value (Richins 1994), authenticity (Grayson and Martinec 2004); identity salience effects (Reed 2004), identity schemas (Kleine, Kleine, and Kernan 1993), Diderot effects (McCracken 1988), possession collections (Baker and Martin 2000); brand communities (McAlexander, Schouten, and Koenig 2002; Muniz and O'Guinn 2001), disposition (Lastovicka and Fernandez 2004; McAlexander 1991; Price, Arnould, and Curasi 2000), involuntary possession loss (Sayre 1994), and anti-constellations (Hogg and Mitchell 1997).

Discussion at the 2005 roundtable was lively, engaging, and generative. Thematically, the discussion emphasized identity issues. After the 2005 roundtable, several participants volunteered their interest in continuing the discussion at another roundtable, with emphasis to be placed on the ordinary product side of the identity/possession dialectic.

The ordinary products an individual uses in day-to-day living—food eaten for breakfast, a pen to jot a note, a scraper to remove ice from a windshield—are neither dramatic nor seemingly extraordinary. Perhaps because such products seem so ordinary, their consumption is often overlooked in consumer research. Yet, ordinary consumption objects fill consumer's homes, and the consumption of them pervades consumer's daily lives (Douglas and Isherwood 1979). Consumers spontaneously use mundane objects such as "utensils, chairs, clothing, foods, and cleansing products" to "account, or provide a perspective for action" on a regular, ongoing basis (Heisley and Levy, 1991; p. 263) suggesting that such everyday objects are not so ordinary, on a functional level. Moreover, mundane consumption objects contribute to, and reflect, identity (e.g., Kleine, Kleine, and Kernan 1993). The most common and pervasive identity projects in which consumers engage often involve the most ordinary objects. Occasionally, mundane objects precipitate extraordinary, unintended consequences (McCracken 1988), or become objects of attachment (Ball and Tasaki 1992; Kleine, Kleine, and Allen 1995; Wallendorf and Arnould 1988). Ordinary consumption objects used regularly have extraordinary implications.

The goals of this Part 2 Roundtable are to:

- Continue and complement conversations initiated at last year's roundtable, "Exploring the Co-Evolution of Possession Constellations, Self, and Identity." Twenty eight (28) scholars participated in the 2005 roundtable. Discussion was lively, engaging, and generative. Thematically, the discussion emphasized identity issues. After the 2005 roundtable, several participants shared their interest in continuing the discussion at another complementary roundtable at which the primary emphasis is placed on the

ordinary product side of the identity/possession dialectic. Hence, discussion at this roundtable will emphasize mundane consumption.

- Bring together consumer researchers interested in exploring the intersection of identity and consumption generally, and the role of mundane ordinary products in consumer's daily lives specifically.
- Initiate establishing a research agenda to further understand such mundane consumption.
- Enable networking of interested scholars leading to research alliances to further understanding of mundane consumption.

SPECIAL SESSION SUMMARY

Space, the Final Frontier: Consumer Adaptation, Resistance and Redefinition of Spatial Limitation in the Marketspace

Teresa Pavia, University of Utah, USA
Marlys Mason, Oklahoma State University, USA

SESSION OVERVIEW

Anyone who has broken a leg can attest that most people go through their day blissfully oblivious to small gradations in slope, curbs, cramped aisles or tight parking places. Nearsighted baby boomers are discovering that poorly lit aisles make reading labels or credit card numbers difficult. Parents of newborns quickly realize that their prime shopping opportunities are often late at night when stores may be closed but, thank goodness, the internet is open. In each case, marketers have assiduously worked to fine-tune the place component of the marketing mix, only to have consumers face idiosyncratic spatial impediments that limit the exchange process.

The focus of this session is to explore the meaning that consumers attach to their spatial relationship with and spatial movement through the marketplace, particularly when experiencing spatial impediments. The topic is approached from a theoretical perspective propelled by existing theories in sociology, geography and semiotics. The social construction of the market defines normative “movement” and thus identifies consumers who cannot participate like everyone else as *other*. Social exclusion is a term used in policy discourse in relation to individuals that are outside the mainstream of the labor and citizenship (e.g., illegal workers, the homeless). At its heart, social exclusion reflects both isolation and segregation (Sommerville 1998), elements that normally reflect *abstract* notions of separateness as well as physically grounded *spatial* disconnection. Research in the area identifies physical disconnection as a manifestation of abstract separateness (e.g., unwillingness to leave the neighborhood due to language barriers) or as impediments to inclusion (e.g., the persistence of enclaves of minorities) (Massey and Denton 1993).

Using ethnographic and interview methods, the presenters investigate the meaning of moving through market space to engage in exchange via the lens of consumers who face specific challenges, either in mobility restrictions, homelessness, or information processing deficits. The three papers address questions of 1) how consumers adapt to being denoted as *other* in this setting, 2) how they resist this demarcation, and 3) how they redefine the market space to make it inclusive rather than exclusive. Building on existing theory in socio-spatial relation that addresses the spatiality of social life (Richardson and Jensen 2003) and extending this thinking into the spatiality of market exchange, the presenters draw from their empirical work to argue that the inherent nature of space, the control of the space, norms and rules about space, and even the language of space are socially constructed and closely linked to power.

EXTENDED ABSTRACTS

“Expanding Retail Spaces: Website Accessibility for Consumers with Visual Impairments”

Carol Kaufman-Scarborough, Rutgers University
Terry L. Childers, University of Kentucky

“When I go to store I find it embarrassing I can’t find what things are without touching them and have to ask for help and sometimes people can’t or will not help. I have to go with people. Shopping online lets me be independent (Teresa, 24).

When examining the experiences of persons with a specific disability, such as vision impairments, it is unclear exactly what their experience of shopping space has been and what, if any, new opportunities are offered by shopping online. The goal of this study is to address these questions building on the work of Baker (2006, 2001) and her work with visually impaired consumers in the physical marketplace.

As Baker (2006) notes, retail store “spaces” are designed assuming that most customers have usable vision and are able to fully experience the colors, décor, displays and signage. Essentially, the physical shopping market defines normative “movement” as being able to drive, walk, or take mass transit to shopping locations, and often is constructed so that the shopper relies on visual cues to determine their route through malls and stores. Moreover, a basic assumption is that all customers can search on their own, navigate through each store, and respond to store cues in making their decisions and purchases. Nothing is further than the truth for consumers who are have significant visual impairments, since the limitations and effort of traveling to the retail space, navigating through unseen or poorly-seen space, and receiving help in shopping may undermine the degree of independence or normalcy that these consumers experience.

The built or physical environment has been criticized as being designed from an “ableist” perspective, assuming that physical places are constructed so that persons who are able-bodied will participate (Chounard 1997; Imrie 1999). Basically, persons who are not able-bodied are not expected to participate, and thus are not “expected customers.” Such criticisms are typically made of the built environment rather than the virtual world of the Internet. In essence, shopping in cyberspace “should” be like taking a trip to the mall without the physical limitations found in most built shopping spaces. That is, it allows persons with disabilities “to transcend the issues of time, space, communication, and the body” (Seymour and Lupton 2004), and more importantly, allows the shopper to feel “normal” in that setting (Baker 2006).

Depth interviews were conducted with 45 persons who have visual impairments in order to examine their comparisons of physical spaces with the virtual space of online stores. Each was interviewed for approximately 30 to 60 minutes concerning their use of the Internet, their assistive technologies, and the web access issues that they felt were most important. The participants had web access and varying degrees of experience and expertise with online shopping. Results show that multiple themes emerged from analysis concerning individuals’ concern for independence, empower-

ment, and quality of information that is engendered through availing themselves of online access to shopping. Additionally, interviews identified a series of impediments to their online shopping experience. These impediments included; the nature of website construction (the lack of Alt tags on pictures), the need for assistance from others to fulfill certain online purchasing tasks (e.g., completing purchase forms), and in many cases, the ambiguity of product descriptions (e.g. ambiguous color names).

Preliminary analysis indicates that the question as whether they choose electronic markets over physical markets because of problems with bricks and mortar stores is a simplistic one. There are multiple issues involved.

- Independence: Many enjoy shopping in physical stores, but complain that their shopping trips are limited to “purpose-driven” outings restricted to the sections of their destination stores that either store employees or personal assistants choose for shopping. Areas with spatial challenges are avoided, eliminating the merchandise from these areas as well.
- Empowerment: Some gather and analyze product and store information online, with subsequent purchase in stores or by telephone. Browsing becomes possible for the first time.
- Improved quality of information: The web provides information that is inaccessible in many store spaces, such as reading product labels (such as, through screen readers) or enlarging patterns and designs.
- Less information: Unable to touch certain types of products for examination.
- Unanticipated problems in storespace: They indicate they may avoid the physical store space due to problems that they have encountered, such as spilled items that present dangers to their guide dogs.

When Baker’s dimensions of normalcy are considered:

- Online shopping not only maintains a feeling of participating in the marketplace for persons with visual impairments. In many instances it increases it.
- To some extent, online shopping allows them to feel treated as individuals, but they prefer personal contact in stores for social interactions.
- Online shopping allows them to feel empowered with new access to information.
- With online shopping, persons with visual impairments feel a more equal access to products and information. A new equal access to written information such as labels can be found.
- Websites are uneven in their accessibility and may assume visual scanning by the user. Information may lack necessary detail to be useful. Designs of certain web elements may not be compatible with assistive technologies.

Our analysis gives new insights into spatial tradeoffs that persons with visual impairments make when choosing a marketplace for their shopping purposes. It is not an “either-or” decision, but instead each type of marketplace presents its own opportunities and challenges.

“The Homeless Renegotiating Marketplaces: Hey! Why is Your Store in Our Living Room?”

Natalie Ross Adkins, Creighton University

Susie Pryor, University of Nebraska

Hill and Stamey (1990) boldly ventured into a previously unresearched area in the consumer behavior field when they sought to understand how the homeless acquire possessions and attach meanings to them. Their research vividly stresses how the homeless face multiple structural impediments to basic interactions within traditional marketplaces (Hill and Stamey 1990; Hill 1991). Homeless consumers routinely experience multiple disadvantages and increased risks for victimization due to their social structural location and “restricted access to housing, employment, and public spaces” (Gatz 2004; Roschelle and Kaufman 2004). Rising rates of homelessness especially among families exacerbate these risks. The National Alliance to End Homelessness estimates the magnitude of people without domiciles in the United States to approach nearly 3 million people per year and more than 750,000 people per night with more than half being comprised of homeless families (www.endhomelessness.org 2005).

For many domiciled consumers and consumer researchers, the homeless are invisible with only occasional glimpses into this reality offered when approached by a panhandler on a city street corner. Due in part to negative public sentiment, disengagement and self-marginalization, and harassment by society and police, many of the homeless avoid use of public spaces for shelter and other living necessities (Hill and Stamey 1990). In sharp contrast, this research examines the socio-spatial dynamics of homelessness in a well-defined downtown retail area (DRAs).

Marketing scholars’ understanding and investigations of the interplay of social and commercial elements in marketplaces, like DRAs, remain limited, although a growing body of work recognizes DRAs’ roles in community development and life (Shils 1997; Presti 2003). Drawing upon the marketing literature on co-production which primarily focuses on its proximal benefits for co-producers (i.e., efficiencies for marketers and services from products for consumers; Bendapudi and Leone 2003; Vargo and Lusch 2004), this research examines other less proximal and more general consequences, including the production and negotiation of marketplace meanings by merchants, domiciled consumers and the homeless inhabiting the research area. We will discuss how in a given community, the creation of meaning is renegotiated through the symbolism of the marketplace and is a source of identification for those involved (McAlexander, Schouten and Koenig 2002).

Specifically, we explore how the homeless in a downtown retail area negotiate and survive in the physical space of the marketplace which was neither “designed nor intended for residence and basic subsistence activities” (Harter, Berquist, Titsworth, Novak and Brokaw 2005, p. 315). Similar to the findings of Adkins and Ozanne’s (2005) study of consumers with low literacy, homeless consumers who successfully reject and renegotiate the negative label and derogatory identities associated with it feel empowered to exert control, choice, and influence in the marketplace (Buffalo and Rogers 1974; Hill and Stamey 1990; Pryor 2006).

The study site was a downtown retail area in a Midwestern city with a population of approximately 90,000. The area encompasses 27 block sides with 130 stores, service establishments, and restaurants. Data collected over a 3 _ year period using multiple ethnographic methods including participant and non-participant observation; semi-structured field interviews; long interviews with retailers and domiciled consumers; and secondary data collection of artifacts (including marketing collaterals and communication materials).

Marketers and consumers who used the DRA in different ways expressed different views about its meanings. These meanings were social, cultural, economic, and political, as well as consumption-related, in nature. Additionally, tensions and inconsistencies in their views about the marketplace's formal, commercial, festive, and other qualities exist between the various groups (Pryor and Grossbart, forthcoming; Peñaloza 2000; Sherry 1990). Yet, there are socially acceptable variations in marketplace meanings because, as it has in other settings, the resulting social capital in the area fosters tolerance or reconciliation of differences (Flora and Flora 1993).

Historically, the merchants and the domiciled consumers in the DRA organize and support charitable events designed to provide resources for the needy and homeless. However, more recently, the merchants in the area have become actively involved in pressing the city to move social service resources out of the DRA and for the passage of additional ordinance and policies governing the transient population and to protect the aesthetic qualities and appeal of the downtown area. As one merchant explained,

"I am entirely tired of the street musicians who hang out across the street from my business," he said. "Many of my customers are senior citizens who find them intimidating and frightening." (FN, DLI meeting, 2001)

We explicate the manner in which several of the homeless engage in co-production with an established spatial area and add "flavor" to the marketplace environment. By actively co-opting marketplace symbols and structures for their own purposes, such as "homeless Santa" who uses the commercial symbolism of Christmas to panhandle and street musicians who sit by entrances to retail outlets singing and playing for a coin, the homeless in the DRA are challenging local merchants efforts to define the space without them.

"Marketplace Power Struggles: Families Confronting Spatial Limitations"

Marlys Mason, Oklahoma State University

Teresa Pavia, University of Utah

As most parents of newborns discover, the ability to move through the marketplace that most able-bodied adults take for granted is immediately changed by the arrival of a child. Over time, families become adept at meeting the physical challenge of engaging as a parent-plus-child consumer aided, in part, by marketplace adaptations such as car seats that integrate into a carriage or parking spots reserved for parents with small children. While physical impediments may be overcome or accommodated, various marketplaces, are understood to be off limits to the parent-with-child consumer due to social norms (e.g., a very fancy restaurant), legal restrictions (e.g., bars or strip clubs), or environmental stresses (e.g., extreme adventure travel). For a variety of reasons most people believe such social exclusion policies are not only acceptable, they are commendable and proper.

The dark side of social exclusion, however, is condemned. Laws and policies have been enacted to ensure equal access to marketplace regardless of diverse attributes (e.g., race, ethnicity, disability). Sellers portray their spaces as accessible and open to all, with mixed races, ethnicities and genders commonly appearing in promotional materials. Is the space of the market really accessible and open to all though? This question raises two issues: can the individual *physically* move into the marketplace, and is the individual *socially excluded* from the marketplace. Families with a child who has a disability provide a window into the complex

relationship that consumers have with the *space* of the market, exclusions consumers experience, and notions of activities that are appropriate for the public sphere.

In the U.S. approximately 20% of the 54.4 million non-institutionalized children between 5 and 20 years of age are designated as having some type of disability (US Census Bureau 2005, Table 34). Although the disabilities in question span a wide range of cognitive, physical, and sensory disabilities, all families of children with special needs remain challenged by barriers that the marketplace presents for far longer than the average family with a typically newborn or able-bodied child.

Using a phenomenological approach, this paper explores the lived experience of families with a special needs child in marketplaces constructed with 'normal' consumers and families in mind. Following prolonged immersion into the special needs community, twenty two in-depth interviews were conducted, with each lasting approximately 1-2 hours. The interviews were largely unstructured using broad guiding questions as initial prompts.

Specifically, we investigate 1) the spatial challenges (both physical and social) that families face in marketplaces, 2) the means that families use to adapt to these challenges, and 3) identifiers of the "other" that consumers experience in the marketplace.

This research has descriptive findings that center on concrete elements of spatial exclusion, and theoretical findings that address the abstract exclusion experienced by the "other". On the concrete level, all informants describe retail environments as not understanding special needs children and families when designing the marketplace. For example, they discuss too few handicapped parking spaces, inappropriate store services and displays targeted to normal kids that trigger inappropriate outbursts in those with behavioral impairments. These negative consumption experiences elevate the family's awareness of the disability and at times create such difficulties that the family voluntarily excludes themselves from the marketplace. To accommodate the special need, our informants discuss making adjustments in fundamental and specific areas such as shopping (e.g., locations, time, medium), travel and vacations, recreation and leisure, vehicles, living spaces, celebrations and holidays, etc. They also discussed larger shifts related to consumption including employment choices that allow the parent the flexibility to work, and major shifts in family roles, particularly roles related to movements between different spatial spheres of the family (e.g., teen doing routine grocery shopping, a shift to traditional gender roles of the mother at home, care giving, and the father outside the home as breadwinner).

The theoretical contributions of this research center around persistent inversions of commonly held notions of spatiality that these families face. Scarry (1985) argues that a unique aspect of pain derives from "an almost obscene conflation of public and private" in which activities that are normally private (such as crying or vomiting) become public, and activities that are normally public (such as eating or conversation) must be done in solitude. The pain of the marketplace for consumers living with physical/mental limitations arises in part from public aversion to a body that does not follow convention public/private norms. At the same time, informants express distress that the acutely visible limitations they display appear to evoke no market response in terms of new products, environments or understanding.

Demarcated as the *other*, parents report both avoidance and resistance, depending on the situation. For example, informants move between in-your-face, up close and personal advocacy for their child, and striving, conformist behaviors such as dressing the child in brand name clothes for outings so he/she looks "cute". Parents report managing their space in ways that increase privacy

and decrease the judgmental public stare: some assume health care tasks specifically to remove other providers from the home, some limit face-to-face confrontations by employing e-mail or letters, and many refuse to meet other shoppers'/patrons' eyes when in public. Parents report assertively managing their environment, but report that most victories are hard won and often transitory. That is, small accommodations are made, but there are no changes to the system to formalize the adaptation.

Our analysis highlights the symbolic meanings that the families attach to their spatial limitations in the marketspace and their adaptations. Consumer resistance is traced both as straightforward complaining and as more subversive "rule bending"; consumer conformance is noted primarily as an effort to fit in and be accepted. These informants speak for other consumers who redefine what they want and will accept from the marketspace and in doing so simultaneously redefine spatiality in their consumption and demand a renegotiation of power between themselves and the marketplace.

SPECIAL SESSION SUMMARY

How Long Does it Seem? Advancing the Understanding of Past and Future Time Perception

Robyn A. LeBoeuf, University of Florida, USA

SESSION OVERVIEW

Consumers often must estimate the lengths of time intervals when making decisions. For example, they might forecast the time until a payment will be received when evaluating interest rates, or might estimate how long they waited in line when deciding whether to revisit a store. These estimates are likely to be influenced by factors beyond objective duration, such as judgments of frequency or likelihood are often biased by ostensibly irrelevant factors (Gilovich, Griffin, and Kahneman, 2002). To further our understanding of how consumers perceive time, the papers in this session explore factors that make time intervals of equal objective length seem long or short. Specifically, these papers examine how the events involved in a time interval affect perceptions of that interval's length.

Faro, McGill, and Hastie begin by examining how perceptions of a past time interval are affected by the relationship between the events denoting the interval's beginning and end. They find that intervals seem shorter when their beginning and ending events have a strong causal relationship than when the causal relationship is weaker; they also find that the type of cause connecting the events heavily influences length judgments. Diehl, Levav, and Zauberman augment this finding by focusing on the *number* of events perceived to have been caused by the beginning event. They find that intervals begun by an event that triggered many subsequent events seem longer than do intervals begun by an event that triggered few events. Finally, LeBoeuf and Simmons extend these findings to perceptions of future time. Building from the suggestion that past intervals seem longer when they contain more events, these authors investigate whether perceptions of future intervals are similarly affected by whether the intervals seem full of events, as opposed to empty. Daniel Read serves as the discussant; his work on intertemporal choice, and particularly on the sensitivity of discount rates to the framing of time intervals, lends him an ideal perspective on this work.

This session highlights common themes emerging from these independently developed streams of research, thereby facilitating general conclusions about factors affecting time perception. These papers thus shed light on important practical issues, such as how consumers perceive, for example, the length of time that they waited for a shipment to arrive or the length of time that they must wait for an investment to mature. Interestingly, the papers presented here also suggest ways in which past and future time perception differ, highlighting the need for additional research to examine whether other established properties of past time perception hold in the relatively unexplored domain of future time perception. More broadly, this research has implications for theories of memory, planning, and intertemporal choice, as discussed in the papers that follow.

EXTENDED ABSTRACTS

“How Long Did That Take? The Role of Causal Attribution in Estimating Elapsed Time”

David Faro, London Business School

Ann L. McGill and Reid Hastie, University of Chicago

Consider the time that elapses between a cause and an effect. For example, the time between using a product and experiencing its benefit, placing an ad and seeing its impact on sales, or developing

a new product and, in doing so, triggering a competitor's response. Understanding retrospective judgments of the time between cause-effect events is important because people rely on these when they later face similar situations (“How long shall I wait for a pain killer to show its effect before I take another pill?”) and when they evaluate efficiency of actions (“How quickly did Microsoft react to Apple's introduction of iPod?”).

Recent research has shown that people rely on their impressions of the strength of the causal relationship between two events as a cue to judge the time between them. A stronger perception of a causal relationship results in shorter judgments of time (Faro et al. 2005). The present work examines the psychological underpinnings of this tendency. We suggest the time-shortening effect of causality reflects a default physics-based view of causal mechanisms. Temporal proximity is an important cue in perceiving causality between physical objects (e.g., Michotte 1963). Given its prominence and early use, the temporal proximity cue might be generalized to other domains (Heider 1944). However, recent research showed that people do not always expect events to be proximate in time in order to link them causally. If the mechanism by which the events are believed to be related entails temporal delay, or a causal force that does not lose its impact over time, the events can be seen as causally related in spite of the lack of temporal proximity (Brickman et al. 1975; Buehner et al. 2003; Haggmayer and Waldmann 2002).

In the first two studies we manipulate participants' salient mental model of causality and examine its effect on time estimates. Building on the above research, we hypothesize that if causes are perceived as factors that lose their force over time, a strong impression of causality will result in shorter time estimates. If, however, causes are perceived as factors that have stable or increasing force over time, an impression of causality will not shorten time estimates.

In the first study participants made elapsed time judgments for causally related pairs of events. Prior to making time estimates, participants were asked to choose (from provided lists) either a) which emotions are associated with the actors in the events, *or* b) which trait characteristics are associated with the actors in the events, *or* c) which situational factors are associated with these events. In a fourth, control condition, participants made time estimates without any choice task. We predicted that emotions would be perceived as a causal force that dissipates over time and hence focusing on these would result in shorter time estimates. In contrast, focusing on traits and situational factors, which tend to be causal forces that have stable impact over time, should result in longer time estimates. Results were in line with these predictions.

In the second study, prior to making time judgments, participants were asked to explain in writing the workings of three physical processes or three biological processes. We hypothesized that thinking about physical processes would trigger a view of causal forces that dissipate over time while thinking about biological processes would trigger a view of causal forces that increase over time. Participants in the physics-prime conditions judged the subsequent pairs of events to be closer in time than participants in the biology-prime condition.

The first two studies manipulated the type-of-cause and showed that the impression of causality shortens time for dissipative causes (emotions, physical forces) but not for stable or increasing causes

(traits, biological forces). This suggests that the inference of short time from causality is a heuristic driven by people's dominant physics-based view of causality. Previous research has shown that people who are low in NFC are more likely to use heuristics for judgment. This suggests that people who are low in NFC would give shorter time estimates for causally related events than people high in NFC. Participants in the third study made elapsed time judgments for causally related pairs of events, but also for pairs that were pre-tested to be causally *not* related. They then completed the NFC scale (Cacioppo and Petty 1982). Results revealed an interaction between NFC and type of event-pair. For the non-causal events, there was no difference between the time estimates for the high and low NFC participants, suggesting that NFC does not affect time estimates in general. For the causal pairs however, as predicted, low NFC participants gave significantly shorter time estimates than the high NFC participants.

The three studies reveal a common pattern. Participants gave shorter time estimates when they focused on dissipative causes. In addition, participants who tend to rely on heuristics gave shorter time estimates for cause-effect pairs of events. The findings suggest the time-shortening effect of causality reflects a default physics-based view of causal mechanisms where the force of a cause dissipates over time. The physics metaphor is a prominent mode of thinking about causality in other contexts and domains (Heider 1944). This form of thinking about causality and its shortening implication for time judgment might underlie the underestimation of time and the impatience with causal processes observed in many contexts.

"1995 Feels so Close Yet so Far: The Effect of Event 'Markers' on the Subjective Feeling of Elapsed Time"

Kristin Diehl, University of Southern California

Jonathan Levav, Columbia University

Gal Zauberman, University of Pennsylvania

Why do some events feel more distant than others? Past research has documented a number of factors contributing to this phenomenon, reporting positive correlations between feelings of recency and greater event importance, vividness, and emotionality. But what about events that are equally vivid or emotional? We

argue that equally vivid or emotional events can feel more or less distant in time depending upon the perceived number of subsequent events precipitated by the target events. We call these subsequent events "memory markers." We hypothesize that events associated with a larger number of markers will elicit feelings of greater temporal distance than equally vivid events that are associated with fewer markers.

Associative network models of memory predict a positive relationship between the number of events subsequent to a target initiating event and the activation of the target event. Greater activation—and stronger memories—should reduce feelings of temporal distance because people typically hold lay theories about the positive relationship between memory strength and memory recency (Schwarz 2005). We predict the opposite: Associating a greater number of subsequent events should divide time into more discrete segments, which will in turn increase the perceived temporal distance of the initiating event. This idea is most in line with the conveyor belt model of memory (Murdock 1974), which suggests that, when trying to assess an event's timing, people scan backwards from the present to the target event. Recency is a function of the memory traces encountered in the scan. This model, however, was tested mainly in laboratory settings using simple word list tasks and has not been extended to the kind of emotional, real life experiences that are of interest to us here.

Note that we are not interested in people's assessments of the exact time an event happened; instead, we focus on how long ago an event *feels* like it happened. In contrast, prior research has focused on people's estimates of elapsed time by comparing respondents' judged timing of an event with its actual calendar date (e.g., Thompson, Skowronski, and Lee 1988). Using the dating method, researchers have identified the phenomenon of "telescoping," which refers to people's tendency to report distant events as having occurred more recently than they actually did (forward telescoping) or the tendency to report that more recent events occurred in the more distant past (backward telescoping; e.g., Morwitz 1997).

We conducted a computer-based survey to investigate our marker hypothesis. Seventy-seven undergraduate students were asked to indicate how recent 19 vivid, national and school-specific public events felt to them. The study was conducted in November 2004 and all target events had occurred in the 2003 calendar year. For each event, participants first indicated their subjective feelings of when the event had occurred using a scale anchored at 1 (feels very recent) and 15 (feels very distant); they could also indicate that they were not aware of the event. Participants assessed their feelings of recency for all 19 events. They then rated the extent of their feeling that each event caused subsequent events on a scale from 1 (triggered no event) to 7 (triggered many events). They also indicated how well they remembered each of the target events (1—not at all, 7—perfectly) and how emotional they judged the event to be (1—not at all emotional, 7—extremely emotional). The order of the events participants responded to was randomly determined for each measure. Finally, they were asked to indicate the month and year that the event occurred.

Accuracy Results. While we were mostly interested in respondents' subjective feeling of elapsed time, we assessed dating accuracy by calculating the difference in months between the dates provided by the respondents and the actual dates on which the events occurred. Using this measure, positive numbers indicate backward telescoping and negative numbers indicate forward telescoping. Across all events of which participants were aware ($n=1150$), we find some evidence of backward telescoping: participants dated the events as having occurred about 2.5 months earlier than they actually did ($t(1149)=7.66, p<.0001$). Unsurprisingly,

dating accuracy increased the more memorable the event ($F(1,76)=13.29, p<.001$), but did not depend on the how emotional the event was judged to be ($F(1,76)=0, p>.8$) or the number of subsequent events that had been triggered ($F(1,76)=0, p>.8$).

Subjective Feeling of Distance Results. Our main prediction regards the *subjective* feeling of elapsed time. Subjective feelings of elapsed time were positively and significantly correlated with the reported ($r=0.25, p<.001$), as well as the actual ($r=0.15, p<.001$), number of months passed. However these correlations were small, suggesting that factors other than objective time may drive feelings of elapsed time.

We performed a median-split based on participants' assessments of the number of events triggered by a target event. For each event we calculated the median number of subsequent events reported. We then determined whether for a given participant an event was perceived as having triggered many versus few subsequent events relative to that median. Next we estimated the effect of this dichotomous variable on participants' experience of elapsed time, while controlling for actual time passed, event memorability, and event emotionality. As one would expect, actual elapsed time had a significant positive effect ($F(1, 76)=35.41, p <.0001$) and event memorability had a significant negative effect ($F(1, 76)=44.39, p <.0001$) on how distant the event felt to participants. Emotionality of the event did not have a significant effect ($F(1, 76)=1.77, p>.18$). Since emotionality and memorability were significantly correlated ($r=0.52, p<.001$), multi-collinearity is a concern. However, estimating the same model excluding memorability also does not reveal a significant effect of emotionality at conventional levels of significance ($F(1, 76)=2.39, p>.12$). More important for our prediction, however, events perceived to have triggered many subsequent events were felt significantly more distant than events that triggered few such events ($F(1, 76)=7.64, p <.01$).

In sum, this study tests whether the perceived number of subsequent events triggered by a target event affects the subjective feeling of time elapsed since the target event. Our findings support the notion that feelings of elapsed time depend on the perceived number of memory markers, even after controlling for the actual time elapsed since the event as well as the event's emotionality and memorability. To test our explanation further, in our next experiment we will manipulate the number of subsequent events that are associated with the target event.

"Perceptions of the Length of Future Time Intervals: A Simulation Perspective"

Robyn A. LeBoeuf, University of Florida

Joseph P. Simmons, Yale University

Consumers often make decisions about future events and transactions. These decisions range from the relatively mundane (e.g., scheduling dental appointments) to the potentially life-altering (e.g., saving for retirement). While researchers have examined specific questions about how consumers discount future dollars

(see Loewenstein, Read, and Baumeister 2003, for a review) and plan future tasks (Buehler, Griffin, and Ross 1994), relatively little work has examined the more basic question of how consumers perceive future time. Even the influential construal-level theory (Trope and Liberman 2003), which discusses how consumers react differently to near-future versus far-future events, is relatively silent on the factors that might make a given event *seem* near or far. In this paper, we explore such factors to understand what makes future time intervals of equal objective length seem relatively long instead of short.

Our work builds on research on past time intervals, and particularly on the finding that past intervals containing many events tend to be estimated as having lasted longer than intervals containing relatively few events (Fraisse 1984). We investigate whether a similar pattern characterizes the perception of future time intervals. Our work also builds on the recent finding that extent-described future intervals (e.g., "four months") tend to be perceived as longer than equivalent date-described intervals (e.g., "June 1 to October 1"), potentially because the former descriptions direct attention to interval length in a way that the latter do not (LeBoeuf 2006). This finding suggests that consumers may be more sensitive to nuances in interval presentation when intervals are described by extents instead of dates.

We thus predict that future time perception should be affected by whether future intervals seem "full" instead of "empty," and that fullness effects should mainly manifest for extent-described intervals. More specifically, our hypothesis is an *interval-simulation* one: those facing extent descriptions may naturally simulate interval passage whereas those facing dates may not; this may lead participants facing extents to be more affected by factors, such as the number of intervening events, that might impact simulations to make an interval "feel" long or short.

Study 1 therefore had a 2 (interval description: date or extent) x 2 (number of events: 0 or 6) x 2 (interval length: four or six months) design. Length was varied within subjects, and the other factors were manipulated between subjects. Some participants were asked to list six things that would happen during a presented interval, whereas others were not; all participants then rated the perceived length of that interval on a seven-point scale ranging from "seems very short" to "seems very long." As predicted, filling date-described intervals did not impact length perceptions. However, filling extent-described intervals made those intervals seem *shorter* than did contemplating empty intervals. Thus, the perceived length of extent-described intervals was sensitive to interval fullness, but, unlike full past intervals, full future intervals seemed shorter than empty ones. This finding makes sense if people naturally simulate the passage of extent-described intervals: Simulating an empty interval may suggest that the interval will feel like a long wait. Simulating a full interval, however, may lead to perceptions of a busy interval passing by quickly.

Study 2 explored the impact of the type of event with which participants filled extent-described intervals. As before, prior to rating interval length, some participants contemplated an empty interval, whereas others were asked to fill the interval with any six unspecified events. A third group filled the interval with six "rare" events, and a final group filled it with six "frequently occurring" events. We predicted that filling the interval with frequently-occurring events would make the interval seem busy, and hence shorter, whereas filling the interval with rare events would make the interval seem empty and long. We found once again that filling the interval with events of unspecified frequency made the interval seem shorter than did filling it with no events. We also found, as predicted, that filling the interval with frequent events made it seem shorter than did filling it with rare events. These results thus suggest

that length judgments depend not only on whether participants fill the intervals, but also on inferences about how full the intervals seem, with fuller-seeming intervals appearing shorter.

An alternative explanation is that length judgments are driven by difficulty, rather than perceived fullness. It may be harder to list rare than frequent events; increased difficulty, rather than decreased perceived interval fullness, may have led intervals in the “rare” condition to seem longer. Study 3 pitted these two explanations against each other by requiring participants to either list five or twelve events in an upcoming six-month interval. If fuller intervals seem shorter, the twelve-event interval should seem shorter than the five-event interval, but if easy-to-fill intervals seem shorter, one would expect the opposite (as participants found it easier to generate five events than to generate twelve). Twelve-event intervals were rated as shorter than five-event intervals, suggesting again that perceived fullness drives length judgments.

Thus, our findings support an interval-simulation hypothesis: when judging the length of an extent-described interval, participants may mentally simulate interval passage. Intervals that feel full and busy seem to “fly” by and are judged as short. Intervals that feel empty are judged as long. Individuals facing intervals described by dates seem less affected by these factors, perhaps because the date format does not lend itself to natural simulation. These results have implications not only for the psychology of time perception, but also for consumer decisions about future events. Consumers scheduling future services, for example, may be affected by how long the intervening interval seems (and thus, by whether that interval is presented as full or empty). Similarly, discount rates will likely be affected by factors, such as those identified here, that increase or decrease perceived interval length. This investigation into future time perception should aid theoreticians and practitioners alike in their attempts to understand and anticipate consumer behavior.

SPECIAL SESSION SUMMARY
The Effects of Mortality Salience on Consumption

Michal Herzstein, University of Delaware, USA

SESSION OVERVIEW

Understanding whether and how consumers react to the possibility of dying is becoming an important issue in marketing. Car accidents, terror attacks, cancer, and other causes of death are becoming more salient in individuals' minds due to their increasing frequency and extended media coverage. Terror Management Theory (TMT; Greenberg et al. 1997) provides an explanation for behaviors exerted when individuals are prompted to think about mortality. TMT suggests that when individuals are reminded of their death they experience existential anxiety, which they try to relieve by bolstering cultural world views and/or enhancing self-esteem. In Western cultures, consumption is an important source of self-esteem. The research in this session contributes to the literature by examining the impact of mortality salience on different consumption and choice patterns. In particular, the first paper shows that different death causes impact differently consumption behavior and product evaluation, as a result of a desire for control. The second paper provides an in-depth view into the moderating effect of mortality salience on the desire for control. The third paper investigates how and why mortality salience changes consumption choices and focus.

The first paper, by Herzstein and Horsky, compares predictions drawn from TMT with how individuals in terrorized areas behave. Three experiments and numerous in-depth interviews were conducted in Israel where terror attacks are frequent. The authors find that these attacks have caused individuals to behave in ways that presumably exert some individual control over the uncertain situation (in order to mitigate their fear of death and continue with their lives). This systematic change in behavior affects products' evaluations and choices. Specifically, luxury items that symbolize high status within the culture were more appealing to participants who were prompted to think about death (by causes such as cancer or car accidents) compared with those who were prompted to think about dying in a terror attack. Luxury products with characteristics that may allow individuals to feel more in control of their environment were also rated higher on the luxury scale by those in the death condition, but those in the terrorism condition stated higher purchase intentions for those products. Individuals' locus-of-control moderated this relation.

In the second paper, Ferraro and Agrawal suggest that one way to relieve anxiety resulting from mortality salience is by bolstering self esteem through desiring and exerting control. Having a greater desire for control counteracts the lack of control over one's death. The authors test this prediction in two experiments. In study 1, they directly measure desire for control and in study 2, they compare the benefits individuals may experience when choosing from a larger set with the psychological costs of such a choice. They find that when mortality is salient, having "too much choice" leads to greater satisfaction than having only limited choice.

The third paper by Mandel and Smeesters examines how mortality salience affects how much consumers buy and how much they spend. Across five studies the authors demonstrate that individuals who are primed to think of their mortality choose to purchase more of the same product for a weekly consumption, buy more products within a food category and spend more money than individuals in the control condition. The authors attribute these results to consumers' need to "die broke" and not to their need to endorse the cultural norm of consumption. The effects of mortality

salience on consumption were more pronounced for consumers with low self esteem, as spending their money makes them feel good again.

EXTENDED ABSTRACTS

"Marketing under Frequent Terror Attacks"

Michal Herzstein, University of Delaware

Sharon Horsky, IDC, Israel

Becker (1973) suggested that fear of death must be present in all human functioning so that the organism is able to arm itself toward self-preservation. However, Becker added, it can not be present constantly in an individual's mental functioning; it must be repressed so he can function normally. Building on that, Terror Management Theory (TMT; Solomon, Greenberg and Pyszczynski 1991) posits that events making an individual's death and mortality more salient lead to existential anxiety. TMT suggests two mechanisms to relieve this anxiety, defending one's cultural worldviews and bolstering one's self esteem. That is, individuals may avoid experiencing existential anxiety by making an enduring mark on the world, for example, through acquisition of items that symbolize high value within their culture (Mandel and Heine 1999). Despite Becker's suggestion that an individual should repress his/her fear of death to allow normal functioning, there are situations in which repression is difficult. For individuals who live in terrorized areas, not thinking about their mortality is practically impossible. For instance in Israel, since September 2000 there have been over 7,000 civilian casualties from more than 80 terror attacks (taking into account population size, this is equivalent to 445,000 casualties in the U.S.). Attacks occurred in buses, coffee shops, restaurants, shopping malls, markets and streets of major cities.

We suggest that when terror attacks are frequent and therefore death is constantly in mind, individuals account for the possibility of dying in a terror attack in their daily functioning, and systematically change their behavior. We confirmed this hypothesis through in-depth interviews we conducted with men and women of diverse ages that live in different cities in Israel. Further, we analyzed secondary data—interviews that were conducted in Israel in 2002. We found that interviewees consistently spoke of ways by which they are managing the risk of terror, and of their need to feel in control. For example, a young man said "when I go out I go only to a specific pub, because it has one door, no glass walls and I sit in the back. So if there is an attack, by the time the suicide bomber comes, I will be able to run away". That is, when the possibility of death is constantly in people's minds, they try to control it by behaving in a calculated manner.

In this research we show that predictions drawn from TMT regarding consumption behaviors do not hold when terror is frequent. Specifically, TMT suggests that concerns about death increase the appeal of products that imbue their owners with status. However, we show that this only occurs when individuals are prompted to think about death as a result of accidents, health related etc. This will not be the case when individuals are prompted to think about their death as a result of terror attacks. We tested the above hypothesis using luxury and non-luxury products in three studies. Participants were undergraduate students at a private college in Israel. In our studies we manipulated mortality salience to create three conditions: terrorism, death (other means of death), and

control (visiting the dentist). We followed standard mortality salience manipulations. The choice of Israel is straightforward as consumers live with daily terror; nevertheless given the globalization of terror the results of this research are indicative for other places.

Following Mandel and Heine (1999), in study 1 after the manipulation and distraction task, participants received four advertisements: two for luxury products (Jaguar and Rolex) and two for non-luxury products (local brands of pretzels and soft drink). After seeing each advertisement, participants were asked three questions (that were combined with good reliabilities): effectiveness of the advertisement, interest in product category and purchase intention for the specific brand. We found that Jaguar appeals more to those in the death condition compared with those in the terrorism and control conditions (results for Rolex were directional and marginally significant). However, there were no differences in the appeal of the non-status products among the three groups. The first study confirmed that while participants in the death condition follow predictions drawn from TMT, participants in the terrorism condition did not. As expected, participants in the terrorism condition did not find luxury products as appealing as those in the death condition.

TMT posits that the protection afforded by subscribing to cultural worldview confers a sense that the world is stable and controllable. According to Arndt and Solomon (2003), reminders of death should increase people's desire for personal control when they have faith in a cultural worldview. However, when faith in the worldview is tenuous, or a basic tenet of the cultural worldview is threatened, the world may seem chaotic rather than controllable. Under these circumstances, Arndt and Solomon found that mortality salience engenders less desire for personal control. However, we found that the frequency of terror attacks has led individuals to behave in ways that presumably exert individual control over an uncertain situation. Further, their need for controllability impacts their products' evaluations and changes their consumption patterns. Therefore, we suggest an exception to our findings from study 1: when high-status products are perceived as fulfilling consumers' controllability need, those in the terrorism condition will state higher purchase intentions but those in the death condition will state higher evaluations. Therefore, the products will be rated higher on the luxury scale by those in the death condition, but will be purchased more by those in the terrorism condition. Locus of control, which assesses the extent to which individuals believe they control their own destiny, will moderate this relation. Specifically, higher purchase intentions will be among those in the terrorism condition that have internal locus of control, as they believe in their ability to control their fate.

The second study featured a 2 (mortality: terrorism vs. death) X 2 (locus of control: internal vs. external) between subjects design. While the former condition was manipulated, the latter was measured. After the manipulation and distraction task, participants saw an advertisement for a high-end home espresso machine. We tested whether home espresso machines could substitute going out to coffee shops (where many terror attacks took place). Results show that participants in the death condition rated the espresso machine as more luxurious than those in the terrorism condition. However, those in the terrorism condition reported higher purchase intentions for espresso machines. In addition, we found that participants in the terrorism condition who have internal locus of control had higher purchase intentions compared with all others.

In the third study, we further investigated the need for controllability. The design was 3 (mortality: terrorism, death, control) X 2 (controllability: high vs. low) between subjects. Controllability

was manipulated by creating two advertisements for the same espresso machine, one suggesting that consumers can invite friends and family to their in-home coffee shop instead of going out (high controllability—no need to go to coffee shops where a terror attack may occur); and the other only mentioned that this espresso machine makes great espressos and cappuccinos (low controllability). Similar to study 2, participants in the death condition rated the espresso machine higher on the luxury scale compared with those in the terrorism and control conditions. Furthermore, those in the terrorism-high-control condition had higher purchase intentions for the espresso machine compared with the other conditions.

In sum, across three studies and numerous in-depth interviews we show that the possibility of an individual's upcoming death has a significant role in how he/she reacts and behaves. The need to feel in control of one's environment is more pronounced when the possibility of death by terror is high. As a result, predictions drawn from TMT do not hold—individuals do not need to perceive themselves as people of significance in the cultural drama to which they subscribe through acquisition of luxury items. The exception of this finding is products that are perceived to allow individuals the feeling of control over their destiny.

“Mortality Salience, Control, and Choice”

Rosellina Ferraro, University of Maryland

Nidhi Agrawal, Northwestern University

Given that people are exposed to death on a regular basis (e.g., a murder on the TV news, a movie with violent themes), it is likely that awareness of mortality can lead to systematic changes in people's behaviors. Recent research in marketing has also suggested that mortality salience (MS) can have an impact on consumption related behaviors, including regulatory choice (Maheswaran and Agrawal 2004; Ferraro, Shiv, and Bettman 2005).

Terror Management Theory (TMT; Arndt et al. 2004) posits that MS leads to existential anxiety and that people cope with this anxiety through bolstering self-esteem or cultural worldviews. The TMT research suggests that after mortality has been made salient, people will seek opportunities to express themselves, to behave materialistically, and to exhibit control over their environment. Based on these findings, we build the case that mortality salience may influence consumers' desire for more options in choice contexts.

A traditional view of choice suggests that more choice is better. Indeed, most people would prefer to choose from larger sets (Iyengar and Lepper 2000). Choice may be seen as an expression of control and empowerment, and so choosing from larger sets might be more desirable and empowering. Choice also provides a sense that people have the opportunity to select the best item and reinforces materialistic opportunities. But choosing from larger sets might also lead to psychological costs resulting from having “too much choice” (Iyengar and Lepper 2000) which manifest in lower satisfaction with the chosen alternative. As a result, while people like to choose from larger sets, they may be more satisfied with options chosen from smaller sets. However, there might be conditions when people are able to overcome the psychological costs of choosing and to experience the pleasures of too much choice.

We propose that MS alters perceptions of the psychological benefits (i.e., the opportunity to express control over one's environment) and costs (i.e., difficulty of making the choice) of choosing from large sets, resulting in the benefits overriding the costs. When mortality is not salient, there is no pressing need to exert increased control or acquire the best option so the costs of choice override its benefits. We suggest that MS will reverse set size effects such that

people under MS will be more satisfied with a chosen alternative if they chose it from a large (vs. small) set. When mortality is not salient, we expected to replicate past research showing that people are more satisfied with options picked from small (vs. large) sets.

Study 1 was a 2 (mortality salience vs. control) X 2 (small vs. large set size) design. MS was manipulated by asking participants to think about their own death or dental pain. Participants were presented with an assortment of six (i.e., small set) or 30 (i.e., large set) chocolates on the computer screen (Iyengar and Lepper 2000). They were asked to hypothetically choose a chocolate from the given assortment. Participants then rated their anticipated satisfaction with the option they selected and with the choice process. There was a significant interaction between MS and set size on satisfaction with the choice process. Participants in the MS condition with 30 options felt more positive about the choice process than did participants with only six options. Participants in the control condition felt equally positive in the small and large set conditions. Also, the results indicate a significant interaction between MS and set size on feelings of having too much or too little choice. In the dental pain condition, participants with 30 options felt they had too many options to choose from while participants in the six-option condition felt they had too few to choose from. This effect was attenuated in the MS condition, with both those having six-options and 30-options feeling more comfortable with the number of options available. This suggests that participants whose mortality was made salient were not overwhelmed by larger sets.

Study 2 was a real choice situation. It was a 2 (mortality salience vs. control) X 2 (small vs. large set size) design. MS was manipulated using drunk-driving advertisements. In the MS (vs. control) condition, participants read a print ad that explicitly mentioned (vs. did not mention) death as a possible consequence of drunk-driving. Participants were presented with an actual assortment of six or 30 chocolates and asked to choose and taste a chocolate from the assortment. Participants then rated their satisfaction with the selected option and with the choice process. Consistent with prior research, in the control group, participants' satisfaction with the chocolate was lower in the 30- as compared to six-option condition. In contrast, in the mortality salience conditions, participants' satisfaction was higher in the large set than the small set. This same pattern was found for participants' feelings about making the choice. There was also a significant interaction with regards to experienced regret. In the control group, participants experienced more regret at having selected the given chocolate in the large rather than small set condition. The effect was reversed in the mortality salience condition, with less regret exhibited in the 30 option condition.

What is the underlying reason why this would occur? We posit that the psychological benefits of more options override the costs under mortality salience due to increased perceived control over the choice environment. We expect that mortality salience increases people's desire for control and this then affects perceptions of control over the choice context. In Study 3, we examine whether mortality salience increases people's desire for control. Indeed, participants in the mortality salience condition expressed a greater desire for control. This effect persisted even after controlling for participants' trait anxiety. Furthermore, the differences in desire for control were not driven by mood.

These findings enrich the literature on both MS and choice. We identify how consumers might use choice situations to exert control and consequently deal with the anxiety produced from mortality salience. Our studies identify MS as a moderator of set size effects as well as explore when and how the benefits of "too much choice" may override its costs.

"Shop 'Til You Drop: The Effect of Mortality Salience on Consumption Quantity"

Naomi Mandel, Arizona State University

Dirk Smeesters, Tilburg University

Since September 11, 2001, Americans have become increasingly aware of their own inevitable mortality. Many people believe that "danger seems to lurk in every corner of life, from children's toys to McDonald's coffee, anthrax to secondhand smoke, West Nile virus to SARS." (Spencer and Crossen 2003). One way that individuals cope with their existential concerns is through their purchasing habits. For example, Mandel and Heine (1999) found that consumers exposed to death-related information demonstrated increased interest in purchasing luxury brands, such as Lexus and Rolex, which may reinforce a consumer's perceived value within a consumer-driven culture. These results have also been replicated among Japanese consumers (Heine, Harihara and Niiya 2002). However, because the above researchers did not control for the prices of the items chosen in their study, an alternative explanation for their results is that mortality salient individuals simply want to spend more money than do control individuals, regardless of the status of the products purchased.

To investigate this possibility, the current research examines whether exposure to death-related stimuli can affect the quantity of items purchased, as well as the dollar value of the purchase. Unlike the few studies that have previously addressed the effects of mortality salience on consumers (e.g., Ferraro, Shiv and Bettman 2005), this research focuses on the quantity of products purchased and consumed, rather than consumers' choices between a given assortment of products. In a series of experiments, we demonstrate that consumers who have been recently reminded of their own impending mortality wish to purchase higher quantities of products, such as food and drinks, than do their control counterparts. We also examine several possible explanations for our results. The various explanations we test are all derived from Terror Management Theory, because mortality salience can affect individuals through various paths.

In Study 1, the mortality salient (MS) group wrote a short essay about their thoughts regarding death, while the control group wrote a short essay about going to the dentist (both of which should result in negative affect, but not necessarily death-related thoughts). Participants were then told to circle all of the items from a prepared grocery list that they intended to buy in the next week. MS participants selected significantly more total items ($M=30.64$ vs. 23.28 ; $F(1, 30)=7.47$, $p<.01$) than did control participants, including significantly more fresh vegetables, fresh meats, canned meats, and frozen foods, as well as snacks and drinks. Therefore, it is unlikely that our participants simply wished to "eat, drink, and be merry" (Ferraro, Shiv and Bettman 2005), since they increased their consumption of both healthy and unhealthy foods. Study 2 utilized the same manipulation as study 1, but asked participants to imagine that they were hosting an informal party for friends, and to circle the items on a hypothetical shopping list of items they might buy for a party. MS participants selected more items from the grocery list ($M=25.64$ vs. 22.73 ; $F(1, 384)=4.84$, $p<.05$), spent more total dollars ($M=\$139.85$ vs. $\$125.02$; $F(1, 384)=4.70$, $p<.05$), and spent a higher percentage of their budgets ($M=131\%$ vs. 113% ; $F(1, 384)=5.84$, $p<.05$) than did control participants. Study 3 replicated these results with individuals' choices of snacks and drinks, and also established self-esteem as a moderator. The MS effect was more pronounced for low self-esteem individuals than for high self-esteem individuals.

The goal of study 4 was to examine whether activating mortality salience also activates the cultural norm of conspicuous

consumption, causing individuals to purchase more as a way to prove their value to society. If this explanation holds, we might expect that activating mortality salience should also activate constructs related to consumption and materialism. Therefore, participants should be more likely to complete word fragments with words related to shopping, money, and/or eating. We also altered the control manipulation (from “dentist” to “pain”) to control for an unintended alternative explanation for our prior results: that people simply don’t like to think about eating immediately after going to the dentist. And while we replicated the main effect of mortality salience found in studies 1-3, there were no significant differences in the number of word completions of investment words, shopping words, or eating words as a result of the MS manipulation. Therefore, the cultural norm explanation was not supported.

Study 5 explored whether MS individuals wish to consume higher quantities in the present time frame because they have a higher discount rate. In other words, perhaps because they believe that they might die soon, they would rather spend their money on items that can be consumed immediately, rather than to save their money, which will be useless to them upon their deaths. If this reasoning is true, they should be willing to spend more money than control subjects in order to consume a product now, rather than at a later date. Following a procedure similar to that of Loewenstein (1988), in one condition we asked participants how much they would be willing to pay to speed up delivery of a purchased item, and in a second condition we asked participants how much less they would be willing to pay in order for the delivery of an item to be slowed down (from its expected delivery date). Manipulations were as in study 4, resulting in a 2 (Prime: death vs. pain) X 2 (Delivery Change: Slow down vs. speed up) between-subject design. As predicted by the “die broke” explanation, MS participants were willing (in both the slow-down and speed-up conditions) to pay a higher premium than were control participants to receive both an iPod (M=\$39.33 vs. \$25.31) and a gift card (M=\$27.29 vs. \$18.52) immediately, rather than later.

In sum, we demonstrated consistently the effect of MS on consumption quantity, using different manipulations of MS and different measures of consumption quantity and spending. We also tested various explanations for this effect. The results indicated that consumers engage in higher consumption and spending, not because they want to endorse a predominant cultural norm (i.e., the norm of consuming), but rather because they want to “die broke”. Consumers may also want to boost their self-esteem by spending their money to make them feel good again. Therefore, effects were more pronounced for low self-esteem consumers than for high self-esteem consumers.

Ordinary Resistance as a Parasitic Form of Action: A Dialogical Analysis of Consumer/Firm Relations

Dominique Roux, Paris 12 University-IRG, France¹

INTRODUCTION

Holt's (2002) article on dialectical relations between consumers and brands has usefully stressed the centrality of the market as the locus of construction of people's identities. Postmodern as well as critical approaches of resistance tended previously to overemphasize either consumers' freedom through emancipatory projects (Firat and Venkatesh 1995) or the market's domination through imposed codes and seductive practices (Murray and Ozanne 1991). But it seems as inaccurate to idealize consumer power, as it is to overvalue market dominance. In challenging the first perspective, poststructuralist approaches have unveiled the mechanisms by which individuality is originally constructed by social fields that tend to shape and reproduce a system of tastes (Bourdieu 1984). As a consequence, consumers are neither ontologically free to choose, nor ontically free to escape socially constructed mental structures acquired primarily through language (Elliott and Ritson 1995). For that reason, individuals are constrained, most often unwittingly, by a web of power-based relations.

Conversely, the taken-for-granted hegemony of firms needs also to be reconsidered. Firms mainly owe their existence to a sufficiently long-lasting willingness on the part of consumers to buy their offerings. They can be challenged both by dissatisfied consumers who denounce their social or commercial practices (Kozinets and Handelman 1998) and by alternative forms of communities, which create shared solidarity upon adversary actions (Giesler and Pohlmann 2003; Hemetsberger 2006). Both parties—firms and consumers—are in fact indissolubly linked by common interests (Holt 2002). Moreover, since each interpretation seems to be shaped by a particular socio-ideological framework, they tend to conceal the inherent nature of power—which is both dialogical and dialectical and cannot be grasped, except in a simplistic manner, from a single perspective. As Foucault (1982) pointed out, resistance must be regarded as the telltale sign of power relations, just as power relations should be considered as inherent elements of social relations. But resistance is also a contingent reaction: though coextensive with human interplay, it does not necessarily happen everywhere, all the time, among all consumers or in opposition to everything. It represents a specific type of response that occurs at the intersection of individuals and their interpretations of a situation. It acts as a sometimes vehement, but other times silent, denunciation of the discourses and practices of power (Hirschman 1970).

In accordance with this dialogical conceptualization of power and resistance, this paper first puts forward a theoretical framework capable of grasping and classifying a wide range of resistant behaviors that have been identified and depicted in recent consumer research literature. Three levels of resistance are suggested—each of them corresponding to a specific means used by firms to make consumers act in expected ways: against the discourses and codes they mobilize through brands and advertising; against the practices and mechanisms they deploy; and finally against firms themselves, rejected as relationship partners.

The paper then defends the idea that uncovering the dynamic and dialectical process by which consumers interact with markets requires going beyond an analytical and often static standpoint. To this end, a phenomenological research approach was chosen as best suited to the exploratory nature of the study. A two-stage procedure, involving introspective essays followed by three in-depth interview sessions, was adopted over an 18-month period. Eight consumers whose profile was delineated as reflexive and critical-minded were recruited by networking through colleagues. The aim of the investigation was to examine which dynamics resistance followed over time, and how it could be related to biographical information. The results are discussed in the third section, in accordance with this constructed and dialectical perspective of resistance. They reveal the importance of the psychic economy of individuals (Bourdieu's concept of *illusio*) through the way people act and respond to firms' strategies.

THEORY

The existing literature on consumer resistance covers a wide range of critical or emancipatory positions adopted by consumers. Writers of a primarily Marxian inclination tend to stress the ideological domination of the market and the consequent need for reflexivity and code-conscious distancing (Hetrick and Lozada 1994; Murray and Ozanne 1991). Within this perspective, consumers are perceived as targets, victims of semiotic formatting through advertising discourses, fashion and constructed mythologies (Barthes 1972; Baudrillard 1998). Exaggerated systems of status differentiation are thus exposed as the result of a constant production of signs. Some authors also accused the system of taking control of the desire of individuals (Dichter 1960), transforming them into conformist and other-directed personalities (Riesman 1950). More recently, other commentators have elaborated approaches to emancipation based upon consumer practices and "bricolage" in a fragmented world (de Certeau 1984; Firat and Venkatesh 1995). Such contributions highlight the various ways in which consumers appropriate goods, discourses and codes in a subtle and creative manner through individual or collective actions (Elliott and Ritson 1995; Thompson and Haytko 1997; Thompson, Pollio, and Locander 1994). Resistance to cultural ideologies is thus manifested by the ability of consumers to decipher and contest meanings embedded in products and services (Duke 2002), sometimes beyond their own conscious awareness (Moisio and Askegaard 2002; Thompson 2004). Communal consumption has also revealed its emancipatory and oppositional power by generating, around a shared outlook, dialectical positions of differentiation and integration/exclusion (Giesler and Pohlmann 2003; Hemetsberger 2006; Kozinets 2002; Muniz and Hamer 2001). Nevertheless, if consumption can be conceptualized as an arena where individuals collect a range of cultural components for constructing their personal or social identities, very little research has given prominence to the interactive construction of resistance (Holt 2002). As made clear by Giesler and Pohlmann (2003), the prevailing static approach to consumer emancipation and the lack of a dynamic perspective calls for new studies able to capture the tensions between consumers and markets.

CONCEPTUAL FRAMEWORK

Of particular relevance to the present research context are Foucault's writings on power (1982), which emphasize the dialogical nature of social relations and the inescapable and structural

¹Funding Acknowledgement:

presence of forces and tensions therein. In this work, we extend his interactionist model of power by examining how resistance is produced as a response to the practices, discourses and even existence of firms. Our conceptual framework supports the idea that resistance would benefit from being analyzed as a diachronic process.

Micro-Physics of Power

Beyond Weber's ([1968] 1921) macro-level conception of political and sovereign power, Foucault (1982) has depicted a micro-level theory of power as the very essence of social relations. Power is defined by Foucault as the ability to govern the actions of others and to structure the scope of their activities. Power works on the field of possibilities of active subjects by prompting, inducing, diverting, facilitating or impeding their room for maneuver. It is always a means of acting on other people's actions and controlling their behavior. Yet power is not violence, nor does it imply submission. On the contrary, power exists only in relation to free subjects who face a wide range of potentialities and have various ways to react. When situations are completely determined, as in slavery, there are no power relationships, only force or physical constraint. Hence, power and liberty are not mutually exclusive; rather freedom is the necessary condition for the existence of power. According to Foucault, power relationships and in submission are structural components of social interplay:

'Power relations are rooted deep in the social nexus, not reconstituted 'above' society as a supplementary structure whose radical effacement one could perhaps dream of... A society without power relations can only be an abstraction' (Foucault 1982, p.208)

In social relations, this micro-physics of power can be located anywhere, although some institutions are more likely than others to exert this type of disciplinary control over individuals (Foucault 1975). Prisons, schools, army camps, hospitals and churches in particular combine both discursive and non-discursive practices that aim at breaking in bodies and commanding souls through internalized mechanisms. Constant self-examination, evaluation and confession are examples of how the micro-physics of power contributes, through individualization, to the binding of subjects to themselves and to ensuring their submission to others. In line with Foucault's approach, the disciplinary power of marketing practices has been analyzed by Marsden (2001) in terms of three main instances: market research information technology as a tool of surveillance; segmentation as a means of categorizing and labeling individuals; and advertising as a way of channeling prescriptive and corrective messages. In contrast to Weber's theory in which power is considered predominantly as domination, Foucault's approach gives a less rigid, deterministic and top-down reading of the distribution of forces. Although institutions and organizations may try to exercise power through disciplinary techniques, subjects are likely to free themselves from these constraints. Power and rebelliousness do not confront each other in a simple oppositional relationship, but exist in a permanent state of provocative tension.

Strategies of Legitimization By Firms and Consumer Tactics of Resistance

By considering the position of manufacturers and retailers, Emerson (1962) and Pfeffer and Salancik (1978) showed how the uncertainty of consumer markets threatens the long-term dominance or even survival of firms. By refusing to buy their products, consumers can adversely affect the achievement of company objectives. They have power over firms to the extent that firms depend

on their cooperation. Because power is primarily founded on dependence, Pfeffer (1981) suggests that legitimization is a relevant strategy to alleviate the vulnerability of firms, by trying to persuade consumers that their offerings are of particular importance for them. To this end, they draw on consumer representations and attempt to alter them in favor of their own interests. They mobilize information, expertise, and selective interpretation of rules, language and symbols to present their corporate decisions as coinciding as closely as possible with the presumed outlook and thinking of their targets. Such legitimization tactics are likely to succeed insofar as they suggest consonant decisions, so reducing the gap between consumer objectives and those of the company. In order to persuade consumers to make the hoped-for decisions, firms can act at three levels (Bourgeois and Nizet 1995): through the products and services they offer; through procedures whose enactment and performance must appear fully to respect consumers' freedom of choice; and by presenting themselves as valued partners in the exchange process. These three levels of legitimization are also implicitly the echo chambers in which consumer discontent is amplified. As shown in Table 1, we propose analyzing the motives for consumer resistance as specific responses to different companies' modes of action. First of all, the content of presumed relevant and congruent decisions presented to consumers are swept aside by consumer claims to freely chosen codes and signs. The repudiation or avoidance of products and brands (Fiske 1994), engagement in oppositional practices, and rejection of mass-marketed meanings and discourses exemplify some reactions of this type. Secondly, consumers can also feel saturated and repelled by the manipulative, if ineffective, advances made by companies (Fournier, Dobscha, and Mick 1998). Selling tactics and "capture plans" are resisted in the name of autonomy and ethics. Complaints, negative word-of-mouth, retaliation, boycotts, subversion and "culture jamming" (Handelman 1999) are among the expressions of dissatisfaction, feelings of harassment and moral sanction applied against companies. And finally, consumers get to the point of questioning the very existence of certain companies as acceptable current trading partners and as responsible actors for future generations. Whereas firms urge consumers to trust them, consumers often choose to ignore or avoid them, and instead opt for voluntary simplicity, patronize alternative distribution channels such as second-hand markets or favor gift-giving and consumer-to-consumer exchanges.

RESEARCH METHODOLOGY

Consistently with the exploratory and discovery-oriented nature of the research, the methodology consisted of a survey carried out over an eighteen month period in a major European capital city. Informants were selected via a "snowballing" technique, initiated by asking colleagues to introduce the researcher to acquaintances they felt to be resistant consumers. A brief definition of resistance was given to identify potential informants, following Fournier's (1998) conceptualization of it as a continuum of opposing forces, ranging from avoidance behaviors to active revolt. Eight volunteer participants of varied gender, age, origin and religious affiliation were finally recruited after agreeing to participate in the two-stage research program.

Stage 1 consisted of a diary study in which participants were asked to note down over a 6-month period (1) perceptions, judgments and feelings they could express in relation to their day-to-day life experience as consumers, and (2) example accounts of what was likely to trigger their distrust, dissatisfaction, irritation and other negative emotions and opinions about the discourses, offerings and practices of companies. Through introspective essays, they were also encouraged to recall, as far as they could, how they had come to react in such a way, against what in particular, and why. They

TABLE 1
Company levels of legitimization and consumer expressions of resistance

Levels of legitimization by companies	CONTENT OF DECISIONS Objects, discourses, signs and values	BEHAVIORS in commercial (capture devices, selling tactics), environmental, social and ethical terms	COMPANIES Themselves as qualified partners
Motives for resistance	Freedom of choice (code-conscious)	Autonomy (trap-conscious)	Electivity (self-definition of who to deal with)
Individual expressions of resistance	Distinction “ Bricolage” Oppositional Loyalty	Complaining behaviors Negative word of mouth Retaliation	Alternative channels Second-order marketing systems Voluntary simplicity
Collective expressions of resistance	Boycotts Counter-cultures Subcultures	Boycotts, Buycott Subversion, Attacks, activism, hacktivism	Communal consumption Gift-giving communities

were also asked, in terms of possible reflexive changes in their consumption choices, what had evolved over time.

Stage 2 consisted of three in-depth interview sessions, each lasting from one to three hours. The first interview aimed at bringing out more information about the events and stories recounted in the introspective essays, in order to acquire a clear sense of the informants' perceptions and meanings. In particular, special attention was paid to potential changes they might have noticed over time in their own feelings toward the functioning of the market. The second interview was guided by a set of questions related to their general consumption choices, life styles and values. This phase was helpful for understanding how their stories could be related to the critical attitude to consumption expressed and enacted in their day-to-day lives. The third interview consisted of a conversation about salient autobiographical elements, i.e. the socio-economic, family, cultural and religious environment in which they had grown up. This stage provided further information for a deeper understanding of informant backgrounds, sensitivities and ways of reacting. The profile was also supplemented by additional interviews with informants' acquaintances in order to triangulate across sources. The interviews took place in the homes of the participants and were loosely structured. All interviews were recorded and transcribed before they, as well as the diaries, were analyzed in terms of content.

Despite the small size of the sample, respondents were almost equally distributed by gender and age, and belonged to several occupational categories (see Table 2). No claim of representativeness is made here, since the research objective was to gain deep insight into their individual trajectories using a biographical framework for analysis. However, several criteria were used to ensure the trustworthiness of the research. The first criterion was persistent and prolonged engagement, which is one of the basic techniques for obtaining a rich description in a research field (Geertz 1973; Lincoln and Guba 1985; Wallendorf and Belk 1989). In this qualitative in-depth study, reliance was placed on lengthy acquaintance with the personalities and stories of informants. Secondly, triangulation was made across sources and methods, using different ways of capturing what informants meant. Thirdly, feedback was obtained by submitting the author's conclusions to the informants. Most respondents agreed with these conclusions, and any that were questioned were re-examined. Finally, variety and contrast were

taken into account for recruitment, with respondents chosen sequentially and selectively in a constant comparative method and search for varied ideological beliefs and critical positions in relation to consumption (Glaser and Strauss 1967).

FINDINGS

Conflicts of representations, denunciations and levels of resistance

The accounts of the informants present themselves as acts of enunciation and of denunciation of what places them in opposition to the discourses and practices of firms. From this standpoint, introspective essays and interviews have functioned, as Boltanski, Thévenot and Porter (2006) show, as opportunities for revealing conflicts that individuals maintain with the commercial world and for justifying values they defend. The main claims underlying their critiques chime with the three levels of resistance referred to in the theoretical approach: resistance to the stratagems deployed by firms, that threaten their autonomy; resistance to promises, injunctions and temptations that hamper their freedom; and, ultimately, choosing consumer practices more in keeping with their own system of representations, their values or sometimes their utopias. Secondly, their discourses also reveal how different psychic economies transmit dominant tonalities to their modes of reaction, of which we attempt to sketch the main elements from their personal trajectories.

Resisting Stratagems, Pressures and Manipulation

“Grandmother, what big teeth you have got! “All the better to eat you up with.”

The first salient theme of the testimonies brings to light the sense of pressure and manipulation that the respondents perceive on the part of firms. Following the deconstruction made by Cochoy (2004) on the snares used by the wolf in Little Red Riding Hood, consumers are aware of the “capture devices”, sometimes crude and often visible, which firms use against them. Three types of practice are thus denounced. Echoing the long-established but still relevant findings of Vance Packard (1957), advertising discourses appear first always as the prototypical instrument of their seductive and dishonest intentions, as indicated by the following example:

TABLE 2
Summary of respondent characteristics

Name	Age	Gender	Occupation, marital status, background, income level	Personal profiles and salient values
Barbara	22	Female	International business student single. Hispanic origin. No income	Artist milieu. Fair Trade and anti-brand oriented.
Vath	25	Male	Student– applied modern languages. Single. Asian origin (Cambodian). No income	Buddhist. Detachment and indifference to material culture.
Elisabeth	38	Female	Interpreter. Single. Polish origin. Low/middle income	Motivated by altruism, pacifism and sustainability. Subscriber to consumer magazines. Non-practicing Catholic.
Sandra	42	Female	Secondary school teacher. Divorced. 2 teenage daughters. Greek origin. Low/middle income	Self-defined as an intellectual rebel. Secondhand and savvy shopper.
Daniel	51	Male	Telecom engineer. Married. 2 children aged 13 and 15. French origin. Middle/high income	Involved in charities, union and green activities. Voluntary simplifier and anti-advertising.
Patrick	61	Male	German teacher. Single. German origin. Middle/high income	Independent. Hoarding behavior, reluctance to spend, high discernment when shopping
Marc	68	Male	Retired art school teacher. Married 1 son aged 39. Judaeo-Spanish origin. Middle/high income	Secondhand shopper. Motto: “ No god no master” . Nonconformist and independent. Agnostic.
Maria	72	Female	Retired nurse. Divorced. 1 daughter aged 40. French origin. Low income	Independent and not easily influenced. Wary and strongly attached to personal freedom. Practicing Catholic

“...You know the Taillefine de Lu biscuits from Danone? They chose a name that makes you think it’s diet product, but in fact they’re laughing at us. The more you eat, the fatter you become!” [Sandra]

Secondly, some respondents denounce “tricks designed to justify higher prices for non-recognized benefits” in brands [Patrick]. The status and effects of fashion in particular are arguments that they dismiss in favor of reasoning based on the use value of a product and its value for money. Finally, some respondents particularly blame sales techniques, which they denounce for their heavy-handed approach and which reveal, not uncynically, paradoxical realities. For example, they draw a parallel between the “humanized robots” that companies use for their vocal servers and the “robotized humans” working in call centers “who articulate stereotyped discourses” [Sandra]. Among some respondents this dehumanization creates a sense of general discomfort, which sometimes gives rise to intense aggressiveness towards remote sales services departments accused of “transforming people into selling machines for other people who have become buying machines.” [Barbara]

Resisting Discourses, Promises and Temptation

“The serpent deceived me, and I ate” -Genesis 3:13

The second resonant theme concerns the content of decisions that firms suggest to consumers. Numerous illustrations insistently

evoke the lack of congruence between the images and representations conveyed by advertising, brands and companies, and the values of the respondents. They feel themselves interpellated in registers that do not correspond to them and which seem to negate their feelings, personality and individuality. Echoing the criticisms of the Frankfurt School on mass culture (Horkheimer and Adorno [1944] 1972), the various comments often call into question the multinationals and the uniformization they produce. To this largely cultural resistance to advertising and the media are added other criticisms in different registers: economic and political (the effects of globalization), environmental (pollution and destruction of resources) and spiritual (anti-materialism and a refusal of excessive commoditization). As a result, resistance is experienced in accordance with three registers, of which the ethical underpinnings are clearly perceptible:

- first, not to give in and to fight against a loss of autonomy that is perceived as a weakness. Recalling the biblical story of the serpent, the temptation is primarily experienced as a loss of self-control,
- next, to draw satisfaction, pride and spiritual elevation from the strength of character that enables these attempts at seduction to be repulsed,
- finally, to accede to a sense of justice that covers various forms of condemnation of firms—their perceived power, the ideological representations they are accused of conveying,

or what they do to vulnerable sections of the population such as children or socially disadvantaged layers. Or, as one of the respondents expressed it:

“While visiting the Greenpeace website or those of other ethical vigilance associations, I see also those which sell GMOs without saying so, or which break the labor laws, or employ children, or make junk products, none of which they mention in their advertising. And I sanction them by not buying their products.” [Daniel]

Selective Consumption: Modulating the Choice of Products and Channels

Since the practices and discourses of firms are central to consumers' themes of resistance, their choice of consumption is built or is modified over time according to their changing relation to the market. The procession of representations and lived experience lead them to avoid the products, brands and firms which become distant from their value system, in accordance with a distinguishing process (Bourdieu 1984). This reasoned identification of a non-self, marked out and kept at a distance, leads them tailor their repertory of consumption through rejection and avoidance or by selecting alternative partners, whether they be competing companies that are more respectful at the economic, social or environmental level, or other market or non-market exchange networks. Thus some respondents say that they turn towards sustainable commercial products [Barbara, Elisabeth], some prefer to supply their needs from secondhand markets [Daniel, Marc, Sandra] or through barter [Daniel], and others tend to reduce their consumption [Marc, Vath, Patrick]. The practices chosen are in any case not mutually exclusive and reflect rather an idiosyncratic blending of micro-practices consistent with their preoccupations. While Holt (2002) has shown how individuals on the margins of society construct themselves in and through the market, we attempt here to show how ordinary consumers, professionally and socially well integrated, question the meaning of their actions, try to find acceptable compromises and reorganize their mode of consumption by mobilizing devised selective repertories within, but also outside of, conventional distribution channels. In contrast to militants attached to alternative associations, who engage in serious, costly efforts highly oriented toward the type of resistance they support (Ferrando Y Puig 2005), these “ordinary” consumers try to cobble together sufficiently satisfying solutions and make use, in an opportunistic and irregular fashion, of the various means that best meet their material and symbolic needs.

No Escape but the Choice of Arms

While Kozinets (2002) and Holt (2002) have good reasons for doubting that consumers can escape the market, it is nonetheless interesting to observe, in day-to-day life and apart from extraordinary situations such as *Burning Man*, how they accommodate themselves to their dissatisfaction with market society. At a psychological level, the testimonies mainly reflect three types of coping strategy in response to the tensions which their relations with the market give rise to—confrontation, avoidance, and reasoned adaptation—which, depending on the circumstances, sometimes coexist. These adaptive strategies reflect some of the major dimensions of coping (Lazarus and Folkman 1984), with the first two tending to be based on emotion (aggressive emotional release or avoidance/disengagement), the third arising more from a positive adaptation based on information, evaluation and judgment.

Save Our Souls: Resistance as a Path to Salvation

Some interviewees mainly manifested an attitude of defiance in relation to the market, which was expressed in aggressive forms of practices and discourses [Sandra, Barbara, Daniel]. Their comments reveal the moral discomfort produced by their immersion in a society, which they felt they had not chosen. Conscious of being unable to escape it, but nevertheless constrained to participate in it, they tend to make their choices on the basis of combative postures, as if the blacklisting of certain firms and products or boycotting the market as a whole helped, through an intense emotional release, to relieve their conscience. Strong moral or religious sensibility in fact betrays a powerful sense of guilt either in relation to the feelings that the market cynically conflicts with, or in relation to the weakest social groups, which they feel they have robbed of a degree of happiness. This guilt then seems able to be considerably attenuated through a critical and distanced attitude towards consumption, as was expressed by one of the respondents:

“When one buys a product, one should ask oneself whether it's toxic, whether or not it contributes to polluting the planet over and beyond the immediate advantages it brings, who it was made by, how much the workers from the Third World were paid, and how many local jobs it's going to destroy.” [Elisabeth]

As Kozinets and Handelman (1998) have shown on the subject of individual boycott practices, resistance can represent a form of moral hygiene and be a means of self-transformation as a corollary to the hope of transforming the world.

The Three Wise Consumers: “See No Evil, Hear No Evil, Speak No Evil”

In contrast to the preceding correspondents, others develop a form of voluntary ignorance and mental deafness in relation to situations that disturb them [Maria, Vath]. This tactic serves to save the psychological effort which would consist of taking the risk of exposing themselves to messages in order then to be obliged to protect themselves from the emotional consequences of the content (tempting psychological stimuli and the conflicts that stem from them). As expressed by one of these two respondents:

“I don't look at ads. I see them, of course—on TV, in the street, in newspapers, but I'm not interested in them. Unconsciously, I don't want to be aware of trends or novelties. This enables me to think, in a way, that I resist the various techniques used by advertising to manipulate us and tempt us.” [Vath]

Forewarned is Forearmed: Positive and Reasoned Modes of Adaptation

Some consumers, on the other hand, stress the importance of adopting an informed, vigilant and adaptive attitude toward consumption [Elisabeth, Marc, Patrick]. Their reactions reveal fewer negative emotions—anger or avoidance—in favor of considered observation of the mechanisms of marketing functioning and a rational analysis of their scope of action. For them, consuming is a game in the sense of *illusio* (Bourdieu and Wacquant 1992): an investment in the field of consumption which is not clearly codified, but the implicit recognition of which matches up to the energy it involves. These aware consumers, mobilizing their intellectual or cultural capital in decoding the practices and discourses of firms, try correctly to anticipate the tactics deployed—no longer being influenced by the latest advertising claims and constantly deconstructing

the stratagems used. Having the appropriate outlook and attitude for understanding the world of marketing, they enjoy participating in the game—not the game of believing the claims of the “adversaries” and of submitting to them, but of remaining actively present in the competition to which they feel themselves invited and whose scope they perceive. Resisting is experienced as an adventure, which calls for a vigilant attitude: against the ease suggested by the prevailing discourse, they thus set up a necessary reflexivity of which the stakes are precisely those of deciphering the day-to-day workings of the market.

DISCUSSION

The biographical backgrounds of the respondents make clear the strong links between the socio-psychological details that have shaped them and their modes of reaction as consumers. The field of consumption is therefore but one specific site of expression of their learned predispositions or habitus (Bourdieu 1984). Some respondents recognize themselves to have been instinctive rebels since childhood and their relation to the world of marketing is one situation among others where their propensity to resist is manifested. This tendency to revolt can be acquired in reaction to a parent, a milieu or an imposed education. For example, Sandra implicitly recognizes that her manner of purchasing is strongly colored by an almost structural vindictiveness in regard to firms—which she views as incompetent, unsatisfactory, and ultimately persecuting—as if the animosity that she says she feels toward her mother was displaced onto other more abstract and substitutive entities. Conversely, resistance can derive for some correspondents from their identification with parents who are themselves anti-authority, committed, militant or simply attached to certain ideas or values. Thus Daniel’s parental home, where the outside world is seen as threatening and full of traps, was able to train him to acquire the intellectual and cultural resources needed for an effective decoding of reality. Barbara reveals that the artistic milieu in which she grew up helped her discover her own clothing codes without having felt the need to conform to fashion, nor to have suffered the consequences of doing so in her relations with her peers. Similarly, among those respondents who favor avoidance over confrontation, philosophical, religious or spiritual trajectories can be found at the root of their tendency toward detachment and psychological distance. Vath, for example, feels himself to be strongly influenced by Buddhism, which both in regard to the world of marketing and in his life in general encourages him to distrust desires and the potential suffering that accompanies them. Maria makes numerous references to the Catholic education she received during childhood in support of her wish to distance herself from advertising discourses viewed as enticing.

While social class and income criteria do little to cast light on the results, the same cannot be said of age and the cohort effect it results in. Thus the oldest respondents are influenced by the very duration of their consumption experience. Born in less economically advanced times, they testify to a degree of disorientation in relation to the acceleration of technology and the overabundance of products, but also acknowledge an acute sense of wastage linked to the increasingly ephemeral nature of commodities [Maria, Patrick, Marc]. Conversely, the youngest, immersed in today’s shifting and evolving system are more aware of the spatial dimension of the world they inhabit. The abolition of distance by the media in general and the Internet in particular gives them a consciousness of universal belonging, which often makes them more sensitive to geographically distant peoples [Vath, Barbara, Elisabeth]. Between these two groups, young adults refer to their educational aspirations for their children, in whom they wish to instill an awareness of consumption that is as reflective and rational as possible, and for

whom they already weigh up the harmful consequences of uncontrolled development [Daniel, Sandra].

CONCLUSION

The aim of this article was to give another perspective on the exploration of consumer resistance strategies, of which many recent works have described the practices and modes of operation. In line with interactionist and contingent approaches to power (Foucault 1982), this paper proposed examining more closely the finely woven fabric of relations between consumers and the market, and going to the source of their resistant postures, using an in-depth approach drawing on their life histories.

As summarized in Figure 1, the main results of the research could make a contribution in terms of three points. First, resistance works like a reverse discursive mirror on the legitimation processes of firms, and does so at three levels: it dismantles the procedures used by companies to make consumers act in accordance with corporate interests; it deconstructs the meaning of decisions offered to them—discourses, products, codes—which they feel fail to correspond to their own value systems; and ultimately they question the legitimacy of companies as valid exchange partners.

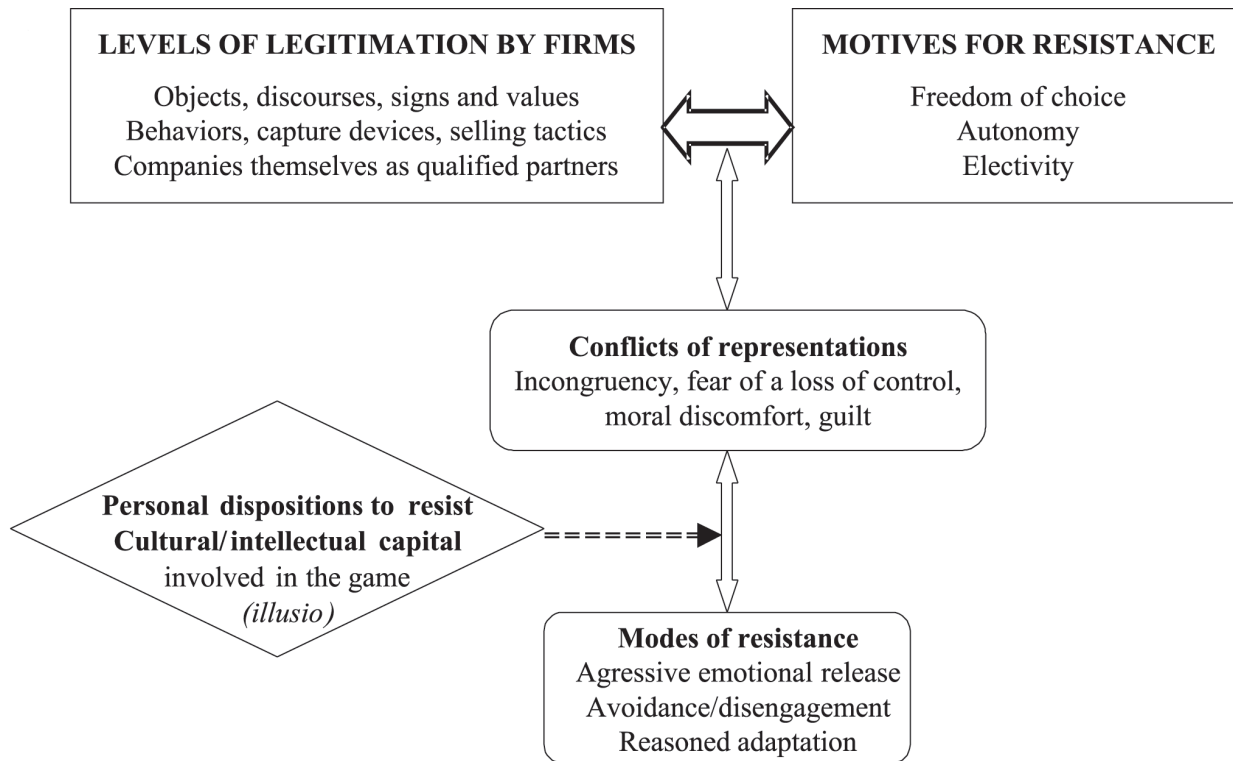

Secondly, in view of this reflexive capacity for decoding practices and discourses, the tactics of resistance vary, depending on the respondents, between confrontation, avoidance and reasoned adaptation. Their psychological profiles predispose them either to engage in the game with offensive or even aggressive energy; or to adopt defensive attitudes based on inertia, evasion or calculated ignorance; or to compose and assemble selective consumption/non-consumption within and outside of the conventional channels by mixing different supply systems.

Thirdly, individual commitments to the game depend on the intellectual and cultural capital that they are in a position to mobilize and which their own dispositions shaped by the environment predisposes them to use. In all cases, confrontation, avoidance and positive adjustment participate in a struggle against certain market realities and in using this to construct an identity-project (Castells 1997). From this angle, the conclusions drawn by Holt (2002) deserve to be re-examined. Although the market does not seem to be threatened overall by the resistance which it lives on and recycles, it does however seem to be parasitized by the critique that it helps feed.

The discourses and devices of firms participate in an exacerbation of decoding reflexes, deconstruction and critical distancing by consumers. Permanently playing with signs can both produce experts and give rise to habituation, saturation and disenchantment. The standard forms of frustration, retreat or guerilla warfare noted in this research are certainly not constructive or politically effective in the way emphasized by some observers or defenders of political consumption (Micheletti 2003). Nevertheless it would be a mistake to underestimate their interest or impact on the pretext that these acts are expressed only in the private sphere and develop in a sporadic and unstable fashion. Work on defection (Hirschman’s ‘exit’ 1970) and retaliation (Huefner and Hunt 2000) has already invited us to pay attention to opposing or reactive behaviors that crystallize an often silent and invisible rejection of the dominant ideology of consumption.

Though apparently inconspicuous and harmless, these behaviors do represent resistance as we defined it. Moreover, their covert nature makes them particularly dangerous for companies, which could easily underestimate their offensive potential. Indeed, many research avenues remain unexplored concerning the analysis and assessment of what de-consumption, alternative ways of acquisition, boycotts, negative word-of-mouth or disloyalty all together represent in terms of monetary losses and for firms and the overall

FIGURE 1
A Model of Possible Consumer's Resistant Responses to Firms

marketing system. Where the market's capacity for recuperation and regeneration has been emphasized as dependent on the very existence of resistance (Holt 2002), it can be said also that these forms of resistance live, in the manner of a parasite, at the expense of the actions and resources of firms whose everyday existence it nourishes. As in biological eco-systems, parasites, though having detrimental effect on their hosts, play however an important part in the regulation of populations. One suggestion, deriving from this metaphor and paralleling Holts' (2002) conclusion, would be that only those companies operating with respect and authenticity are in a position to resist consumers' deeper critical vigilance.

Globalization and Rituals: Does Ramadan Turn into Christmas?

Ozlem Sandikci, Bilkent University, Turkey
Sahver Omeraki, Bilkent University, Turkey

ABSTRACT

This study explores how the dynamics of consumer culture and globalization interact with Islamic beliefs, rituals and behaviors, and revive and modify local rituals in order to fit with modern consumption-driven lifestyles. Specifically, we focus on urban Turkey and discuss how Ramadan rituals are being reinvented, modified and reinterpreted at the marketplace. We argue that the commercialization of Ramadan is neither an instance of cultural imperialism nor an instance of postmodern disorder. Rather, commercial logic and consumerist ideology hybridize Western and non-Western traditions and practices, creating new expressions of existing rituals.

INTRODUCTION

Across the Muslim world, there are numerous signs that Ramadan, a time of fasting, prayer and reflection, is transforming from a religious month to a cultural and commercial holiday. The spirit of capitalism is felt in practices ranging from the marketing of specialty items (e.g., fasting calendars, lanterns) emblazoned with company logos to the Ramadan feasts promoted by restaurants and hotels, the Ramadan greeting cards, the Ramadan sweepstakes, and the Ramadan themed shopping malls and supermarkets. During the holy month in 2005, to the surprise of many, a shopping mall in Dubai even featured “a Ramadan display with an uncanny resemblance to a nativity scene, complete with moving camels, a village elder reading stories and a desert scene” (Fattah 2005). It appears that Ramadan has taken on the commercial trappings of Christmas and Hanukah and is transforming from a religious ritual to a holiday marked by consumption. Intrigued by these developments, our paper explores how the dynamics of consumer culture and globalization interact with Islamic beliefs, rituals and behaviors and reshape them to fit with modern consumption-driven lifestyles. Specifically, we focus on urban Turkey and discuss how Ramadan rituals are modified, reinterpreted, and reinvented in the marketplace. We begin our paper by offering a brief review of the literature on holiday rituals and their transformation under the logic of capitalism and consumerism. Next, we present the findings of an ethnographic study conducted in the fall 2005 in the cities of Ankara and Istanbul in Turkey and outline the market and consumption related actors, activities, and experiences observed in the enactment of the Ramadan ritual. We conclude by discussing the implications of commercialization of rituals for consumers as well as consumer researchers.

RITUALS AND THE CONSUMER CULTURE

Following the interest in rituals as incidences of symbolic consumption (Belk, Wallendorf and Sherry 1989; Holbrook and Hirschman 1982; Rook 1985) several studies investigating numerous consumption rituals appeared in the marketing literature (see Otnes and Lowrey 2004 for a recent anthology). Much of this work deals with the nature and implications of consumption during ritual occasions such as Christmas (Belk 1989; Sherry and McGrath 1989), Thanksgiving (Wallendorf and Arnould 1991), birthday parties (Otnes and McGrath 1994), and wedding (Lowrey and Otnes 1994). In contrast to Rook’s view of rituals as “extremely resistant to innovation or deviation” (1985, p.253), many studies demonstrate that rituals, ritual artifacts and ritual meanings are

subject to dynamic changes (Goodwin, Smith and Spiggle 1990; Otnes, Kim and Lowrey 1992), that rituals are influenced by and influence social and cultural contexts (Belk 1989; Otnes and Scott 1996), and that new rituals can arise as a result of rapid social changes (Kreinath et al 2004).

Studies of consumption rituals observed in non-Western contexts provide more insights into understanding the dynamism of rituals and the relation between rituals and structural developments, such as the effects of modernity and globalization. For instance, in their study of the Chinese religious rituals practiced in Singapore, Kiong and Kong (2000) show that because conditions of modern living—smaller dwellings with new spatial arrangements—altered the conceptions of sacred space, related rituals had to be redefined and even replaced by invented rituals. Similarly, work on henna night (Ustuner, Ger and Holt 2000) and dowry (Sandikci and Ilhan 2004) rituals in Turkey reveal that both rituals went through a period of demise, mainly as a result of changing lifestyles and roles of women, but then were reinterpreted and recontextualized in accordance with the conditions of modern living.

Another set of studies focus on the effects of globalization and discuss how Western-originated rituals get adapted in non-Western contexts. Prominent in this research stream is the work on Christmas and its global spread. As these studies document, Christmas is celebrated in non-Christian countries as diverse as Japan, India, Trinidad, and China (Bodenhorn 1993; Miller 1993; Moeran and Skov 1993; Kimura and Belk 2005). Yet these are creolized or hybridized adaptations, which help incorporate Christmas into local culture. Similarly, Creighton’s (1993) work, which offers an exegesis of Valentine’s Day in Japan, reveals how foreign rituals are not just adopted but domesticated.

Overall, research suggests that modernity, capitalism and globalization influence rituals in two major ways. On the one hand, one can observe revitalization of certain local rituals, resulting in reinterpretation of a disappearing or already lost rite through the lens of the contemporary consumerist lifestyle (e.g., henna night in Turkey). On the other hand, some rituals travel to cultures that did not historically observe them. In such instances, the ritual often gets reinterpreted in the imported context and is experienced through a combination of ‘original’ and ‘new’ artifacts, scripts and performances (e.g., Christmas in Japan). Whether proof of Western cultural imperialism and global homogenization or instances of hybridization and local appropriation, both the spread of Western rituals in non-Western countries and the revitalization of local rituals in new forms in diverse parts of the world are eminent. Furthermore, what is also eminent is that these processes are aided by multinational as well as local companies and media, who gain significant financial benefits from such adopted or reinvented rituals.

Indeed, commercialization surfaces as a key vector underlying the experience of rituals, be it Christmas or Ramadan, and the synergy between celebration and commerce continues to grow strong. Commercial logic and consumerist ideology hybridize Western and non-Western rituals, creating new forms of traditions. We argue that Ramadan in Turkey, and in many other Muslim countries, have become a mix of local and global, old and contemporary, religious and secular artifacts, performances, and meanings.

THE STUDY

Each year, during the ninth month of the lunar calendar, Muslims perform their religious obligation of Ramadan fasting. For a whole month, from sunrise to sunset, adult Muslims whose health permits abstain from food, drink, and sexual activity. Many modern Muslims consider Ramadan “the most important of the ritual duties” and “even if a person does not comply with the requirements of five prayers a day, observance of the fast is still likely” (Rippin, 1993, p. 133). Ramadan is regarded as a time for reflection and spiritual discipline, for expressing gratitude for God’s guidance and forgiveness of past sins, for acknowledgment of human dependence on God, as well as remembering and responding to the needs of the poor and hungry (Esposito, 1991). The month of Ramadan traditionally includes post-sunset feasts (*iftar*) and celebrations that are usually rather private and family centered (Jomier, 1991, cited in Keenan and Yeni, 2003) and followed by special night prayers. Nightly dinners are commonly provided for the needy, but here too, the focus tends to be on parents, children, friends and community alms-giving.

However, in recent years performance of Ramadan rituals in Turkey began to take place more in the public space and in a visibly consumption-oriented manner. For instance, five-star hotels offer lavish Ramadan feasts, Ramadan festivals take place in high-traffic historical sites, and shopping malls transform into Ramadan themed environments offering a variety of shopping and entertainment experiences. Underlying such changes are both state agencies and private companies who cooperate with each other to revive the interest in public celebrations of Ramadan and attract visitors. Indeed, more and more, Ramadan looks like other Western-originated holiday rituals such as the New Year’s, St. Valentine’s Day, and Mother’s and Father’s days that are already celebrated in Turkey but almost exclusively as holidays of consumption.

In this study we focus on three contexts that Ramadan celebrations take place. First, we look at Ramadan festivals organized by the Istanbul municipality. Each year, the municipality organizes three major festivals at three different sites: in the square next to the Blue Mosque, which is a major tourist area in Istanbul; in *Feshane*, a historical building converted to a convention center in the late 1980s; and, *Talimhane*, a recently renovated historical street next to Taksim square, which is both a commercial and tourist area. The second context that we explore is shopping malls, specifically, Bilkent Shopping Centre and Migros Shopping Mall in Ankara. Bilkent Centre is located in an upper class neighborhood whereas Migros Mall is located in a lower class district. Both places can be accessed by public transportation. Finally, we focus on up-scale hotels and restaurants in Istanbul and Ankara that offer *iftar* meals. These feasts were initially offered only by the five star hotels and up-scale restaurants. Observing their success, nowadays, several establishments provide *iftar* meals to a variety of market segments at a variety of prices.

We collected data in the fall 2005, before, during and after the month of Ramadan. The primary data collection method employed was an ethnographic participant observation of the different contexts. Observations were made in Istanbul and Ankara, in several shopping malls, Ramadan festival sites, streets, hotels and restaurants. Informal interviews with retailers participating to the different festivals as well as with the shopkeepers in the malls were conducted. Moreover, a collection of secondary data sources, comprising of advertisements, magazines, newspapers and Internet websites, informs our analysis. Once the data collection was over, the authors independently went through the field notes, photographs and the visual archive in order to identify conceptual categories and themes. Next, the categories and themes identified

were discussed among the authors and any disagreements were resolved.

RAMADAN FESTIVALS

Since the takeover of the governance of Istanbul by the Islamist Party after the 1992 local elections, the municipality has been organizing Ramadan festivals. Although there are some variations across the festivals conducted at different locations, what these festivals commonly involve are a wide selection of food and ample opportunities for shopping and entertainment. The municipality promotes the festivals as an attempt to revitalize the spirit of “old” Ramadans and constructing a space that brings together people from all social classes and creates a sense of community (Istanbul Bulteni, 2005). As no entrance fee is charged, indeed people with limited income can visit the festival areas; however, in order to partake in the joy of the festivals one needs to spend money, i.e., on food and entertainment activities.

The biggest and oldest of these festivals is the one held at the square next to the Blue Mosque. During October 2005, for a whole month, the area was transformed into a big market place, packed with more than hundred stands selling food and beverages as well as all kinds of paraphernalia. In each day of the Ramadan month, thousands of visitors crammed the square before the sunset and waited until the time that daily fasting would be over. After the meals were eaten shopping and enjoyment of various cultural activities began. The activities included religious panels addressing different aspects of Ramadan and Islam as well as artistic performances. The performances mostly included traditional art forms, such as *karagöz* (traditional shadow show) and *meddah* (an earlier form of stand-up shows), which have been very popular during the time of the Ottoman Empire but were long forgotten in the modern era. On the other hand, for those who were interested in shopping, the stands offered a wide range of selections from religious objects, such as Qurans and spiritual books, to electronic appliances and Chinese-made decorative ornaments. Moreover, several local and global companies promoted their products by distributing samples and other promotional materials. As in other festival areas, the stands were built in the style of the traditional Ottoman houses and the vendors were dressed in traditional Ottoman attires. Replicating the Ottoman house transformed the stalls into stores that tell stories, places that create a memorable consumer experience (Kozinets, et al., 2002).

Similar activities and goods were visible at the festival conducted at *Feshane*. Past the entrance gate to the building, one was confronted with the food court named as the “Ottoman Street.” Here as well, all the food stalls were in the form of miniature replicas of traditional Ottoman houses. After the *iftar* meal, visitors enjoyed their coffees and teas in a traditional coffeehouse located near to the food court. Next to the coffeehouse was a small theater where plays and concerts were performed. However, this entertainment was available only to those who paid the \$10 cover charge. The main building, on the other hand, was almost like a trade show; several companies were busy promoting their products and services to the wandering visitors. For example, banks promoted credit cards while mobile phone companies advertised their new fares. Not only information but also certain goods were distributed freely. Unilever Company, for example, distributed bowls of its newly launched instant soup and cups of Lipton brand flavored teas. There were also several brands of cars and motorcycles on exhibit. Many people waited in line to be photographed standing next to their dream car or motorcycle, while others posed with *Celik*, a cute robot functioning as the symbol of a local appliance manufacturer. At both festival places, a very popular activity was being photographed as an

Ottoman sultan. For \$10, one could be easily transformed to a sultan or his wife, complete with the period attire and look, and immortalize this instance with a color photograph. Couples as well as families rushed into, creating long queues every night. Candy and beverage stalls spread all over the festival areas were very popular as well.

While the Blue Mosque and *Feshane* festivals had a more mass appeal, the *Talimhane* festival claimed to offer a more “authentic” and exclusive Ramadan experience. The stalls placed alongside the street were again in the form of replications of the traditional Ottoman houses. However, instead of selling food and cheap paraphernalia, these stalls hosted craftsmen who were invited from all over Turkey by the municipality in order to promote and sell their art to the tourists as well as the upper-middle class residents of Istanbul. Along with handicraft replications of Ottoman art and jewelry the decorations used in the area attempted to create a more “authentic” revival of the past. Several real-life size black and white photographs portraying scenes from everyday life in the Ottoman period were placed next to the stalls. For example, visitors drinking Turkish coffee and smoking hookahs were sitting in front of a photograph of a traditional coffeehouse, while at the background of the visitors resting on an Ottoman style couch was a photograph of a living room of an Ottoman house. Moreover, actors dressed in Ottoman style dresses were strolling along the street, posing frequently with visitors to be photographed. Overall, for a month *Talimhane* was transformed to a nostalgic Ottoman neighborhood complete with the images of the Ottoman house, the grocery store, the coffeehouse, the spice store, and the whirling dervishes.

Taken as a whole, the municipality, by creating these festive consumption spaces, makes Ramadan an attractive event to the retailers, residents and tourists. In the mean time, the municipality also profits as it rents the stalls for around \$10,000. Through the intersection of sacred (religion and history) and profane (shopping and leisure), public authorities and retailers, attempt to sacralize the ordinary commercial commodities (O’Guinn and Belk, 1989), most of which are commonly available. Similar to theme parks like Disneyland, a “dedifferentiation of consumption” is evident as different institutional spheres become increasingly interconnected with each other (Bryman, 1999, p.33). This tendency is also evident in the Ramadan festivals as we see a tendency for eating, shopping and leisure to become “inextricably interwoven” and very difficult to separate (Bryman, 1999). Through a selective portrayal of history (Goulding, 2000), the Ramadan festivals also resonate with the trend of the “commodification of history” (Barthel 1996), which involves consumption practices related to the past. This themed past however, is cleansed from all the negative effects that may break the marketable theme and thus, places present a simulation of the Ottomans’ glory.

SHOPPING MALLS

Shopping malls become another site for the revival of the commodified version of the Ramadan ritual. The literature provides evidence that shopping malls have become venues for activities other than shopping and destinations in their own right (Bryman, 1999). Malls nowadays, provide a wide variety of services, such as restaurants, banking facilities, cinemas and leisure facilities for children, allowing individuals to participate in activities other than shopping (Sandikci and Holt, 1998). During the month of Ramadan, both of the shopping malls that we examined were turned into festive places themed with Ottoman symbols. Similar to the festivals organized by municipalities, the malls after *iftar* provided live music, shadow shows, and plays for the children.

The main entrance of the Migros Shopping Mall was decorated with some massive gold colored Tulips, which welcomed the

visitors with a reference to the old Ramadan days. The mixture of gold and tulips reminds the entrances of the luxurious Ottoman palaces with their renowned gardens and rich interiors, often described as paradises on earth. Located next to the main entrance were a miniature of the Blue Mosque in purple color and a miniature of an Ottoman neighborhood. The interior of the mall was further decorated with lively colored *fezzes*, which were initially used by the Ottoman soldiers and then were adopted as an everyday hat by the Ottoman men. Lively colored ribbons similar to the ribbons hold by the Ottoman army band were hanged between the *fezzes*. The corridors were decorated by purple lanterns, which connoted the lanterns used to light the streets in the Ottoman Empire. The decorations combined the pre-modern symbols of the most significant era of the Turkish history with modern and fashionable colors, such as turquoise blue, green, red and purple.

Apart from the decoration, the mall was transformed into a festival space after the post-sunset *iftar* feast. A traditional coffeehouse, with its stools and small tables, was set up on the third floor of the mall. In the same area, a small stage, where traditional performances (e.g. *karagöz* and *meddah*) and live music were performed, was built. Individuals could watch these activities from the upper floor as well, where the food court is located. Additionally, small stands were located all over the mall, which sold nostalgic candies and beverages (e.g., cotton candy, toffee apple, cotton halva).

Although the decorations in the Bilkent shopping mall were less spectacular, the atmosphere was similar. Here as well, a stage to host various performances was built. With Oriental lanterns and fabrics, Turkish carpets, a wooden carriage full of Ramadan candies, straws sprinkled down on the floor and waitresses dressed in Ottoman clothing, the place was reminiscent of the Ottoman past. The spirit of Ramadan also transformed the supermarkets located at the malls. Ramadan streets featuring different stands selling snacks eaten when breaking the fast, such as olives, dates and pitas, were built inside the supermarkets in both malls. The decorations at the Migros supermarket were an extension of the decorations used inside the shopping mall, colored fesses and ribbons, gold tulip-like decorations and different kind of lanterns were placed all over the shop. In the supermarket at the Bilkent shopping mall, there was a Ramadan Street comprising of stands made to look like the facades of the Ottoman houses. A wide variety of snacks and products that were related with Ramadan were available for purchase.

Overall, both malls attempted to create a simulation of the pre-modern agora or bazaar. The prehistoric market was essentially social, characterized by crowds, close physical context, and highly personal interchange, which provided for an exciting, festive environment (Gumpert and Drucker, 1992). Malls nowadays attempt to replicate the feeling of market through design and atmospherics, recreating a simulated controlled “urban” environment (Gottdiener, 2001). Likewise, shopping malls, through the commodification of social experience, seek to re-construct the spirit of the publicly-celebrated Ramadan experience, an experience that has lost its public appeal during the making of the modern republic. The Ottoman theming allows consumers to experience the collective but forgotten past through fantasy, similar to Disney’s Main Street, which allows consumers to experience a suburban town in America (Holak and Havlena, 1991). But although nostalgia draws from the past, it is clearly a product of the present. As Panelas (1979) argues nostalgia is always evoked in the context of current modern fears and anxieties. Shopping malls resolve the modern societies’ anxieties through providing security in all their entrances, offering a controlled environment cleansed from the unexpected events (pickpocketing, street fights etc.) that contaminate the municipality festivals.

HOTELS AND RESTAURANTS

From fast-food chains like McDonalds to luxurious five star hotels, restaurants offer different menus in a variety of price ranges. The most conspicuous consumption of *iftar* feasts occurs in five star hotel and restaurants, which through advertising try to create an alternative “elite spirit” of Ramadan. The market offers to its elite Muslim followers the ability to experience the sacredness of the month at an exclusive environment. However, rather than being available to anyone wishing to attend (Procter, 2004), luxurious hotels and restaurants re-produce differences in class positions, as *iftar* dinners cost \$30 or more per person.

Similar to the other contexts, hotels and restaurants promote the revival of the ritual by emphasizing the Ottoman references. For example, the advertisement for Polat Renaissance Hotel portrays the Blue Mosque in the days of the Ottoman Empire. The picture shows Ottoman merchants gathered around the garden of the mosque dressed in the attires of that epoch. The ad attempts to draw an analogy between the mosque and the hotel by alluding to the fact that religious centers were also commercial centers in the pre-modern times (Ibrahim, 1982). Similar to the religious centers of the Ottoman epoch, the hotel creates a sacred centre in their commercial space. The hotel claims an “authentic” revival of the past and welcomes its visitors to the most “authentic” experience of Ramadan. Another five star hotel in Istanbul, Ceylan Intercontinental, associates its brand name with the word *iftar*. Just after sunset when the fasting is over, televisions channels declare the end of the fast by the announcement “Now, it is the time for *Iftar*”. Alluding to the announcement, the Ceylan Intercontinental advertisement reads “Time for Ceylan in Ramadan”. The ad also features the characteristic signature of the Ottoman Sultan in the form of a music note, which further emphasizes the courtly quality of *iftar* at Ceylan Intercontinental.

The Ramadan feast at the five-star hotels and up-scale restaurants included a plethora of dishes, starters, main dishes and sweets, which reflect the abundance of choices presented to the modern consumer. Consumers enjoyed their *iftar* either in set menus or in American style buffets. The choice of a menu dining was not limited to a single fixed menu. Rather, hotels and restaurants offered at least four different menus in order to respond to their customers’ tastes. Moreover, individuals could create their own customized menus. The food offered was a combination of the rich cuisine of the Ottoman Empire and a variety of options among Turkish and World cuisines (e.g. Mexican, Italian and Greek cuisine). The consumer was not limited to the local tastes of his/hers country; rather, food acquired a global taste. Not only the choices of the food, but also the presentation of the food created an elite feast. The food is often served in copper cutleries, which used to be the tableware at the Ottoman Empire. Live traditional Turkish music also was performed throughout the feast. In some of the restaurants, even *Whirling Dervish* performances were carried out. Some restaurants revived traditions that were long forgotten, such as “*Di? Kirasi*”. During the Ottoman times, when a family invited visitors for the *iftar* feast, the hosts also gave small gifts to their guests. Modernizing this ritual, an upscale restaurant, *Asitane* offered gifts like silver cigarette cases and amber rosaries to its patrons.

The nostalgia created in these contexts are based on an elite longing for the past, a longing for the lives of the Sultans and the life at the Ottoman palaces, rather than a longing for a collective past (Holak and Havlena, 1991). Ottoman Sultans enjoyed all aspects of the imperial glory such as the art, leisure and richness of the cuisine, without having to wait for the sacred month of Ramadan (Sakaoglu and Akpınar, 1999). Through their sophisticated decorations, selection of dishes and entertainment activities, the up-scale restaurants

and five-star hotels attempted to create a simulation of a Ramadan celebration at the Ottoman palace. Thus, although Ottoman theming was present in all three contexts that we discussed and similar cultural motifs were used to invoke the Ottoman past, their differential use enabled companies to differentiate the offerings in order to appeal to different consumer markets (Gottdiener, 2001).

CONCLUSION

This study contributes to the literatures on rituals and globalization by studying how rituals are modified, reinterpreted, and reinvented in the marketplace. We discuss how the interaction of the global and local revive and transform the practices and the meanings of Ramadan ritual. In their study of Christmas celebrations in Japan, Kimura and Belk argue that Western holidays like Christmas, Valentine’s Day, and Halloween, which have complex cultural ideologies behind them, “threaten to displace traditional local holidays” (2005, p.325). However, we argue that in some cases, rather than displacing, they might revive and modify existing local rituals. Our findings indicate that the commercialization of Ramadan is neither an instance of cultural imperialism where Western life forms erase local life forms under the disguise of globalization (i.e., McDonaldization, Ritzer, 1995), nor an instance of postmodern disorder, characterized by liberating experiences and themes erasing the limits of the modern project (i.e., Disneyization, Bryman, 1999). Ramadan is rather like “traffic in things” (Jackson, 1988) and a process of glocommodification (Ram, 2004). Jackson (1998) argues that commoditization is like traffic, in which various agents encourage the revival and transformation of meanings and responses. Similarly, Ram (2004, p. 27) discusses global commodification as a dual process that “combines structural uniformity with symbolic diversity”.

At the symbolic level, there are distinctive characteristics that differentiate the ritual of Ramadan from other holidays and create a unique experience for the Muslim followers. Different forms of post-sunset *iftar* feasts and celebrations together with the use of the symbols of the Ottoman Ramadan festivals encourage a local heterogeneity. On the other hand, contemporary rituals are still edited in accordance with the needs of the profit-oriented industries (Schmidt, 1991), and thus reproduce the deep-seated social relationships involved in their production and consumption (Ram, 2004). The global consumerist ideology facilitates and strengthens the consumption of “sacralized” commodities in the form of products, services, places, and experiences, and offer consumers a new occasion for shopping and leisure. Ramadan turns into a “glocommodified” (Ram, 2004, p. 27) ritual, combining a variety of symbols connoting religious values and beliefs as well as markers of global consumption ethos. Theming, which underlies all three contexts we discussed, operate as a major instrument of commodification.

Although this glocommodified ritual encompasses many features that appear to fit postmodern theories, many modern foundations shape the ritual. Unlike, Beardshow and Bryman (1999), who argue that themed environments include many of the reassuring securities of modernity such as physical safety, comfort and hygiene, we argue that more powerful actors such the nation state and the existing social hierarchies reproduce modern foundations. Our results indicate that local municipalities and the market have forged close ties for the revival of the religious ritual. Municipalities transform religious and historical places into temporary commercial markets. While the local government profits from organizing the sites, retailers profit by finding another channel to market their products. However, what underlies this cooperation is not only the profit motive, but also the state’s political ambitions.

The Islamist party, which controls the governance of major cities as well as the country, emphasizes both the religious and Ottoman values for the contemporary Turkish identity and takes advantage of any incidence that can be converted into some form of cultural and religious propaganda. As Kopytoff (1986) argues the commoditization of holidays is significantly related to “the cultural and ideological premises that suffuses its working”. Thus, in contrast to postmodernist theories, rather than an erosion of the state’s ability to forge national and in this case religious identities (Firat and Dholakia, 2003), the nation state becomes a primarily agent in the revival of the ritual.

A second feature that contradicts the liberating experiences of post-modernity is the reproduction of social structures, which creates a deprived experience of the ritual for many individuals. In contrast to the conceptualization of festival celebrations as being available to anyone who wishes to attend (Procter, 2004), Ramadan festivals reproduce social inequalities. For example, the luxurious feasts in five-star hotels and restaurants and certain forms of entertainment in the municipality festivals, which require payment of a cover fee, limit accessibility. Rather than acting as a ritual that emphasizes ultimate unity and equality of all believers before God (Esposito, 1991; Creighton, 1993), Ramadan festivals reinforce accepted social hierarchies.

Overall, this study offers an initial attempt to explore the forms of revival and modification of local rituals in the marketplace. As this study was primarily composed of an analysis of representation, more insights can be gained through conducting in-depth interviews with the agents that have the power to edit rituals, as well as the individuals, who consume these rituals. Questions of how rituals influence each other and how consumers make sense of the local and the global, the past and the contemporary, offer a range of opportunities for further research.

Team-Sponsorship in the Formula One—Does it affect Brand Perception? An Empirical Assessment in the German Car Market

David M. Woisetschläger, University of Muenster, Germany

INTRODUCTION

Sponsorship as a marketing tool has grown remarkably during the last two decades, especially with respect to the endorsement of worldwide sports events. Besides the FIFA World Cup™ or the Olympic Games, the Formula One is the only event with a comparable global character taking place in 17 countries all over the world, ranging from Brazil to Japan, from Australia to Italy and, for a short time, the US. It consequently stands to reason, that especially many big international companies use Formula One as a platform for building, strengthening and holding up their brand equity. With its extension to Shanghai in 2005, the Formula One has become fully globalized.

The Formula One Circuit is financed predominantly out of sponsorship money, while TV broadcast and entrance fees are of only minor importance. In the past, the Tobacco Industry has been one of the biggest contributors to the Formula One. Since the European Union ordered the tobacco companies to back out of the sponsorship deals by 2006, the teams now have to find new business partners. Consequently many global players like Emirates, Red Bull and Intel are entering the Formula One. However, companies that engage in Formula One sponsorship have to be sure about the effectiveness and efficiency of their engagement. Companies expect an effect of sponsorship on the brand, more specifically on brand awareness and on brand image dimensions. Brand awareness relates to the strength of a brand in memory, and the likelihood and ease with which the brand will be recognized or recalled under various conditions (Silverman et al. 1999). Brand image is defined as “perceptions about a brand as reflected by the brand associations held in consumer memory” (Keller 1993). The favorability, strength and uniqueness of brand image permit the brand to be strategically differentiated and positioned in the consumer’s mind.

In the present paper, I take a closer look at the Formula One activities of Toyota and its impact on the brand awareness and brand image dimensions in the German consumer market. In the last decades, the Toyota Motor Corporation (TMC) has been subject to several studies and been a main attraction to both competitors and the scientific communities (e.g. Womack et al. 1990). While the specific capabilities of TMC in technology, total quality management (Kaizen) and efficiency (Kanban) contributed to its current dominant position in most world markets (above 10 percent market share world wide), its market position in Germany remains weak (about 4 percent market share in 2004; Frank 2004). Especially in Germany, Japanese brands are valued for their functional attributes but are evaluated poorly concerning the non-attribute based image such as personality and character, attractiveness and likeability (Vogel et al. 2006). One of Toyota’s most important aims in the Formula One is to improve its non-attribute based image (Toyota 2005).

I contribute to the literature by analyzing (1) antecedents of sponsorship recall that can be explained through prominence heuristics and involvement, (2) consequences of sponsorship recall on the evaluation of brand awareness and brand image dimensions that are explained with mere exposure effects. (3) Both antecedents and consequences are analyzed for two measuring points using a panel of 2.116 (1.131) consumers. (4) Finally, I take a look at the change of brand awareness and brand image between the two measurement points and assess, whether the “fit” between the image of formula

one and the sponsoring brand plays a critical role in the process of image transfer.

THEORETICAL BACKGROUND AND HYPOTHESES DEVELOPMENT

As sponsorship became more and more important in terms of growing budgets since the late 1980s, research on sponsorship had been intensified accordingly to this development. Five research streams (nature of sponsorship, managerial issues, measurement of sponsorship effects, strategic aspects, and legal and ethical issues) have been identified by Cornwell and Maignan (1998) and updated by Walliser in 2003 including later—primarily European—research. In this study, the issue of measurement of sponsorship effects is addressed.

Measurement of sponsorship effects is still a topic that is of growing interest to both the scientific community and practitioners. Sponsorship has been found to affect (1) brand awareness (e.g. Quester and Thompson 2001), (2) brand image/associations (e.g. Javalgi et al. 1994; Pope and Voges 1999,), (3) employees (e.g. Grimes and Meenaghan 1998), (4) purchasing intention (e.g. Bennett et al. 2002; Pope and Voges 1999, 2000; Speed and Thompson 2000), (5) and even investor relations and stock market prices (e.g. Cornwell, Clark and Pruitt 2004; Cornwell and Pruitt 2001). Especially the potential influence of sponsorship on brands has been subject of several studies (e.g. Grohs et al. 2004; Gwinner and Eaton 1999; Javalgi et al. 1994; Speed and Thompson 2000).

However, the analysis of the effect of sponsorship on brand image over time has been only subject of very few research works (e.g. Quester and Farrelly 1998; Becker-Olsen and Simmons 2002; Grohs et al. 2004; Pitts and Slattery 2004). A reason for that could be the lack of sound theoretical underpinning of the effects of sponsorship.

For instance, Cornwell, Weeks and Roy (2005, p. 21) claim, that research on sponsorship effects “is lacking theoretical frameworks of how sponsorship works in the minds of consumers” and provide a number of theoretical explanations of sponsorship effects. More precisely, they identify a number of processing mechanics that provide a theoretical explanation of sponsorship on a cognitive, affective and behavioral level (Cornwell, Weeks and Roy 2005, p. 22).

For my investigation of effects in the context of Formula One Sponsorships, I draw back on (1) prominence heuristics, (2) the mere exposure effect and (3) balance theory.

(1) Prominence heuristic, as analyzed by Pham and Johar (2001), proposes that well-known brands are recalled more frequently in comparison to less known brands. They claim, that sponsorships for brands that are less known should be avoided, when other—well known—brands are engaged in a sponsorship in the same field.

More specifically, sponsorship recall is influenced by existing knowledge about the brand, and the involvement of a particular person with the product category of the brand and the sponsored event. Following the heuristic of brand prominence, one can argue that high brand equity—which is defined as difference in consumer choice between the focal branded product and an unbranded product given the same level of product features (Yoo et al. 2000) will make it more likely that a specific sponsor is recalled. This rationale

is confirmed by the findings of Pham and Johar (2001). Therefore, one can hypothesize that

H_{1A}: The higher the brand equity of a specific sponsor, the more likely it will be recalled.

Furthermore, it could be expected that product-related involvement and involvement with the specific event will lead to a higher probability, that a person will recall the sponsorship stimulus. In a low-involvement condition, consumers will process the stimulus less intensively (Krugman 1965, 1966). This rationale is confirmed by the findings of Grohs et al (2004). Hence, it is proposed that

H_{1B}: The higher the product-related involvement, the more likely the sponsorship will be recalled.

H_{1C}: The higher the event-related involvement, the more likely the sponsorship will be recalled.

(2) The mere exposure effect suggests that in absence of other stimuli (Baker 1999), repeated exposure to a stimulus will lead to an affective reaction (Zajonc 1968). Sponsorship is—similar to advertising—often directed to respondents in a situation where they pay low attention to the stimulus (e.g. because of concentrating to the event). Therefore, it has to be repeated several times in order to attract the attention of a respondent's mind (Baker 1999). Existence of the mere exposure effect is confirmed by several studies (e.g. Bennett 1999; Olson/Thjomøe 2003).

On the basis of the existence of mere exposure effects, it is proposed that if a person is able to recall Toyota as a Formula One sponsor or advertiser, the awareness and image of the brand (as defined in the introduction of this article) will be significantly more favorable than for persons that do not recall the any of those two stimuli. This is in accordance with findings in existing literature (e.g. Bennett 1999). Hence, I hypothesize that

H_{2A}: If a sponsor is recalled, its brand awareness will be significantly more favorable.

H_{2B}: If a sponsor is recalled, its brand image will be significantly more favorable.

(3) The attitude toward the event (i.e., event image) is supposed to influence the processing of the sponsoring stimulus. Many authors claim, that a "fit" between the sponsored event and the sponsoring brand is essential to realize an image transfer (e.g., Cornwell et al. 2005; Dean 2002; Hastie 1980). However, learning is less likely to take place if sponsor and sponsored event are already perceived as "congruent". Following balance theory (Heider 1946, 1958), I propose that a positive distance in evaluation of the event relative to the brand in $t=1$ will lead to an increase in awareness and image transfer (increase in favorability of brand dimensions) in $t=2$. According to balance theory, people that identify a sponsor to be associated with an event or team in the first place and have a relatively negative opinion about the sponsoring brand in comparison to the sponsored event will evaluate the brand more positively over time. Based on assimilation-contrast theory (Sherif and Hovland 1961), a decrease in favorability of the brand dimensions is expected, if the brand is evaluated better than the event in $t=1$ using the same explanation as above. Since the brand is evaluated more positively than the event in the first place, the knowledge of a relatively negative cue (i.e., that the brand is engaged in sponsoring an event with a negative image) will lead to a less favorable evaluation of the brand in $t=2$. No effect is expected for a "fit" i.e. a relatively similar evaluation. Therefore, it is hypothesized that

H_{3A}: A positive difference in evaluation of the event image relative to brand awareness/brand image leads to an increase in brand awareness/brand image favorability.

H_{3B}: A negative difference in evaluation of the event image relative to brand awareness/image leads to a decrease in awareness/brand image favorability.

METHODOLOGY

Questionnaire Development and Pretesting

To measure the respondents' perceptions with regard to brand awareness and brand image a pool of sample measures was generated based on literature review (see appendix). The items were pretested using a sample of 20 German undergraduate marketing students. These subjects did not participate in the following field survey. Regarding question content, wording, format and layout there were no signs of any misunderstanding reported by the respondents.

Measurements

On that basis a questionnaire was developed consisting of three different parts. In the first part, the respondents were asked to name car brands they could remember from (1) advertising and (2) sponsoring a Formula One team. Following Baker et al. (1986) and Keller (1993), I decided against asking for ad/sponsorship recognition, since the unaided awareness of a brand is supposed to be a required condition for the purchase of more complex products e.g. cars. Moreover, the measurement of recognition would be subject to several biases, e.g. interest of a person in the brand (Bennett et al. 2002, p. 177) and, more importantly, to a bias in the second survey.

In the second part, the respondents were asked to evaluate several brand related constructs (brand awareness, brand equity and several image attributes) for Toyota and one of 13 other brands.¹ These brands were only included in the questionnaire to avoid a possible identification of the questionnaires purpose in the second survey. Sponsor-related variables were measured using multi-item scales. All items are measured on 7-point Likert-type scales, with anchors of 1=strongly agree and 7=strongly disagree. Based on Yoo et al. (2000) 3 of their items were used to measure a sponsor's brand awareness and 4 items to measure brand equity. Several items from Verhoef et al. (2004) and from the Allison-Fisher Barometer of Awareness and Imagery (as described in the article of Scott and English (1989), see appendix for the list of items) were used to measure brand image and the image of the sponsored event. Conceptualizing brand image, Park and Srinivasan (1994) postulate that brand image consists of an attribute related dimension and a non-attribute component. I follow Park and Srinivasan (1994) and postulate that brand image (in the case of automobile brands) consists of two dimensions: Functional trust, which consists of attributes that are closely linked to quality and hedonic image which is built by attributes that represent the personality and imagery of a consumer.

Finally the respondents were asked for their interest in cars in general, their involvement with the Formula One and socio-demographics.

Sample and Data Collection

To test the hypotheses, data was collected via internet. A questionnaire was mailed to 40,927 E-Mail addresses in Germany.

¹These 14 brands were selected because they account for 86.06 % of the German car market in 2004. The remaining 13.94 % of the market contains several niche producers with little relevance to the market as a whole.

Goodness-of-fit statistics: CFI (0,942); TLI (0,933); RMSEA (0,071); SRMR (0,035).

The population was chosen based on a selection of E-Mail addresses that is representative to Germany concerning age, gender and region with support of CIAO Online Surveys. A total of 4,173 respondents answered the first survey in January 2005, 2,116 of them also participated in the second survey in July 2005 (one week after F1 season height in Hockenheim, Germany), equaling a response rate of 10.2% (50.5%). 48.1% (51.4%) of the participants were male, average age of the participants was 38.9 (standard dev. 11.6) and 38.5 (11.9) in the second survey. The first dataset was split into two equal parts. An exploratory factor analysis was conducted and all constructs were identified as proposed above. One item was eliminated from the brand awareness construct due to low indicator reliability (BA2) and from the event image construct (IF1) for the same reason. The results of the confirmatory factor analysis with the second part of the dataset are depicted in table 1 below.

RESULTS

To test the effect of brand equity and involvement on the recall of Toyota as a sponsor of a Formula One-team, a logistic regression

was conducted with the dichotomous variable “recall” as dependent, and brand equity, product-related involvement and event-related involvement as independent variables for one measuring point. Studentized residuals, Cook’s Distance and multicollinearity were examined to determine if assumptions of logistic regression were violated.

As can be seen from table 2, all three constructs exhibit statistically significant positive influence on the likelihood a sponsor is to be recalled. The influence of event-related involvement is highest, followed by brand equity and product-related involvement. All three Hypotheses H_{1A} , H_{1B} and H_{1C} are confirmed, also with the replication using the second dataset. The model fits well since only four iterations were needed until no further improvement of the likelihood was achieved (improvement $< .001$) and the likelihood-ratio test led to highly significant results. Nagelkerke’s R^2 ($NR^2 = .232/.184$) is satisfying.

The effect of Ad and Sponsorship recall on the dependent constructs is tested by conducting a MANCOVA. The required assumptions were checked as discussed in existing literature (e.g.

TABLE 2
Logistic Regressions of drivers of Sponsorship Recall (measuring times 1/2)

***p<0.01; **p<0.05; *p<0.1; n₁=1040/n₂=784

Tabachnik and Fidell 2001 pp. 282 and pp. 329). Since the assignment to different groups (dependent on recall of the independent stimuli) could not be randomized by default, group sizes vary strongly. Therefore, the dataset was reduced in order to achieve equal group sizes (random samples from the larger groups). The constructs are not normally distributed and homogeneity of variances of the dependent variables was slightly different. According to Olson (1974, pp. 894) and Bray and Maxwell (1985, pp 33), these violations can be accepted if the dataset is large enough and the group sizes are equal. As described in table 3 below, cell size in the first dataset is 270 (2x2x270=1040 total) and 196 (2x2x196=784 total) in the second dataset.

Unweighted means of the item scores were used as values for the dependent constructs. The construct of event-related involvement interacts with the independent factors, therefore only product-related Involvement is used as a Co-Variable. Results of the MANCOVAs of the two measurements indicate significant main effects and an insignificant interaction effect. The influence of product-related involvement is also significant in both surveys. Following Cohen (1988), the strength of the effects is rather small (only ad recall yields the 5.9 % level of a middle-sized effect).

Follow-Up-ANCOVAs were conducted to determine the effect of the stimuli and Co-Variable on each dependent construct. As can be seen from table 4, all main effects are significant for each construct. However, the strength of the effects differs largely. In the first round, the effect of ad recall on brand awareness and non-attribute-based image is much higher than in the second survey, on the contrary, the effect of sponsorship recall is much stronger in the second survey. Since Toyota was relatively successful in the

Formula One Season 2005 up to the measuring point in late July (57 points compared to a total of 8 points in the 2004 Season), this offers a possible explanation of the increase in sponsorship effect. The weakening of the ad effect could be explained due to the fact that one of the most expensive advertising measures of Toyota—the role of media presenter of the German Soccer League “Bundesliga” – was absent for more than a month because of the season break.

Lastly, post-hoc-tests were conducted to check, whether the hypothesized effects show into the proposed direction. As described in tables 5A (first survey) and 5B (second survey), the knowledge of a stimulus leads to a significantly better evaluation of each brand construct. Therefore, our Hypotheses H_{2A} and H_{2B} can be confirmed.

Finally, I take a look at the change of brand awareness and brand image dimensions between the two measuring points. As proposed in Hypothesis H₃, we a more positive evaluation of the brand Toyota in t=2 is expected if the image of Toyota is evaluated relatively worse comparing to the image of Formula One in t=1. Only consumers are included in this analysis that could at least once recall Toyota as a Formula One sponsor. Results in table 6 show that only the group that evaluated Toyota relatively worse comparing to Formula One (“positive distance”) in the first place has a significant awareness/image enhancement, giving support for Hypotheses H_{3A} and H_{3B}.

IMPLICATIONS AND DISCUSSION

The findings of this study confirm that sponsorship recall is significantly influenced by perceived brand prominence (brand equity) and both product- and event-related involvement. There-

fore, the sole measure of recall does not offer an unbiased conclusion of sponsorship effectiveness. Moreover, the impact of sponsorship on the brand has to be separated statistically by other possible influences. A first attempt was made in this paper by including advertising recall as a complementary promotion action of companies. The change of brand awareness and brand image dimensions over time was found to depend on the relative evaluation of event image vs. brand image in the first place. This result is in accordance with balance theory and attribution-contrast-theory but contradicts empirical results of other authors (e.g. Speed and Thompson 2000; Dean 2002).

Further research should focus on gaining insights about how the sponsorship message is processed by consumers. Possibly experiments are particularly suitable to deepening the understanding about processing of the sponsorship message in comparison to field studies. However, especially from a practitioner's perspective, rigorously conducted field studies in a real context can lead to an improvement of current sponsorship evaluation practice which is often based on recall measures solely or evaluation of broadcast time. The use of panel data is adequate to analyze individual responses (e.g. change in attitudes or behavior) over time.

APPENDIX

List of Items

Product-related involvement

- IP1 I am very interested in cars in general
- IP2 I know a lot about cars
- IP3 I regularly catch up on news about new car models

Event-related involvement

- IE1 I regularly watch Formula One
- IE2 Formula One is important for me
- IE3 Formula One means a lot to me

Event-Image

- IF1 Formula One stands for sportiveness
- IF2 Formula One is likeable
- IF3 Formula One is unique
- IF4 Formula One is attractive
- IF5 I can identify myself with the Image of Formula One

Brand Equity

- BE1 It makes sense to buy X instead of any other brand, even if they are the same
- BE2 Even if another brand has the same features as X, I would prefer to buy X
- BE3 If there is another brand as good as X, I prefer to buy X
- BE4 If another brand is not different from X in any way, it seems smarter to purchase X

Brand Awareness

- BA1 I can recognize X among other competing brands
- BA2 Some characteristics of X come to my mind quickly
- BA3 I can quickly recall the symbol or logo of X

Attribute-based Image (Functional)

- F1 I can trust X
- F2 I can rely on X
- F3 X is a really dependable car
- F4 Cars of Brand X last a long time
- F5 Cars of Brand X are excellent in workmanship

Non-attribute-based Image (Hedonic)

- H1 Cars of Brand X are good looking
 - H2 X builds cars with personality and character
 - H3 Cars of Brand X are sporty
 - H4 Cars of Brand X are attractive
 - H5 Cars of Brand X are desirable
 - H6 Cars of Brand X are young
-

The Commercial Appeal of Communism. Semiotic Tensions in the U.S. Stoli Advertising Campaign

Natasha Tolstikova, University of Maine, USA
Matthias Bode, University of Hannover, Germany

EXTENDED ABSTRACT

In 1994, the advertising campaign for Stolichnaya vodka appeared in the U.S. consumer magazines. The original works of young Russian artists were united into a campaign with the slogan "Freedom of Vodka." The ads attracted attention with colorful images created in the style of what a few in the U.S. have been familiar with as Russian Lubok, Russian Constructivism, and Socialist Realism. The Stoli advertising campaign is a juncture where several topics that have been the preoccupation of recent advertising studies, such as the predominance of visual imagery in contemporary advertising, the relationship between art and advertising, and the changing nature of advertising in postmodern age. The campaign provides a ground for advancement in the analysis of advertising. This article establishes a new visual figure of speech called "semiotic tension." Semiotic tension is the syntactic relation that binds two elements in their negative relation to each other. The specific quality of semiotic tension is the affective interpretive pleasure of tension. The moment of closure is focused more on the recognition of tension than the emergence of a coherent semantic solution. The dominant syntax of the Stolichnaya ads is based on the juxtaposition of opposites, driven by the basic antagonism of addressing North-American consumers with an anti-capitalist, Soviet-style aesthetics.

The time of the binary division between the "hard-sell" advertising with its logic and the "soft-sell" advertising, with its emotional appeal, is long gone. Instead, advertising together with the western affluent societies became more colorful, faster, louder, and more complex. The science of semiotics offered a set of tools to make this new world readable: as Saussure defined it, "a science which studies the life of signs at the heart of social life" (1974, 16).

In our analysis of the Stolichnaya campaign we want to demonstrate a semiotic process that has been neglected in advertising semiotics so far. We suggest a *layers of tension model*, that emphasizes an advertisement feature charged by a tension between elements within the ad. First, tension can be constructed on the level of re-contextualization, based on the use of referent systems in the ad. The second level of tension can occur in setting up the syntactical relationship between the relevant elements of the ad. While we take on a structuralist perspective in the textual mechanism of the ad, we do not assume a requisite resolution of the tension between the elements. In this aspect, we adhere to a post-structuralist perspective, emphasizing a more active reader in the negotiation of meaning and the possible openness of realized meanings.

Semiotic tensions are similar to the ad feature of resonance, developed by McQuarrie (1989), McQuarrie and Mick (1992). They define the rhetorical figure of resonance as a repetition of elements within the ad which echo with one another and lead to a multiplication of realized ad meanings. Resonance does not include simple ambiguity or opaqueness, but a doubleness of elements. Semiotic tension is also based on a syntactic relation, but, rather, the echo rests upon the negative feature of oppositions than the resonant positive feature of sameness. Metaphorically, the two semiotic features share a similar force binding two elements and can be distinguished as adhesion based on tension and cohesion based on resonance. Contrary to resonance, semiotic tension emphasizes more the interpretive process than the final semantic result. Based on the aesthetic theory of Berlyne (1971) and Meyer (1956) we

argue that for a positive affective aesthetic response to an ad the activated expectation is temporarily inhibited. In the semiotic tension model the disparate elements are the cause of the inhibition. Contrary to the post-structuralist position of permanently inhibited closure, we see the moment of closure in the perceived tension.

All the images of the 1994 Stoli advertising campaign have several features in common, such as original art stylized to look like early Soviet propaganda arts and the slogan, "Freedom of Vodka," written across each image. On the macro level, these features create a common tension in each image, such as a negative echo between the goals of public agitation, aiming to change the mentality of the whole human being versus commercial agitation, aiming to change one aspect of life, the purchasing patterns. Another persistent semantic tension is between the different meanings of freedom to the Soviets and Americans. While ideological propaganda claimed that Soviets were free from the oppressive forces of capitalism and hailed a freedom from unemployment, the U.S. ideological propaganda elevated freedom of choice, especially in the consumer goods realm; free to choose Stoli over other vodka. In addition, each ad contains individual tensions created by relations between elements that have to do with the meaning of symbols in a different cultural contexts.

The 1994 Stoli advertising campaign can be viewed as an act of symbolic cannibalism where representations of the enemy's ideology are appropriated. On an ideological level it definitely helped that the old enemy was brought down and lost the power of a latent threat. However, the old symbols still regained a certain charge, defined in a symbolic opposition.

We argue in this paper, that the quality of the campaign remains abstruse when analyzed in a post-structuralist and postmodern perspective. To see the Stoli ad as another example of a free-floating signifier chain is missing the point of a connectedness between the sign elements that comes from the negative echo of semiotic tension.

With our paper we nourish the hope for a more semiotically enlightened analysis of advertising that remembers again the virtues of methodological pluralism and gets over the choking postmodern fixation.

Attribute-Value Functions and the Importance of Attributes

Koert van Ittersum, Georgia Institute of Technology, USA

Joost M.E. Pennings, University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

Introduction

The validity and reliability of attribute-importance measurement is highly method-dependent. We propose to evade this method-dependency by shifting our attention to decision makers' value functions of attributes and investigate if and how the global and local shape of these value functions relate to different dimensions of attribute importance.

Attribute-value functions reflect the idiosyncratic valuation of an attribute at different attribute levels, relative to decision makers' reference points (Tversky and Kahneman 1991). We investigate the relationship between the *global* shape (i.e., S-shape, convex, concave) and the *local* shape (i.e., reference point, loss aversion, diminishing sensitivity) of attribute-value functions and the *global* and *local* importance of attributes (Goldstein 1990). The global importance of attributes reflects the importance of an attribute as a stable characteristic that does not depend on a specific stimulus set. The local importance of attributes reflects the importance in judgment and depends on the stimuli set under consideration.

Theory and Hypotheses

Our main proposition is that the shape of attribute-value functions relates to the importance of attributes. First, we hypothesize that *the global importance of an attribute polarizes and thus relates to decision makers' reference points* (H1), *increases decision makers' loss aversion* (H2) and *increases decision makers' diminishing sensitivity* (H3). These hypotheses are based on the notion that decision makers for whom an attribute is important based on personal values and needs (i.e., high global importance) will purchase products that perform maximally on that attribute and consequently develop a reference point that equals an attribute level at the end-poles of the relevant range of attribute levels (Kalyanaram and Winer 1995) (H1). Furthermore, the global importance of an attribute will positively influence the effects of changes in the attribute levels as reflected in decision makers' loss aversion (H2) and diminishing sensitivity (H3).

Building on the hypothesized effects of the global importance on decision makers' reference points, loss aversion, and diminishing sensitivity, we hypothesize that *the global importance of an attribute increases from decision makers with a convex value function for the attribute to decision makers with an S-shaped and concave value function* (H4).

The local importance of an attribute is generally operationalized based on the differences in valuation of attribute levels in a judgment or choice task. The difference in valuation depends on decision makers' reference points and loss aversion, which results in a steeper value function in the loss domain. Hence, *if (most of) the attribute levels in the judgment or choice task reflect a loss, the local importance will be larger than when (most of) the attribute levels in the judgment or choice task represent a gain* (H5). The relationship between the *global shape* of a value function and the *local importance* of an attribute follows a pattern comparable to that of the relationship between the global shape and the global importance of attributes (H6).

Study

To test our hypotheses, a study, involving 189 participants at a large southern university, was conducted. We studied rental

rooms on two attributes: monthly rent and size (square feet). The *global importance* of both attributes is determined using the direct rating method (1=not important, 9=important). A measure for the *local importance* of both attributes was obtained using a full factorial judgment task with five levels for each attribute. To determine the *global* and *local shape* of the value functions of both attributes, we asked the participants to rate their valuation of the full range of 12 relevant attribute levels for one attribute at the time. Participants rated their valuation of rooms with 12 different rent levels as well as their valuation of rooms with 12 different sizes (0=I do not appreciate it, 100=I highly appreciate it). The global shape of the value functions is estimated using the EXP-IPT technique, which fits the attribute-level valuations for each individual to both the negative exponential function (EXP) and the log of the inverse power transformation function (IPT) (cf., Pennings and Smidts 2003). The former function is either fully concave or fully convex over the entire value function. The latter function is S-shaped.

Next, the *reference points* for both attributes were determined by asking participants to indicate what the rent and size of their current room is. To establish participants' *loss aversion* and *diminishing sensitivity*, we rely on the direct-rating data and employ the two-piece value function technique. Based on the self report reference points, we divide the value function into a gain and loss domain and estimate the EXP function separately for both domains. The *loss aversion* for an attribute is calculated by establishing the ratio of the slope of the value function in the loss domain and the slope of the gain domain. To establish the *diminishing sensitivity* concerning an attribute, we use the second derivative of the EXP function, calculate the relative change in valuation for each pair of independent variable levels, and determine the average diminishing sensitivity across domains.

Results

In line with H1, H2, and H3, we find significant relationships between the global importance of attributes and participants' reference points, loss aversion, and diminishing sensitivity. In line with H4, we find that the global importance of an attribute is highest (lowest) among participants with a convex (concave) value function. The global importance of those with an S-shaped value function falls in between. We find a significant relationship between participants' reference point and the local importance of both attributes, confirming H5. In line with H6, we find that the local importance of an attribute is highest (lowest) among participants with a convex (concave) value function for the attribute.

Finally, we examined the predictive validity of the global and local shape of value functions and find that the global and local shape of attribute-value functions predict choice up to 85.3% correctly.

Conclusions

We conclude that the shape of attribute-value functions relates to the importance of attributes, and as such drive judgment and choice behavior. Hence, measuring decision makers value functions for an attribute may yield more valid and reliable attribute-importance measures.

Why Not Buy the Leading Brand? A Preliminary Investigation of the Dynamics of Brand Choice

WoonBong Na, KyungHee University, Korea

YoungSeok Son, Hallym University, Korea

Roger Marshall, Auckland University of Technology, New Zealand¹

BACKGROUND

In most markets there is an identified market leader and several market followers. It has been suggested in the recent literature that although this is sometimes merely a pioneer effect, it may also be a consumer effect (Rettie et al. 2002). If the leading brand does indeed have a compelling competitive advantage, the question arises of why *anybody* should bother buying the follower brand?

We will first construct a (SEM) research model of the consumer selection process, couched in terms of perceptions of hedonism, utilitarianism and price fairness. These three latent variables are developed below. Differences in the evaluations of purchasers of leading and following brands, which might explain why people do sometimes opt for what appears at first sight to be a sub-optimal purchase solution, are then explored.

Price Fairness, Utilitarian and Hedonistic Perceptions

Cost-benefit perceptions are colored by the preconceptions of consumers about what is fair in regard to the price demanded in a trade (Kamen and Toman 1970); thus price fairness could form a reasonable perceptual proxy for actual price in a purchasing situation. Two items are drawn from Monroe (1990) to indicate the "Price fairness" latent variable in the research model.

Utilitarian benefits are primarily instrumental, functional and cognitive (Chandon et al. 2000). Following Keller and Davey (2001), Aaker (1991) and Keller (1993) this latent construct is indicated by perceived brand performance, quality and credibility.

Hedonism represents the emotional side of purchasing (Ruth 2001). Brand feelings, from Keller (1993) and Keller and Davey (2001), is the most "generic" aspect, and forms the first indicator variable for the latent construct. Symbolic imagery, the second indicator variable, is the emotion related to the socially visible icon used in the marketing of the service or product (Solomon 1983). Once the imagery evoked in a brand has been interpreted, a consumer will relate the image to his or her own life and infer either positive or negative emotional values to them. This aspect of hedonism, our third indicator variable, is referred to by Keller (1993) as usage imagery. Finally, "experiential" hedonism stems from prior experience with the brand (Keller 1993; Mathwick et al. 2001). Our structural model simply postulates that the three latent variables, Price fairness, Hedonic and Utilitarian perceptions of brand leads to brand satisfaction which, in turn, drives repeat purchase intention.

RESEARCH METHOD

A short questionnaire was designed, and used with 405 university student. Responses provide information about their actual brand choice, and their perceptions of the price fairness, utilitarian and hedonic features of the brand selected and the brands in the unselected category. Each of the observed variables is represented by a single 7-point Likert-type item using questions drawn from the established scales used in the literature discussed above.

The markets selected were jeans, sneakers, digital cameras and mobile telephones. Most of the information needed to categorize market leadership was available from public secondary data, and where there was doubt then markers were approached and consulted to confirm the brand shares.

RESULTS

For the model using data from those purchasing the leading brand, all the paths are significant, with Utilitarianism having the highest standardized estimate—of .85 as against .41 and .35 for Price fairness and Hedonistic perceptions respectively). The model fit statistics are satisfactory for exploratory work (RMR=.12; GFI=.88 and AGFI=.80).

For the follower brand data the results are similar. The model paths are significant, with Utilitarianism again having the strongest standardized estimate, of .84 as against .44 and .33 for Price fairness and Hedonistic perceptions. The model fit statistics are also satisfactory (RMR=.17; GFI=.90 and AGFI=.82).

Scales are then formed for each of the latent variables. All scale items contribute toward their respective scale and the Alpha's are adequate (Alpha_{Utilitarianism}=.76; Alpha_{Price fairness}=.78; Alpha_{Hedonism}=.75. Scale means are then calculated to allow comparison between the perceptions of purchasers of Leading and Following brands by t-test.

We first consider the case of the purchasers of Leading brands, and compare their perceptions of the Leading and Following brands with respect to the three new variables. There is no significant difference between their perceptions of Price fairness between brands. However, the perceptions of this group of both the Utility and Hedonism of Leading and Following brands are significantly different (Hedonism_{Leading}=5.56, Hedonism_{Following}=5.19, $t=2.38$, $p=.02$; Utilitarian_{Leading}=5.87, Utilitarian_{Following}=5.14, $t=4.06$, $p<.001$).

When we consider the perceptions of purchasers of Following brands, a different picture emerges. Although there is no perceived difference in Hedonism between the brands, both Price fairness and Utilitarianism are seen to be superior for the Following brand (Price fairness_{Leading}=4.15, Price fairness_{Following}=5.11, $t=4.49$, $p<.001$; Utilitarian_{Leading}=5.90, Utilitarian_{Following}=6.37, $t=4.06$, $p<.001$).

DISCUSSION

Fundamentally, the differences between purchasers of leading and following brands lie in the trade-off patterns. Leading brand buyers trade off hedonism and utilitarianism with relatively little regard to price; whereas purchasers of Follower brands trade off price against utilitarianism with comparatively little regard to hedonism. Purchasers of leading brands believe that they gain greater utilitarian and hedonistic benefits from the purchase of the leading, rather than following, brand. Their counterparts—those who purchase one of the second-tier brands—believe that they not only get a fairer price but also get superior utility from buying the second brand. For these consumers, then, the trade-off is about price and utilitarian benefits.

Consideration of these results leads marketers back to basics. Functionality remains paramount—poor quality or low functionality

¹This work was supported by Korea International Research Foundation Grant (KRF-2004-B00206).

will surely result in the loss of custom even for Leading brands. Nevertheless, it seems as if perceptions of hedonism attached to brands is a differentiating factor between Leader and Follower buyers, although satisfaction stems primarily from utilitarian benefits. While those buying leading brands have no problem paying a price premium, price seems unimportant as an element of satisfaction relative to hedonistic and functional benefits.

Utility Blindness: Why Do We Fall For the Deal?

Maggie Wenjing Liu, University of Toronto, Canada

Dilip Soman, University of Toronto, Canada

EXTENDED ABSTRACT

Although often viewed as a suboptimal consequence of price competition by many academics and marketers (Chandon, Wansink and Laurent 2000), sales promotion is not readily to be replaced by other sales policies such as everyday-low-price. Over years consumers and retailers seem to have an unceasing interest towards products in a deal. However, the fundamental question in promotion research—why consumers respond to the deals, has always been a controversial one. Behavioral literature on promotions is generally focused on either consumer demographics, or economic benefits from the deal (Chandon, Wansink and Laurent 2000). The psychological process under consumers deal responses are often either neglected or oversimplified. The present research addresses consumers' response to promotion from the information perspective and explores its underlying cognitive process.

Classical economics theory stresses maximization of utility under the assumption that consumers are rational buyers who maximize the economic gains from a purchase transaction. Richard Thaler (1985) came up with the theory of acquisition-transaction utility that consumers evaluate transaction by total utility, which is the sum of acquisition utility (utility derived from the purchased good minus the price paid for the good) and transaction utility (internal reference price minus the purchase price). The idea that consumers base their purchase decision on total utility has been widely accepted and applied to marketing research, especially in the sales promotions area (e.g., Grewal, Monroe, and Krishnan 1998; Lichtenstein, Netemeyer, and Burton 1990).

However, in the real life consumers often seem to disobey the principle of total utility. As indicated by the phenomena that nearly everybody's house contains something we bought in a deal but seldom or never use, consumers might fall for an attractive deal even when the total utility from the purchase is negative. There could be many reasons accounting for such blindness to utility, including consumers' deal proneness, overestimation of their consumption, etc. However, deal proneness alone cannot fully explain why a consumer would buy worthless things when the total utility is zero or negative, but reject an unattractive deal even if it does no harm to the total purchase value (Simonson, Carmon and O'Curry 1994).

The present research tries to address consumers' response to promotion from an information processing perspective, as well as explore the underlying process for consumers' deal reactions. In this paper we propose the notion of utility blindness, which claims that under limited information processing, consumers would base their purchase decision solely on the perceived gains from the deal (i.e. transaction utility) rather than total utility. When the deal is attractive enough, people would buy products even when the total utility is little or negative; on the other hand, an unattractive deal would decrease people's purchase likelihood even when the total utility is not affected by the promotion.

Three lab studies are described to test the existence and underlying process of utility blindness. In the first study, utility blindness is showed to exist even in knowingly "rational" groups like PhD students of economic/business major. When the deal is attractive enough, they would fall for the deal despite that buying the product would lead to little or negative total utility.

In study 2 we not only identify the salience of transaction utility as a moderator of utility blindness, but also demonstrated two

sides of the coin: when people perceive positive transaction utility in a deal, they are willing to buy the product regardless the total utility; while when they perceive transaction disutility (negative transaction utility) in the deal, they are not likely to buy the product even though total utility remains the same.

In a third study, we demonstrate that utility blindness occurs when people process the deal information in a limited manner. Priming subjects with different information focus (focusing on either benefit only or both benefit and cost) in a preliminary task should change their information focus, hence the tendency to fall for utility blindness. Effect of utility blindness is moderated by cognitive load, since it impairs people's capability and resources in information processing. People are more likely to fall for utility blindness when they are under cognitive load and when the transaction utility is salient. Such blinding effect of a deal is in spite of individual differences in deal proneness, mood, involvement, pre-vention/promotion focus, risk attitude, and need-for-cognition.

Contributions, managerial implications, and limitations of the present research are summarized in the conclusion section. For future research utility blindness could be extended into bad-deal-good-product scenarios, other economic contexts (time, money and effort) and social relationship problems.

The Effect of Mindsets on Consumer Decision Strategies

Alison Jing Xu, Hong Kong University of Science and Technology
Robert S. Wyer, Jr., Hong Kong University of Science and Technology

EXTENDED ABSTRACT

Purchase decisions often involve two steps. First, consumers tentatively decide whether or not they want to make a purchase, based on the options available and their immediate need for the type of product being considered. Then, if this process results in a positive decision, consumers decide which of the potential alternatives they prefer. This sequence of mental actions is represented as a purchasing procedure in memory. Generally, a procedure is composed of subgoals that are causally or temporarily related. Thus the attainment of each subgoal is a precondition for pursuing the one that follows it. Consequently, the consideration of any subgoal presupposes that the previous goal has been attained successfully.

We propose that consumers whose attention is called to the first subgoal of deciding whether to buy are likely to engage in the operations required to attain it and, if the decision is affirmative, they may proceed to the next subgoal in the sequence. However, if consumers are induced to consider a subgoal at a later stage (e.g., deciding which to buy), they will presumably employ routines to identify the most preferred alternative. However, they are unlikely to reconsider whether they want to make a purchase at all. Instead, they will assume that they have already decided to buy something. As a consequence, consumers are ultimately more likely to make a purchase in the second case than in the first one.

Further, we propose that in the second case, consumers may develop a “which to buy” mindset that will guide them to make a selection among the alternatives. In the mean time, however, this mindset may also prevent them from considering the preceding segment of the purchasing procedure (i.e., whether to buy). If consumers are asked to consider whether to make a purchase at all at the outset, they are likely to develop a “whether to buy” mindset. Once a mindset is activated, it will also persist to influence one’s reactions to subsequent activities. Specifically, we propose that consumers who develop a “which to buy” mindset in one situation will be more likely to consider which alternative activity is better in subsequent scenarios instead of considering whether or not they want to engage in the type of activities. If consumers develop a “whether to buy” mindset, however, they are more likely to consider whether they want to engage in the type of activities at all in response to the same subsequent scenarios. In addition, the same reasoning suggests that people who develop a mindset in one situation will exhibit a similar mindset in a later purchase situation. Therefore, consumers who have a “which to buy” mindset are more likely to make a purchase again in an unrelated situation.

Three studies examined these possibilities. The first study showed that participants who were primed to consider which computer they prefer at the outset (preference-first condition) were more likely to make a purchase than those who were primed to consider whether or not they would like to purchase one of the computers at the outset (whether-first condition). And this is true no matter the two alternatives have all unique features, have unique positive features and common negative features or have unique negative features and common positive features. In addition, the same effect was observed regardless of whether the no-purchase decision was revocable or irrevocable.

In the second study, we used two methods to infer the existence of a “which to buy” mindset. In one case, participants stated which computer they preferred, and in another case, they indicated which

computer they disliked more. In a third condition, they were asked to decide whether or not they would like to choose one of the computers. Participants in both the preference-first condition and the dislike-first condition evaluated the two computers more favorably than those in the third condition, and this was true regardless of whether the two computers had all unique features, unique positive and common negative features, or unique negative and common positive features. The assumption that participants in the first two conditions developed a “which to buy” mindset was further evident in the thoughts they generated in response to eight unrelated scenarios describing decision situations in daily life. That is, their thoughts pertained more often to which of two activities they prefer or dislike to engage in rather than whether to engage in either.

The third study showed that participants who were induced to consider which computer they prefer in the first situation were more likely to choose one of two vacation spots in a subsequent situation (rather than deferring decision). Both the two computers and the two vacation spots had unique positive attributes and unique negative attributes. Thus the different purchase rates we observed in this study are consistent with our hypotheses but cannot easily be addressed by earlier theories of choice deferral (e.g., Dhar and Nowlis 2004; Dhar, Huber and Khan forthcoming).

“Confidentially Yours”: Restricting Information Flow Between Trustees Enhances Trust-Dependent Transactions

Vincent Mak, The Hong Kong University of Science and Technology
Rami Zwick, The Hong Kong University of Science and Technology

EXTENDED ABSTRACT

In marketing and social networking it often happens that an agent would like to build relationships with a multitude of other agents under resource constraints. For example, a firm may give discounts to a portion of customers to cultivate loyalty, but it cannot do too much of that to too many customers at the peril of profit margins. Moreover, discounts or other forms of relationship building gestures do not guarantee future benefits; much depends on the reciprocating propensity of the receiving agents.

Another important factor that potentially influences such strategizing is whether the receiving agents are allowed to communicate with each other about how much benefit they have received. The extent of information flow between receiving agents varies from case to case. In some types of buyer-supplier contracting, for example, the transacting parties are bound by the contract terms not to disclose deal information to third parties.

Our main objective in this paper is to study how restricted information flow influences the amount and distribution of resources put into relationship building. We attempt to abstract the relationship building aspects of the above mentioned scenarios into one involving a trusting agent and a number of potentially reciprocating agents, and study it through an extension of the well-known trust game or investment game in experimental economics. We investigate how restricting information flow between trustees can enhance trust and reciprocity in trust-dependent transactions through extending the traditional one-to-one trust game to settings involving $N > 1$ trustees. We consider: (a) investor's strategy in deploying investments, and (b) trustees' responding behavior, under conditions that vary in two parameters—the value of N and, more importantly, an information condition relating to whether a trustee only knows the amount received by her or whether every trustee knows the investment received by every other trustee.

We propose that, if the investor considers the problem based on a simplified, “baseline” model of expected trustee reciprocity, the optimal strategy of a risk neutral investor is one with which positive investment packages at no more than two different levels are sent out to some—but not necessarily all—of the trustees, while the remaining trustee(s) receive nothing (a set of investment packages has one level if all the packages are of the same amount, two levels if all the packages are of either one of two different amounts, and similarly for higher levels). We then investigate the effect of non-baseline concerns including investor risk aversion and, under the unconstrained information condition, (a) effects on reciprocity induced by uneven distribution of investments, (b) free-riding of the moral obligation to reciprocate, and (c) distributional fairness. In our theoretical development, we argue that the basic characteristics of the investor's optimal strategy in the baseline model would be preserved even if these additional concerns are included under the constrained information condition. Under the unconstrained information condition, our theoretical conclusion is that the investor's optimal strategy would include up to only one positive investment level, rather than two in the constrained information condition. Moreover, total investment would decrease when information flow is unconstrained, compared to when it is constrained.

We then report two experiments designed to investigate investor strategy and trustee behavior. In Experiment 1, we focus on investor behavior. Subjects were randomly divided into investors and trustees (neutral terms were used in the instructions). The

investor had an endowment of HK\$50 (1US\$=HK\$7.8) in each played game, while the trustees had no endowment. Any investment of the investor was tripled when it reached the trustee. The strategy method was used on the investors' side. That is, each investor was asked to decide how to invest in seven games varying in information condition and number of trustees; at the end, only one of those games was actually played with randomly and anonymously matched trustee(s). Within-subject analysis of the data lends support to all our investor hypotheses. Total invested amount increases and investment portfolio exhibits a greater variety (i.e. more levels of investment) when information flow between trustees is restricted, compared to when it is not so. We also observe, as predicted, that the number of trustees receiving positive investments does not change across information conditions; the increase in total investment is predominantly driven by an increase in average investment among trustees who receive positive investments.

Experiment 2 was designed to test trustees' behavior—in particular to try to isolate evidence of reaction to unfairness and moral obligation free-riding. Again, subjects were randomly assigned to be investors or trustees such that each investor was matched randomly and anonymously with two trustees. Both investors and trustees were presented with a menu of six investment patterns for the $N=1$ game and 12 investment patterns for the $N=2$ game with full information condition. The players' endowments and the general rules of the games were as in Experiment 1. Each trustee was then asked to decide, for each investment pattern, how much to reciprocate (if at all) if that investment pattern was chosen by the investor to be actually played. Within-subject analysis of the trustees' stated reciprocated amounts supports our conjectures regarding trustee behavior and considerations. Fundamentally, it shows that, in the full information condition, a trustee's reciprocating behavior is dependent not only on her received amount but also on the other trustee's received amount. The data are also consistent with our hypotheses about trustees' reaction to non-uniform investment distribution and moral obligation free-riding, although reaction to increased overall generosity may have weakened some of the predicted effects. In particular, we find evidence that a trustee's propensity to reciprocate in the full information condition can be undermined in the face of any unfair distribution of investments, including when the trustee him/herself is receiving more than the others—a significant example of scenarios in which being treated preferentially does not necessarily lead to better “performance” in return.

The Effect of Superstitious Beliefs on Consumer Judgments

Thomas Kramer, Baruch College, CUNY, USA

Lauren Block, Baruch College, CUNY, USA

EXTENDED ABSTRACT

Despite their large impact on the marketplace, we currently know very little about how superstitious beliefs influence purchase likelihood ratings and consumer satisfaction. In a series of studies, we show that consumers are less (more) satisfied with products following product failure for which they hold positive (negative) superstitious associations. Furthermore, we demonstrate that consumers are more (less) likely to purchase products with prices for which they have positive (negative) superstitious associations, even compared to the identical product priced lower (higher). These effects are limited to Asian consumers for whom the superstitious associations with the particular colors and numbers exist.

While academic research has recognized the importance of various elements of the social and cultural environments in marketing (e.g., values, Han and Shavitt 1994; goals, Aaker and Lee 2001; or language, Luna and Peracchio 2005), individuals' superstitious beliefs and their impact on consumer behavior have received very little attention. This lack of investigation into superstitious beliefs is all the more surprising given its strong impact on the marketplace. For example, between \$800 and \$900 million is lost in business in the United States each Friday the 13th because people do not want to go to work or tend to business in general that day. Additionally, an increasing number of U.S. companies are adopting the principles of feng shui, often hiring feng shui experts who apply these superstitious Chinese practices to offices in such esteemed companies as Smith Barney and Morgan Stanley (Tsang 2004).

However, we currently know very little about how superstitious beliefs (e.g., Vyse 1997) affect consumer behavior, and the current paper seeks to address this shortcoming. Over a series of studies, we explore how positive and negative superstitious beliefs influence purchase likelihood ratings and consumer satisfaction. Specifically, individuals often rely on superstition or superstitious rituals in the hope that these behaviors will help them perform better. Analogously, we expect that superstitious associations with product attributes will also influence expected product performance, and, importantly as investigated in this research, consumers' satisfaction following product failure. For example, Ang (1997) finds that quality expectations are greater for products with brand names for which consumers hold positive superstitious associations. Differences in expectations, in turn, are likely to influence how satisfied consumers will be (Oliver 1980; Oliver and Bearden 1985). Accordingly, we suggest that consumers are likely to be less (more) satisfied with a product for which they hold positive (negative) superstitious beliefs following product failure.

In Study 1a, we test if Taiwanese consumers would be less satisfied following the failure of a product for which positive superstitious associations with its color exist. In particular, we show that participants expect to be less satisfied with a red (positive superstitious beliefs) versus green (neutral) rice cooker following product failure. Next, in Study 1b, we generalize the previous findings from positive superstitious associations to negative superstitious associations, and to a new attribute (price). We show that Taiwanese participants are more satisfied with a failed product priced at TW\$ 6,444.44 than the same product priced at TW\$ 6,555.55.

While the first two studies demonstrate the effect of superstitious beliefs on satisfaction, the next two studies address the

question of whether superstitious beliefs will actually influence how likely consumers are to purchase a product. In particular, Study 1c test if participants are more likely to purchase a product with which they have positive superstitious associations, as compared to higher-priced product with which they do not. As expected we show that purchase likelihood for a portable radio is greater when it is priced at a "lucky" TW\$ 888 than at a "neutral" TW\$ 777. Next, Study 1d generalizes the previous findings from positive superstitious associations to negative superstitious associations and demonstrates that participants are less likely to purchase a product priced at an "unlucky" TW\$ 6,444.44 than the same product priced more expensively at a "neutral" TW\$ 6,555.55.

Study 2 tests and rules out an alternative explanation for these results that suggests that participants may have formed quality associations, expecting the higher priced radio or digital camera to be of better quality, which in turn may be reflected in the higher purchase likelihood. Eliminating the potential confound of price/quality inferences, we next investigate superstitious beliefs concerning numbers by manipulating the quantity of a product sold in a set. Additionally, Study 2 investigates the cultural basis of superstitious beliefs by including both Taiwanese and US participants. That is, if the findings we have obtained are based on culturally shared superstitious beliefs as we hypothesize, then we should replicate our previous results with the Taiwanese participants, but not with the US participants whose culture does not include these superstitions.

Providing evidence for the robustness of the effect of superstitious beliefs on satisfaction, Study 2 shows that following product failure, Taiwanese consumers expect to be significantly less satisfied with products that contain an attribute (i.e., the number in the set) with which they have positive superstitious associations, as compared to products that do not. However, confirming the culture-bound nature of superstitious beliefs, this effect is only obtained for Taiwanese consumers for whom the number 8 is associated with good luck. Additionally, we once again show that superstitious beliefs also affect purchase intentions. In particular, we find that superstitious associations with the number 8 led Taiwanese participants to indicate greater purchase likelihood for a set that contained fewer tennis balls, while the reverse was found for the US participants for whom superstitious associations with the number 8 do not exist.

Our studies thus demonstrate a robust effect of superstitious beliefs on Chinese consumers' behavior, including instances when superstitious beliefs cause consumers to make purchase decisions that run counter to economic rationality. That is, Taiwanese consumers are more likely purchase a product at the higher "lucky" price, are less likely to purchase a product with a lower "unlucky" price, and are more likely to purchase the "lucky" product with fewer units contained in the package. In contrast, the US consumers, for whom no such superstitions exist, adhered to the more rational choice paradigm.

Ambivalent Relationships and Projection onto Indexical Objects

Deborah D. Heisley, California State University, Northridge, USA

Deborah Cours, California State University, Northridge, USA¹

ABSTRACT

It is well-established in consumer culture theory that an object's meaning often resides in its ability to represent or trigger memories of others or relationships with others. The context of familial intergenerational transfers of gifts and heirlooms has been a particularly fertile area for investigating this phenomenon. This article draws on the findings from a study of heirlooms. It merges insights from the semiotic perspective of objects representing others with a projection perspective where consumers project their ambivalence about relationships with others onto their relationships with the objects that index those others.

INTRODUCTION

In this article, we focus on the projection of ambivalent feelings regarding relationships onto objects which index those relationships. We discuss the importance of the construct of projection in making sense of this behavior. This behavior is most pronounced when the feelings are negative and possibly even socially unacceptable. Three examples are drawn from a study of intergenerational transfers to illustrate this phenomenon. In our data, consumers act out their ambivalence about significant relationships with objects that index those relationships.

LITERATURE REVIEW

Ambivalence

Levy's work demonstrates his "...preoccupation with the inherent ambivalence that characterizes and energizes our cognitive and emotional lives." In "Stalking the Amphisbaena," (1996/1999) he chooses the mythological creature with a head at both ends to symbolize that ambivalence. We recognized the ambivalence toward familial relations evident in our data and corresponding acting out behaviors directed toward indexical objects. As we reviewed the consumer behavior literature to glean an understanding of this behavior, we were able to build several models of signification to help us understand the relationships between the consumer, objects, the origin of the objects, and groups. Finally, we turned to the projection literature to better understand the acting out behavior that we saw emerging as a result of consumer ambivalence.

Objects Represent Others

Consumers often have special possessions that represent other people in their lives. Csikszentmihalyi and Rochberg-Halton (1981) find that, when asked to name their favorite things, many people identify photographs, heirlooms or other such objects because they remind the owner of a loved one. Belk (1988) mentions heirlooms repeatedly in his discussion of the extended self, and adds "the acquisition of possessions of another person that have been intimately associated with that person" (p. 151) to Goffman's (1971) list of "six modes of interpersonal contamination." Wallendorf and Arnould (1988) find that favorite possessions reinforce social relationships, often through their ability to stimulate memories of others. In Grayson and Shulman's (2000) discussion of "irreplaceable possessions," (p. 17), they apply Peirce's semiotic model ([1897] 1940, pp. 98-101) and focus on the "indexical" function of

irreplaceable possessions. They conclude that "irreplaceable special possessions are indices because they have a "real, factual, and spatial" connection with the special events and people they represent" (p. 19).

This literature invokes five elements (see figure 1). The first element of the model is the object. The second element is the origin of the meaning of the object. This origin is most often a person, but it can also be an event or a place. The third element is the contamination process by which the object's meaning is individualized through association with the origin. The fourth element is the consumer. The fifth element is the indexical relationship between the consumer and the object. Our interest is in the consumer's relationship with the object and with the origin. We are not concerned here with issues such as ownership status.

Objects Represent Relationships with Others

A more complex view of the semiotic process focuses on relationships. Csikszentmihalyi and Rochberg-Halton (1981) found that many people, termed "warm," value possessions because of the relationships those objects represent. In the consumer behavior literature, Wallendorf & Arnould (1988) established that objects can also represent our relationships with others ("social linkage"). Richins (1994a) found that when informants were asked to think of a possession that was important to them, at least sixteen percent discussed "sentimental objects representing interpersonal ties (e.g., gifts, photos album, family heirlooms)" being outnumbered only by "assets (e.g. house, property, money)" and transportation as the most commonly reported type of valued possessions (p. 509). In Richins' piece on materialism (1994b), content analysis of special possessions yielded the dimension "representation of interpersonal ties" with sub-categories of "symbolic ties to others, gifts, and symbols of family history" (p. 527). Curasi, Price and Arnould (2004) discuss keepsakes as "indexical symbols, items with an evidentiary function, able to serve as a testament to important life events (Grayson and Shulman 2000), of immediate descendants' relationships with their deceased kinsfolk (Belk 1990), and provide vehicles for creating, shaping, and sustaining memories (Finch and Mason 2000)" (p. 610). The relationship model becomes a bit more complex (see figure 2). There is a relationship between the origin and the consumer, the origin contaminates and individualizes the object, and the object then serves the consumer as an index of his or her relationship with the origin.

Objects as Iconic Representations of Group Membership

In their study of intergenerational transfers within kin groups, Curasi, Price, and Arnold (2004, p. 619) differentiate between "the corporal indexical associations of irreplaceable individual cherished objects or keepsakes" and "inalienable wealth [which] is not an interpersonal, indexical symbol, as are keepsakes, but rather, in Pierce's terms, an iconic one." They go on to explain that "[a]lthough inalienable possessions lack the corporal indexical associations of irreplaceable individual cherished objects or keepsakes, they retain evidentiary associations that make them irreplaceable." Thus, for inalienable familial wealth, the relationship between the consumer and the origin is not necessary. The origin individualizes and contaminates the object. The object becomes an iconic representation for the group. The consumer's relationship with the object then serves as an index for their relationship with the group (see figure 3).

Object Relations: Conceptual Grounding

Kleine, Kleine, and Allen (1995) studied “person-possession relationships” (p. 327) from the perspective of the self. They point out that one “archetypal theme” in the development of the self is “affiliation versus autonomy seeking.” “Affiliation seeking is apparent when possessions reflect connections with others, with one’s heritage or tradition, or with occasions spent with important others or reflect being in touch with or cared for by others” (p. 328). Again, semiotically, this is viewed as indexicality (Grayson and Shulman

2000). Kleine, Kleine and Allen go on to explicate the importance of consumers feeling that an object is “me” or “not me” in determining their attachment to the object. The “me-not me” distinction was previously mentioned by Levy (1963/1999) in his discussion of symbolism and lifestyle.

Fournier (1998) and Ahuvia (2005) establish brands as worthy of relationships and objects as worthy of love (respectively). Fournier points out that brands can become “animated, humanized, or somehow personalized” and that this is one way to “legitimize

the brand-as-partner.” That is, she first establishes that a brand can represent an “other,” and then argues that this representation makes the brand a legitimate relationship partner. She identifies three processes of animism. The relevant process for our study of ambivalence and indexical objects is when “these brands can become so strongly associated with the past-other that the person’s spirit comes to dwell in the brand and is evoked reliably with each use” (“[a] brand of air freshener that grandmother kept in her bathroom, a floor cleaner that an ex-husband always used”) (p. 345). Again, this represents indexicality. Ahuvia (2005) establishes a person’s ability to “love” an object, a term that is in a more limited sense reserved for living things. He concludes that love objects can “serve as indexical mementos of key events or relationships in the life narrative” (p. 179).

Neither Fournier’s or Ahuvia’s informants articulate the ability of an object to be equivalent to a person (instead of indexing one) and to therefore be an appropriate relationship partner as the following informant does:

“This [painting] is my great, great grandfather. I’ve had it since childhood. It’s more than just a portrait—it’s a person!” (Rochbert-Halton 1984, p. 171), as quoted in Belk 1988, p.149).

One could argue that for this informant, the object has moved beyond indexicality to iconic representation in which the object serves as more than a referent but as a veritable illustration or representation of the person (Grayson and Shulman 2000) or the relationship.

Object Relations: Behavior

The literature on the disposition of special possessions (Lastovicka and Fernandez 2005; Price, Arnould, and Curasi 2000), and on the creation of families’ inalienable wealth from individuals’ cherished possessions (Curasi, Price, and Arnold 2004) observe how a consumer’s relationship with an object impacts his or her behavior toward it.

Price Arnold & Curasi (2000) examine “older consumers’ disposition of special possessions” and determine that these possessions had meaning as “narrative mnemonic life tokens,” “totems (totemic symbols of skills and competence),” or “emblems of kinship structure” (p. 187). Notably they do link relationships with the object to disposition behaviors. However, they are examining a donor-object-recipient relationship from the perspective of the donor. We examine the behavior toward the indexical object from the recipient’s perspective.

More relevant to our interest in ambivalent relationships and indexical objects is the Lastovicka and Ferandez study on how “interpersonal relationships influence product disposition” (2005, p. 814). It builds on Kleine, Kleine and Allen’s (1995) work and examines how informants dispose of objects that have a negative valence and are either “never me” or are “extensions of a past-undesired self” (2005, p. 815). Similarly, Grayson and Shulman (2000) refer to a “negative case analysis” where “an indexical possession might be devalued (such as its representation of a disliked parent...)” (p.21). It is this sort of negative affect and socially undesirable feeling that encourages consumers to project their consumer-origin or consumer-group relationship onto the consumer-indexical object relationship.

Karen, one of Fournier’s (1996, rev. 1997) “brand-person relationship” informants, provides an example of how consumer *behavior* toward an indexical object can mirror feelings toward the origin. “Well, we were using the Hellman’s because that was the brand Jim [ex-husband] wanted. He hated the Miracle Whip...I

didn’t care much but now that I am alone, we’re back with the Miracle Whip. No more Hellman’s” (p. 15). Curasi, Price, and Arnould (2004) also discuss the behaviors surrounding inalienable wealth as “kratophony” when “caretakers are likely to encase objects in protected environments, subject them to ritual use, and limit who handles them” (p. 617). They mention display, careful packing, and storage. They also discuss the “failure of transmission” (p. 615) and the “stories of objects that should have been but were not kept” (p. 618) that indicate ambivalence.

Projection

Rook (2006) presents an excellent review of the use of projective techniques in marketing. Rook reports that the use of projective techniques in market and consumer behavior research declined dramatically in the 1970’s, but is now enjoying renewed interest. The seminal piece that renewed interest was Sidney Levy’s “Dreams, Fairly Tales, Animals, and Cars” (1985/1999). As Rook points out (p. 5), the use of projective techniques has been carried on mostly by a set of researchers who have been affiliated with Levy and the Marketing Department at Northwestern University at some point in their career (Rook 1988; Heisley and Levy 1991/1999; McGrath, Sherry and Levy 1993/1999; Belk, Ger and Askegaard 1997; Zaltman 1997).

Our data is not about projective techniques, but “projection” done by people in their symbolic life among objects and other people. Our informants use objects that index others or their relationship with others to act out their ambivalent feelings toward those people and/or relationships. The interpretation of the data requires an understanding of the psychological process of projection. Freud (1950) describes projection as a process that occurs in mentally normal persons; “The projection outwards of internal perceptions is a primitive mechanism” (p. 64). Internal perceptions (senses, emotion, cognitions), of which the person may not be even aware, are “ejected ... into the external world, and thus detached from them and pushed on to [something] else” (p. 62). Projection, in which the person is unconscious of the internal perceptions that have been projected to the external world, is more likely to occur when such projection would result in a relief of conflict (p. 92). This serves as a defense function, in which negative or conflict-laden emotion is “displaced” onto an object (p. 61). However, Freud maintains, projection “also occurs when there is no conflict” (p. 64).

Projection is a psychological process that has been much studied. As a general phenomenon it involves the transference or displacement of internal or “primary” emotions and cognitions onto secondary objects such as other people, experiences, and physical objects. Derived from psychodynamic study, the concept helps to explicate various behavioral processes of externalization. Harold Lasswell applied psychoanalytic theory to political processes, and referred to the displacement of private affects onto public objects in the political sphere (Baas 1979).

Projection serves to reduce conflict (ambivalence) that is often unconscious so that one tends to assert one response or the other, often denying negative feelings, saying one thing and doing another. Some forms of projection are called “acting out,” to indicate that the behavior is responding unreasonably to situations or objects in expression of inner needs. It was the resonance between our informants’ ambivalence in their relationships and their acting out toward the objects that indexed those relationships that in turn led us to the concept of projection.

METHODOLOGY

Nineteen in-depth interviews were conducted by trained graduate students at a major West Coast business school. The interviews lasted from 30 minutes to 2 hours in length. The interviews were

transcribed verbatim, resulting in hundreds of pages of data. Interviewers and researchers completed bracketing exercises and kept journal notes. All informants discussed the intergenerational transfers they had received. Nine of the informants had also been donors of intergenerational transfers. The sample consisted of 13 women and 6 men. The informants ranged from working class to upper-middle class. Informants were from twenty to eighty years old, represented all marital statuses, and were of Judeo-Christian background (including Jewish, Catholic, and Protestant). They represented different family structures, including families with adoptions, stepchildren, various ages of biological children, and childless adults. Sometimes we interviewed multiple informants from the same family. Data was thickly coded. In this article we highlight three instances of ambivalence, projection, and acting out from the 18 interviews.

THREE ILLUSTRATIONS

Similar to Mick and Buhl (1992), Fournier (1996 rev. 1997, 1998) and Ahuvia (2005), we will draw on three particular case studies to illustrate ambivalence, projection, and acting out.

Michael's Crystal

Michael goes to great lengths to save objects that were from his father, much as he tried to salvage his relationship with his estranged father. Mindy described some "heirlooms" that her husband, Michael, bought at the estate sale conducted when his absentee father died. Of particular concern to Mindy are the crystal glasses that have broken but with which Michael refuses to part. Mindy offers her own interpretation of the meaning behind Michael's fanaticism about keeping the broken crystal:

Mindy: "Also...I wanted to get on tape that heirlooms count extra in these 'dysfunctional' families. They don't have love. He [husband, Michael] is very sensitive about his heirlooms. He bought some [of the heirlooms] from the estate...so they would still be in the family.

[Some of the stuff was moved] from garage to garage, and the stuff was not wrapped correctly. We came across some broken crystal; the wine glasses' stems were broken. Then when we unpacked the stuff, he says 'this stuff can be fixed' and I looked at him, [and said] 'this cannot be fixed.' I have to tell you, I am super sensitive, but some of this cannot be fixed. [He told me,] 'I cannot throw this out; you will have to throw this out.' These were not glasses to him; it was like throwing out love.

Having no heirlooms I do not understand this, but I do know that his father was not around in his life. His father left when he was five. Never sent him a birthday card, and then when Michael was 20 he went to search for his father, he found him up in L.A. and he made a relationship with his father and his father's wife Joyce. He forged this relationship. But from ages 5 and up, I mean, we are talking no father, no nurture.

I guess the crystal means a lot more than broken glass. He couldn't throw it out; I had to throw it out. Some of it we saved [because] he thinks it still can be fixed, [it only has] tiny cracks. He says somebody can file the glass down. I don't know, eventually he will want it. He loves using stuff from his father and from his father's father."

Michael's father had abandoned Michael at a young age. Upon his father's death, Michael bought the crystal glasses to keep them

from leaving the family, much as he had tried to keep his father in the family. Even when the crystal breaks, much like the family was broken; Michael tries to save it, just as he tried to forge a relationship with his father. Others may not see much use for the box of broken glasses, just as some people might not have thought his father could be of much use to the family after having abandoned Michael. Michael holds hope that the glass can be fixed, just as he held hope that he could fix the relationship with his father, a relationship he worked hard to "forge." Michael is maintaining his relationship with his father through his hope about the broken glass. This example demonstrates the recipient's relationship with the object (Michael tried to save the crystal) as a projection of the recipient's ambivalent feelings about his relationship with the donor (Michael tried to "forge" a relationship with his father).

Sarah's Bracelet

Perhaps the most powerful instances of projection occurred when informants described negative actions and/or attitudes toward heirlooms that mirrored, though not necessarily consciously, relationships with the donors or recipients. They were often able to verbalize feelings about the relationships with the objects (representing the donors) that they might not have been willing or able to talk about if directly asked about the relationship with the donors.

One's relationship with heirlooms can reflect the anger, pain and disappointment that people experience in their families. For example, Sarah, an upwardly mobile MBA student, was resentful of her parents' working class background and their discomfort around nicer things. Sarah's mother kept her heirlooms (beautiful possessions that fit poorly in the working class existence) stored away in a box and, according to Sarah, had "no appreciation whatsoever for beautiful objects or objects of value. Like she doesn't care. She'd prefer that they didn't exist around her." Sarah is an upwardly-mobile, successful career woman. She aspires to those finer things around which her mother felt discomfort.

Striking projection occurs with Sarah's story about a bracelet she had been given from her family. Sarah is separated from her family by social class and through emotional distance. This distance is reflected in Sarah's actions toward an intergenerational transfer:

Sarah: "Although I don't consider it an heirloom, I did lose a really beautiful silver bracelet that had been my grandmother's or my great-grandmother's, I'm not really sure whose it was to begin with. But it was really, really pretty, and I wore it all the time and I thought it was so awesome, like totally, I *always* had it on. And when I was in Paris, it fell off. And you know what's really bizarre? This is really weird. I sort of knew that I had dropped it, I kind of felt it falling off, but I didn't stop for some reason. Like I'd look at my wrist, and in the back of my mind have the sense that I was losing my bracelet. Anyhow, it fell off. I never saw it again..."

"How did I feel? I felt like, 'Shit, I should have...' I felt like, three hours later, 'Oh my God, I really did lose it back there.' I thought that was really stupid that I sort of sensed that I was losing it and didn't stop to see if it was on my wrist or not. So mostly I felt dumb and stupid because I lost it."

Sarah was at a point in her life when she was trying to maintain a connection to her family while simultaneously distancing herself from her working class background. She is shamed by her family's class membership. As she is engaging in travel in Paris, a behavior that will contribute to her continued growth away from her working

class origin, her heirloom bracelet slips off of her wrist. She knows what is happening, just as she knows that her growth away from her family is happening, and she continues to walk down the streets of Paris, while her family literally slips away from her. Sarah's behavior reflects her ambivalence toward the family that the object represents. We note that Sarah explicitly states that she does not consider this bracelet to have been an heirloom, and that Sarah claims to be unclear about the object's history or origin. At a deeper level, Sarah's story about the bracelet allows her to express regret about her loss, but does not set her up for social disapproval for her actions. She would not be able to easily tell the same story about how she did not "look back" while allowing the distance with her family to build. Her relationship with the bracelet serves not only as a mirror of her relationship with her family, but as a vehicle to express emotion, such as regret, in a socially acceptable manner.

Deloris' Victrola

Deloris provided another example of how informants' relationships with objects reflect their familial disappointment. Deloris was adopted as a baby, but grew up to know her birth mother and her biological sisters, who had been raised by her biological parents. Deloris received only one object from her biological mother, a "tiny Victrola" that had "old fashioned, tiny records." Her behavior toward that object resonates with her relationship with her biological mother:

Deloris: "I sold it [loud squawk]. I wanted to lie to you and say I still had it, but I couldn't. I sold it, and it broke my heart afterwards."

Brent: "Why did you sell it? You just didn't feel you had any use for it?"

Deloris: "Well, at the time... I had it in one of the garages and we had a garage sale, and someone, a fellow said, 'Did you have any old things?' And I said, 'Oh well, come back to this old garage I have in the back.' And so he saw that and offered me some money, and I said okay. Never again, mm-mm. I really feel bad about that."

Brent: "And why do you feel bad about it?"

Deloris: "'Cause it's cute and it's antique and you'll never see another one like that. That was gorgeous. I must've been out of my mind when he wanted to buy it. I said okay. But I had so many things around; I wanted to get rid of things. And that's what happened."

Similarities between Deloris, the Victrola, and her adoptive experience are striking. The Victrola did not fit well into Deloris' life at the time (she had put it in storage). She transferred the object to a stranger. She felt remorse afterwards; she even wanted to "lie" about it and exclaimed "it broke my heart afterwards." Yet, she then distances herself from the object, as the adoption separated Doris from her birth mother. When asked why she feels bad it is because "it's cute" and "you'll never see another one like it. That was gorgeous." These adjectives sound like descriptions of a baby. We also note that Doris focuses on the attributes of the object and does not express remorse that she has lost a symbolic connection to her birth mother. The Victrola was the only object that Deloris received from her birth mother, yet she sold it from her garage to a stranger.

Deloris may be acting out her unresolved feelings of anger and abandonment toward her birth mother with the Victrola. Just as Doris had kept and treasured other objects as heirlooms from other people, her birth mother had kept and raised other children. As with Sarah's bracelet, the Victrola might have provided Doris with a means to express her emotion toward her birth mother's actions, the ability to give away something from her birth mother just as her

birth mother had given her away. It might be socially awkward for Doris to talk about these feelings about her mother and the adoption, but the possession provides the vehicle for her to tell her story.

Deloris' behavior with regard to the Victrola reflects the permanent status of her relationship with her biological mother. Sarah's rejection of her family as she moves socially upward may be temporary—once she becomes comfortable and accepted in her new social position, she may find a way to resolve her current discomfort with her family's position and re-establish ties.

GENERAL DISCUSSION

The genesis of this article is the recognition of our informants' ambivalence toward certain relationships in their lives and the way this ambivalence manifests in acting out on objects that represent that relationship. This realization turns us toward the literature in consumer behavior on the meaning of goods, particularly where the object's meaning draws on relationships between consumers. Our data is drawn from our study of intergenerational transfers. The literature on symbolism and the meaning of things (Levy 1963/1999; Levy 1985/1999; Csikszentmihalyi, Mihaly, and Rochberg-Halton 1981), favorite things (Wallendorf and Arnould 1988), special possessions (Price, Arnould, and Curasi 2000; Richins 1994b), irreplaceable possessions (Grayson and Shulman 2000), cherished possessions (Curasi, Price, and Arnould 2004), meaningful possessions (Lastovicka and Fernandez 2005), loved objects (Ahuvia 2005), and possession attachment (Kleine, Kleine, and Allen) is gleaned for insights. Much of this literature refers to objects that are intergenerational transfers within a kinship structure. We construct three models that represent the literature with regard to the relationship that can develop between a consumer, an object, and others, and the creation of meaning within that relationship structure.

We settle on the semiotic concept of the indexical object as a rich explanation of the relationship we observe between our informants and the objects they discuss in the interviews (Shulman and Grayson 2000). The contamination concept explains the individuation of the object by our informants' kin (Belk 1988). In order to understand the ambivalence that we observed in our informants' relationships with their kin and their concurrent acting out on the objects that index those kin, we turn toward the ambivalence (Levy 1996/1999) and projection (Rook 1988) literature. Finally, we take the reader through three case study examples of projection and acting out by the informants.

The Spyglass Self: A Model of Vicarious Self-perception

Noah J. Goldstein, Arizona State University, USA

Robert B. Cialdini, Arizona State University, USA

EXTENDED ABSTRACT:

How do we as consumers come to know who we are, and how does that influence how we act? Over a hundred years ago, Cooley (1902) described reflected appraisals—how people come to define themselves by observing how others appraise and respond to them—as the *looking-glass self*. We propose that consumers come to know who they are not only through a looking glass, but through a spyglass as well. That is, in addition to defining themselves by registering how others respond to them, we propose that observers can also define themselves by examining how psychologically close others respond—not to them, but rather to circumstances relevant to the observers' self-concepts.

In light of self-perception theory (Bem 1967), which posits that we infer our own attitudes and attributes from observing our own behaviors, and research demonstrating that individuals' self-concepts often expand to include close others, we suggest that when observing a behavior carried out by a close other, the attributes individuals infer from that person's behavior should carry over to inferences about *their own* attributes—almost as if they had observed themselves performing that behavior. This change in self-perception should drive these individuals to behave consistently with these new attributes, often leading them to conform to the originally observed behavior.

In this study, we propose and test a model of these vicarious self-perception processes and examine implications for behavioral conformity. According to the model, observers will internalize the attributes demonstrated in the actor's behaviors to the extent that the observer feels a sense of shared identity with the actor. In addition, self-perception changes on the part of the observer should only occur if the actor's behavior appears to be free of powerful situational forces—that is, changes should occur when observers have reason to make dispositional rather than situational attributions for the actor's behavior.

To test the central hypotheses of this model, participants read the transcript of a purported interview in which the interviewee helped give directions to a stranger who was lost. Before reading the transcript, half of the participants were informed that their and the interviewee's brainwaves greatly overlapped, creating a sense of merged identity; the other half were given no brainwave feedback. In addition, half of the participants learned that the interviewee helped because he or she was paid to do so (a powerful external controlling force for the behavior), whereas the other half of the participants did not learn this information. After filling out questionnaires assessing their perceptions of their own attributes, participants were asked if they would be willing to help the researchers by completing additional surveys.

Consistent with the proposed model, participants were more likely to help the researchers only when they shared a merged identity with the interviewee and only when they were led to make a dispositional inference for the interviewee's behavior. Moreover, the increase in these participants' prosocial behavior was fully mediated by changes in participants' self-perceptions relevant to the originally observed behavior (e.g., self-perceived generosity). The data also rule out potential alternative explanations such as modeling or associative priming.

This study also demonstrates the relative context-independence of vicarious self-perception by showing the predicted effects

despite the fact that there was little connection between the details surrounding the originally observed behavior (giving directions and guidance to a "lost" foreigner) and the details surrounding the helping dependent measure that we employed (aiding the researcher collect additional data). As Freedman and Fraser (1966) demonstrated in their investigation of the foot-in-the-door technique, participants need not see a clear connection between the content of the first request and the second. If changes in self-perceived attributes are driving these increases in prosocial behavior—which they appear to be—then the similarity of the details between the two requests are not of paramount importance; instead, what is critical is simply that the changes in self-perception following the first behavior are relevant to the attributes necessary to engage in the second.

One implication of these findings is that influence agents could potentially make use of vicarious self-perception processes in what could be considered the "vicarious-foot-in-the-door technique." In utilizing such a strategy, an influence agent attempting to secure a target consumer's compliance to a sizeable request could, in the presence of the target, make a smaller, seemingly unrelated request of someone with whom the target feels close. After securing compliance from the close other, influence agents could then make the larger request of the original target. So long as the target perceived the close other to have freely chosen to comply with the first request, this strategy should be effective, an outcome due to the target's self-perception changes after observing the close other comply with the first request. The target need not see a clear connection between the *content* of the first request and the second. Instead, as suggested above, what is pertinent is that the attributes relevant to the close other's compliance following the first behavior are relevant to the attributes necessary to comply with the larger request.

Although the current paper focuses on individuals' self-perceptions related to the area of prosocial behavior, a severely understudied area in consumer research, vicarious self-perception processes should operate in other areas as well. For example, if consumers observe someone with whom they feel close purchasing a product indicative of risk-taking (e.g., skydiving lessons), they should come to see themselves as more risk-taking. This change in self-perception should, in turn, affect the types of products that these consumers would consume, including products outside the domain of the observed behavior (i.e., in this case, outside the area of leisure activities). Specifically, such consumers might choose a product whose image is associated with greater risk-taking (e.g., Mountain Dew over Coca Cola), a hypothesis open to empirical verification.

SPECIAL SESSION SUMMARY

Processes and Outcomes of Consumer Interactions within Brand Communities

Stefânia Ordovás de Almeida, University of São Paulo, Brazil

Utpal M. Dholakia, Rice University, USA

SESSION OVERVIEW

Over the last decade or so, customer communities have become established venues of marketing action for many products and services. The surging academic interest in this area can be traced to Muñiz and O'Guinn's (2001) seminal paper, in which they defined brand community as "specialized, non-geographically bound community(ies), based on a structured set of social relationships among admirers of a brand" (Muñiz and O'Guinn, 2001, p.412), and laid the theoretical groundwork for studying such communities.

In many cases, brand communities are organized, sponsored, and orchestrated by marketers; in other cases, they are entirely developed and run by enthusiast customers. Brand communities are interesting for various reasons. One reason is that they are relatively new, and so, from a managerial standpoint, much remains to be learnt regarding how to make them work effectively as marketing programs, how they compare with more traditional programs like image advertising or event sponsorships in reaching the desired outcomes, and what their limits and limitations are. From a consumer behavior standpoint, there are many interesting psychological and sociological processes at work within these communities, often in conjunction with each other, that haven't yet been studied.

In this session we bring together cutting-edge research studying the processes and outcomes of consumer-consumer interactions within brand communities. The findings of the first paper by Muñiz and Schau reveal that the use of community-generated content impacts brand community members in interesting and significant ways. Using a netnographic approach, they studied the firm-sponsored community of the Jones Soda Company, and discovered it to have all the key markers of community that prior research had identified (Muñiz and O'Guinn 2001). Yet, the firm tried to make the brand marginal to the community by strategically providing choices of flavors, promotional materials and distribution. The authors consider the theoretical and practical implications of this approach.

The second paper by Prykop, Tavassoli, and Herrmann bases its analysis on the sociological concept of scenes (Irwin 1973) where a shared fascination with an activity or topic provides a feeling of belonging to participants. The authors then adopted a social psychological lens to study the role of self-definition and social identification on brand choice within customer communities organized around product categories. They also studied how to persuade customers effectively under the different conditions, employing a structural equation model to test their hypotheses.

The third paper by Almeida, Dholakia, and Vianello uses a netnographic approach to compare customer behaviors and outcomes of managerial significance in firm-managed and customer-managed communities. They found that firm-sponsored communities tend to be targeted toward specific, well-defined consumer segments and seem to be used by consumers more for instrumental purposes. In contrast, customer-managed communities are more broadly appealing and are used for "off-topic" conversations and activities.

Despite the diversity in these papers, as evidenced by authors' different disciplinary perspectives, their use of diverse methodological approaches, and differences in the specific issues emphasized in the studies, they all unequivocally show that empowered and socially interacting consumers are transforming the way marketing is practiced by consumer-oriented firms.

EXTENDED ABSTRACTS

"The Impact of Market Use of Consumer Generated Content on a Brand Community"

Albert M. Muñiz, DePaul University

Hope Jensen Schau, University of Arizona

Many studies have demonstrated that members of brand communities are capable of extensive, and increasingly professional, creation of brand content (Brown, Kozinets and Sherry; Schau and Muñiz 2006). Indeed, the ascendancy of communally-embedded, empowered consumers is now a marketplace reality (Flight 2005; Ives 2004; Morrissey 2005). However, little work has examined how the use of such community-created content impacts the community or its members. While several marketers have played lip-service to this idea, and a few have included token amounts of user-authored content in advertising campaigns (Ferriss 2002), only a few marketers have made extensive efforts to use consumer-created content. As a result, we have no insight into how extensive use of consumer-generated content will impact a brand community.

Jones Soda relies heavily upon its community of loyal users for the creation of branding content (Business Week 2005). From product innovations (flavors) to packaging (labels, cap quotes), promotions (stickers, web content, price points) and advertising, Jones Soda gives its 12-24 year old target consumers considerable input into the brand's attributes and personality (Underwood 2005). Through the Jones Soda interactive website, consumers are asked to rate suggested new flavors and are invited to submit photos and copy that would fit in advertisements and on the packaging. Jones Soda representatives follow up website research with a mobile Jones promotional vehicle that arrives at events like the X Games and high schools sports competitions to give away promotional material and have consumers try and rate Jones soda products. The promotional vehicle stocks flavors of interest (new and experimental) and actively solicits consumer feedback on site.

Jones Soda thus has several points of departure from most previously encountered brand communities. It is a new brand, which actively solicits and applies user input. It is from a product category not previously examined-consumer package goods-and thus represents a broadening of focus. It is largely inorganic, a corporately created brand community. Based on these difference, one could expect a vastly different form of brand community.

We conducted a netnographic study (Kozinets 2002) of the Jones Soda brand community. This community possesses all three of the markers of brand community identified by Muñiz and O'Guinn (2001). We found a brand community that relies extensively on the Internet to organize an immediate feedback loop between consumers, the firm and the marketplace. We also witnessed an attempt by the marketer to make the brand marginal via the strategic choice of flavors, promotional content and distribution strategy. This strategy may have been designed to instill "desired marginality" (O'Guinn and Muñiz 2005) in the brand and community. Finally, we found ample room for personal transformation and consumer empowerment via the Jones Soda brand community.

The construct of brand community is well-defined and yet still currently under-researched and under-theorized. This study of Jones Soda allows us to demonstrate the power of inorganic communities to harness consumers' creative efforts for marketing

success. Beyond the focus group approach to product development and marketing, Jones Soda has brought consumers into the production of value and given them unprecedented input into all marketing related decisions.

“How to Get in With the in Crowd”

Catja Prykop, Credit Suisse

Nader T. Tavassoli, London Business School

Andreas Herrmann, University of St. Gallen

Our findings contribute to the literature on brand communities (e.g. McAlexander, Schouten and Koenig 2002, Muñiz and O’Guinn 2001) and consumption-related interactions in high-risk leisure consumer contexts such as skydiving, where interactions represent strong interpersonal bonds: “a shared of ritualistic experience that transcends ordinary camaraderie” (Celsi, Rose and Leigh 1993; p. 12). Findings from this literature are most descriptive of consumers with a high degree of identification with a social category. Building on research on the notion of “collective” social identity, we find that there are qualitative differences to previous research in contexts with strong interpersonal bonds, in that different levels of self-definition represent distinct forms of self-representation with different origins, sources of self-worth, and social motivations (Brewer and Gardner 1996). Relatedly, we find that the drivers of brand choice are moderated by the strength of consumers’ social identification with a scene.

The overwhelming focus of previous research has also been on the fabric and dynamics of the community and to some degree, in the case of brand communities that are centered on and supported by a single brand, their relationship to the focal brand. In contrast, our focus is on brand choice—among a competitive set of brands—for consumers affiliated with non-brand centered social categories. We base our theoretical framework on the sociological concept of scenes (Irwin 1973) where a shared—even mundane—fascination with an activity or topic provides a feeling of belonging. We tested our theoretical framework in a large-scale empirical study (N=1570) in two leisure scenes: the golfer scene and the snowboarder scene. We show that intra-personal (personal identity; Sirgy 1982) and interpersonal (social identity) aspects of the self jointly affect brand choice. We further demonstrate that (1) the effects of brand-self congruity and brand-scene congruity are mediated by functional-, emotional-, and social brand values, and (2) that these effects are moderated by consumers’ level of social identification with the scene.

We further tested a managerial implication from the results of a structural equation model in an experimental study on advertising effectiveness. We found that ads advocating products’ functional benefits provide a more successful positioning for individuals with low scene identification, whereas ads positioned around social benefits are preferred by individuals with high scene identification.

“Understanding Differences between Firm-Managed and Customer-Managed Brand Communities”

Stefânia Ordoús de Almeida, University of São Paulo

Utpal M. Dholakia, Rice University

Silvia Vianello, Università Ca’ Foscari di Venezia

Grappling with the waning effectiveness of advertising campaigns, the growing consumer resistance toward aggressive direct marketing programs, and increasingly empowered consumers, many marketers have become more and more interested in organizing, nurturing, and monitoring brand communities where their customers can interact with one another (Algesheimer, Dholakia, and Herrmann 2005; McAlexander, Schouten and Koenig 2002; Muñiz and O’Guinn 2001; Schouten and McAlexander 1995).

Despite having considerable practical significance, little research has examined differences between firm-managed and customer-managed brand communities. This issue is especially pertinent to many firms that have recently launched community sites only to find pre-existing thriving communities established and managed by their own customers. Some unanswered questions that we focus on are: Do customers favor a particular type of community and are they entrenched within it? Does company involvement reduce the enthusiasm of participating customers? Which communities have a greater number of social interactions and are more effective in disseminating knowledge? Do these communities favor different sorts of interactions? To examine these questions, we compared and contrasted brand communities supported by the firm and those organized by customers for two different branded products: NI’s LabVIEW software and the Microsoft XBOX game console.

Results of our Netnographic analysis (Kozinets 2002) revealed considerable overlap in customer memberships across the firm- and customer-managed communities. Many of the most active participants tended to post and respond to messages actively in both community venues. However, there was a clear demarcation in what these communities are used for. Firm-managed communities tended to be employed primarily for instrumental purposes by customers, such as seeking assistance with a specific problem, learning about upcoming product launches, events, etc. In contrast, customer-managed communities allow more for broader “off-topic” interactions not necessarily involving the firm’s products and brands. In these communities, we found the emergence of small friendship groups of a firm’s customers.

Furthermore, we also found firm-managed communities to be largely targeted toward specific, well-defined consumer segments by the firm. In contrast, customer-managed communities appeared less clearly targeted, and were likely to be formed by members of customer groups that the firm may have overlooked. As such, customer-managed communities may enable the discovery of new marketing opportunities for the firm. Based on these and other findings, we will discuss how firms can manage their own communities more effectively, and how they can play a meaningful role in customer-managed communities. In the ACR session, we will also discuss the theoretical issues emerging from our research, as well as highlight promising research opportunities.

SPECIAL SESSION SUMMARY
Fighting Obesity in Away-from Home Consumption: Healthier Food, Better Nutritional Labels, or Menu Assortment?

Pierre Chandon, INSEAD, France
Brian Wansink, Cornell University, USA

SESSION OVERVIEW

More than 47 percent of the money Americans spend on food is spent away from home, mostly in fast-food restaurants and vending machines. To the relief of nutritionists and public policy officials, fast-food restaurants have shifted their focus from super-sizing to offering healthier food and to making nutritional information more salient. For example, much of the success of Subway, the fastest-growing fast-food franchise, has been attributed to its “healthy” positioning (Barrett 2003). Similarly, McDonald’s will voluntarily add detailed nutritional information on hamburger packages. But why then are obesity rates showing no sign of abating?

The presentations in this special session examine whether objectively healthier food and better nutritional information may, ironically, contribute to obesity and whether a different approach, based on offering different portion sizes and bundles, may effectively lead people to choose smaller portions.

The first two presentations show that consumers may not be making healthier food choices when eating in healthier restaurants or when nutritional information is salient. Chandon and Wansink show that the restaurant brand (e.g., Subway vs. McDonald’s) and the presence of healthy items on the menu prime healthy or unhealthy anchors and bias consumers’ estimates of the number of calories contained in their fast-food meals. Calorie underestimation caused by healthy primes then lead people to indulge in high-calorie side orders or desserts. In the end, people may end up consuming bigger meals, yet believe that they consumed fewer calories at healthy restaurants than at unhealthy ones.

In the second presentation, Bloom and Bolton show that more accessible and easier-to-digest nutrition labels only improve food choice among ambivalent consumers. They find that the choices of consumers with either strongly positive or negative attitudes toward nutrition were not influenced by nutrition labels. These effects are robust, regardless of whether nutritional labels contain information on calorie and on the number of minutes on an exercise bike it would take to burn them off the calories or simple red flags, such as those adopted by leading food marketers.

What then can public policy and responsible marketers do to lead people towards healthier food choices? The third presentation suggests an innovative solution. Sharpe, Staelin, and Huber argue that simply adding healthier alternatives on the menu and providing better nutritional information may not be enough. They find that, because of extremeness aversion, simply offering one smaller portion size on the menu (e.g., a 12-oz drink) leads people to choose smaller drinks. In contrast, they find that the current established super-sizing practices lead people to choose larger portion sizes, even when the discount is minimal.

SPECIAL SESSION SUMMARY

Do we Always Judge a Book by its Cover? The 'How' and 'When' of the Effect of Consumers' Stereotypes on Evaluations of Products and Services

Shashi Matta, Ohio State University, USA

SESSION OVERVIEW

Research on stereotypes has an extensive history within psychology, and social cognition in particular. Stereotypes are beliefs about the characteristics, attributes and behaviors of members of certain groups (Hilton and von Hippel 1996). Consumer researchers have acknowledged the importance of stereotypes and have examined the role of consumers' stereotypes in evaluations of products, firms and services. Stereotypes that have been researched in consumer behavior include *gender* (e.g., Gilly 1988; Fisher and Dube 2005), *country-of-origin* (Maheswaran 1994; Gurhan-Canli and Maheswaran 2000), and *occupations* (Iacobucci and Ostrom 1993; Babin, Boles and Darden 1999).

Researchers have long been fascinated by why, how and when people use stereotypes. More interesting, perhaps, are the questions of 'how' and 'when' stereotypes affect judgments that people make. In this special session, we address these questions by examining the multifaceted effects of consumers' stereotypes, and how and when they affect consumers' judgments. The four papers investigate consumers' stereotypes of *gender* (Folkes and Matta), *race* (Faro and McGill; Morris), and *consumption* (Perkins, Pinter, Greenwald and Forehand) on judgments of *products* (Folkes and Matta; Perkins et al.), *services* (Faro and McGill; Folkes and Matta), and *advertising* (Morris). Each of these papers made a unique contribution to collectively enhance our understanding of the 'how' and 'when' of consumers' stereotypes.

In the first paper, Folkes and Matta show that stereotypes about the gender of an organization's leader influence consumers' inferences about the quality of the organization's product or service, and also about gender-typed attributes of the product or service. They vary the leader's gender in a male dominated profession, and the ambiguity of information about the leader's competence. Faro and McGill, in the second paper, continue this investigation of how stereotypes affect consumers' evaluations of services. They examine racial stereotypes, and show that the social context of the judgment (in the presence of others or alone) and consumers' self-monitoring moderate the effect of racial stereotypes on consumers' response to advice by a service provider. Respondents in their experiments were asked to make an investment decision based on the recommendation of a financial advisor who was either White or Black. Consumers' racial stereotypes also feature in the third paper, in which Morris examines the role of a lifestyle variable—urban identification—on consumers' evaluations of ads with White or Black actors. While Morris investigates urban identification, Perkins and colleagues, in the final paper, examine the role of another kind of identification—implicit partisanship (a trivial connection between a consumer and a consumption group)—on evaluation of products consistent with group stereotypes. The session is therefore structured with links that facilitate the flow of ideas from one paper to the next.

Overall, the session attempts to present a rich and varied perspective on how and when consumer's stereotypes affect judgments of products, services and marketing communication. Together, the four papers address both situation variables (e.g., information ambiguity, presence of others in judgment context, implicit partisanship) and individual difference variables (e.g., self-monitoring, urban identification) that affect the role stereotypes in

consumer judgments, and provide evidence for the processes by which these variables affect that relationship. We believe that this session guides us towards an understanding of the 'how' and 'when' in stereotypes research.

EXTENDED ABSTRACTS

"When Women Lead, Do Consumers' Perceptions of Her Firm Follow?"

Valerie Folkes, University of Southern California
Shashi Matta, Ohio State University

Our research examines when consumers' gender stereotypes influence perceptions of an organization's products and services. In particular, we hypothesize that stereotypes about the gender of an organization's leader influence consumers' inferences about the quality of the organization's product or service, and about gender-typed attributes of a product or service.

Consumers receive information about a firm's leaders from a variety of sources, including news articles, publicity releases and advertisements. That information about the leader may influence consumers' inferences about the organization's products and services. A leader is perceived as a prototypical group member or one that represents the organization's ideal (van Knippenberg and van Knippenberg 2005). In fact, leaders' and members' characteristics are related, with top leaders' personalities and values being similar to their employees' (Giberson, Resick and Dickson 2005). People are likely to assume that leaders impose their values on the organization and that the organization selects leaders that reflect its values. Hence, consumers may generalize from their inferences about the characteristics of a firm's leader to characteristics of the service delivered by subordinates, as well as to attributes of products created by the firm.

If information about leaders does influence consumers' perceptions of products and services, then the leader's gender may also affect those evaluations. Some research suggests that evaluations will be more negative when the firm is led by a woman. People respond negatively to a female leader because the traits associated with leadership are those more frequently linked to traditionally masculine stereotypes than traditionally feminine stereotypes (Powell and Butterfield 1989). On the other hand, research by Matta and Folkes (2005, study 3) found that a woman leader in a male dominated occupation was evaluated as more competent than a male leader when both performed in an excellent manner.

Our studies attempt to resolve the contradictory findings of Matta and Folkes' study with previous research on negative evaluations of women leaders, as well as to investigate generalizations from the leader's characteristics to the service delivered by subordinates and to the firm's products. Few studies have examined the impact of a firm's leader on products and services, and those few studies show mixed results. For example, Freiden (1984) compared effects of various types of product endorsers (the firm's CEO, a typical consumer, a celebrity, an expert) portrayed in an ad for a fictitious product and found no endorser sex differences in spokesperson effectiveness.

We conducted two experiments that investigated consumers' inferences from high level leaders on perceptions of the type of

service delivered by the leader's subordinates. Both studies manipulated ambiguity of information about the leader's competence. Previous research led us to expect that perceivers would be more favorable toward a female in a stereotypically male role when she performs in an unambiguously competent manner than when competence is ambiguous (Heilman and Haynes 2005; Heilman, Wallen, Fuchs and Tamkins 2004). We reasoned that Matta and Folkes' (2005) findings reflected the unambiguously excellent performance of the woman. Matta and Folkes' findings should not extend to a leader if competence is ambiguous.

To enhance ecological validity, all studies presented participants with information about an actual organization and the organization's leader. Participants read information about the leader in a male dominated occupation who was described to half the participants using her actual name and to the other half using a masculine name. Results showed that characteristics of the male leader in a male dominated profession were similar to subordinates, suggesting generalization from leader to follower. When the male leader's performance was unambiguously competent, the service delivered by subordinates was rated more positively than when his performance was ambiguous. Further, inferences about his sex-typed characteristics (e.g., the extent to which he had agentic or communal traits) were similar to inferences about his firm's service providers' sex-typed characteristics.

Characteristics of the female leader were less likely to be generalized to her subordinates. As with the male leaders, less ambiguity about a woman leader's performance led to more positive evaluations of her compared to when her performance was more ambiguous. Unlike the male leaders, the unambiguously excellent woman was considered more competent than her subordinates, whereas the ambiguously performing leader was considered less competent than her subordinates. Further, respondents were more likely to perceptually isolate the ambiguously performing leader from others in her firm, and to assume that her sex-typed traits were not generalizable to her subordinates.

Study 2 investigated effects of ambiguity and the leader's gender on perceptions of subordinates as well as on product perceptions. Respondents had actual product experience and then evaluated the product. Respondents' evaluations of the organization's output reflected characteristics of the leader rather than characteristics of the subordinates. Hence, inferences that a woman leader had more feminine characteristics than did a male leader affected perceptions of product attributes, with respondents describing products as having more feminine characteristics when the leader was a woman than when a man. The results of these studies indicate that consumers' gender stereotypes about an organization's leader can influence evaluations of an organization's products and services.

"Racial Stereotypes in Consumer Judgment: The Effect of the Presence of Others"

Davis Faro, London Business School

Ann McGill, University of Chicago

Stereotypes have been shown to play an important role in consumer judgments (e.g. Maheswaran 1994; Gurhan-Calni & Maheswaran 2000). In the present research, we examine the role of racial stereotypes in the evaluation of services and, in particular, how the social context of the judgment—in the presence of others or alone—may affect the influence of stereotypes.

Intuition might suggest that racial stereotypes would play less of a role in the evaluation of services in a more public context because buyers would want to avoid any appearance of prejudice. This intuition is consistent with recent consumer research that has

highlighted how the presence of others may trigger processes of impression management (e.g., Ariely & Levav 2000; Fisher & Dube 2005; Ratner & Kahn 2002; Argo, Dahl & Manchanda 2005). In this view, consumers may downplay the role of race in their judgments or even provide "politically correct" judgments in which services provided by African-Americans are judged more favorably in public than in private. However, public contexts may cause other effects than those dictated by impression management concerns. Specifically, research on stereotypes has shown that control of stereotypical judgment requires cognitive resources that the presence of others may diminish (Gilbert & Hixon 1991). Therefore we might observe situations in which the presence of others would actually result in *more* stereotypical judgments (e.g. Lambert et al. 2003).

The present research examines these opposing predictions and relies on individual differences in self-monitoring to predict the direction of the effect that the presence of others would have on evaluations of services provided by minority groups (Snyder, 1974; Snyder & Smith, 1986). Self-monitoring shows particular promise in exploring opposing effects of social presence because it captures differences in sensitivity both to social cues to providing socially appropriate responses and to the distractions caused by the presence of others. Specifically, we predict that for high self-monitors, consistent with prior research on impression management, the presence of others will result in more favorable evaluations of services provided by an African-American (Fiske & Von Hendy 1992; Olivier, Snyder & Livingstone 2004). By contrast, low self-monitors tend to be more anxious in social circumstances and generally to look inward, rather than outward, for cues to behavior. This unease and inward focus might result in more stereotypical judgments in the presence of others, that is, less favorable evaluation of the service.

The first study examined these predictions in the context of an investment decision to be made based on a recommendation by an African-American (versus White) financial advisor. Participants were asked to allocate a sum of money to a stock recommended by the financial advisor and they made their judgments alone or in the presence of a white confederate. The confederate was merely-present in the room and was unable to see participants' responses (Zajonc, 1965). Results revealed the predicted three-way interaction of social presence, race, and self-monitoring. High self-monitors invested more for Black advisor in public versus alone and, further, invested more for the Black advisor than the White advisor in public. This pattern of results reversed for the low self-monitors. Investment levels were lower for the Black advisor in public versus alone, and, further, lower for the Black than for the White advisor in public.

The results of the first study are in line with the account that high self-monitors were better able to control an activated stereotype in public than low self-monitors. The second study was designed to explore an alternative process by which self-monitoring may influence judgments. Specifically, high self-monitors may be so attuned to the demands of the social environment that these individuals may not even activate the stereotype. To test this account, participants in the second study completed the same investment task but also took part in a word completion task that was aimed at measuring activation of racial stereotypes (Gilbert & Hixon 1991). Results indicated that high self-monitors were not less likely to activate the stereotype. Further, the pattern of results from the first study was replicated, but only for those people who activated the stereotype, consistent with the view that results are driven by differences in ability of high and low self-monitors to control the stereotype when evaluating the service.

Results of these two studies demonstrate the opposing effects that public presence can have on the prevalence of racial stereotypes in the evaluation of services. Findings show that public presence can result in more or less politically correct evaluations, depending on individual differences in the sensitivity to social desirability concerns (self-monitoring). We expect that this pattern of results would extend beyond the context of service evaluations, to contexts such as judgments of foreign products or advertising messages involving minority members. The studies presented here reflect the multifaceted influence that public presence can have on consumers' judgments.

“Beyond Demographics and Stereotypes: Effects of Urban Identification on Responses to Actor Race in Advertising”

Marlene Morris, University of Georgetown

Consumer behavior researchers have identified many criteria by which to segment consumers to explain and predict their behavior (Zaichowsky 1985; Bettman 1979). While marketers have historically viewed the marketplace in terms of demographics such as race, consumers are increasingly identifying themselves on lifestyle rather than demographic terms. Marketing research has also historically focused on segmentation based upon ethnicity to understand and predict consumer behavior, including specific measures of degree of ethnic identification, examining subcultures such as blacks (Whittler 1991, Williams & Qualls 1989, etc.), Hispanics (Webster 1994) and Jews (Hirschman 1981). In recent years, researchers have begun to follow marketers' shift from the use of demographic data as the primary basis for understanding and categorizing consumers and predicting their behavior, to segmentation variables with more explanatory power such as subculture and lifestyle. One particular lifestyle segment that crosses racial, ethnic, age and geographic boundaries in an unprecedented fashion is the urban subculture. Despite the great deal of attention that the urban segment has received from marketing and advertising practitioners in recent years, there is currently little understanding of its effects on consumer behavior and effectiveness of marketing communications. The urban segment generally takes multiculturalism for granted and sees things less in terms of black and white than cool or un-cool, making demographic and ethnicity-based segmentation less insightful for newer generations of consumers and behavioral research. Identification with this segment and its characteristic ethnic diversity also creates some confusion about which cultural cues are now seen as stereotypically representative of a particular ethnic group.

Marketers have only recently identified and acknowledged the urban population as a lucrative consumer lifestyle and sociopolitical segment in and of itself, as well as a powerful mechanism for reaching and influencing broader audiences of consumers. The pervasiveness of this segment along with over \$890 billion per year in buying power in the U.S. alone (Stavraka 2001) makes it a highly sought-after one for marketers. The current research seeks to examine the effects of urban identification on evaluations of advertising and shows that urban identification mitigates previous findings regarding similarity effects in advertisements.

Existing research in advertising has examined subjects' responses to ads featuring same- and other-race actors. While studies consistently show that minority (i.e. black) subjects respond more positively to ads featuring same-race actors and related race cues (Appiah 2001), results for the larger majority population are inconclusive, with researchers assuming that there is no significant effect of actor race or race cues on non-black populations. The current study examines the effects of urban identification on majority populations' responses to ads and finds that within a non-black

population, non-urban identifiers prefer ads featuring white actors; however, non-black urban identifiers prefer ads featuring black actors with preference measured in terms of ad liking, similarity of ad to self, identifying with the actor, perceiving a similar style, personality, culture and style of actor's dress and liking for the actor.

Study results call into question current advertising industry belief and practice, which focuses on demographics—specifically race—as the basis for market segmentation. It also challenges existing notions of stereotypes and effectiveness of in-group and out-group categorizations and cues by showing that particular psychographic and lifestyle variables—urban identification in this instance—mediate the effects of racial stereotypes on consumers' responses to advertising.

“Ladies and Gentlemen, Lend Me Your Attitudes...Implicit Attitude Formation As a Result of Group Membership and Consumption Stereotypes”

Andrew Perkins, Rice University

Brad Pinter, Penn State Altoona

Anthony G. Greenwald, University of Washington

Mark Forehand, University of Washington

Previous research has established that individuals' cognitions and attitudes may form as a result of membership in a group to which that the individual belongs. This *minimal group effect* (Tajfel, Billig, Bundy and Flament 1971) suggested that the mere assignment of an individual to a randomly selected group resulted in discrimination against other competing groups. Recent research suggest that *implicit partisanship* may be unconscious in nature, in that individuals automatically self-associate with groups, leading to feelings of in-group bias and out-group discrimination (Greenwald et al 2002, Pinter and Greenwald 2004). Pinter and Greenwald found this robust effect across numerous experimental settings suggesting that implicit partisanship is a category level effect, such that a meaningful group membership is created automatically, with the potential to influence behavior. The current research extends these findings by exploring the formation of attitudes toward target objects that have been randomly associated with a novel group and consumption stereotypes tied to that group.

Two experiments were conducted to explore the potential for attitude formation toward novel objects (experiment 1) and fictitious brand names (experiment 2). Participants were initially told that they would be participating in a campus-wide scavenger hunt, and would be randomly assigned to one of two groups, designated as either team Triangle or Circle. Following random assignment to one of the groups, participants were instructed to complete a simple categorization task that prompted them to first examine a list of ten names of the other students who were members of the two five-member competing groups. Within the group that the participant was assigned, one of the names was replaced with “yourself”, an indication that the participant was a member of that group. Following a thirty second exposure to the list of fictitious student names, participants then completed a trivial categorization task that compelled them to separate the two groups of names using two behavioral responses, in this case, pressing either the ‘d’ key or the ‘k’ key on a computer keyboard. Thus, a participant who was assigned to the Circle team might be required to press the ‘d’ key whenever the name of his team was presented on the screen (as well as the word “yourself), and press ‘k’ whenever the names of the other team members were presented on the screen. Following this task, participants were then instructed that they would be looking for the scavenger hunt targets: either analog or digital clocks described as present on campus (experiment 1) or fictitious automobile brands

said to be located around campus as part of a vehicle manufacturer's promotion. In order to learn which target category of objects was to be scavenged, participants completed another categorization task that required the same behavioral response (again, pressing either the 'd' or 'k' key) when presented with either the target object or names of their own team. The word "yourself" was omitted in this task, so that the participant never directly associated a self-representative word with the target objects. Following the manipulations, participants completed two Implicit Association Tests (IATs; Greenwald, McGhee and Schwartz 1998) that measured self association and attitude toward the target object or brand. The experiments differed only with regards to the target object.

The results suggested that subjects spontaneously generated positive implicit self-associations as well as positive implicit attitudes toward the target objects that were sorted together with their group during the experimental treatments. Specifically, a participant assigned to the *circle* group, who categorized their group members with the *Ace* brand model names, subsequently self-associated with and generated a positive implicit attitude toward the *Ace* brand, even though there was no direct linkage of self with the *Ace* brand during the experiment. The formation of these types of attitudes may be explained within a cognitive consistency framework (Greenwald et al. 2002). Greenwald and colleagues suggest that links in memory spontaneously form in order to balance identity triads in memory. Extending these findings, the current findings suggest that these triads may be more complex than the relationships between three objects in memory. In essence, the current project posits that a link should form in memory between the self and a target object as a result of that individual's group membership, and the subsequent association of that target object to the group, but not directly to the individual. These results suggest that consumers have an implicit bias toward products that are stereotypical for their in-groups, even when that stereotype is arbitrary and is not based on personal experience. Moreover, the findings suggest that consumption stereotypes (beliefs about the appropriateness of products and brands for a particular group) may drive preference without conscious deliberation. A third experiment is currently underway to assess whether attitudes formed in the way described above influence purchase intention and other explicitly stated behavioral outcomes.

ROUNDTABLE
Philosophy and Consumption
Janet Borgerson, University of Exeter, UK

Conversations continue around Philosophy and Consumption after last year's roundtable attracted 45 participants, encouraging consumer researchers to reflect on philosophical concepts, frameworks, or philosophical figures that have impacted, and continue to impact, the way each of us asks questions, conceptualizes problems, and carries out our arguments and analysis. This session spurs interaction between scholars with a variety of interests and research paradigms who are engaged—whether implicitly or explicitly—in philosophically informed consumer research.

The session's purpose is to continue conversations around recent efforts that draw upon philosophical and ethical concepts and theories in accomplishing consumer research. Examples include research on tragedy; consumer objects as resources for consumer identity work; constructions of “consumers that matter”; and consumer subjectivities constituted through interaction with brands and marketing representations. Just as crucial was the issue of inspiration: that is, certain ideas or the way things are said or connected together can inspire us to look at and engage with a question, or the world, differently. The goal is to gather together scholars who are engaged in philosophically informed consumer research, and to provide theoretical resources for interested researchers and consumers. The session's organizer holds a Ph.D. in Philosophy and writes on consumer identity constitution, consumer agency, and ethical concerns in marketing and consumer behavior.

Some of last year's group, and some new people as well, have been asked to provide insight into their own experience and contribute to this on-going conversation. Whereas last year every attendee (all 45!) introduced him or herself and said a bit about their interests, this year each of the invited ‘panel’ will prepare a five minute elaboration of a philosopher/thinker or a philosophical perspective, or a single concept or notion that has contributed, disrupted, or encouraged certain aspects of their own writing, questioning, and/or research. This brief presentation is not meant to provoke anxiety or suggest the need for deep and extensive knowledge about philosophers or history of ideas, etc. Rather, we each get to hear a little more about how others think, what creates a lasting, or only momentary, influence that makes a difference, as well as, opening up discussion around a diversity of interests and methodologies. Questions and discussion among all attending researchers will follow.

Clearly, the concerns of philosophy and the marketplace intersect. Moreover, turning to philosophy can help clarify assumptions, theory, and methods within consumer research. Philosophy questions, and thus adds rigor to, the coherence of arguments. At a pragmatic level, philosophical considerations and ethical investigations, and the ability to undertake both, allow for thoughtful, careful, and aware research, including an understanding of epistemological and ontological issues regarding, e.g. consumer identity, corporate social responsibility, and consumption generally.

SPECIAL SESSION SUMMARY

Time and Decision: New Perspectives on Present-Biased Preferences

Selin A. Malkoc, University of Minnesota, USA

SESSION OVERVIEW

Consumers are constantly faced with decisions about the timing of their consumption. Consumers evaluate investments and savings (costs incurred now for future gain), redemption of cash refunds and rebates (a wait period followed by earnings) and indulgent consumption (benefits experienced now but with a cost (e.g., to one's health) incurred later). Prior research has consistently shown that people have a preference toward the present, overweighting near outcomes compared to later outcomes. Furthermore, this impulsivity has been shown to decline with time (i.e., hyperbolic discounting or present bias; Thaler 1981). That is, when making a decision between smaller-sooner and larger-later rewards, individuals' implied rate of discounting (or preference for smaller-sooner outcomes) is higher over a short compared to a long time horizon. This pattern of behavior has been attributed to impulsivity (Loewenstein 1996), to differences in cognitive representations between near and future events (e.g., Zauberman and Lynch 2005) or to an individual difference in time orientation (e.g., Zimbardo and Boyd 1999).

The papers in this special session propose new perspectives for understanding present-biased preferences. These papers challenge current theorizing in this domain and provide boundary conditions for existing findings. In particular, they demonstrate that impatience (1) is better measured by a motivational present value approach, (2) is better understood if prior consumer decisions are taken into account and (3) might not always be as robust as previous research has suggested.

The first paper, by Ebert and Prelec, argues that conventional measures of intertemporal preference systematically underestimate consumers' present value of future outcomes. They develop a motivational measure that is based on the exerted effort to obtain outcomes at different times, and show that the traditional measures of time preference (e.g., WTA) systematically underestimates present value. The authors suggest that this may reflect how people assess rewards using a monetary scale and discuss the psychological differences in monetary and motivational measures.

The second paper, by Malkoc, Zauberman and Bettman, explores the role of previous tasks in consumer impatience. The authors demonstrate that prior decisions change processing concreteness (focus on the big picture versus details) and systematically affect present bias. Their results indicate that consumers show less present bias when in abstract mindsets, compared to when they think concretely (even when the prior task is unrelated)-introducing a new conceptualization and showing that present bias is moderated by the extent of context-dependent thinking.

The third paper, by Read and Frederick, examines the longitudinal aspect of present bias. The authors note the cross-sectional nature of the experiments that demonstrated present bias and examine such intertemporal preference reversals in three longitudinal studies. They find support for preference reversals in line with hyperbolic discounting *only* when the sooner outcome is immediate. These findings suggest that present-biased preferences support a quasi-hyperbolic form. In addition, these results provide boundary conditions for present bias, indicating the importance of temporal proximity to the outcome.

Collectively, the three papers in this special session provide new insights about consumer impatience and time discounting, by

offering new measurement, conceptualizations, and psychological drivers for present-biased preferences.

Following presentations, Drazen Prelec, the session discussant, provided an overview of how these papers inform and qualify the findings of previous research, as well as noting some of the ways in which the session offers diverging perspectives on intertemporal preferences.

EXTENDED ABSTRACTS

"A New Method of Measuring Temporal Discounting: The Motivational Present Value of Future Rewards"

Jane Ebert, University of Minnesota

Drazen Prelec, Massachusetts Institute of Technology

A wide range of people's behaviors in the present are motivated by longer-term or future concerns: employees work for future bonuses or to invest for retirement; students study to obtain a degree; and people exercise for future health. Many researchers and policy-makers are interested in the rates at which people discount such future concerns, or the value they place on them relative to the present, with the underlying assumption that this *present value* provides a measure of the importance or motivational power of people's future concerns on their present behavior (e.g., Chapman et al. 2001; Kirby et al. 1999).

Measures of present value most commonly used ask people to explicitly state the present value of a future reward, such as "What is the equivalent value to you today of \$120 in one year?" Obtained discount rates using such measures vary considerably, but overall they tend to be positive and rather high (see Frederick et al. 2002 for a review). If our goal is to use discounting measures to understand or predict those behaviors that are motivated by future concerns, then a present value should, ideally, represent the equivalent motivational power in the present of an event in the future. So, for example, a future reward of \$25 that a person assigns a present value of \$20 should have the same motivational power for that person as a present reward of \$20. However, for several reasons we suspect that conventional explicit discounting measures may provide a poor measure of the present motivational value of future rewards, and, if anything, are likely to overestimate this present value and so *underestimate* the discount rate. So, even if people explicitly say that a future reward of \$25 has a present value of \$20, they may nonetheless behave, and even expect to behave, as if it has a present value of, say, \$10. I.e., the discount rates people will demonstrate in their behavior, and even in how they expect to behave, will be higher than those measured using conventional discounting measures. We attempt to demonstrate and examine this in the current research, through the development of a new measure of discounting that assesses the motivational present value of a future reward.

In our first study, we develop a method that 1) pits effort against a future reward to assess the motivational value of the future reward (specifically, we assess how long people exert effort working on a simple task in the present in order to gain a future reward), and 2) calibrates the effort expended for the future reward against the effort expended for different immediate rewards to assess the motivational present value of the future reward. We compare the present value we obtain using this motivational measure with that obtained for the same participants using a conventional discounting

measure, and find that the present motivational values we obtain are lower than the present “explicit” values obtained on the conventional discounting measure: i.e., the future has less motivational force than we might expect given conventional discounting measures. This suggests that the present value captured by the conventional discounting measure is not the present motivational value we might wish to assess.

Two important features of our comparison of the motivational and explicit present values are: first, the same future rewards are used for both measures precluding arguments that people simply value different future quantities differently, and second, the calibration of the effort people expend for future rewards against the effort they expend on the same task for immediate rewards precludes arguments that people simply value different present quantities, e.g., effort versus money, differently.

In the second of our studies, we replicate this finding for future rewards and demonstrate that people are similarly inconsistent in their present values for uncertain or probabilistic rewards, where again the conventionally obtained explicit present values are lower than the motivational present values. In two subsequent studies we strengthen the conclusion of the first two studies, that participants’ motivational present values are inconsistent with their explicit present values, where the motivational values are systematically lower. We also examine whether the presence of effort in our motivational measure may account for this result and we compare participants’ motivational present value with the present values obtained on several alternative discounting or present value measures. In study 3, we develop a within-subjects version of our task, which aids consistent responding across the motivational and conventional discounting measure and so provides a stricter test of our result. In addition, we show that the presence of effort in our motivational measure of present value is unlikely to be responsible for our finding that present motivational values for future rewards are lower than people’s present explicit values. In study 4, we replicate these findings and examine the differences in present value obtained between several alternative discounting measures that resemble our motivational and explicit measures in different respects.

By attempting to measure the motivational force of a future reward, this research has taken a novel approach to understanding the myopic behavior people show in their day-to-day lives. Previous work interested in the motivational power of rewards in choices that trade-off desires in the present and the future has generally focused on the motivational power of immediate rewards, e.g., work on visceral effects (Loewenstein 1996) or mental effort (Baumeister and Vohs 2003) on self-control. In contrast the current research focuses on the motivational power of future rewards.

“Impatience is In the Mindset: Carryover Effects of Processing Abstractness in Sequential Tasks”

*Selin Malkoc, University of Minnesota
Gal Zauberman, University of Pennsylvania
James Bettman, Duke University*

Extant research on intertemporal choice has demonstrated that people are not only highly impulsive, but also display present bias by using higher discounting for shorter delays (e.g., Thaler 1981). Although there is ample evidence documenting present bias, relatively little is known about its underlying mechanism. Explanations offered include both affective (Loewenstein 1996; Rachlin and Raineri 1992) and cognitive processes (Malkoc and Zauberman 2005; Zauberman and Lynch 2005). These accounts, however, have conceptualized intertemporal decisions independently of any tasks previously engaged in and have focused on responses triggered by the focal outcome, such as outcome-specific feelings (i.e., deprivati-

tion) or cognitions (i.e., representational proximity) as the driving force behind present bias.

In the current work, we suggest that the tasks people have previously engaged in have systematic effects on processing concreteness and that these changes in concreteness of processing might be sufficient to explain dynamic inconsistencies in preferences. Building upon ideas from the psychology of verbal processing (e.g., Paivio 1971) and processing orientation (e.g., Navon 1977), we argue that when in concrete processing mode, individuals are more myopic and context dependent, leading to present bias. When the processing mode is more abstract, however, preferences show more intertemporal consistency, attenuating present bias. Three studies manipulating processing specificity with prior tasks provide support for this prediction.

Based on research showing that abstract thinking is facilitated when evaluating non-comparable options (Johnson 1984; Malkoc et al., 2005), in Experiment 1 participants (N=102) were provided with two cameras presented on seven attributes (either alignable or non-alignable) and were asked to compare them. Next, they were told to imagine shipping the camera and were asked how much they would need to save to delay its receipt by 3 and 10 days. As expected, we found a 2-way interaction between time horizon and alignability ($F(1, 106)=5.653, p<.05$), demonstrating an attenuation in present bias when participants evaluated non-alignable options.

Experiment 2 (123 participants) manipulated abstraction with an unrelated elaboration task. Participants first wrote their thoughts about the Digital Millennium Copyright Act and were directed to think either about implications for a specific and concrete consumer (their roommate) or for the more abstract notion of consumers in general. Next, participants completed a separate cash refund study where they delayed the receipt date of a \$75 cash refund by 4 or 10 weeks. The analyses again found an interaction between abstractness of mindset and time horizon ($F(1, 120)=4.309, p<.05$), with less present bias shown when thinking about the broad implications compared to a specific exemplar.

In experiment 3 (231 participants), we manipulated processing concreteness with a supraliminal priming task to further test the boundaries of our effect. Participants first completed a word search puzzle that had either concrete or abstract words embedded in it. Presented as an unrelated task, participants next indicated their WTA to delay the redemption of a \$75 gift certificate by 3 and 12 months. Results replicated the two previous studies, with a significant 2-way interaction ($F(1, 229)=4.66, p<.05$) indicating diminished present bias when participants were primed with abstract words.

In sum, the current work demonstrates that intertemporal decisions are systematically influenced by the previous tasks people engage in. That is, prior decisions change the specificity (concreteness vs. abstractness) of processing and have systematic effects on present-biased preferences. Specifically, we show that when in abstract mind sets, people act less present-biased compared to when they think more concretely, suggesting that the extent of present bias depends on the abstractness of mindset, which can be influenced via prior experiences.

“Longitudinal Time Inconsistency”

*Daniel Read, University of Durham
Shane Frederick, Massachusetts Institute of Technology*

We investigated the hyperbolic discounting model of intertemporal choice, according to which the discount rate is a function of delay-to-outcome, with shorter delays being associated with a higher discount rate. Its major prediction is that people will predictably change their prior plans with the passage of time.

FIGURE 1

Hyperbolic discounting

FIGURE 2

Quasi-Hyperbolic discounting

TABLE 1

Study	Time until SS	Shift ratio
1	> 24 hours	0.54
2	< 24 hours	1.25
3	< 1 hour	1.88

Specifically, if we hold the interval separating two outcomes constant, preference will often switch from a larger-later outcome (LL) to a smaller-sooner one (SS) as the two options move closer in time. The general idea is illustrated below. Figure 1 shows that as time passes, SS becomes increasingly attractive relative to LL. Preferences always move in the direction of SS, and sometimes they will ‘reverse,’ as in the illustration, when SS becomes superior to the formerly preferred LL.

Most experimental tests of this prediction have not investigated it in the dynamic form just described. Rather, they have relied on a potentially misleading cross-sectional design involving many choices over different pairs of dated outcomes, taken from the vantage point of a single date, rather than a longitudinal design involving many choices between a single pair of dated outcomes, made from the vantage point of different dates. We conducted three experiments using a longitudinal design. These experiments were done over email with an international sample, mostly from the United States.

Respondents made choices at multiple times between Amazon gift certificates to be received at specific future *dates* outcomes, one smaller-sooner (SS) and one larger-later (LL). The dependent measure was the choice between SS or LL, and whether preferences shifted as time to receipt diminished. The delay between the final choice and SS differed across experiments, from less than a day to less than an hour. This is important because the *quasi-hyperbolic* discounting model, predicts preference reversals will occur if the time to earliest SS is *very* short, as shown in Figure 2.

In our experiment, the measure of interest was the ratio of preference reversals in the LL?SS to those in the SS?LL direction—the shift ratio. Models of hyperbolic discounting predict this shift ratio will be greater than 1. In our studies, we observed the following as shown in Table 1.

In Experiment 1, when SS was delayed by about one day, we observed no net tendency for “hyperbolic” preference reversals. In fact, there was a weak but clear tendency for preferences to reverse in the *opposite* direction. In Experiment 2, when SS was delayed by

less than one day, there was a slight tendency for hyperbolic reversals. Only in Experiment 3, when the more immediate reward could be obtained in one hour, did evidence for hyperbolic reversals clearly emerge. Thus, these three studies provide support for the quasi-hyperbolic model.

In Experiment 3, we also asked people to explain their choices. Two reasons were frequently and clearly given for the *LL*?*SS* switches. Some offered remarkably explicit *psychophysical* explanations for hyperbolic discounting, pertaining to the perceived similarity of the two time points, as Rubinstein (2003) has postulated. Others referred to a desire to satisfy *immediate spending needs*. Usually, these needs were imminent, and often discovered over the course of the experiment—leading those who initially chose *LL* to switch to *SS*. Such explanations suggest an explanation for preference reversals and for various other phenomena in intertemporal choice. People are more likely to think of earlier needs than later ones. They are typically impatient because they are usually thinking of earlier needs. They become more patient with longer intervals because the delayed payoffs aren't pertinent to imminent needs. However, as time to rewards elapses, imminent needs again become salient, causing an impatient shift. We also believe that the differential salience of needs can explain the magnitude effect, the delay-speedup asymmetry, and other empirical regularities.

SPECIAL SESSION SUMMARY

Changing Colors of My Thinking Hat: Influence of Situational and Task-Related Factors on Thinking Styles

Monica Wadhwa, Stanford University, USA

SESSION OVERVIEW

Much research in consumer information processing and decision making has been devoted to differences in thinking styles. Consumer behavior theorists and psychologists from different persuasions have distinguished between various thinking styles such as experiential versus rational modes of thinking (Epstein 1983, 1985), system-1 versus system-2 thinking styles (Kahneman 2003, Kahneman and Frederick 2002, Stanovich and West 1998, 2000), analytic versus holistic thinking styles (Nisbett 2001) and broad versus narrow thinking styles (Martindale 1985, Mednick 1962). Differences in thinking styles have been mostly attributed to dispositional differences (Martindale 1985, Mednick 1962) and cultural factors (Chiu 1972, Nisbett 2003, Nisbett and Miyamoto 2005). In contrast, little effort has been devoted to other important facilitators of thinking styles, particularly situational and task-related characteristics, which often guide consumer behavior (Belk 1975). A broad purpose of this session, therefore, is to push forward the boundaries of research on thinking styles by exploring situational and task-related factors that impact consumer information processing and thinking styles.

The specific objectives of this session are a) to outline new measures of experiential versus rational thinking styles engendered by the nature of task and b) to examine how task-related factors (e.g., constraints) and consumer environment can impact thinking process, specifically creative thinking process. Keeping in mind the broad range of audience that ACR conference attracts, the three papers in this session represent a diversity of topics in the domain of thinking styles that are relevant for marketers and consumers, ranging from the “task-specific thinking styles” (Novak and Hoffman), to the role of constrained thinking process on creative enjoyment and motivation (Dahl and Moreau), to overt visual attention and creative thinking (Shiv and Wadhwa).

The session will begin with a focus on “task-specific thinking styles”. Thomas Novak and Donna Hoffman will present their work that focuses on tasks as elicitors of thinking styles. More specifically, Novak and Hoffman develop a two-dimensional scale to measure the task specific thinking style. Novak and Hoffman demonstrate the importance of task specific thinking style over and above the dispositional thinking style for task performance. Furthermore, they show that the congruence of the task and task specific thinking style improves task performance, while incongruence between the task and task specific thinking style worsens performance on the task.

The focus of this session will then shift to the role of constraints on creative thinking on the enjoyment of and motivation on creative experiences. Page Moreau will present her work with Darren Dahl that examines how constraints imposed on creative thinking influence consumers’ motivation and overall task enjoyment. More specifically, Dahl and Moreau demonstrate that consumers enjoy the creative experience more in the presence of constraints such as receiving step-by-step instructions. However, they demonstrate that constraints imposed on the target outcome lower the enjoyment of the creative experience for high-skill individuals.

Finally, Monica Wadhwa will present her work with Baba Shiv focusing on the role of overt attention on creative thinking

process. Shiv and Wadhwa demonstrate that the breadth of overt attention engendered in the process of scanning an external visual field impacts the breadth of covert attention (i.e., internal attention), which subsequently impacts creative thinking in a subsequent unrelated consumer creativity task. More specifically, the authors argue that scanning a broad versus a narrow visual field (e.g., watching a movie on a 40-inch versus a 17-inch screen) can broaden the scope of covert attention, which, in turn bolsters creativity on a subsequent consumer creativity task of coming up with creative gift ideas.

In an effort to increase audience participation, the session will have the services of Amitava Chattopadhyay as a discussant. Amitava has expertise in the areas of creativity, consumer decision making, branding and marketing communication. His work has appeared in several journals including the Journal of Marketing Research, Journal of Consumer Research, Journal of Marketing, Marketing Science and Management Science. Amitava, thus, has a unique perspective for discussing these papers and leading a discussion about an appropriate research agenda for continued work in this area.

EXTENDED ABSTRACT

“New Measures of Task-Specific Experiential and Rational Cognition”

Thomas P. Novak and Donna L. Hoffman

Decades of theoretical and empirical research in social and cognitive psychology provide strong evidence that consumers process information in two distinct and qualitatively different ways: rational and experiential (Epstein 1994; Hogarth 2005; Kahneman and Frederick 2002, Kahneman 2003; Sloman 1996; Smith and DeCoster 2000; Stanovich and West 1998, 2000; and Strack and Deutsch 2004). A key commonality among modern dual process theories is the existence of two qualitatively different and interoperating systems, each best suited to its own purpose.

Despite this growing body of research, there has been surprisingly little research attention devoted to directly measuring how different tasks directly impact thinking style. Further, attempts to simultaneously measure the two dimensions of thinking style as either situation-specific or as an enduring state are even fewer and lack validation in a broad context.

To that end, we conducted three comprehensive studies. First, we developed and cross-validated new two-dimensional scales to measure what we term *task-specific thinking style* (TSTS) using a series of experimental tasks designed to induce primarily rational or experiential thinking. Our highly reliable TSTS measure was, as predicted, best fit by a two-dimensional factor structure. Rational TSTS was higher for rational tasks and experiential TSTS was higher for experiential tasks, providing empirical support for the idea that cognitive tasks can be arrayed along a continuum of cognition. Congruence of task and TSTS improved task performance, and incongruence worsened task performance; thus TSTS is an important process variable in understanding task performance. Both the task itself, as well as dispositional tendencies to adopt a particular thinking style, predicts TSTS. As expected, the TSTS adopted for a task is explained more by the task itself than by

dispositional differences in thinking style, supporting the use of experimental tasks to prime thinking styles and suggesting TSTS as a manipulation check for such tasks. Since dispositional tendencies predict TSTS, disposition influences the degree to which a priming task is likely to be effective, and thus disposition should be measured as a covariate when attempting to prime thinking style.

More importantly, we use TSTS to systematically test congruence effects between the demands of a task and the thinking style adopted when performing the task. We examine when congruence between thinking style and task increases actual and perceived task performance, decreases task difficulty, increases involvement, and improves mood—and if congruence effects are found for both rational and experiential tasks that require qualitatively different processing styles. Our findings contribute to the literature on congruence effects involving thinking styles, and argue for task specific thinking style being routinely measured as a process variable when considering performance on a broad range of consumer activities. For example, we find that for experiential tasks, a “low cognitive engagement” strategy results in relatively high performance, but at a personal cost to the respondent. This is a particularly interesting result since although low effort strategies hurt performance (accuracy) on rational tasks (e.g. Payne et al. 1993), but not on the experiential task—low effort strategies are psychologically detrimental as respondents employing a low effort strategy perceive the experiential task as more difficult and their mood and involvement suffers. This suggests that the effort-accuracy tradeoff may not apply to experiential tasks—thinking “too much” hurts performance, while thinking “too little” seems to help.

We also hypothesized that *dispositional thinking style*, an enduring predisposition toward predominantly rational or experiential thinking, plays a key role in determining the thinking style employed in a given task, beyond the demands of the task itself. Dispositional tendencies create heterogeneity in how different individuals approach the same task, contributing to congruence or incongruence of TSTS with the task. The results show that some of the variation in whether an experiential or rational thinking style is adopted for a task will result from dispositional tendencies. Thus, TSTS provides an important mediating link between a broad, dispositional cross-situational thinking style, and performance on tasks that are congruent or incongruent with a thinking style.

Our TSTS scales may also prove useful in reconciling apparent observed conflicts in thinking style. Some theories assume the two thinking styles work in a mutually exclusive manner (Brewer 1988; Fazio 1986). Others assume sequential processing, with the more rapid experiential thinking preceding rational thinking (Fiske and Neuberg 1988; Gilbert 1989; Wegener and Petty 1995). Our approach, following Epstein (1991) and other modern dual process theories, assumes the two operate both simultaneously and sequentially. While our experimental tasks indicated largely *oppositional* effects of the two styles, it is likely that other tasks might demonstrate *synergistic* effects, with both experiential and rational TSTS correlating positively with task performance (in this case, the “dual thinking styles” strategy we observed in some of our experiments would be optimal). For example, Donovan and Epstein (1997) demonstrated that priming intuitive knowledge can facilitate intellectual performance, and Norris and Epstein (2003a) demonstrated numerous situations in which both thinking styles predict in the same direction.

Our findings are also relevant for everyday activities consumers engage in. The thinking style differences we observed on laboratory performance tasks suggest we can and should expect to find differences in rational compared to experiential task-specific

thinking for work vs. play (Babin, Darden and Griffin 1994; Hammond, McWilliam and Diaz 1998; Wolfinger and Gilly 2001), directed vs. nondirected search (Bloch Sherrell and Ridgway 1986; Bloch, Ridgway and Sherrell 1989), choice among specific alternatives vs. navigational choice (Hoffman and Novak 1996; Deci and Ryan 1985), and planned purchases vs. impulse buys (Rook 1987).

Recently, cognitive neuropsychologists have utilized brain imaging tools such as fMRI to support the presence in the brain of dual thinking styles (Goel 2003; Goel and Dolan 2003) and biochemical theories of emotion speculate that “gut reactions,” for example, may literally reside in one’s stomach (Pert 1997). Our empirical results demonstrating the importance of task-specific thinking style over and above dispositional thinking style for task performance may provide further impetus to scientists seeking neurological and chemical pathways that correspond to human cognition and task performance.

"Thinking Inside the Box: Why Consumers Enjoy Constrained Creative Experiences"

Darren W. Dahl and C. Page Moreau

Since paint-by-number kits surged in popularity in the 1950's, consumers have sought out products designed to assist them in being creative. "Self-expression for the time deprived" has created demand for products offered by firms ranging from specialty crafts (e.g., Martha Stewart) to home improvement (e.g., Lowe's). Among the many products offering constrained creative experiences are kits (e.g., model trains, needlepoint), how-to guides (e.g., cook books, home repair, landscaping), and inspirational sources (e.g., home improvement programs). We consider these products as offering "constrained" creative opportunities because the products themselves explicitly constrain elements of the process (via a set of

instructions) and/or the outcome (via a visual representation of the end product). The recent sales growth in these categories suggests that consumers value these constraints, and a central objective of this research is to understand why.

More specifically, the goals of this research are first, to understand consumers' motivations for engaging in creative tasks and second, to examine how constraints influence the quality of those experiences. A qualitative study is initially used to address these goals. Two experiments then build on the qualitative results, offering the first experimental evidence documenting the conditions under which consumers enjoy creative activities. The experiments also measure and test specific mediators to explain why consumers enjoy such tasks.

In the qualitative study, twelve respondents from eight different hobby areas (woodworking, scrap-booking, sewing, cooking, model building, card-making, quilting, jewelry-making) discussed their motivations for undertaking their hobbies. They also explained how products in their areas (e.g., kits, books, classes) influenced their experiences. Data analysis from these interviews revealed seven different basic motivations for undertaking the creative tasks, with the needs of competence and autonomy the most frequently discussed. The data also helped to identify the key pros and cons offered by creativity products. Interestingly, most of the products influenced the needs for competence (positively) and autonomy (negatively).

The findings from the qualitative study suggested the relevance for cognitive evaluation theory (CET) for further studies of consumers' creative experiences (Ryan and Deci 2000). The theory focuses specifically on two important determinants of self-motivation, the needs for autonomy and competence. Thus, we derive a series of hypotheses based on the theory to predict how the constraints imposed by creativity products (e.g., step-by-step instructions and target outcomes) will influence consumers' motivations during and enjoyment of creative experiences. In the experimental studies, participants engaged in hands-on creative tasks: cookie-making and decorating.

In the first experimental study, two factors were manipulated between-subjects: (1) instructions (step-by-step provided vs. not provided) and (2) target outcome (picture of the final product provided vs. no picture provided). Participants were 100 undergraduate students who were each shown to their own cookie-making station which contained a set of tools, pre-made dough, pre-made white icing, food coloring, and cookie decorations. At that point, both experimental manipulations occurred and all participants proceeded in making their cookies. After completing the cookie-making process, participants completed a survey instrument that contained the dependent variables of interest: competence, autonomy, and task enjoyment.

The results reveal an interaction between the two constraints (instructions and target outcome) on task enjoyment, such that participants reported the highest levels of task enjoyment when a full set of instructions was provided without a target outcome. To better understand this interaction, we performed mediation tests which revealed that perceived competence fully mediated and perceived autonomy partially mediated the effect. When instructions were provided without a target outcome, perceived competence was at its highest. Perceived autonomy was also high under these conditions, and the relatively high levels of both of these factors resulted in the greatest enjoyment. Those receiving no target outcome and a set of instructions had both the ability to successfully follow task guidance (competence) and the freedom to create an individualized design (autonomy).

The first experimental study assumed no level of prior experience in the study participants, and through randomization, miti-

gated any effects that such differences would have on motivation and enjoyment. However, prior skill levels are likely to have an important influence, not only on one's likelihood of purchasing a creative product, but also on the likelihood of enjoying the experience offered. Thus, the second experimental study examined the influence of skill level and one constraint (target outcome) on motivation and enjoyment. In this second study, all participants were provided with a full set of instructions. Target outcome was manipulated between-subjects, and prior baking skill was measured and subsequently dichotomized to create a high and a low skill group. The task and procedure was largely the same as that described in the first experimental study.

The results from this second study revealed that prior skill level may be a critical segmentation variable for manufacturers of creativity products. Those participants with low skill levels were able to achieve levels of perceived competence and task enjoyment comparable to those experienced by the high skill participants when a target outcome was dictated. Under these conditions, people of all skill levels had similar perceptions of task difficulty. For those with high skill levels, however, perceptions of competence and autonomy declined significantly when a target outcome was specified and consequently, task enjoyment declined as well.

While the study of creativity has received growing attention, Sternberg and Dess (2001) note that "we do not know enough about this important psychological process" (p. 332). Certainly this statement also applies to our understanding of consumers' experiences during and motivations underlying creative tasks. While restricted in its scope, our research is designed to initiate a more thorough examination of consumers' creative experiences.

"The Eye's Mind and the Mind's Eye: Impact of Overt Visual Attention on Creative Thinking"

Baba Shiv and Monica Wadhwa

"Eyes cannot be held responsible when the mind does the seeing"...*Pubilius Syrus*

Scanning our visual environment is an activity, which human beings engage in most of our waking lives. As consumers, we constantly scan our market-environment for information. Furthermore, depending on the size of the visual field, scanning the market environment might involve either a broad or a narrow scope of overt attention. For instance, one could shop for a particular wine (say, Merlot) from an online wine market with all the wines cluttered in a narrow visual area, thereby requiring a narrow scope of overt attention. Or, one could shop for the same wine from an online market with all the wines widespread in a broad visual area, which would require a broad scope of overt-attention. Take another example, that of watching a movie on a weekend. One could watch a movie on a 17-inch TV screen, which would require focusing on a narrow visual area, or one could watch it on a 50-inch TV screen, which would entail focusing on a broad visual area. A question that arises is, would scanning a broad visual field versus a narrow visual field to search for a wine, or watching a movie on a 50-inch rather than on a 17-inch screen make one more creative in a subsequent task of coming up with creative gift ideas for a friend? We posed this

question in a short survey to twenty consumers. All the survey respondents replied to this question in the negative, suggesting that based on common intuition, scanning the environment in one task should not impact creativity on a subsequent unrelated task.

Contrary to the common intuition, however, we argue that the way we scan our consumer environment can impact our creativity on a subsequent unrelated task. Specifically, we propose that a broad scope of overt attention can broaden the scope of covert attention, which, in turn can bolster creativity on a subsequent task. Our predictions are consistent with literature on visual perception, which suggests that the mechanisms underlying perceptual and conceptual attention are high correlated (Grosbras and Paus 2002; Kosslyn 1980). Furthermore, research on creativity suggests that a broad versus a narrow scope of internal attention is likely to bolster creativity (Mednick 1962). Thus, drawing upon the two streams of research, creativity and visual perception, we hypothesize that a broad overt attention associated with scanning a broad visual field is likely to enhance the covert breadth of attention, which can be beneficially applied to a subsequent consumer creativity task.

The results from our three studies support our predictions. In study-1, we utilized a movie-consumption (movie clips from the movie *Top-Gun*) task. Specifically, we manipulated the overt scope of attention by manipulating the size of the screen on which participants watched the movie. In the broad overt-attention, respondents watched the movie on a 50-inch screen, while in the narrow overt-attention respondents watched the movie on a 17-inch screen. Consistent with our predictions, respondents in the broad overt-attention condition generated more creative ideas than those in the narrow overt-attention condition. More interestingly, those in the broad overt-attention condition drew gift ideas from a significantly broader range of product categories than those in narrow overt-attention.

We replicated our results of study-1 in study-2 using a different consumption scenario. In study-2, respondents engaged in an online wine search task, and thereafter participated in the creative gift ideas task. Respondents were asked to search for Merlot wine from an online wine-market containing ten different wines. We manipulated overt attention by manipulating the size of the wine market. In the broad overt-attention condition, the wines were scattered across the screen covering the entire 15-inch display, while in the narrow overt-attention condition, all the wines appeared in the center of the screen in a small circle. Thereafter, as in study-1, all respondents participated in the creative gift-idea task. As in study-1, those in the broad overt-attention condition generated more creative ideas and drew ideas from a significantly broader range of product categories than those in narrow overt-attention condition. These results suggest that overt-attention impacts covert-attention, thereby impacting creativity on a subsequent task.

Our exposition thus far suggests that the breadth of covert attention with its concomitant effects on creativity is influenced by the overt attention associated with the size of the external visual field. Specifically, we suggest that the broad scope of overt attention bolsters the breadth of covert attention, which can be beneficially applied to a subsequent consumer creativity task. If our exposition is valid, then narrowing covert attention by asking respondents to restrict eye-movement and focus on one object in the scene versus focusing on the entire scene during the external attention task should attenuate the visual field effects on creativity in the broad-overt attention condition. This logic formed the basis to provide stronger evidence for our conceptualization in experiment 3. In experiment-3, respondents engaged in a car race task. Respondents were shown cartoon-car race clips on either an 8-inch or a 30-inch screen. Half of the respondents were made to restrict eye-movement by asking them to focus on a specific car in the

center of the screen, while others were asked to pay attention to all the cars on the screen. Consistent with our predictions, we show that in the broad-overt attention condition, the effects of scope of overt-attention on subsequent creativity task were attenuated when respondents were asked to restrict eye-movement. However, restricting eye movement did not impact performance on the subsequent creativity task in the narrow overt-attention condition.

Our results from the three studies suggest that a broad overt attention associated with scanning a broad visual field as opposed to narrow overt attention associated with scanning a narrow visual field enhances the scope of covert attention, which can be beneficially applied to a subsequent consumer creativity task. Our results have important implications for marketers' merchandising strategies. In these studies, we manipulated broad versus narrow visual attention using three different strategies—a movie consumption task, an online wine market task and a car-race task. However, broad versus narrow visual attention can be activated using various in-store strategies such as store placement. Moreover, a lot of time retailers end up with an overstock of goods that they put on sale. It is likely that just manipulating the size of display could help consumers think of more creative uses for such items and therefore buy more of the assorted on-sale items.

The Process by Which Brand Committed Consumers Evaluate Competitive Brands: The Case for Similarity and Dissimilarity Testing

Sekar Raju, University at Buffalo, USA
H. Rao Unnava, Ohio State University, USA

EXTENDED ABSTRACT

Most research on brand commitment has focused on how people defend their attitudes when faced with information that *undermines* their attitudinal position. However, the effects of attitudinal commitment may not be limited to mounting defenses only when an individual's attitude is challenged. As Chaiken, Liberman and Eagly (1989) observe, individuals not only resist information that is counter to their preferred positions, but may also actively undermine information that "supports non-preferred positions." The process by which committed consumers evaluate competitive brands even when those brands do not attack one's preferred brand is studied in this research. Specifically, the cognitive processes that are involved in generating the bias is examined.

When asked to make a judgment about an object, it is not made in isolation, but is made with reference to some other object or a standard. We first argue that high commitment consumers will choose the brand that they are committed to as the comparison standard while low commitment consumers are more likely to select an exemplar, or a prototype as the standard (See Raghunathan and Irwin 2001).

Next, since low commitment consumers are not 'attached' to any one brand they are likely to be more 'inclusive' in their focus while high commitment consumers are 'exclusive' in their intent since their focus is on preserving the existing brand attachment and have a reason to limit their consideration set. This inclusive versus exclusive focus of low versus high commitment consumers should translate to how they evaluate an advertised brand. Low commitment consumers, because of their interest in including other brands, will tend to look at the *similarities* between the advertised brand and their current set of preferred brands. On the other hand, high commitment consumers, because of their interest in excluding other brands, will focus on the *differences* between the advertised brand and their preferred brand. These differences in the type of processing that an advertised brand is subjected to will translate into differences in attitudes toward the brand for high versus low commitment consumers. The focus on similarities will make low commitment consumers assimilate the advertised brand toward their preferred brand (assuming the advertisement message is strong and persuasive). The focus on differences will make the high commitment consumers contrast the advertised brand away from their preferred brand (e.g., Mussweiler 2003). Three studies are reported that examine these predictions.

In the first study, the objective was to show that consumers who are more versus less committed to a brand will rate a new competitive brand differently due to differences in the level of similarity or dissimilarity they focus on. As expected, when provided an advertisement for a new brand, high commitment participants seemed to generate more dissimilar thoughts while low commitment consumers seemed to generate more similarity thoughts.

In the second study, a more specific test for similarity/dissimilarity testing was adopted. It was argued that if both high and low commitment consumers are instructed to focus on the similarities between their preferred brand and the advertised brand, the effect of the instructions on low commitment consumers should be marginal because they already focus on the similarities, but the

effect of the instructions on high commitment consumers should be greater because it changes the nature of their processing and makes them focus more on the similarities between the two brands. The focus on similarities should lead the high commitment consumers to report greater similarity between the advertised and their preferred brand than they would do in the absence of such instructions. Thus, compared to a control condition, high commitment consumers who are instructed to focus on the similarities between an advertised brand and their preferred brand would report greater similarity between the two brands and more positive attitudes toward the advertised brand, whereas there would be minimal effect of such instructions on low commitment consumers. The results of this study confirmed these expectations.

Finally, the third study was conducted to test the proposition that high commitment individuals invoke their preferred brand as the standard while low commitment individuals invoke either an exemplar or prototype as the standard for comparison. Using a priming manipulation and argumentation similar to that we employed in study 2 we find that high commitment individuals have a more positive evaluation of the advertised brand when asked to focus on the differences between an advertised brand and a less preferred brand (rather than their most preferred, and therefore committed brand) However, since low commitment individuals are more inclusive and use an exemplar or prototype brand for comparison purposes, having them focus on the differences between a less preferred brand and the advertised brand had a less effect on their brand evaluations.

These set of studies suggest that committed consumers are more likely to invoke their preferred brand and focus on how the advertised brand is different from it. This process, we find, results in committed individuals contrasting the advertised brand away from their preferred brand, and thus lower their evaluations. On the other hand, we find that less committed individuals' focus is on the similarities between the advertised brand and the brand they invoke. Due to the focus on similarities, less committed individuals are more likely to assimilate the advertised brand towards the brand that comes to their mind, and thus generate more positive evaluations.

While Ahluwalia (2000) found that high commitment consumers employ various biased processing mechanisms to counter information that attacks their attitudes, it appears that the biased processing mechanisms that are employed by high commitment consumers are different when faced with information about competitive brands. When faced with an advertisement for a competitive brand, high commitment consumers instinctively appear to adopt a 'rejection' mode of processing where they are seeking out ways to undermine the brand. This is accomplished primarily by contrasting the advertised brand away from one's preferred brand by focusing on how the new brand is different from their preferred brand.

Agent Gender and Sex-Typed Social Influenceability in Online Communication

Eun-Ju Lee, Chung-Ang University, Korea

Past research in gender and social influence has repeatedly found that men are generally more influential than women in most persuasion settings (Carli 2001). Men have power and status based on expertise and authority; the typical role of men is to lead, direct, and accomplish goals through job-related competence; thus, men are "agentic." Since persuasion is about changing attitudes and dominating over other's issue positions, persuasive attempts could basically be considered a masculine, rather than a feminine, task. Thus, it is not surprising that men exert more social influence when it comes to hard-core persuasion than women do. However, women might achieve social influence differently. The traditional social role of women is that of care-taker. Women are expected to be domestic, communal, and submissive. Having relatively lower social status and less power than men do, women are expected to be nice and benevolent, not necessarily display power, assertiveness, and dominance. Having genuine interest in others well being, benevolent and feminine individuals are trusted by others and their recommendations can be accepted equally well.

To date, gender research has found ample evidence that gender-stereotypical sex roles are prevalent in interpersonal relationships. In this study, I revisit gender influenceability in the e-commerce context where consumers interact with a computer agent while shopping. The context of human-computer interaction (HCI) provides a unique environment where social characteristics, such as personality, of a computer agent can be created or even manipulated (Moon and Nass 1996). For example, a computer agent can be given an artificial gender identity that emulates that of a human being. How would people treat a computer agent when the agent assumes a human-like gender identity?

In this study, a computer agent simulation is conducted where a computer agent with a contrived male or a female gender identity (the first experimental factor) interacts with consumers who are in the market for digital cameras. The "gendered" agent provides product information and shows four cameras with detailed attribute descriptions. During the consumer shopping process, the gendered agent uses two different levels of sales aggressiveness (the second experimental factor). I argue that an agent's counter product recommendation for a more expensive item could be interpreted as a display of confidence, aggressiveness and even self-interest, all of which are strong male stereotypes (Bem 1974). Based on sex-role stereotypes, a male agent's use of aggressive sales tactic may be viewed as more acceptable than a female agent's use of the same sales tactic. An overtly dominating and aggressive sales tactic used by a female agent may likely face consumer distrust because such behavior violates the traditional female sex-role.

The social influenceability of a computer agent in online communication is enhanced through consumers' perceptions of the agent's competence and benevolence. The more competent and the more benevolent the agent is perceived to be, the more likely consumers are to have intentions to trust the agent. Thus, I associate the influenceability of a (male or female) computer agent with subjects' trust in the agent. Next, I discuss the multi-dimensionality of consumer trust by examining cognitive, affective, and intentional aspects.

CONCEPTUAL BACKGROUND

In this paper, I examine agent influenceability in terms of consumer trust. The basic premise of this paper is that a communicator can achieve higher social influence when one is trusted than

not. Therefore, earning consumer trust means acquiring social influence. The importance of trust in interpersonal relationships as well as online-based relationships cannot be overstated in marketing. Golembiewski and McConkie (1975) note that "perhaps there is no single variable which so thoroughly influences interpersonal and group behaviour as does trust...". Trust is the fundamental driver of interpersonal relationships and social order (and disorder) and has been studied extensively. Trust facilitates one's decision-making when finding relationship and/or business partners. In the sales literature, the dependability of a retail salesperson is among the buyer's most critical concerns. Furthermore, trustworthiness is found to be of the greatest importance among the many characteristics of a salesperson (e.g., friendly relationship, personable style, patient buying assistance, and quick service) for the buyer to determine future business with the salesperson (Hawes, Rao, and Baker 1993).

Consumer trust is multidimensional-having cognitive, affective, and intentional aspects (Lee 2002). Cognitive trust is based on an agent's competence. Lewis and Weigert (1985) views trust as predictions and expectations that an agent will perform a job competently. The definition of trust by Rempel, Holmes, and Zanna (1985) suggests that trust is merely the degree of confidence one thinks about a relationship. Another definition by Zaltman and Moorman (1988) suggests that trust represents the extent to which the parties can predict one another's performance; having faith that the other party will perform in a responsive manner with expertise and knowledge.

Trust also has an affective component. Luhmann (1979) suggests that true trust begins where (cognitive) knowledge ends. Benevolence refers to genuine interests in the other party's welfare (Rempel, Holmes, and Zanna 1985), and a "genuine responsiveness" to the needs of the other party (Friedland 1990). In close interpersonal relationships, trust is often conceptualized in terms of attributions concerning the partner's benevolence (Deutsch 1962; Giffin 1967; Pearce 1974). Benevolent partners have genuine, friendly interests in the other party's welfare (Rempel and Holmes 1986), aside from their egocentric motives (Mayer, David, and Schoorman 1995). Thus, perceiving a partner's benevolence includes feeling close to and cared by a partner who is on the trustor's side, because the partner cares about the trustor's best interest, not his or her self-interest.

Finally, trust is intention. Giffin (1967) cites risk as an essential element of trust. When one trusts another, something is risked by the trustor. Zaltman and Moorman's (1988) definition of trust adds the "intentional" dimension to the meaning of "trusting." Often trust represents the trustor's willingness to depend on the trustee in a complex, uncertain, and risky situation. According to Rousseau et al. (1998), trust is better understood as the intention to rely on a partner—a psychological state to accept vulnerability based on positive feelings (affective basis) and expectations (cognitive basis) (Rousseau et al. 1998, p. 395). If one truly trusts an agent, one must be willing to rely on the agent in the decision-making process (Moorman, Zaltman, and Deshpande 1992), and willingly be ready to place one's resources at the disposal of the agent (Coleman 1990; Rempel, Holmes, and Zanna 1985; Zand 1972). Accordingly, trusting intentions can be defined as the willingness to delegate decision power to the party to be trusted.

Given that consumer trust can have three aspects (competence, benevolence, and trusting intention), if a "gendered" agent demon-

strates a recognizable aggressiveness in his/her sales tactic, what role does the agent's sex play in subjects' evaluation of the competence and benevolence of the agent, and the intention to trust the agent?

HYPOTHESIS

Past research in gender influence has found that in general men are perceived to be more influential than women. Gender stereotyping includes greater scrutiny of women's assertive leadership behaviors and greater acceptance of men's display of competence and knowledge. Carli (2001) notes that "men have more right to act as authorities than women do, and that women must communicate communal motivation more than men. As a result, not only would people generally be more open to the influence of men than that of women, but women's influence would be more conditional than men's, dependent on the use of an influence style that corresponds prescriptively to the stereotypical female role" (p.726).

As noted earlier, empirical evidence shows that women are in general less influential than men are in persuasive communication setting. Such influenceability differential by agent gender depends on the context of interaction with various moderating influences in operation. People are more open to the influence of men than that of women, and more importantly, whatever influence women can achieve may be more conditional than men's. Gender-typing of the task is one example; women's influence is found only in feminine and domestic tasks (Carli 2001). The importance of masculine competence might become more pronounced in masculine areas such as technology and management than in feminine areas (Carli 2001). The Persuasion Knowledge Model (Friestad and Wright 1994) also suggests that consumers expect the content and type of message (e.g., information on masculine products) to be consistent with the characteristics of a communicator (e.g., male gender identity).

Since competence and power are masculine traits, unless women temper their expertise or agency with displays of communality, warmth, and niceness, prescriptive sex stereotypes can reduce competent women's likeability and influenceability (Rudman and Glick 2001). Such prescriptive sex stereotype can penalize women whose communication style appears to be too agentic and masculine (Rudman and Glick 2001). A male communicators' display self-confidence can be taken as competence; while similar presentation of masculine assertiveness by a female communicator can create a backlash effect in the form of losing audience trust (Rudman and Glick 2001).

Agent's sex and sales aggressiveness are the two focal manipulation factors in this experimental study. The experimental procedure and simulation protocols are as follows. Agent's sex was manipulated using gender-typical names (John or Jane) and faces (a male or a female cartoon face with the warm script). In order to vary the levels of aggressiveness in sales tactic, recommendation price and a display of agent's self-confidence were used. Under a more aggressive condition, the agent would counter the consumer's original choice of camera with another camera that was 10% more expensive and said "I am sure that this is a superior choice than your earlier choice of camera." In a less aggressive condition, the agent quoted a price that was 10% less expensive for the same camera and said "I think you *might* like this camera better than your earlier choice of camera." In both conditions, the cameras recommended by the agent were identical except for the price.

Making a recommendation that can invalidate a subject's own choice is a dominating behavior in itself and can trigger reactance to the invasive recommendation (Fitzsimmons and Lehmann 2004). When the sales recommendation involves a price upgrade, it can be

considered a display of confidence, independence, dominance, and even self-interest, all of which are strong male stereotypes (Bem 1974). Therefore, I hypothesize that when a female agent make a price upgrade recommendation, she will suffer from significant loss of consumer trust in terms of deterioration of perceived competence, benevolence, and trusting intention—due to the mismatch of her dominating/aggressive behavior with the submissive and compliant female stereotype. However, a male agent's identical behavior will less likely result in the loss of his trustworthiness as a result of the male stereotypes of self-assurance and dominance. Accordingly, my research hypothesis addresses these sensitivity differentials based on agent gender on all three dimensions of consumer trust, when the agent makes an aggressive price upgrade recommendation.

H1: As the agent adopts a higher, as opposed to a lower, level of aggressiveness in sales tactic:

- (a) the perceived competence of a female agent will diminish to a greater extent than the perceived competence of a male agent will;
- (b) the perceived benevolence of a female agent will diminish to a greater extent than the perceived benevolence of a male agent will; and
- (c) subjects' intention to trust a female agent will diminish to a greater extent than their intention to trust a male agent will.

In the next section, I explain the experimental procedure that tests the aforementioned research hypotheses using a computer agent simulation.

METHODOLOGY

This study employed a 2 (agent gender: male and female) X 2 (aggressive price recommendation: 10% less expensive and 10% more expensive) between-subject design. Subjects were recruited from a population of young adults (undergraduate college students) in a large land-grant US University. Undergraduate students were deemed appropriate for this online consumer behavior experiment, because they generally spend considerable time on the Internet. A total of 95 students participated in the experiment. Students were randomly assigned to one of the four conditions.

Interface Protocol. The experiment required some computer-programming resources in order to enable different social characteristics of the computer agent, e.g., agent gender. Macromedia's Authorware 5.2 was utilized to create the prototype of the agent program. The base protocol of the shopping simulation included several sections including (1) a brief introduction of the agent (in the male agent condition, a male face with the name of John was projected on screen; in the female agent condition, a female face introduced her as Jane); (2) provision of information about important features of digital cameras (e.g., resolution, screen size, and zoom size) (3) Agent's request for subject input regarding the importance of each feature when purchasing a digital camera; (4) Agent's presentation of four cameras that could match the respondent's preferences revealed from the preference inquiry in section #3; (5) subject choice of one camera among the four cameras shown in section #4; and (6) Agent's recommendation of a different camera that had two levels of upgraded features and was 10% more (or less) expensive than the subject's earlier choice of camera in section #5.

Measures. Competence is the confidence in the agent's capability with respect to the role performance. The following measurement items were adopted and modified from what had been origi-

TABLE 1
Experiment Results by Condition

<i>Agent Gender</i>	<i>Sales Tactic</i>	<i>Competence</i>	<i>Benevolence</i>	<i>Trusting Intention</i>
Male	Non-Aggressive	14.29	15.03	9.18
Male	Aggressive	15.20	14.25	8.50
Female	Non-Aggressive	14.70	16.59	9.00
Female	Aggressive	13.47	14.28	7.61

nally proposed by Smith and Barclay (1997), Geller (1999), and Moorman, Zaltman, and Deshpande (1992): (1) When it came to camera, [Agent name] knew enough to give me a good advice; (2) I trust [Agent name]'s expertise in cameras; (3) I had confidence in [Agent name]'s expertise in cameras; and (4) I was confident in [Agent name]'s knowledge about cameras.

The following measure for benevolence were modified from the previously published scales by Ganesan (1994), Hawes, Rao, and Baker (1993), and Price and Arnould (1999): (1) [Agent name] seemed to care about me; (2) [Agent name] made me feel good; (3) [Agent name] was like a friend during the shopping experience; I felt close to [Agent name] during the shopping; and (5) [Agent name] responded to my needs in a caring way (a new item created for this study).

Trusting intentions were measured using the following items modified from by Moorman, Zaltman, and Deshpande's measures (1992): (1) I was willing to let [Agent name] make important choice decisions for me; (2) I was willing to trust [Agent name] to make camera purchases even when I was unable to monitor his/her activities; and (3) I would be comfortable giving [Agent name] responsibility to make camera purchase decisions for me. At the end of experiment, respondents were debriefed and thanked for their participation. Reliability for the three trust scales was acceptable (Competence Chronbach's $\alpha=0.77$; Benevolence Chronbach's $\alpha=0.90$; Trusting Intention= 0.74) and thus a summed score of each trust construct was used for subsequent statistical analyses.

Manipulation Check. All subjects answered correctly when asked about the gender of the agent they interacted with while shopping for cameras. Subjects were also asked to choose from the following whether the camera recommended by [Agent name: John or Jane] was (1) more expensive; (2) the same price; or (3) less expensive than their own choice. All subjects answered correctly. Respondents then evaluated the level of aggressiveness of agent's sales tactic using a 5-point scale ranging from "not at all aggressive" (=1) to "extremely aggressive" (=5). Respondents evaluated the agent recommending a 10% price upgrade with strong self-confidence to be more aggressive ($M=2.98$) than the agent recommending a 10% price discount ($M=2.58$, $t=2.06$, $p=0.04$). In order to check for potential confounding, the agent's attractiveness and likeability were measured using a seven-point semantic differential scale. The results of t-tests demonstrated that the male and female agents did not differ significantly in terms of attractiveness ($t=0.29$, $p=0.76$), likeability ($t=0.08$, $p=0.93$), attitude toward agent ($t=0.51$, $p=0.60$), perceived agent warmth ($t=-0.77$, $p=0.44$), or perceived agent coldness ($t=-0.32$, $p=0.74$). In addition, for the item of "I was confident about the agent's expertise," the male and female agents did not differ significantly ($t=1.41$, $p=0.16$), although the male agent received a slightly higher mark ($M_{\text{male}}=3.66$, $M_{\text{female}}=3.44$).

RESULTS

A multivariate analysis of variance (MANOVA) was conducted using the three summed scores of agent competence, agent benevolence, and trusting intention as dependent variables and two manipulation factors (agent gender and aggressive price recommendation). The mean figures are shown in Table 1. The multivariate test showed that the MANOVA model was overall significant (Wilks' Lambda= 0.02 , $p=0.00$; Hotelling's $T=36.81$, $p=0.00$). The multivariate main effect of agent gender on the three trust scales was only marginally significant (Wilks' Lambda= 0.92 , $p=0.000$; Hotelling's $T=0.08$, $p=0.06$), and the multivariate main effect of aggressive price recommendation was insignificant (Wilks' Lambda= 0.93 , $p=0.121$; Hotelling's $T=0.06$, $p=0.12$).

In order to test the research hypothesis, I examined the interaction effect between agent gender and aggressive price recommendation on each trust construct. Given the sex role stereotype, female agent's aggressive product recommendation (i.e., recommending a product that is more expensive than the anchor price) is incongruous with the typical female sex role, it was earlier hypothesized that subjects' trust perceptions about the female agent's competence, benevolence and trusting intention would erode to a greater extent than their perceptions about the male agent would.

The results of planned contrast tests showed that H1 was overall supported. For the female agent, the perceived competence diminished significantly ($F_{1, 46}=4.03$, $p=0.05$) when the agent adopted a more aggressive sales tactic ($M=13.47$) than when the agent adopted a less aggressive sales tactic ($M=14.70$). However, for the male agent, the difference in perception of the agent's competence by the higher recommendation price ($M=15.20$) compared to the lower recommendation price ($M=14.29$) was not significant ($F_{1, 45}=1.29$, $p=0.26$). Thus, H1a was supported. Interestingly, there was directional evidence, while insignificant, that the male agent could be perceived to be more competent when he recommended a higher-priced camera compared to when he recommended a lower-priced camera, which was opposite to what was observed with the female agent, because her attempt at up-selling did weaken subjects' perception about the female agent's competence. For the male agent, the perceived benevolence did not diminish significantly ($F_{1, 45}=0.30$, $p=0.58$) as a result of increasing sales aggressiveness ($M_{\text{high price}}=14.25$ vs. $M_{\text{low price}}=15.03$). However, the same attempt to switch subjects to a higher-priced item resulted in a significant weakening of the perceived benevolence of the female agent ($F_{1, 46}=5.28$, $p=0.02$, $M_{\text{low price}}=16.59$ vs. $M_{\text{high price}}=14.28$), thereby supporting H1b. The contrast test between the male and female agents again demonstrated female vulnerability in terms of trusting intention. A more aggressive sales tactic did not affect subjects' intention to trust the male agent ($F_{1, 45}=0.79$, $p=0.37$; $M_{\text{high price}}=8.50$ vs. $M_{\text{low price}}=9.18$), but it negatively affected subjects' intention to trust the female agent ($F_{1,$

$t_6=4.37, p=0.04; M_{\text{high price}}=7.61$ vs. $M_{\text{low price}}=9.00$). Thus, $H1c$ was also supported.

I also checked for potential influences of subject sex on three trust constructs and found no significant main effect of subject sex, nor was the interaction effect between subject sex and agent gender on competence, benevolence, and trusting intention found to be significant.

DISCUSSION

Among various communicator attributes that enhance influenceability, competence and benevolence are essential factors people use to assess the validity of information provided by the communicator. A competent agent can provide valid information because s/he knows what is right and wrong based on expertise and knowledge. A benevolent agent will provide the best information within his/her knowledge based on genuine willingness to help and serve customers. Biernat and Fuegen (2001) note that "the very essence of gender stereotype defines men to be instrumentally competent and agentic compared to women" (p.707).

The gender stereotypes also prescribe women to be less task-competent and more submissive than men because women are traditionally associated with the homemaker role (Fuegen et al. 2004). Leadership traits are also gendered (Kawakami, White, and Langer 2000). Since leaders are expected to be competent, task-oriented, masculine, and even "charismatic," a successful leadership role may conflict with the traditional female gender stereotype. Carli (2001) notes that since people are more open to the influence of men than that of women, whatever influence women can achieve is more volatile than men's. Kawakami, White and Langer (2000) describe a women's paradox. If women adopt a masculine leadership style, they will be disliked and if they adopt a nurturing female leadership style, they will be liked, but deemed incompetent. Thus, when women hold leadership positions, they are vulnerable to "prejudiced evaluations and lowered effectiveness" (Eagly et al 1995, p.126).

While the gender of a communicator could be a peripheral cue (background variable) rather than central (issue-relevant) information in the context of the Elaboration Likelihood Model (ELM, Petty, Cacioppo, and Schumann 1983), subjects often associate communicator gender with content expertise, such as men have more expertise than women, for example in technology arena. The Persuasion Knowledge Model (Friestad and Wright 1994) proposes that experts deliver strong messages and non-experts deliver weak messages. Thus, male salesmen are expected to make strong recommendations based on competence and confidence, whereas female sales associates are expected to deliver weaker (and benevolent) product recommendations. When these expectations are violated, consumers might engage in deep cognition to look for an answer. If the source (a female agent) has an apparent self-interest (e.g., seeking more profits) in her advocacy for higher priced products, "the inconsistency between message and source is interpreted as a manipulative mal-intent and evokes a negative response" (Artz and Tybout 1999, p.52). My experiment results suggest that male communicators' display self-confidence in technology can be taken as competence; a display of masculine assertiveness by female communicators can engender a backlash effect in the form of her losing consumer trust.

IMPLICATIONS

The results of this study shed light on salesmanship and leadership for both genders. For male salesperson, competence is the major influence factor and a male agent who is perceived to

possess sufficient expertise and competence can make a strong sales recommendation to upgrade consumers' product choice without losing his credibility. Introduction of higher-priced items by a male agent can be even viewed as a display of expertise and self-confidence in content knowledge especially in the sales of male-oriented products. On the other hand, women stereotypically are not expected to have much expertise in technology. Therefore, a female (and supposedly non-expert) agent's recommendation of higher-priced cameras could have triggered consumer doubt of her hidden motives, and as a result, consumers might have readjusted their evaluation of her based on this evidence of dishonesty and self-interest. A better sales technique for a female agent that could have been a recommendation of an alternative which provides a better value to a customer. A subtle delivery of non-aggressive product recommendations by a female agent could have been taken as a sign that she is honest and cares about the customer, thereby possibly enhancing her influenceability *via* a display of feminine benevolence.

Given the fact that during the past decade, the number of women occupying and seeking managerial and leadership positions have grown exponentially, my results have important implications for women in leadership positions. Women in leadership positions in male-dominated areas should not lose benevolence and genuineness while they seek higher social influenceability through masculine charisma. A woman leader in a managerial position who appears to be competent *and* benevolent at the same time, demonstrating an androgynous leadership style may likely achieve higher social influence than a female leader who is simply masculine and dominating (Bem 1974).

CONCLUSION

The purpose of this experiment was to examine the sex-typed influenceability of male and female agents when a computer agent utilizes two different product recommendation styles. In one condition the agent attempted to switch consumers to a more expensive alternative, and in the other condition, to a less expensive product. If the agent were an effective persuader, subjects would likely trust the agent even after the price upgrade attempts. On the other hand, if the agent were not an effective persuader, such attempt would be detrimental to the agent's credibility. How would the agent's gender interact with individuals' evaluation of the agent competence, agent benevolence, and their intentions to trust the agent?

This study revisited the issue of gender and social influence in the e-commerce context where consumers interacted with a computer agent program that had a contrived gender identity. The results of my study confirmed female vulnerability when she assumed an assertive salesman style that is inconsistent with typical female stereotype. It was found that the female agent suffered from a significant loss of influenceability when she adopted an aggressive recommendation style. Subjects thought that the more aggressive female agent was less competent, less benevolent, and thus they were less likely to trust her.

Based on the experimental findings that subjects' judgment of agent's trustworthiness was affected solely by the contrived gender identity, not by what the agent did or said, I argue that male and female agents could achieve social influence differently because an individual's initial assessment of the agent's trustworthiness is socially constructed, being affected by prevailing sex role stereotypes. Male salespersons could enhance their competence and product expertise to increase their influenceability. Female salespeople should communicate their genuine interest in the customer's welfare and their willingness to serve the customer. In male-

dominated product areas, a female agent might not want to make aggressive product recommendations hastily, because the gender stereotype could cause a backlash and harm her credibility.

The limitation of this experiment is that I used only one consumer electronics product that could be rather male-oriented. Eagly, Karau, Makhijani (1995) found, in their meta-analysis, that leadership effectiveness depended on the gender-typing of a task, i.e., men are more competent than women in male-oriented domains, and women are more effective than men in female-oriented arenas. Future research should examine how product gender-typing can interact with communicator gender identity in achieving high social influence. For example, if a female product (e.g., lipstick) is used, a female, as opposed to a male, agent has higher content expertise. In such a case, will a female agent still be penalized for an aggressive upgrade recommendation? How will a male agent be viewed if he makes aggressive recommendations for the products he does not have much expertise? Since the current experiment provides evidentiary data of online viewers' discriminatory practice toward female-gendered computer agents who behaved in a masculine style, future research needs to investigate whether online viewers would seek the same level of gender-norm compliance from male-gendered agents in online sales encounter.

In conclusion, by adopting a unique research context in which a computer agent interacts with human consumers, I found that computer agents in human-computer interaction (HCI) are not free from sex-role stereotypes, even if the gender identity of the computer agent is contrived. Female identity becomes a disadvantage when the job description requires an assertive salesman style that is inconsistent with typical female stereotype. Therefore, marketers are advised to select different sales technique if their online agents are "gendered."

Let Your Workspace Speak for Itself: The Impact of Material Objects on Impression Formation and Service Quality Perception

Joost W.M. Verhoeven, University of Twente, The Netherlands
Thomas J.L. Van Rompay, University of Twente, The Netherlands
Ad Th.H. Pruyn, University of Twente, The Netherlands¹

ABSTRACT

Inspired by studies exploring the role of material objects in impression formation, the impact of personal and professional objects on person perception and service quality evaluation were investigated in a healthcare setting. Results showed that material objects affect service quality perceptions through a cognitive route, incorporating office professionalism and perceived competence of the physician, and through an affect-driven route, incorporating attractiveness of the office, agreeableness of the physician and experienced affect. In healthcare services, this affect-driven route seems to be of particular importance.

INTRODUCTION

Among consumer researchers, environmental psychologists, and marketers it is well established that products and material objects present meanings beyond their appearance and function; people surround themselves with possessions that express and reinforce a personal identity (Belk 1988). Schlenker (1985) assumed that by creating and altering their environments, people may try to display a more glorified picture of themselves. Not only do we use objects as a means for self-expression, but other people use such information in everyday settings to form impressions of what occupants of specific environments, e.g., houses or offices, are like (Gosling *et al.* 2002).

In order to explain the mechanisms through which individuals impact their personal environments and the ways in which observers draw inferences about occupants of such environments, Brunswik (1956) proposed his 'lens model'. In his view, physical objects in the personal environment can serve as a lens through which observers perceive underlying constructs such as the occupant's interests, personality or values. A framed picture of a happy family in an office, for instance, can serve as a lens 'through' which an observer perceives the occupant as empathetic or warm. Similarly, an observer may infer from a baseball hat on a cabinet that the occupant is interested in sports. Naturally, observers will try to attend to those cues that are most accurate in conveying the true identity of the target person.

The degree to which people attend to environmental cues is likely to vary with the type of setting. Particularly in novel or ambiguous situations, i.e., situations in which standardized scripts or clear-cut information are lacking, people are likely to form impressions, judgments and perceptions based on objects present in the physical environment (Kay *et al.* 2004). In order to reduce uncertainty, resulting from the absence of clear-cut information, customers are likely to attend to aspects of the tangible environment (Verhoeven, Pieterse, and Pruyn 2006). In services marketing literature, uncertainty is often assumed to vary with information verifiability. In credence services, dominant attributes cannot be verified by the average consumer (even after purchase and consumption), because (s)he lacks the technical expertise or the means to make a reliable assessment, or because claim verification would

take an unrealistically long time (Darby and Karni 1973; Zeithaml 1981). It can be argued, therefore, that the effects of the physical environment on impression formation are more pronounced for services characterized by low information verifiability (i.e., credence services) than they are for services with high information verifiability (i.e., experience services).

Although the significance of environmental cues in commercial (Turley and Milliman 2000) and healthcare settings (Dijkstra, Pieterse, and Pruyn 2006) is well established, less is known about the effects of particular objects and the processes underlying this type of impression formation. Do objects in a doctor's office, for instance, primarily affect us on an affective level or do they first and foremost impact our cognitions? To provide an answer to these questions, we employed an experimental design, using simulations of service environments, to study the effects of two types of objects commonplace in offices: objects relevant to the profession of the occupant and objects expressive of personal tastes and interests. It is our contention that these types of objects are particularly influential with respect to ratings of doctors on perceived competence and perceived friendliness or empathy: attributes referred to as 'hard' and 'soft' respectively (Driver and Johnston 2001). Since these constructs are considered primary determinants of service quality perceptions (Driver and Johnston 2001), we will also assess the relative contributions of these attributes on perceived quality of care. Before elaborating on our design, however, we will discuss studies that have explored the role of specific types of objects in organizational contexts.

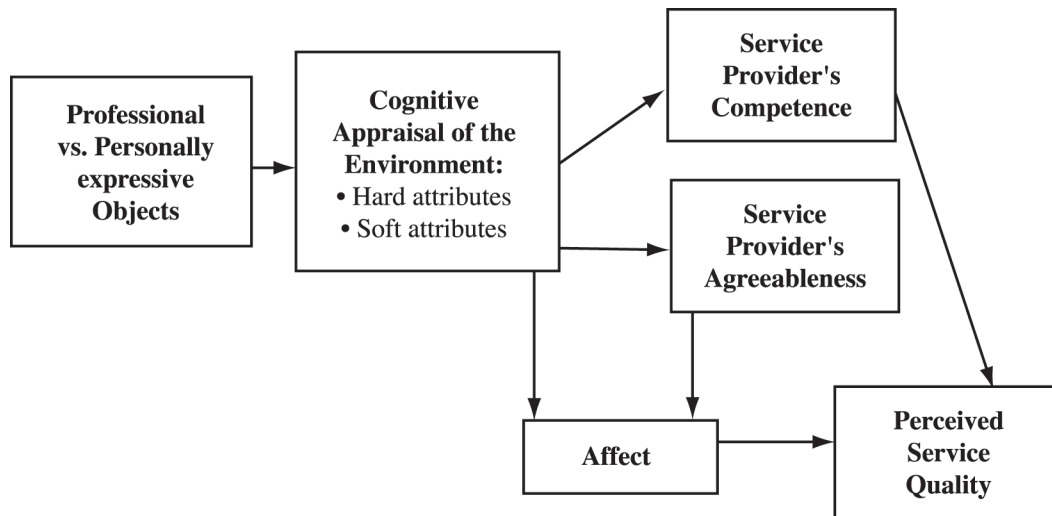

THEORETICAL BACKGROUND

Several studies have assessed the role of overall office design on perceived traits of office occupants (Cherulnik and Sounders 1984; Tedeschi and Melburg 1984). Cherulnik and Sounders (1984), for instance, showed that occupants of high-status offices are judged as more neat, critical, sincere, intelligent, proud, responsible, ambitious and less superstitious, gullible, lazy and noisy than occupants of low-status offices. Of particular interest to our present purpose are studies that have explored the role of particular objects using experimentally manipulated slides of offices (Campbell 1979; McElroy, Morrow and Wall 1983; Morrow and McElroy 1981). Morrow and McElroy (1981), for instance, showed that the presence of status symbols (e.g., diplomas) led to higher ratings on occupants' achievement orientation and rank. They further found that friendliness, extroversion and feelings of welcomeness in office settings in part relate to the arrangement of furniture, mirrored in an 'open' (desk against the wall) or 'closed' (desk between occupant and visitor) setup (Morrow and McElroy 1981).

Although in these studies the effects of specific kinds of objects or set-ups were studied, environmental cues are not perceived in isolation; rather, their combined effects give rise to a holistic image that shapes subsequent consumer experiences, comprising both affective and cognitive components (Bloch 1995). In this process, observers 'transfer' perceived characteristics of the physical environment to the occupant. Clearly, design aspects of offices can, in line with the needs of office occupants, convey different 'messages' (Ornstein 1989). People may in some situa-

¹The authors gratefully thank Johan Jonker, Albert Polman and Dr. Job van der Palen for their assistance in developing the panorama photos.

FIGURE 1
A conceptual model of cognitive and emotional effects of material objects

tions desire to be looked upon as high-status or powerful (hard attributes), but at other times as involved, caring or friendly (soft attributes). Arguably, office professionalism impacts perceptions of physicians in terms of hard attributes whereas office attractiveness shapes perceptions of physicians in terms of soft attributes. With respect to financial services, e.g., a bank, it may be crucial (from a managerial point of view) to foremost foster impressions of competence or professional success, whereas our choice for a general practitioner may sooner be based on perceptions of the personnel's friendliness or involvement.

This process of impression formation has been shown to play a particularly important role in Service Quality appraisal (Grove and Fisk 1989). As services are actions or performances rather than products, in the eyes of customers the employees delivering the service *are* the service (Zeithaml, Bitner, and Gremler 2006). As a result, the evaluation of the service hinges on the consumer's impression of the service provider. A similar line of reasoning holds that services are hard to evaluate due to the specific characteristics (i.e., intangibility, heterogeneity, simultaneous production and consumption and perishability), and that therefore customers form expectations about the quality of service based on their impressions of the organization and the employees (Parasuraman, Zeithaml and Berry 1985). Several studies indicate that emotions arising from interactions with personnel and the environment (Mehrabian and Russell 1974) shape such expectations and are thus critical factors in the appraisal of service quality (Chebat, Davidow, and Codjovi 2005; Laroche *et al.* 2005). In line with these studies, we propose that affect positively influences perceived service quality. The foregoing discussion leads us to propose the conceptual model depicted in Figure 1.

METHOD

Pretest

To make an informed decision regarding the selection of stimulus materials for our study, a pretest was conducted among 54

students (13 males, 41 females; mean age 19.7) of the University of Twente. They were instructed to carefully watch 10 pictures of objects commonplace in a physician's office and imagine what a male physician with the displayed object in his room would be like. For each of the 10 pictures, they were asked to rate the personality of the physician on a 39-item personality scale. The questionnaire consisted of the 35 items in the Big Five personality questionnaire (Goldberg 1992) and some traits typically relevant for physicians: 'professional', 'expert', 'reliable' and 'involved'. For each of the 39 traits, participants indicated on a nine-point scale to what extent they considered these applicable to the physician. Each participant rated 10 pictures. In total, 20 pictures of objects were tested.

Exploratory factor analysis was conducted on the 39 personality traits. Based on the total explained variance and the interpretability of the factor structure, a five factor solution was adopted. An examination of the terms composing each factor led to naming them as follows: Competence (e.g., professional, responsible, intelligent; $\alpha=.95$), Agreeableness (e.g., warm, kind, involved; $\alpha=.91$), Extraversion (e.g., energetic, talkative, assertive; $\alpha=.90$), Emotional stability (e.g., calm, relaxed, at ease; $\alpha=.83$) and Creativity (e.g., imaginative, creative, curious; $\alpha=.73$). On the whole, this factor structure resembles the structure reported by Goldberg (1992). However, some traits of the original intelligence factor ('intelligent', 'analytical' and 'reflective') and some of the added items ('professional', 'expert' and 'reliable') loaded on the conscientiousness factor, broadening the meaning of the factor to 'competence'. For this study, only the first two factors, deemed most important, will be discussed and elaborated on.

Out of the 20 objects, the six objects that received the highest scores on competence were selected for the professional condition: scientific articles, a medical illustration, professional books, a framed master's certificate, a mockup of lungs and a mockup of respiratory organs. The six objects that scored highest on agreeableness were selected for the personally expressive condition: a miniature ship, African sculptures, toy cars, a speaker set, a soccer team shawl and a decorative hat. Interestingly, objects receiving

high scores on competence received low scores on agreeableness and vice versa: a physician displaying a professional object was judged as more competent ($t=16.38, p<.001$) and less agreeable ($t=6.09, p<.001$) than a physician displaying a personally expressive object.

In addition, participants were asked to rate four scenarios in order to check the verifiability manipulation (i.e., the degree to which a procedure can be evaluated after its completion). Based on these results, a 'credence' scenario (describing a procedure that cannot be evaluated after service delivery) and an 'experience' scenario (describing a procedure that can easily be evaluated) were selected. Participants indicated that, after the treatment, they were better able to evaluate the success of the 'scar treatment' (the experience scenario) than the success of the 'Hepatitis B treatment' (the credence scenario) ($t=11.57, p<.001$). Both scenarios are presented in the next section.

Design and Procedure

A two (professional vs. personally expressive objects) x two (experience vs. credence service) scenario design was employed for the purpose of this study. All 81 participants were individually invited into the research lab. The instructions and scenarios were displayed on a computer screen and read as follows:

Scar treatment (experience condition):

A scar on your cheek has been bothering you for quite a while. Now you really want to have it removed, so you decide to call for an appointment with a doctor. Not knowing what to expect, you search for information on the Internet. As it turns out, you will be able to evaluate the result of the surgery right after the procedure. At the time of the appointment you check in at the hospital. As the physician is not quite ready to see you yet, an assistant takes you into his office and asks you to wait. While waiting you take a good look at the physician's room.

Hepatitis B treatment (credence condition):

You've recently paid a visit to a blood bank for the very first time. They tested your blood on several diseases. As it turns out, you are suffering from Hepatitis B, an infection of the liver. You never noticed anything and you don't know what needs to be done. You decide to call for an appointment with a doctor. Not knowing what to expect, you search for information on the Internet. You learn that you won't be able to evaluate the result of the intervention after the procedure since you did not, and will not, have any noticeable symptoms. At the time of the appointment you check in at the hospital. As the physician is not quite ready to see you yet, an assistant takes you into his office and asks you to wait. While waiting you take a good look at the physician's room.

Prompted by the instructions, participants next explored a QuickTime 360 degree panorama photo of a room containing either the professional objects or the personally expressive objects (see Figure 2). Using the mouse, participants were able to control speed and angle of presentation. After 70 seconds, the view switched to a 6-second movie presentation of a doctor stepping into the office apologizing for the wait. Subsequently participants were asked to fill out the questionnaire.

Measures

To assess the impact of the experimental manipulation on participants' impressions of the physician, participants were asked to rate his personality on a computer-administered 39-item personality questionnaire (identical to the one used in the pretest). In line

with the results from the pretest, exploratory factor analyses revealed the same factorial structure. Cronbach's alphas for the five factors ranged from .71 for Creativity to .94 for Competence.

The cognitive evaluation of the service environment was measured using a 13-item environmental appraisal scale, including the 10-item environmental appraisal scale (Bitner 1990) and the items 'appearing friendly', 'comfortable', and 'clean'. Two factors emerged from an exploratory factor analysis conducted on these items: Professional (e.g. efficient, organized, professional; $\alpha=.82$) and Attractive (e.g. pleasant, attractive, comfortable; $\alpha=.92$). The emotional response was assessed with a 6-item pleasure scale (Mehrabian and Russell 1974). This scale proved to be one-dimensional and reliable ($\alpha=.93$). An adjusted SERVQUAL questionnaire (Parasuraman, Zeithaml, and Berry 1988) was used to determine the evaluation of the service ($\alpha=.93$).

RESULTS

Analysis of variance showed that participants in the professional condition rated the office as more professional ($M_{\text{professional}}=5.18$) in comparison to participants in the personally expressive condition ($M_{\text{personally expressive}}=4.67, F(1, 79)=4.09, p<.05, \eta^2=.049$). However, the office manipulation did not have a direct effect on perceived physician's competence ($F(1, 79)=.23, \text{NS}$) or agreeableness ($F(1, 79)=.55, \text{NS}$). The office containing professional objects was judged as less attractive ($M_{\text{professional}}=2.76$) than the office containing personally expressive objects ($M_{\text{personally expressive}}=4.67, F(1, 79)=7.41, p<.01, \eta^2=.086$). Consistent with the latter finding, participants in the professional condition reported to have less positive emotions ($F(1, 79)=5.97, p<.04, \eta^2=.070$), and a lower perceived service quality ($F(1, 79)=7.26, p<.01; \eta^2=.084$) than participants in the personally expressive condition. Contrary to our expectations, none of these effects were qualified by the experience-credence manipulation.

To better understand the relationship between these variables, Structural Equation Modeling was used to test the theoretical model. The direct and indirect effects were estimated by means of path-analysis using Amos. The model shown in Figure 3 has a very good fit ($\chi(10)=14.45, p=.15, \text{CMIN}/df=1.45, \text{GFI}=.96, \text{TLI}=.96, \text{CFI}=.98, \text{RMSEA}=.075$). All relationships are significant at $p<.05$.

Not surprisingly, a positive relationship ($\beta=.35$) exists between the objects in the office and perceived professionalism of the office, indicating that the office containing professional objects is perceived as more professional than the office containing personally expressive objects. The negative relationship between the objects in the office and perceived attractiveness ($\beta=-.29$) implies that the office in the personally expressive condition is perceived as more attractive than the office in the professional condition. However, the object manipulation accounts for only 9% of the variance in office attractiveness.

A direct relationship emerges between the two dimensions of service environment appraisal, suggesting that office attractiveness is a significant predictor of office professionalism ($\beta=.45$). Office professionalism in turn strongly affects the degree to which the physician is perceived as competent ($\beta=.64$), whereas office attractiveness strongly affects the perceived agreeableness of the physician ($\beta=.48$). In line with our predictions, these results indicate that observers indeed project specific attributes of the environment onto the physician. It should be noted that, as was the case with the environmental attributes, the physician's personality traits are not unrelated: perceived agreeableness affects perceived competence ($\beta=.25$).

The emotional experience is greatly affected by both the perceived attractiveness of the office ($\beta=.70$) and to a much lesser degree by the perceived agreeableness of the physician ($\beta=.25$).

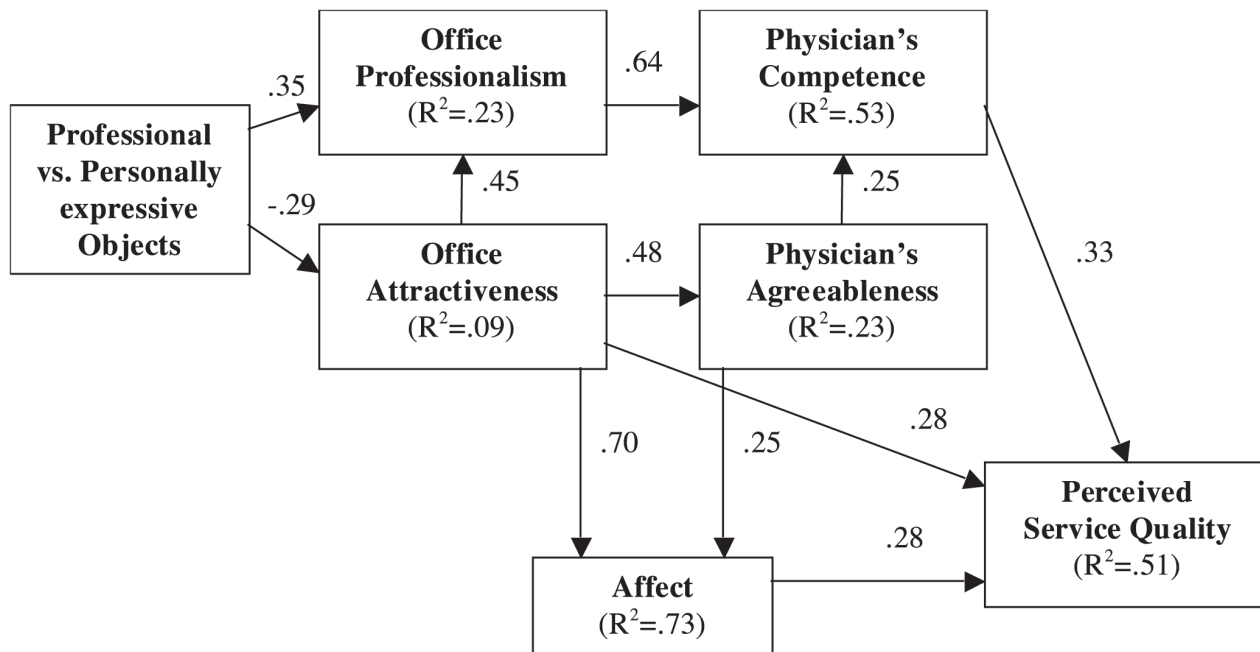

FIGURE 2

Panorama snapshots of the office in the personally expressive (top) the professional (bottom) condition. Note that the actual stimulus materials were interactive 360 degree panorama photos rather than these stills.

FIGURE 3

Estimated path model (standardized regression coefficients, explained variance in brackets)

These two variables account for 73% of the variance in emotion. The significant relationship between perceived physician's competence and perceived service quality ($\beta=.33$) confirms our hypothesis that consumers evaluate service quality based on their impression of the service provider. The attractiveness of the service environment also directly affects service quality evaluation ($\beta=.28$).

As expected, experienced emotion is a significant predictor of service quality ($\beta=.28$).

DISCUSSION

The results of this study confirm our hypotheses about particular types of objects in a healthcare setting, thereby further advanc-

ing our understanding of the ways in which environmental factors impact consumer experience. Although research assessing effects of interior design on consumers' responses are not new, many studies suffer from a lack of experimental control, making it hard to demonstrate relations between specific types of environmental stimuli and consumer experience.

The presented model suggests two different response 'routes' in consumers' evaluations of service encounters: a cognitive 'hard' route through which the physician's competence is assessed, and a more affect-laden 'soft' route centered on perceived friendliness or agreeableness (c.f., Driver and Johnston, 2001). Perceived competence was shown to be primarily affected by professionalism of the office, and thus dependent on the presence of profession-related objects. Perceived friendliness, on the other hand, was shown to be primarily affected by the attractiveness of the office. Thus, offices containing objects expressive of personal tastes and interests were perceived as more attractive and elicited a more positive emotional response in comparison to offices containing profession-related objects. Interestingly, these findings are in line with findings reported by Pruyn and Smidts (Pruyn and Smidts 1998) indicating that perceived attractiveness of waiting rooms in healthcare settings primarily impacts consumers' emotional response. These combined findings corroborate our assumptions that perceived attractiveness can be considered a soft attribute whereas perceived professionalism constitutes a hard attribute.

Perceived competence of the physician turns out to be an important predictor of perceived service quality. Attractiveness of the environment and perceived agreeableness of the service provider influence perceived service quality indirectly through experienced affect. The importance of such soft attributes is further underscored by the positive relation between office attractiveness and office professionalism, indicating that soft attributes also impact hard attributes. In literature, the relative importance of hard and soft attributes with respect to service quality appraisal is expected to vary with the type of service (Cronin and Taylor 1994; Parasuraman, Zeithaml, and Berry 1994). As one would expect, in high anxiety and high contact services, soft attributes play a greater role in service quality appraisal than hard attributes. For this reason, participants generate more favorable expectations with respect to service quality in the personally expressive condition than in the professional condition.

Contrary to our expectations, the effects of objects were not moderated by information verifiability. Although information verifiability was successfully manipulated, the scenarios may have failed to generate differences in perceived uncertainty. After all, it is this experienced uncertainty (arising from low information variability) that is expected to moderate the effects of the environment on service provider- and service quality evaluation. Another explanation relates to the fact that most consumers are unfamiliar with (technical) procedures in healthcare services, the outcome of which will always be somewhat uncertain. As such, healthcare services in general carry predominantly credence characteristics. Although it was clear in the experience scenario that the outcome could be evaluated after the treatment, no information regarding the outcome of the scar treatment was given, and the two service encounters might not have been distinctive enough along the verifiability continuum.

The ecological validity of our study was increased by simulating the office using QuickTime 360 degree panoramas rather than 'standard' photos and by introducing the target of impression formation (i.e., the physician) by means of a short movie presentation. In doing so we hoped to portray a realistic service encounter. In bringing physician and environment together (as is the case in

'real life'), an interesting avenue for future research opens up. That is, in addition to investigating the impact of the physical environment on person perception, it would also be of interest to study the impact of person characteristics on environmental appraisal and consequent service quality appraisal. Variations in person characteristics such as age or self-assuredness may prompt consumers to attend to different aspects of the environment or lead them to evaluate environmental factors differently in terms of cue validity (Brunswick, 1956). The impact of profession-related objects (communicating competence), for instance, may vary depending on the degree to which the physician is perceived as confident or insecure; status symbols may trigger an image of high standing for an elderly man radiating confidence, whereas adverse effects may be anticipated if the office is occupied by a young inexperienced person.

Finally, our results are of interest in the light of recent findings in priming research. As Kay et al. (2004) have shown, objects can subconsciously influence people's behavior and evaluations. Future research will have to address the question to what extent and under what conditions (sub-)conscious processes underlie the effects of objects in servicescapes. With respect to healthcare settings, for instance, one could argue that soft (i.e., affect-related) attributes are activated without consumers being aware of the relevant influence, whereas awareness is needed for observers to draw conclusions about hard attributes. But regardless of how, and under what conditions, objects impact consumer experience, present research demonstrates the importance of attending to physical objects in service settings and the messages they convey.

A Two-Step Model of Service Dissatisfaction: Theory and Evidence

Lisa C. Wan, The Chinese University of Hong Kong
Haksin Chan, The Chinese University of Hong Kong

EXTENDED ABSTRACT

The literature on consumer (dis)satisfaction has largely focused on its antecedents, notably, expectations, disconfirmation of expectations, performance, attributions, and equity. Few empirical studies have addressed the consequences of (dis)satisfaction, let alone the consequences of service (dis)satisfaction. In addition, individual-difference variables rarely appear in previous (dis)satisfaction models.

This paper presents a two-step model (see figure 1) that highlights the moderating influences of two individual-difference variables, both on service dissatisfaction and on the ensuing complaining behaviors. It also reports a study that examined several hypotheses based on the proposed model.

Research Hypotheses

Previous research (e.g., Smith, Bolton, and Wagner 1999) has distinguished between process and outcome failures in service encounters. From the perspective of the consumer, the former involves the loss of *social* resources (e.g., status, esteem), whereas the latter involves the loss of *nonsocial* resources (e.g., money, time). We propose that the two types of service failure would trigger different patterns of consumer behavior, subject to individual differences in concern for face (CFF) and belief in fate (BIF).

Concern for face is defined as the extent to which an individual shows regard for and interest in the protection and enhancement of face (i.e., *public* self-image) in social interactions. Since services are performed for people by people, service failures are inherently face-threatening (Brown and Levinson 1987). Given the fundamental difference between a process failure and an outcome failure, however, face issues should be more salient in the former than in the latter. We thus predict an aggravating effect of CFF on service dissatisfaction, and that this effect would be stronger for a process failure than for an outcome failure.

Belief in fate is defined as the extent to which an individual believes in fate/luck as an impersonal force shaping events and outcomes. When service failures occur, the notion that "it is meant to be" or "I am just unlucky" would help alleviate discontent. However, fatalistic notions are seldom invoked when an obvious interpretation is available (Pepitone and Saffiotti 1997). Relative to an outcome failure, a process failure involves an unambiguous causal agent, namely, the service provider. Hence, we predict a mitigating effect of BIF on service dissatisfaction, and that this effect would be stronger for an outcome failure than for a process failure.

According to Singh's (1988) taxonomy of consumer complaint behavior (CCB), dissatisfied consumers may engage in public actions (e.g., complaining to management) or private actions (e.g., negative WOM). Both CFF and BIF are expected to affect CCB over and above their influences on dissatisfaction.

Given the same level of service dissatisfaction, consumers higher (vs. lower) in CFF may be more motivated to restore "self-face" by complaining to management. Alternatively, however, they may be more restrained because of their concern for "other-face." As far as private actions are concerned, consumers higher (vs. lower) in CFF are likely more motivated to spread negative WOM because it may signal to others their exquisite taste, thereby enhancing face.

The effects of BIF on CCB are predicted to be uniformly mitigatory. Consumers higher (vs. lower) in BIF should be less likely to complain to management or engage in negative WOM, by virtue of the perceived futility of attempts to change the status quo.

The research hypotheses are summarized as follows:

- H1: When a service failure occurs, consumers who are higher (vs. lower) in CFF will be more dissatisfied.
- H2: The aggravating effect of CFF on service dissatisfaction will be stronger for a process failure than for an outcome failure.
- H3: When a service failure occurs, consumers who are higher (vs. lower) in BIF will be less dissatisfied.
- H4: The mitigating effect of BIF on service dissatisfaction will be stronger for an outcome failure than for a process failure.
- H5a: Given the same level of dissatisfaction, consumers who are higher (vs. lower) in CFF will be more likely to complain to management.
- H5b: Given the same level of dissatisfaction, consumers who are higher (vs. lower) in CFF will be less likely to complain to management.
- H6: Given the same level of dissatisfaction, consumers who are higher (vs. lower) in CFF will be more likely to engage in negative WOM.
- H7: Given the same level of dissatisfaction, consumers who are higher (vs. lower) in BIF will be less likely to complain to management.
- H8: Given the same level of dissatisfaction, consumers who are higher (vs. lower) in BIF will be less likely to engage in negative WOM.

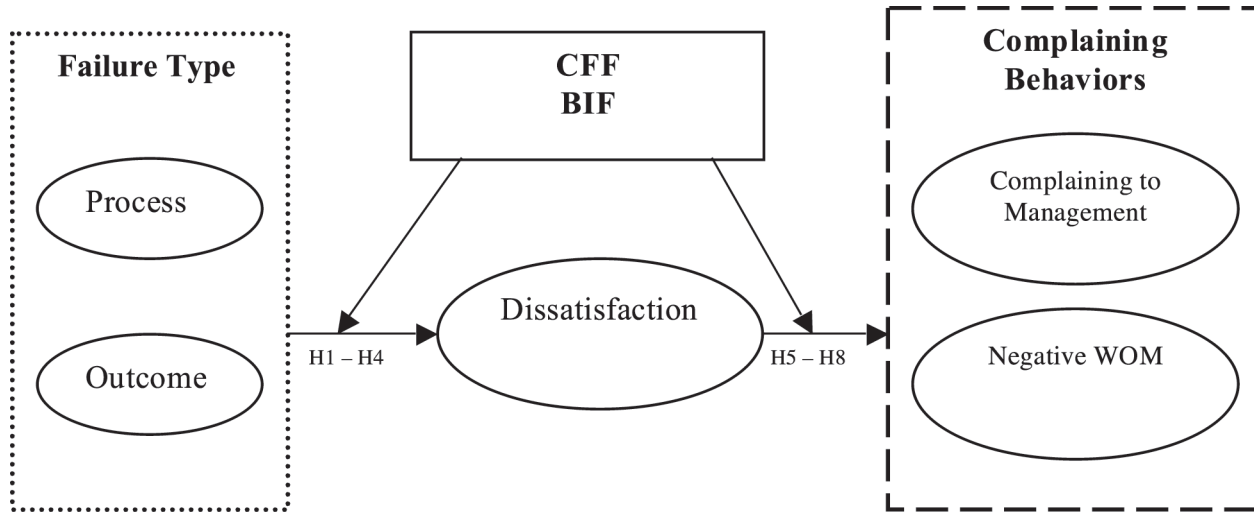

Method and Results

The hypotheses were tested with a scenario-based experiment. Participants were 108 business executives from a part-time MBA program at a large, international university. They were randomly assigned to either a process failure or an outcome failure condition in a hotel scenario, and their CFF and BIF scores were measured after they gave their dissatisfaction ratings. The hotel scenarios and the measurement scales were adapted from previous research.

Confirming hypotheses 1 and 2, we found a CFF main effect and a CFF x failure type interaction. Participants higher in CFF were more dissatisfied, and this effect was more pronounced in the process failure condition. Nonetheless, the data supported hypothesis 4 but not hypothesis 3. There was no BIF main effect, despite a BIF x failure type interaction. Specifically, participants higher in BIF were less dissatisfied only in the outcome failure condition.

With the level of dissatisfaction controlled for, CFF had a negative (i.e., mitigating) effect on the intention to complain to

FIGURE 1
A TWO-STEP MODEL OF SERVICE DISSATISFACTION

management but a positive (i.e., aggravating) effect on negative WOM intention. This pattern supported hypotheses 5b and 6. On the other hand, BIF had a marginally negative effect on the intention to complain to management, lending some support to hypothesis 7. This variable also showed an attenuating effect on negative WOM intention, thus confirming hypothesis 8.

Conclusion

This paper extends consumer (dis)satisfaction research by showing that CFF and BIF impact the (dis)satisfaction process at two junctures. They first interact with failure type to influence service dissatisfaction, and then affect the ensuing CCB. The two-step model has important theoretical and managerial implications, and points to many avenues for future research.

Consumers' Arrogance: Construct Conceptualization and Preliminary Validation Evidence

Ayalla Ruvio, University of Haifa, Israel
Aviv Shoham, University of Haifa, Israel
Shlomo Hareli, University of Haifa, Israel

EXTENDED ABSTRACT

People engage in self-promotion to impress others. Self-promotion can help achieve one's goals when received positively but can lead to perceptions of arrogance when received negatively (Hareli and Weiner 2000). Consumer arrogance (CA) is more specific than general arrogance and is conceptualized as a multidimensional construct reflecting individuals' tendency to communicate achievements via possessions and the abilities related to their acquirement. This definition recognizes that possessions can convey arrogance when used to symbolize success and achievements (O'Cass and McEwen 2004).

Research in psychology viewed arrogance as a dimension of narcissism (Emmons 1984) and conceptualized it as reflecting one's belief of being a special person, who should only be associated with likewise individuals (Boyd and Helms 2005). Other lines of research focused on what makes individuals seem arrogant to others and showed that people seem arrogant when they communicate their quality publicly (Ben-Ze'ev 1993; Hareli, Weiner, and Yee 2006). Likewise, such a perception is enhanced when individuals communicate that their achievements were attained thanks to their desirable qualities. Although high achievers are admired, such communications are received negatively as arrogant people are disliked (Hareli and Weiner 2000; Wosinska et al. 1996).

We use the theoretical lens of possessions as an extension of the self to conceptualize CA as a trait. Possessions are a safe means to convey one's image to express identity publicly (Tian et al. 2001). They symbolically signal accomplishments, making them a form of communication of owners' superiority (Hirschman and LaBarbera 1990). Thus, we conceptualize CA as a communicated exhibition of superiority through products and consumption. Individuals use verbal and non-verbal self-presentational CA strategies to impress others—the wider their range and the higher their frequency the higher their perceived CA (Baumeister 1982).

Verbally, individuals can exhibit superiority by stating their accomplishments or showing-off their possessions (Gauld and Shotter 1977). Hence, high-CA individuals should present their purchases as superior to others' (*purchase superiority*) and show them off (*showing-off through purchases*). Third, high-CA individuals will perceive themselves as experts, opinion leaders, or market mavens (Feick and Price 1987). Thus, verbal CA includes perceived and expressed "*I know best*" mentality compared to others.

Non-verbally, consumers can use branded products (*brand-name self-assertion*), valued because of their inherent status (Dawson and Cavell 1987), to communicate superiority (O'Cass and McEwen 2004). Additionally, *exhibitionism-based purchasing* signifies individuals' increasing conspicuous consumption (Powderly and MacNutly 1990; Riesman 1950; Vigneron & Johnson 1999).

Having conceptualized CA as a five-dimensional trait, we embarked on a study to develop a CA scale. An open-ended elicitation procedure was used first to generate an initial item pool which will be consistent with the public's view of CA. Students (n=67) were queried about their perception of the expression of arrogance through buying, consuming, or using products. Then, in the second phase, an experienced editor reviewed all responses. She eliminated ambiguous/repeated statements. Three scholars reviewed

the remaining 76 statements independently to identify dimensions and assign statements. This stage required agreement by all three. The dimensions were labeled brand-name self-assertion, exhibitionism-based purchases, "*I know best*" mentality, showing-off through purchases, purchase superiority, and unnecessary purchases. Except for unnecessary purchases, all CA dimensions were pre-conceptualized. However, since unnecessary purchases emerged, we incorporated it post-hoc and the final list included 46 items.

The purification stage was designed to meet the challenge of item parsimony and maintenance of the structure of CA. Data were collected from 130 students on the CA items and the CSII, status consumption, and price-prestige relationship scales. Reliability analyses and uni-dimensionality tests of CA dimensions reduced the list to 29 items corresponding to our five-dimensional structure with one new dimension. This phase also tested the CA scale for nomological validity and found that it was related positively to CSII, status consumption, and price-prestige sensitivity.

Since the motivation for CA is to elevate the possessor's social status, future research should examine high-CA individuals' tendency to consume products that can communicate superiority and achievements to others preferably using representative samples. Future research should also test the discriminant and nomological validity of CA through constructs such as vanity and materialism, preferably cross-culturally since CA is an individual trait, exhibiting it might be considered less desirable in collectivist cultures.

Sustained Consumer Fascination

Canan Corus, Virginia Tech, USA

Julie L. Ozanne, Virginia Tech, USA

ABSTRACT

While product involvement is a central concept used to define intense product-consumer interactions, recent researchers are contributing new constructs to better understand highly engaged brand relationships. In this study, the concept of *sustained consumer fascination* is introduced to help understand the intense and enduring relationships that arise among consumers and consumption activities. Based on online gardening diaries and in-depth interviews with avid gardeners, we propose that the concept of sustained consumer fascination is composed of surprise, creative engagement, restorative escape, and insight.

The Brand Dislike Construct: Scale Development and Application to Actual Brands

Daniele Dalli, Università di Pisa, Italy

Silvia Grappi, Università di Modena e Reggio Emilia, Italy

Simona Romani, Università di Sassari, Italy

Giacomo Gistri, Università di Pisa, Italy

EXTENDED ABSTRACT

Brand dislike occurs when consumers express explicit negative judgments toward a brand that can be either formed during the evaluation task or retrieved from a negative attitude stored in memory. There are several factors that lead to the emergence of brand dislike and even theoretical explanations are sparse and fragmented: the first section of the paper reviews the main research approaches that have addressed this topic, trying to integrate them in a single framework.

Specifically, three distinct stream of research will be reviewed and organized: customer/brand relationship (Fournier, 1998; Fajer, Schouten, 1995), the metaphoric, symbolic and relational properties of negative opinions and judgements (Wilk, 1997; Bourdieu, 1987; Douglas, 1996; Douglas and Isherwood, 1996) and finally, political consumption and consumer resistance (among others, Ozanne and Murray, 1995; Firat and Venkatesh, 1995 and Holt, 2002).

With this framework in mind, we have started the development of a research project to understand the brand dislike construct and to create the basis for measuring it. In detail, our research objectives in this paper are:

- A preliminary explorative qualitative analysis directed at understanding the concept of brand dislike from the consumer's perspective (Dalli et al., 2006);
- the development and validation of a brand dislike scale integrating the dimensions emerging from the literature review and the results of the qualitative analysis;
- the application of the validated scale to actual brands to test the relevance of the dislike factors identified in the previous phase.

The main result that emerged from the qualitative analysis is a complex but coherent picture that is broken down into three levels (product, user and corporate) and several factors, each of which can be strictly related to the literature outlined in the paper. In this sense, the research purpose of giving a descriptive picture of the consumers' perspective about disliked brands has been achieved.

The generation of a scale for measuring brand dislike has been the second step of this research project. Following the scale development procedure guidelines that Churchill (1979) and DeVellis (1991) proposed, we obtained a psychometrically sound and operationally valid measure for the brand dislike construct based on fifteen items.

Eight out of fifteen items clearly relate to the corporate level, broken down into three different factors: "manipulation and deceit", "carelessness toward the environment" and "outdated communication"; five additional items relate to the user level broken down into two different factors: "poor distinction capability" and "excess of distinction" and, finally, one item relate to the product level and, specifically, to "poor product performance".

Finally, to test the relevance of the dislike factors, the previously validated brand dislike scale has been applied to actual brands. This application provides some interesting results. Five factors come out from the analysis. Eight items out of fifteen clearly relate to the corporate level, broken down into three different

factors: as we found in the previous phase of analysis, these three factors are "manipulation and deceit", "carelessness toward the environment" and "outdated communication". Five additional items relate to the user level and, differently from the previous phase of analysis, we found only one factor collecting all the items related to the user level. Finally, as we found in the scale validation analysis, two items relate to the product level and, particularly, to "poor product performance".

Therefore, the factors identified seem quite stable and able to almost completely cover the theoretical model on which the empirical analysis is grounded.

The main contribution of the paper is in the direction of the development of a specific measurement tool for negative brand attitudes, provided that no special methods like this do exist, and that it's a long time that attitude literature is claiming for the development of specific instruments to measure negative attitudes.

In addition, this new scale adds to the extant literature by establishing a basis for further theoretical advances on the relationship between brand dislike and buying behavior; the focus in this case should be on the nature and strength of this relationship, given the different impact of the six identified and verified factors on overall brand dislike. In fact, according to whether or not the consumer dislikes the brand because of one or another of the identified factors, the implications in behavioral terms are not necessarily the same and of the same intensity.

Finally, the application of the scale to actual brands has led to interesting results and seems promising not only from a theoretical point of view but also from a managerial one. The 15 item scale can serve as a useful diagnostic tool; it allows to identify the factors on which consumers build negative evaluations and to set up the necessary countermeasures.

Toward a Theory on the Content and Structure of Money Attitudes

Steven Michael Burgess, University of Cape Town, South Africa

EXTENDED ABSTRACT

Rising consumer debt, compulsive buying, credit card abuse, and bankruptcy have focused attention on money attitudes, which are beliefs people hold about money and exchange situations. In this paper, we address the important need for systematic work toward a comprehensive theory on the content and structure of money attitudes. Building on work by Yamauchi and Templer (1982), we propose a theory on the contents and structure of money attitudes, develop a new measurement scale, and rigorously test its psychometric properties.

We define money attitudes as interpersonal, attitudinal [affective, behavioral, cognitive] beliefs that express [individual, collective, mixed] values concerned with money [independence...quality] and are evaluated in importance [very important to very unimportant] in order to guide behavior within the context of money and money situations. Our definition relies on the assumption that money is by its nature a medium that is intended to facilitate interpersonal exchange. Money situations, like all interpersonal situations, involve complex fields in which past and present interpersonal influences are embedded in an equally influential socio-cultural matrix (Wiggins and Trobst 1997). We posit that money attitudes are attitudinal beliefs that are operant in money contexts and express individual, collective, and mixed values.

Yamauchi and Templer (1982) proposed five money attitudes: power-prestige, retention-time, distrust, anxiety, and quality. In our work, we note the value-expressive role of attitudes and their less central position in the human belief system, in which hierarchically-held values and attitudes are managed for consistency. We draw on Schwartz (1992) widely-accepted values theory to propose the motivational contents of money attitudes, noting our expectation that money attitudes will serve the same the same universal requirements of existence identified by Schwartz: needs of individuals as biological organisms, requisites of coordinated social conduct, and requirements for the smooth functioning and survival of groups. Our conceptual approach allows us to distinguish nine money attitudes that are derived by refining and extending Yamauchi and Templer's (1982) money attitudes.

We postulate that money attitudes will have a circumplex structure. The circumplex is the product of a motivational continuum at a more basic level, even though we discriminate among individual money attitudes in our theory. Consequently, following the logic employed by Schwartz (1994), we partition the circumplex into individual money attitudes that represent conceptually-insightful choices about boundaries between fuzzy sets. An examination of the content of our money attitudes suggests two underlying and possibly orthogonal bipolar dimensions underlie their structure. One bipolar dimension pits self-assurance (independence) against insecurity (anxiety, distrust, power). The other bipolar dimension opposes conservation (conservatism, ubuntu) and consumption (time-simplicity, stimulation, quality).

We construct a 49-item scale, the *Money Portraits Survey* (MPS), to assess the structure and contents of the theory, following the textual portraits approach of Schwartz' *Portraits Value Questionnaire* (Schwartz et al. 2001). The approach asks respondents to compare textual portraits of people, who implicitly place priority on a particular money attitude. The direction of comparison is important, because it increases the likelihood that the respondent's similarity judgment will focus on the implied values.

In study 1, which was a pretest, the MPS and PVQ were administered to 117 MBA students. Coefficient alpha internal

reliabilities of the subscales were in the range .63-.87, with only two scales below .70. Following the procedure of Schwartz (Schwartz et al. 2001), we assess whether items intended to measure money attitudes are located in contiguous regions in the space (i.e., content) and whether the regions are located relative to one another as expected (i.e., structure). Thus, we adopt a confirmatory, configurational verification approach using similarity structure analysis (SSA), a nonmetric multidimensional scaling technique that is especially appropriate when testing hypotheses that array the constructs of interest on a continuum in space (Davison 1983; Dillon and Goldstein 1984). The money attitudes emerged in the hypothesized order. Forty-one items were located in the hypothesized regions while only seven items were located in regions adjacent to the hypothesized region. Just one item emerged in an unexpected region not adjacent to its hypothesized region. Money attitudes had expected relations with the PVQ values. After careful inspection, we selected 33 items for inclusion in two field assessments of the new scale.

In Study 2, we administered the MPS to 200 people using mall intercepts outside cinemas in major metropolitan areas. The money attitudes emerged in the hypothesized order, except that one emerged on the periphery of another (which is consistent with the theory). Thirty-one items emerged in hypothesized regions and only two items were located in adjacent regions. The fit of the SSA model was good (i.e., the model fit index, stress=.16, c.f. Johnson and Wichern 2002). When data parcels were created by averaging the scores of items intended to measure each money attitude and the model was assessed, the fit was excellent (stress=.04).

In Study 3, a professional marketing research company administered the MPS to 415 bookstore customers. SSA results was similar to Study 2 and fit to the hypothesized structure was acceptable (stress=.18). The hypothesized structure emerged, although two money attitudes reversed order, which is consistent with the theory. All items are located in hypothesized regions except two items located in regions adjacent to their hypothesized location. An SSA of the data parcels suggests an excellent fit (stress=.05).

The larger sample size in Study 3 allowed us to assess the fit of these data to a more rigorous circumplex structure using Browne's covariance structure modeling approach (Browne 1992). The approach is analogous to the confirmatory factor analysis and provides information about model fit to a circumplex structure using some of the same indices. The results present an acceptable fit ($\chi^2(17)=79.06$, RMSEA=.097, RMSEA 95% confidence interval (.074-.115) (c.f. Browne and Cudeck 1992). The hypothesized structure is confirmed by the 95% confidence intervals of the polar angles.

The new MPS emerges as a reliable and valid tool to measure money attitudes that is easy to administer and analyze. Future work should focus on the antecedents and consequences of money attitudes.

Does a Medium Context Have a Priming or an Interference Effect? It Depends on How You Look At It

Wim Janssens, University of Antwerp, Belgium
Patrick De Pelsmacker, University of Antwerp, Belgium
Maggie Geuens, Ghent University, Belgium

EXTENDED ABSTRACT

Previous literature has found that a medium context can have an effect on the responses to an embedded ad (e.g., Moorman et al. 2005). Some authors find a congruency effect between context and embedded ad (priming effect, e.g. Yi 1990a) and others find no effect or even opposing effects and this latter is attributed to the interference and/or contrast theory (Bryant and Zillman 1994). In case readers follow the page lay-out, the medium context is processed first and subsequently the embedded ad. However, most often no formal check for this is done, i.e. how people really read the magazine or newspaper pages is not traced. Hence, several questions can be raised: did people read the context first and subsequently the ad, did the ad attract so much attention that the ad was read first and subsequently the context, did people switch from medium context to ad and vice versa a number of times, and do these different reading sequences have an impact on whether congruency or contrast effects occur? If these reading sequences do matter, they could perhaps explain why previous results in mainly print setting were not robust with respect to the congruency and contrast effects that were found. Indeed, whether priming (a context serves as a primer, resulting in more positive ad responses) or interference (the target ad 'melts down' in the medium context, resulting in less positive ad responses) occurs may depend on the context-ad sequence (Furnham, Bergland, and Gunter 2002).

In this paper, by means of three studies, the priming as well as interference effects are studied. By means of eye-tracking we specifically focus on the attention path that respondents have when there is simultaneous exposure (i.e., context and ad are shown at the same time). The studies were operationalized in a medium in which different presentation orders of the stimuli (ad and medium context) are realistic, namely the web. More precisely, a computer ad was combined with a congruent computer web page or an incongruent car web page. Impact was measured by attitude towards the ad (four items) and click intention.

In the first study, we found that in a pure priming setting (a prime, followed by the web ad) the expected congruency effect was present for both attitude towards the ad and click intention. When the web ad and prime (web page) were shown simultaneously after the prime, this congruency effect vanished and for click intention, it even turned into a contrast effect. This finding warrants further research into the effect of context after an ad as well as the effect of being simultaneously exposed to web ad and web page. Therefore, a second study was done. It was shown that when the web page appeared after the ad ('pop before') a contrast effect was found, in a condition of continuous simultaneous exposure of web ad and web page (banner-like condition), no effect was found, and in a condition of a web page, followed by a web page with web ad, followed by web page, a congruency effect was found (which can be called a 'backward priming the prime' effect) for both attitude towards the ad and click intention. Eye-tracking information showed that in the third condition, respondents only switched a minimal number of times between web site and web ad (i.e., twice: from web page to ad and back to web page). This condition does not differ much from the second condition in study 1 (web page only, followed by web ad and web page). The differences between these two conditions were the

extra web page after the web ad and web page, and the fact that in the 'web page-web page with web ad' condition almost half of the respondents switched more than two times between web site and web ad. In the third study it was indeed shown that the number of switches is a moderating factor. In this study, respondents were only exposed to the 'continuous simultaneous exposure to web ad and web page' condition. Our results indicated that when the number of switches was low, congruency effects were found, while as the number of switches increased, this congruency effect diminished and even reversed into a contrast effect. A possible explanation for this finding is that the number of switches between ad and medium context can be seen as a reverse indicator of attentive processing. Hence, the way people look at the medium context and the ad (even when simultaneously exposed) may impact the type of 'medium context-ad' effect that will occur.

These findings are relevant because the type of medium context effect may depend on the way people watch medium context and ad. For example, our results suggest that banner ads may not be the most appropriate advertising strategy as it depends on the number of switches between medium context and ad (which is difficult to know a priori), whether a congruent or a contrasting medium context is recommended. A thematically congruent context is recommended in case of a pop-under or a pop-up (which people look at and subsequently close).

With respect to the discussion on the viewing behaviour influencing the type of medium context effect that occurs, further research could try to focus on the suggested 'backward priming the prime' principle in order to study the possible effect of the time that the last prime is seen. Such a study may be operationalized in a real-life study, where exposure times to medium context and ad are not forced. Hence, a clickable version of the experiment is recommended to find robustness for our results, although possible confounding effects must be taken care of. Further research could also examine the moderating role of context liking and context-evoked arousal, in websites as well as in other media (e.g., television).

When Advertising Integration with Media Content Fails and Succeeds

Jing Wang, University of Iowa, USA
Bobby Calder, Northwestern University, USA

ABSTRACT

Consumers are exposed on a daily basis to more and more advertising. A key strategy that some advertisers have embraced in the face of this increasing level of media clutter is to integrate their advertising with media content. In Study 1, we show that if the viewer is highly engaged by the content and transported into the world of the program, then an integrated ad can be more intrusive to consumers' transportation experience. In such cases, advertising effectiveness is reduced when consumers are more transported into the media content. However, Study 2 shows that if the advertising does not intrude on the transportation experience, an integrated ad could benefit from having similar themes as the media contents. Therefore, a high level of media transportation leads to increased advertising effectiveness.

Convergence of Interests—Cultivating Consumer Trust Through Corporate Social Initiatives

Shuili Du, Boston University, USA

C.B. Bhattacharya, Boston University, USA

Sankar Sen, Baruch College, USA

EXTENDED ABSTRACT

This paper examines the social and business benefits of a Corporate Social Responsibility (CSR) initiative and explicates the link between the social and business benefits. Social benefits refer to the impact of a CSR initiative on society, most notably on the intended beneficiaries of the initiative. The business benefits include both transactional outcomes such as purchase, and relational outcomes such as consumer advocacy behaviors toward the company/brand (e.g., word-of-mouth). We posit that trust, the key determinant of relational commitment (Garbarino and Johnson 1999; Ganesan 1994), is the mediating variable linking the social and business benefits.

We define trust as the perceived credibility and benevolence of a company (cf. Doney and Cannon 1997; Ganesan 1994). By making a difference to the social cause (i.e., generating social benefits), a CSR initiative could build consumer trust as it signals that the company is serious about bettering social welfare (the benevolence dimension of trust) and is competent in effecting positive social change (the credibility dimension of trust). Greater trust then leads to consumer loyalty and greater support for the company, as indicated by product purchase and consumer advocacy behaviors.

Persuasion knowledge model (Friestad and Wright 1994) suggests that consumers will naturally make attributions about the motives underlying a CSR initiative. Drawing upon literature on interpersonal trust (McAllister 1995; Rempel, Holmes and Zanna 1985), we posit that only intrinsic motives (i.e., a genuine concern for social welfare) are diagnostic of the company's trustworthiness and therefore are likely to mediate the relationship between perceived social benefits and trust. Extrinsic motives (i.e., a desire to increase sales, to improve reputation, etc.) are unlikely to play a role in cultivating trust.

We use a quasi-experiment involving a real-world CSR initiative to test our hypotheses. Our empirical context is the Crest Healthy Smiles 2010 program, which is sponsored by Crest to address disparity in oral health by providing education, tools and access to dental care services to children in economically disadvantaged neighborhoods across the country. A key component of this initiative is the "Cavity Free Zones program", in which Crest partnered with a national non-profit organization, Boys and Girls Club of America (BGCA), to teach dental health as well as provide dental care tools to underprivileged children. Our treatment group consists of Hispanic parents whose children have participated in the "Cavity Free Zones program", and therefore have benefited from the initiative. The control group consists of Hispanic families who have not participated in the program, but have similar demographic characteristics and are selected from the same neighborhoods (i.e., as indicated by zip codes) as the treatment group. Difficulties in contacting members of the treatment group via BGCA organization resulted in a lower than desired sample size, a total of 53 complete surveys, as compared to 305 respondents in the control group. In the survey, we used several methods to reduce demand effects and the social desirability bias, such as putting questions about the Crest Health Smiles program at the very end, and when asking questions about Crest, we ask the same questions about Colgate so as to conceal our research purpose. Prior to conducting the survey, we did several focus groups with both the treatment group and the

control group to get a richer understanding of the social initiative and to yield measurement items for our constructs.

Findings from the quasi-experiment provide support for most of our hypotheses. ANOVA analysis with group as the independent variable shows that, relative to the control group, the respondents in the treatment group reported that their children have greater motivation to engage in dental care behavior, and indeed are likely to floss and visit dentists more frequently. Such difference in health motivation and health behavior is indicative of the social benefits the Crest Health Smiles program has generated. Regarding the business benefits, we find that, relative to the control group, the respondents in the treatment group display greater trust in the sponsoring brand Crest, are more likely to purchase Crest products, and express greater intention to engage in relational behaviors toward Crest. Further, mediational analysis indicates that, as we expected, trust mediates the relationship between participation in the initiative and brand behaviors. To examine the dynamics of trust, we analyzed the data of the treatment group only. Consistent with our expectation, perceived social benefits of the CSR initiative are positively related to trust in the sponsoring brand Crest. In addition, intrinsic attributions mediate the link between perceived social benefits and brand trust, whereas extrinsic attributions are not related to either perceived social benefits or brand trust.

This research provides important insights into the phenomena of corporate social initiatives. It highlights the role of social benefits as a key antecedent to business benefits of a CSR initiative, showing social and business interests can be complementary. It provides a process explanation of how CSR initiatives generate business benefits: CSR initiatives yield business benefits via cultivating consumer trust, increasing consumer purchase and advocacy behaviors and thus improving the long-term business prospects of the sponsoring company/brand.

The Effects of Different Category Context on Target Brand Evaluations

Myungwoo Nam, INSEAD, Singapore
Brian Sternthal, Northwestern University, USA

EXTENDED ABSTRACT

Contrary to previous studies of contextual priming effects, which focus on the effects of priming same category exemplars or traits, the current study examines how the evaluation of a target brand is affected when the context is a brand from a category other than the one in which the target holds membership.

Only a few studies have investigated the effects of priming other category products on target evaluation. The predominant finding is an assimilation effect (e.g. Stapel et al. 1998; Raghunathan and Irwin 2001). However, Meyers-Levy and Sternthal (1993) found a contrast effect when resource allocation was substantial. These observations raise the question of when a contextual prime from a different category will prompt assimilation and when it will stimulate contrast.

In understanding how other category products affect the evaluation of a target product, we posit that consumers evaluate a target product in a two-stage process: interpretation and judgment. At the interpretation stage, consumers first attempt to form a cognitive representation of ambiguous target information. If the information associated with another category product is accessible at this time, consumers are more likely to interpret the ambiguous target information as consistent with the context. This process will result in an assimilation effect. Assimilation is not the only possible effect of context that might occur during encoding. Making the context highly accessible may prompt consumers to recognize that the context influenced their representation of the target, and thus prompt them to correct for this bias. The process of correcting for the effect of context may result in a contrast effect if individuals overcorrect for the bias.

The judgment process is defined as locating the value of a stimulus along a specified dimension. To locate the value of the target interpreted at interpretation stage, it has to be compared to some referent or standard. If context information is used as a comparison standard at the judgment stage, the evaluation of the target is likely to be contrasted away from the context because the target and context are members of different categories.

Three experiments provide empirical support for the hypothesis. Experiment 1 investigates the moderating role of expertise on the impact of a contextual prime from a different category on target evaluations. We anticipated that experts would use a contextual prime when interpreting the target stimulus and exhibit an assimilation effect. Novices were expected use a contextual prime as a comparison standard that is manifested in a contrast effect. The results were consistent with this hypothesis. Novices exhibited a contrast effect whereas experts exhibited an assimilation effect when a different category context was primed.

In Experiments 2, the effects of increasing the accessibilities of the benefits associated with the prime on target evaluations were investigated. The notion is that increasing the accessibilities of the benefits will have different effects on novices and experts. We expected novices to include the benefits activated by the context prime when the benefits are highly accessible. On the other hand, experts were expected to correct their initial judgments because highly accessible benefits are likely to alert them of a biasing influence of the prime. The accessibility of benefits associated with the prime was manipulated by asking participants to write an appropriate word that best described the brand that was presented

in the context. The results in the low accessibility condition replicated our previous findings. Consistent with our previous findings, experts exhibited assimilation and novices exhibited contrast. Different outcomes emerged when the benefits implied by prime were made accessible. Here, novices exhibited assimilation. They responded in the same manner as experts did in the control condition. On the other hand, increased accessibility of information related to the prime alerted experts to correct their initial judgments. In the process they overcorrected and thus exhibited a correction contrast.

Experiment 3 shows that even when the contextual prime is made highly accessible, reducing the resources available for the processing task results in a comparison contrast for novices and an assimilation effect for experts. To examine this possibility, respondents were asked to engage in a secondary task while evaluating the target product.

These findings have important implications for contextual priming literature. They suggest that contexts from other categories can affect a target evaluation and that the specific context effect found is influenced by the respondent's knowledge of the target category and the accessibility of the contextual prime. The data also provide a means of distinguishing comparison and correction contrast by manipulating availability of cognitive resources. In so doing, the research questions whether factors such as the type of contextual prime (exemplar vs. trait) and the extremity of the prime are uniquely related to specific contrast effects, as has been suggested in the literature (Moskowitz and Skurnik 1999).

SPECIAL SESSION SUMMARY
Casino Gambling: Meanings, Motives and Marketers
June Cotte, University of Western Ontario, Canada

SESSION OVERVIEW

Generally speaking, the longer a gambler plays in a casino, the more likely that gambler will lose. What motivates consumers to gamble in casinos? How and why do gamblers play the games that they do? What is likely to trigger their urge to gamble? What role does the casino marketer play in gambling consumption? What aspects of the casino servicescape contribute to problem-gambling behavior?

These are important questions, given the massive increase in commercial gambling in North America. In 2003, there were 443 commercial casinos in the United States (not including racetrack casinos, or 'racinos'). From 1993 to 2003, U.S. consumer spending in commercial casinos rose from \$11 billion to \$27 billion. This means that in the U.S., consumers spend more in casinos than they spend on movies or amusement parks (American Gaming Association 2004). In terms of visits to casinos, about 53 million Americans visited a commercial casino in 2004, and the average number of trips to a casino, for those who have been, is almost 6 trips per year (American Gaming Association 2004). This means that Americans now make more visits to casinos than they do to major league baseball games. Although actual numbers in Canada are smaller (there are 60 government run casinos in Canada), the proportional increase in casino gambling is about the same. This seems particularly striking, as casino gambling basically began in Canada about 1993, yet casino revenues climbed to CDN\$4 billion by 2003 (Statistics Canada 2004).

There is a long history of research into gambling, across many disciplines. Historically, researchers focused on the pernicious effects of gambling, particular on the lower classes (see, for example, Veblen, 1899). Studying the underlying motives for gambling has also been popular across many social science disciplines: sociology (Bloch 1951; Fisher 1993; Frey 1984; Goffman 1967; Martinez 1983; Zola 1963), psychoanalytic theory (Bergler 1957; Fuller 1974), psychology (Custer 1982; Kusyszyn 1984; Montgomery and Kreitzer 1968; Moody 1992; Skinner 1953; Walker 1992), and the interdisciplinary study of play and leisure (Brenner and Brenner 1990; Caillois 1979; Csikszentmihalyi 1990; Herman 1967, 1976; Huizinga 1955; Smith and Abt 1984). As Cotte (1997) points out, the variously studied motives for gambling can be categorized into three general groups: economic (e.g., gambling as rational utility-seeking), symbolic (e.g., gambling as risk-taking, gambling as symbolic control, gambling as love), and hedonic (e.g., self-esteem enhancement, pure pleasure-seeking and play). What is still missing, however, is study on gambling as consumption (one exception is Loroz 2004). That is, gambling is more than a leisure behavior. It is a consumption site, albeit a unique one, and a place to explore consumer identity negotiation and the role of the market system (and marketers) in consumer behavior, at both more meso and individual levels. In short, casino gambling offers a fruitful opportunity to study consumer culture and its societal implications, making a contribution to consumer culture theory (CCT) (Arnould and Thompson 2005).

This session brings together three sets of researchers who have investigated the topic of casino gambling from a variety of very different perspectives, and with diverse methods. The first presenters take a public policy perspective, demonstrating the impact of casino design on resultant gambling behavior. From a different methodological perspective than traditional CCT projects, these

researchers are nonetheless focused on how consumers interpret the casino servicescape, and the possibly pathological outcome of a failure to deal well with the marketer-designed aspects of the casino environment. The second group of researchers takes a more managerial perspective, examining the meanings of casino gambling loyalty programs to consumers. The final presentation does not directly address societal implications, or managerial implications, but is focused on uncovering the identity projects gambling consumers are engaged in as they integrate regular gambling into their day-to-day lives.

In the first presentation, Finlay et al. examine the effects of varying environmental elements in casino design on the resultant emotional experiences of both problem and non-problem gamblers. The effects of casino lighting and color scheme were tested in two very different styles of casino theme: the *playground* design and the *gaming* design. They discuss the important implications for both casino design and treatment programs for problem gamblers. Their study adds to our understanding of the impact of the casino servicescape on dark-side consumption behavior.

From a more managerial perspective, Hendler and Braun-LaTour study whether casino loyalty programs create emotional commitment to a casino resort, or simply generate a feeling of entitlement to discounts and benefits. Casino slot clubs are the entities in the casinos that operationalize the collection of customer data and the delivery of loyalty program benefits. Seeking to better understand the impact of slot clubs on casino loyalty, these researchers investigate the deep meanings and emotions associated with such clubs. Their work is at the intersection of marketer-intended meanings, and the understood and enacted meaning of the consumer (Cotte and Ligas 1998). Within a theoretical framework of loyalty behavior, their work could help casinos—and perhaps other industries—to foster commitment to a brand or product, and perhaps avoid costly efforts that do not translate into attitudinal and behavioral loyalty.

Finally, Braun-Latour and Cotte present ZMET-style data on regular, local, casino gamblers in Las Vegas, Nevada. They examine three types of gamblers (slots vs. table gamblers vs. internet gamblers). They suggest that regular casino gamblers are a unique consumption subculture. With the increasing access and prevalence of casino gambling, both on-line and live, a better understanding of this subculture is important. Consumer research can benefit from a focus in this area because the nature of the marketer/casino and consumer exchange relationship is adversarial. Consumers know that casinos seek to gain their money, and consumers seek to beat the marketer; they consume to win. Consumption here is not as straightforward as exchanging money for experience (as in movie-going). The actual co-creation of the experience involves an explicit recognition that each party seeks to gain at the expense of the other. So studying the creation of consumer identity in this consumption domain can unearth unusual insights not possible in other sites.

The session also includes a discussion leader (David Sprott) with expertise in public policy and gambling. His comments concerning the potential societal implications of casino gambling should add a provocative conclusion to an engaging discussion. The proposed session should be quite attractive to at least four groups of ACR researchers: (1) those interested in transformative consumer research, particularly concerning "dark-side" behaviors, (2) those

researchers who work in the area of consumer motivation and goals, (3) researchers interesting in aspects of service provider loyalty, and (4) CCT researchers interested in a multi-method, multi-perspective approach to this unique consumption practice. We anticipate a very fruitful interchange of ideas among the various authors who will be presenting the three papers, the discussion leader, and with the audience members as well.

EXTENDED ABSTRACTS

“The Effect of Visual Stimuli in Casinos on Emotional Responses and Problem Gambling Behavior”

Karen Finlay, University of Guelph

Vinay Kanetkar, University of Guelph

Jane Londerville, University of Guelph

Harvey H. C. Marmurek, University of Guelph

We present the results of an experiment examining whether manipulations of environmental variables within gaming venues elicit emotions that influence problem gambling behaviour. We introduced the manipulations within two contrasting macro casino designs. The Kranes (1995) “playground” design is intended to be inviting and energizing, properties induced by thematic combinations of sunlight, warm colors, accessible green space and moving water. The Friedman (2000) “gaming” design places the gambling machines as the dominant decorative feature in a casino, relegating décor to highlight and enhance the equipment layout.

Within each macro casino design, it is possible to vary specific environmental elements that impact on emotional reactions to the gambling setting. In this study, we varied lighting (flashing versus static) and color scheme (bright versus monotone) that were expected to impact perceived levels of arousal. The index of gambling behavior was the stated intention to gamble beyond planned levels of time and money. It was hypothesized that flashing lights and the use of bright colors would increase arousal and the propensity to gamble irresponsibly in both the playground and gaming designs.

We ran two studies. In the lighting study, each participant viewed two videos of a gambling casino. One video represented a playground design and the other a gaming design (order was counterbalanced across participants). For half of the participants, both videos had static lighting; for the others, both videos had flashing lights. In the color study, each participant also viewed two videos of a gambling casino (playground; gaming). For half of the participants, both videos had bright coloring; for the others, both videos had monotone coloring. Thus, for each study, the design was a 2 x 2 mixed factorial where the between-subjects factor was the treatment (lighting or coloring) and the within-subjects factor was the design (playground and gaming).

Eight videos of a variety of casino settings were edited to 3-minute scenarios representing the following conditions: playground flashing; playground static; gaming flashing; gaming static; playground bright; playground monotone; gaming bright; gaming monotone. The participants were 188 gamblers who received \$30. Testing took place in small groups (3-10) in a mini theatre-style setting. Participants were asked to imagine how they would feel in the casino setting they were about to see.

Following each of two videos they viewed, participants completed 7-point scales measuring arousal and intention to gamble irresponsibly. Intention to gamble irresponsibly was gauged using a five-item, 7-point scale anchored by “totally disagree” and “totally agree.” Statements included, “I would have trouble quitting without placing one more bet at this place,” and “I would gamble/play more money than I intended at this place.” Arousal was measured with a 6-item scale (Mehrabian and Russell, 1974).

Respondents were asked to mark the spot on a -3 to +3 scale closer to the adjective anchor that better described their feelings about the casino simulation they had just viewed. Adjective descriptors for arousal included “calm” versus “excited” and “unaroused” versus “aroused.”

The intention to gamble excessively was stronger for the playground design ($M=3.88$) than for the gaming design ($M=3.28$), $F(1,90)=14.13, p=.00$. Gambling intention was marginally higher for flashing lights ($M=3.61$) than for static lighting ($M=3.28$), $F(1,90)=2.87, p=.09$. The interaction between design and lighting treatment was not significant. Arousal was significantly higher for playground than for gaming designs, $F(1,94)=17.05, p=.00$, and for flashing lights than for static lighting, $F(1,94)=6.75, p=.01$. The interaction of design and lighting approached significance, $F(1,94)=3.62, p=.06$. Flashing lights led to a greater increase in arousal for the gaming design (flashing $M=4.90$; static $M=4.16$) than for the playground design (flashing $M=5.19$; static $M=4.93$).

The interaction of macro design and color significantly affected excessive gambling intent, $F(1,89)=7.08, p=.01$. Whereas coloring had no effect on gambling intentions in the playground design (monotone $M=3.60$; bright $M=3.75$), the intention to gamble excessively was significantly higher for monotone ($M=3.49$) than for bright ($M=2.82$) colors in the gaming design.

Our research indicates that the incremental information afforded by flashing lights and bright colors impact emotions and gambling behavior. In both the playground and gaming designs, heightened arousal induced by flashing lights appears to exaggerate poor decisions made by gamblers who may be chasing losses by betting more than planned, spending more money than planned or by engaging in unplanned additional games.

Although coloring did not affect arousal, bright colors reduced negative gambling intentions in a gaming casino. This unexpected outcome may be related to the typical coloring within a casino. For the playground design, a variety of color formats may be typical. For the gaming design, bright coloring may be more common. Monotone coloring in the gaming casino may be incongruent leading to distraction and loss of control. Further research is required to test that hypothesis. At the conference, we will discuss the implications of these effects for public policy.

“An Assessment of the Value of Slot Clubs as Drivers of Casino Loyalty”

Flavia Hendler, University of Nevada–Las Vegas

Kathryn A. Braun-LaTour, University of Nevada–Las Vegas

Previous research has indicated that loyalty programs may not generate attitudinal loyalty or repeat purchases. In fact, some loyalty programs offer financial benefits and complimentary offers that basically translate into price discounts. Within particular markets, firms may be obliged to match benefits offered by its competitors in a form of price war, turning those programs into costly liabilities that do not necessarily strengthen their relationship with customers. A question that arises is whether loyalty programs, as they are currently structured, create emotional commitment to a brand or simply generate a feeling of entitlement to discounts and benefits. Another important question is what, in fact, creates loyalty.

The goal of our research is to better understand the impact of slot clubs on casino loyalty, where loyalty is defined as “a level of commitment to an organization or product that exclude competitors from the consideration set.” Casino slot clubs are the entities in the casinos that operationalize the collection of customer data and the delivery of loyalty program benefits. We investigate the deep meanings and emotions associated with such clubs using qualita-

tively-derived perceptual maps of mental models of slot clubs and casinos and their underlying constructs. Our findings enrich our understanding of the loyalty construct and reveal personal meanings associated with slot clubs and casino mega-resorts.

Traditional research methods are unable to fully evaluate the efficacy of loyalty programs. For example, when faced with a questionnaire, consumers may indicate that some benefits are important simply because they are widely offered within an industry, even if they do not necessarily impact the purchase decision. A methodology that explores emotions and unconscious motives will provide a better picture of the underlying dimensions of loyalty towards a casino brand and a loyalty program. Therefore, we used a qualitative methodology, namely the ZMET technique. By using images, metaphor elicitation, and laddering probes, this research focuses on the deep and multi-faceted meanings of a slot club from a consumer standpoint.

We will present data on Las Vegas slot customers, including local (Las Vegas residents) and non-local customers of a casino resort. High-rollers usually receive highly personalized treatment, while gamblers with low levels of play do not receive significant benefits. For this reason, this research focuses mainly on mid-range customers. Using Backman and Crompton's (1991) categorization to classify customers according to their level of loyalty, only truly loyal customers (displaying attitudinal and behavioral loyalty) are included in the sample.

The study of the deep emotional meanings of loyalty in casinos is particularly interesting because intuitively the purchase motives in gaming are highly emotional and perhaps even irrational. At the same time, casino customers may be highly value-driven, taking full advantage of the benefits provided in the clubs. In addition, each Las Vegas mega-resort is unique in terms of theme, location on the strip, and target market. In this sense, the casino product is not a commodity, and every property has potentially a different appeal to each customer. Furthermore, casinos track highly detailed information on customers. Particularly on slot machines, even penny transactions are recorded-as long as customers use their loyalty cards. Having this information allows casinos to customize offers and benefits to players according to the amount wagered and behavioral data (preferences, frequency of visit, etc.). However, the club loyalty benefits are generally quite similar among different establishments, resulting in the loyalty club becoming simply a form of discounting. For all the reasons above, the Las Vegas slot clubs are a good terrain to explore the deeper meanings of loyalty and reward programs more generally. Thus, this study should help casinos—and perhaps other industries—to foster commitment to a brand or product, and perhaps avoid costly efforts that do not translate in attitudinal and behavioral loyalty.

“Not Leaving Las Vegas: Identity Projects of Local Vegas Gamblers”

*Kathryn A. Braun-LaTour, University of Nevada–Las Vegas
June Cotte, University of Western Ontario*

Traditionally the gambling literature has treated slot machine and table gamers similarly, and on-line gambling has not been investigated at present. Observation shows that these three types of gamblers exert very different behaviors; the slot player tends to be more introspective, focusing on their machine and winnings, whereas the table gamer has to be more social, interacting with the dealer as well as other players. On-line gamblers need not leave their homes, although they enter a simulated casino environment.

But how does one get into the mind of a gambler? Observation does not reveal gamblers' inner motivations. Focus groups and surveys, while they may try to understand the gambler's behavior,

are subject to all sorts of biases which are likely to skew the results. For instance, a gambler may not consciously know or be able to articulate why they gamble or, in many cases, they may not want to admit why they gamble. For these reasons we allow participants to express themselves through images, the language of the brain, which helps reveal their underlying emotions and motivations. Using as a template the methodology developed by Gerald Zaltman (ZMET), we ask participants about their thoughts and feelings about gambling, using participant-supplied pictures as visual cues. Using techniques adapted from psychotherapy, cognitive neuroscience, psychology, and sociology, interviewers take participants through a series of exercises designed to reveal the fundamental feelings and beliefs that drive their actions.

We completed thirty one-on-one interviews that, on average, lasted about 75 minutes. We asked ten regular slot machine gamblers, ten on-line gamblers, and ten table gamers to bring in pictures of what gambling meant to them. The resulting interviews were driven by the pictures, as well as by some structured (primarily projective and sensory-related) questions we developed beforehand. The resulting data was about 900 pages of transcribed interview text and 150 scanned images. We coded the data, both verbal and visual, for important ideas and themes, and constructed maps connecting these ideas to form a comprehensive understanding of gambling and its role in gamblers' self-identity.

We uncover some intriguing findings about gamblers' interpretive strategies as they confront the marketplace culture of casino gambling, both live and on-line. In particular, we answer Arnold and Thompson's (2005) call for more examination of the use of localized cultural capital (gambling expertise) in defining self, and in-group/out-group status. Our results are organized as juxtaposed themes, including: social vs. anti-social; “brain-flushing” escape vs. active mental engagement; things that matter vs. things that don't; genuine vs. contrived environments; chasing highs vs. avoiding lows; tourists vs. “real” gamblers; winners vs. losers. Our presentation will use the images as well as the text to communicate the nuances and implications of our research.

SPECIAL SESSION SUMMARY

Instant Choices versus Slow-Developing Preferences: How Preferences Form and Change over Time

Wendy Liu, University of California Los Angeles, USA

SESSION OVERVIEW

By now it is accepted in consumer research that preferences are not innate, but instead are constructed in specific contexts (Bettman, Luce and Payne 1998). This view is amply evidenced in research demonstrating the instantaneous processes of preference construction, such as how people use information contained in a decision context to make choices. What is less understood, however, are preference construction processes that take place over time. That is, instead of making instant choices, people often develop preferences over time. How are preferences developed over time, and what are the characteristics of such processes? This session presents four papers that consider the dynamic course of preferences. Two of the papers—Amir and Levav, and Hoeffler et al.—focus on preference learning and change during the process of making multiple, successive choices and evaluations. The other two papers—Dijksterhuis, and Liu—discuss preference development during extended decision-making occasions.

Amir and Levav study how people develop preferences from making choices. They distinguish between learning of tradeoffs between conflicting attributes and learning a preference within a given context. They find that when people are forced to tradeoff attributes, they are more likely to develop preferences that are stable across contexts. In contrast, when people choose within contexts that avoid tradeoffs, they form a preference for that context only and show less preference stability across different contexts. The latter point suggests that sometimes repeated choices of the same option do not mean that a subjective attribute value has been learned, but that the decision-maker has simply learned that he or she prefers an option within a certain context. Hoeffler et al. investigate the impact of experience with options on preference learning by juxtaposing intensiveness (number of repetitions) and extensiveness (variety of options) in experience with options, and show that extensiveness leads to greater learning and better developed preferences for the products.

The next two projects turn to preference development in extended decision-making episodes. Liu examines the changes in preferences that occur when the consideration of the options is interrupted. Specifically, an interrupting interval causes changes in the processing of the options such that greater attention is given to the desirability rather than feasibility of the options, resulting in preferences drifting towards attractive but less feasible options such as high-risk high-return, and high-quality high-price options. Dijksterhuis on the other hand notes that over time, people may have the opportunity to process options offline, i.e., through non-conscious processes. The author contrasts conscious contemplation and non-conscious processing, and demonstrate periods of non-conscious processing can result in preferences for objectively superior options, and greater satisfaction over time.

The four projects together seek to present new perspectives on consumer preferences by focusing on the dynamic dimension of preference formation and change.

EXTENDED ABSTRACTS

“Choice Construction versus Preference Construction: The Instability of Preferences Learned in Context”

On Amir, University of California San Diego

Jonathan Levav, Columbia University

A relatively common interpretation of preference stability is that it reflects a condition in which the decision-maker has learned the value he or she places on each attribute. A consumer with stable preferences is, by this view, less likely to fall “prey” to the influence of contextual variables on choice. In this paper we argue that preference stability does not necessarily reflect a process of learning tradeoffs or some understanding of one’s subjective value for attributes. Instead, we suggest that when preferences are learned in context, e.g., when repeated choices are made from a set that includes an asymmetrically dominated (decoy) option, people simply learn their preference for generic properties of a choice set, rather than their preferences about the attributes themselves. We call this *choice construction*. In contrast, if a person is asked to make repeated choices between two options, he or she will be forced to make a tradeoff between one attribute and the other. This process will induce *preference construction*, and should yield preferences that are stable across contexts.

Our experiments included two phases for all participants. In the first phase, the “tradeoff learning task,” participants made six successive choices between equally priced options that varied only on two attributes; every choice required a tradeoff between these attributes. Each successive set of options became increasingly stronger along one attribute rather than the other, thus requiring increasingly difficult tradeoffs.

Experiment 1’s tradeoff learning task was structured in one of three ways. In the control (Binary Choice) condition participants made repeated choices between two options. In the Attraction condition participants made repeated choices between the same two options plus a third, asymmetrically dominated decoy option. In the Compromise condition the third option included an attribute level combination that placed it exactly between the attribute level combinations of the binary set. The objective of the Attraction and Compromise conditions was to create a choice situation in which participants would be more likely to use contextual cues to make their decision, rather than having to learn their subjective attribute importance weights.

The learning task was followed by a filler task and then a “target choice phase.” The target choice in all experiments presented participants with three options in an attraction effect setup. The choice set included options representing a trade-off more extreme than the last decision of the learning phase. In order to test for preference stability, the decoy was set to be asymmetrically dominated by the option at the opposite extreme from the participant’s last selection in the learning phase (i.e., their sixth decision). We assumed that this last selection reflected a strong preference for one attribute over the other. Our key dependent variable was whether participants were “tempted” by the decoy, and thus “switched” away from their previously preferred attribute combination. We expected that participants in the Attraction and Compromise conditions would switch more than their control condition counterparts

because the trinary choice sets would enable them to develop a preference for contextual cues rather than engage in the difficult act of trading-off one attribute for another. We also asked participants to indicate how strongly they preferred their chosen (target) option on a one to nine scale. We expected strength of preference to be greater for participants in the control condition because their preferences should be relatively more stable than experimental condition participants.

Our predicted data pattern emerged as expected. The proportion of participants who were “lured” by the decoy in the final, target choice was significantly lower in the control condition (31.2% switched) than either the Attraction (47.3%) or Compromise (59.3%) conditions. Additionally, mean preference strength was greater for non-switchers than switchers. This pattern becomes more extreme when we differentiate those participants who fell prey to the context from those who did not.

In our second experiment we confirm our interpretation that participants in our binary conditions learned trade-off values but that trinary condition participants did not. In this experiment we replicate the Binary Choice and Attraction condition procedures from Experiment 1, but also add a pair of similar conditions where we manipulate the difficulty of learning trade-offs in the experiment’s learning phase by presenting participants ranges of attribute values, rather than a precise number (e.g., “restaurant food quality: 3-3.5 stars”). We find that in both range conditions—Binary and Attraction—participants are more likely to be tempted by the decoy in the target choice. That is, when attributes are described in ranges, the Binary condition participants behave like those in the trinary condition. We argue that this is because the range manipulation made attribute trade-off learning more difficult, which ultimately led to less stable preferences.

In our third experiment we demonstrate that when participants are prodded to pay special attention to the tradeoffs inherent in their choices, they produce more stable preferences even when the choices are made in (a trinary choice) context. We replicate our procedure and basic result from the Binary and Attraction conditions of experiments 1 and 2, but find relatively high and equal preference stability irrespective of the presence of a contextual cue in the choice set when we give the simple instruction to pay special attention to the tradeoffs among the attributes. Thus, in study 1 we present the finding that preferences are less stable when learning in context. In study 2 we are able to exacerbate this difference, and in study 3 we are able to attenuate the difference. Throughout we replicate the basic difference between choice and preference construction that we find initially in study 1.

In summary, we present evidence distinguishing preference construction from choice construction. This perspective offers a new approach to understanding the persistence of context effects. Finally, we propose a more nuanced way to think about what choices imply about underlying preferences.

“Preference Exploration and Learning: The Role of Intensiveness and Extensiveness of Experience”

*Steve Hoeffler, University of North Carolina
Dan Ariely, Massachusetts Institute of Technology
Pat West, Ohio State University
Rod Duclos, University of North Carolina*

“Not alone age matures one, but breadth of experience and depth of reflection.” —Ross (1948, p. 214)

People’s preferences change dramatically over time. In most cases, the changes are too slow to draw attention, but when people look back at their past preferences, they sometimes find it shocking

to realize how much they have changed. These changes occur in most consumption domains. In addition, they include aspects for which people both increased and decreased their liking over time. A few examples of such changes are realizing that grilled cheese sandwiches are no longer the culinary ideal, developing a taste for beer, and looking forward to visiting a modern art museum. Yet knowing that preferences change is different from understanding how and why they change.

Prior research has focused on two broad classes of factors that exert influence on preference learning. One class of factors (e.g., biology and exposure) has a direct influence, whereby preferences respond to lower-order forces such as biological adaptation and sensory feedback. The second class of factors (e.g., informational goals and social learning) has an indirect influence, whereby preferences are subject to higher-order forces such as cognitive representations of (un)desirable end states. Both classes are important because they relate to the way a person learns about and constructs preferences. Despite the wide range of literature covered, however, we found a dearth of research on the role of breadth of experience in the preference formation process. Thus, we attempt to remedy this shortcoming by refining/partitioning the “experience” construct by introducing two new subconstructs: intensiveness and extensiveness of experience.

We succinctly define intensiveness of experience as the amount or frequency with which a person has been exposed to a product category. Alternatively, we define extensiveness of experience as the breadth or the variety of exposure a person has accumulated in a product environment throughout his or her consumption history. Intensiveness and extensiveness of experience are likely to be positively correlated in the real world, yet they need not accrue simultaneously. As suggested previously, it is possible to develop one aspect of experience (e.g., intensiveness) without necessarily enriching the other (e.g., extensiveness).

In light of this argument, we contend that a person’s preference formation will be influenced by the nature of prior experience. More specifically, the primary goal of this research (studies 1-2) is to examine whether preference learning (as indicated by the ability to identify, predict, and appreciate higher-quality products) is afforded more readily by intensiveness or extensiveness of experience. Our secondary goal is to identify some of the factors and mechanisms impacting extensiveness of experience and preference exploration (studies 3-5).

In study 1, to examine the relationship between experience and preference learning, we surveyed the intensiveness (e.g., number of years drinking beer, and number of beers consumed in a typical week) and extensiveness (e.g., number of brands regularly consumed, number of beer types experienced, and number of brands experienced) of experience of our research participants. Following this initial questionnaire, we tested participants’ knowledge of the category in a series of semantic tasks. From the performance exhibited on these tasks, we inferred the amount of preference learning accrued over time. We find that, while intensiveness of experience could not predict preference learning, extensiveness of experience did. Participants with higher breadth were better able to discriminate quality, knew a greater number of countries legitimately famous for producing high-quality beer, and were better able to estimate the alcohol content of beers.

In study 2, we used similar questions to estimate intensiveness and extensiveness of experience, but adopted a new set of dependent variables. In addition to the semantic measures of preference learning, we used sensory measures (e.g., blind test tastes). Again, we find that high-extensiveness participants were better able to identify and appreciate high-quality products and accurately predict their preferences than low-extensiveness participants. Inten-

siveness of experience, on the other hand, did not confer any benefit. To the extent that preferences are the product of both sensory and semantic knowledge, we infer that extensiveness of experience enhances both understanding of the product category and preference learning.

After identifying the advantages associated with extensiveness of experience, we next examine three mechanisms impacting the decision to experiment with novel alternatives in the real world. We use the term “preference exploration” to describe the very selection of novel options and the corresponding increase in people’s extensiveness of experience. So what are the factors that affect preference exploration?

The first factor we identify is the availability of a quality signal favoring novel options. In study 3, participants who were led to believe that novel juices (e.g., tamarind, guanabana, maracuja, and guava) were more popular in a foreign country were more likely to select those juices for trial. The second factor is the similarity of an advocate of a novel option. In study 4, when a similar model (i.e., a person of same age and gender) promoted the selection of a novel option, participants were more likely to demonstrate a willingness to try the item. The third factor is the favorability of a novel experience. In study 5, participants who had a negative initial experience with a novel juice were more likely to stay with familiar options in subsequent trials.

Far from construing intensiveness and extensiveness of experience as ends of one continuum, we present these constructs as two correlated, but potentially separable, dimensions along which individual experiences vary. Furthermore, we believe that both constructs can sometimes interact to influence the preference formation process. Finally, inspired by recent research in neuroscience (Munakata and O’Reilly 2003), we conjecture that, to the extent that preferences are the product of both semantic and sensory knowledge, intensiveness can play a preference-solidifying role by strengthening the linkages between the knowledge acquired through sensory exploration and that acquired through semantic exploration.

“The Effect of Decision Interruption and Suspension on Preferences”

Wendy Liu, *University of California Los Angeles*

Previous research in judgment and decision making has mainly focused on decisions made in one continuous manner—the person is presented with a choice, thinks through it, and selects the course of action. However, in real life, decisions are often interrupted or suspended. For example, a multitasking manager may be juggling several issues on the same work day. Thus when he/she faces a decision problem, he/she may need to attend to other businesses before returning to make the decision. Similarly, a consumer may be considering a purchase, but may sit on the decision for some time while pursuing other things in life.

Do interruptions and suspensions in decision making change people’s preferences? In this research, I focus on the change in information processing due to an interruption or suspension. Specifically, I propose two modes of attribute processing, namely, *compulsory processing* versus *voluntary processing*, and argue that when a decision is considered for the first time, the attributes of options are processed under compulsory mode such that they receive attention proportional to their perceived relevance to the decision. However, an interruption stops this processing, and when the decision resumes, the processing of the problem switches from compulsory mode to voluntary mode—upon a “revisit” to the problem, people (unintentionally) become more focused on aspects of the problem they are more naturally drawn to. In particular, I propose that compared to compulsory processing in which an option’s desirability (benefits, rewards) and feasibility (costs, con-

straints) are equally relevant, people voluntarily give greater attention to the desirability of options, and less attention to the feasibility of options, resulting in systematic shifts in preferences. I examine this possibility in two decision contexts, namely, risky choice, and price-quality tradeoffs, and show that an interruption or suspension makes people more risk-seeking, and more likely to choose high-price high-quality options.

Study 1 examines the effect of decision suspension on risky choice. Participants were given 6 decisions involving one option with a larger but less probable gain and another with a smaller but more probable (sometimes sure) gain. Consistent with prior research, winning is desirable, while the probability of winning indicates its feasibility (Sagristano, Trope and Liberman 2002). For each decision, half the participants were told that they should first learn about the choice, but not make a decision; instead they would turn to a different task. The interrupting filler task asked the participants to count backwards (e.g., “count backwards by 4 from 92 to 8”), typing down each step to make sure they followed instructions. Upon completion of the filler task, they were shown the risky choice again and asked to make a decision. The other half completed the filler task prior to the risky choice (thus equating any potential “priming” effect of fillers), and then made the choice at once without suspending it. In all 6 decisions, those who suspended their decisions were more likely to choose the risky option; the increases range from 7% to 14%, pooled average=10%, $p < .005$. Further analysis shows that the total amount of time spent on the decisions did not differ between conditions, and did not account for the effect.

Study 2 extends the result of study 1 on risky choice to unexpected interruptions. Specifically, this computerized study controls the process of reading about the options and deciding, by introducing information about the options gradually. After the last option’s information was presented, the no-interruption subjects spent an average of 8 seconds to come up with a decision. The interruption subjects were interrupted unexpectedly 3 seconds after the last information was presented (and hence have not made up their mind) and were asked to perform a filler task. Again, when they resumed, they were more likely to choose the riskier option (increase=23%, $p < .005$).

Study 3 conceptually extends the effect of interruption to another domain, namely, price-quality tradeoff. Because high quality is desirable while price serves as a feasibility constraint, interruption shifted preferences towards the high-quality high-price option over the low-quality low-price option (increase=8%, $p < .05$). Further analysis suggests consistent with the underlying mechanism of voluntary attention to desirability, the effect is stronger for hedonic products (11% increase) than for utilitarian products (4% increase), the later being instrumental to other goals but lack desirability in and of themselves.

In summary, this research examines the effect of decision interruption and suspension on preferences, and demonstrates a shift towards desirable but less feasible options due to a switch from compulsory to voluntary mode of information processing. This research has significant implications for marketers and consumers.

“New Insights on the Benefits of Unconscious Thought”

Ap Dijksterhuis, *University of Amsterdam*

Common knowledge dictates that conscious deliberation is the best strategy for making choices. Thorough contemplation, it is usually argued, leads to choices that are objectively better. We show that choosers can also engage in unconscious thought: After people have gathered information about various choice alternatives, they leave the development of a preference for one of the alternatives to the unconscious. In lay terms, people can “sleep on it”. We present

research showing that unconscious thought is often superior to conscious thought. In addition, we present research that sheds more light on how unconscious thought works, and we present some preliminary evidence about the moderating role of expertise in the fruitfulness of unconscious thought.

We base our recent research on the recently posited Unconscious Thought Theory (UTT; Dijksterhuis & Nordgren, in press). This theory postulates various characteristics about conscious thought and about unconscious thought. We argued that conscious thought is essentially very precise, but also suffers from low capacity. Unconscious thought, on the other hand, is less precise but also has no (or at least less) capacity issues. This led us to formulate and test the “deliberation-without-attention” hypothesis about the relation between mode of thought (conscious versus unconscious thought), complexity of choice and quality of choice. We hypothesize that simple decisions are made better after conscious thought, whereas complex decisions are made better after unconscious thought. We indeed found evidence for this, both in the laboratory as well as among actual shoppers (Dijksterhuis, Bos, Nordgren, & van Baaren, 2006).

In our laboratory studies, we presented our participants with information about four choice alternatives (e.g., four different cars) differing in overall attractiveness. These cars were either described by few aspects (4) or by a lot of aspects (12). After participants had read the information, they were either given time to consciously think about the four cars, or they were distracted so they could only engage in unconscious thought. We repeatedly showed that conscious thinkers more often chose the best car than unconscious thinkers when the choice context was simple (i.e., 4 aspects per car), but that unconscious thinkers made a better choice than conscious thinkers under conditions of complex decisions (12 aspects per car). We also have evidence that unconscious thought leads to more post-choice satisfaction among actual shoppers who bought complex products (e.g., furniture) but that conscious thought leads to more satisfaction for simple products (e.g., small appliances).

Recent research also shows that unconscious thought is goal-directed. We only engage in it when we are motivated to do so. In various experiments, we gave people a information about various alternatives, before dividing people into two conditions. In one condition, we distracted people for a few minutes but told them beforehand that they later had to choose between the alternatives. In another condition, we merely distracted people and told them they could forget about the choice alternatives. Only in the first condition we found effects of unconscious thought. That is, only people who knew they would have to make a choice later on made good decisions.

In all experiments that we had done until recently, participants were given all information relevant for making a choice. But what if people do not have this information? Is unconscious thought still helpful? In order to examine this, we looked at the role of expertise. In an 8-week period, participants were asked to predict scores in the Dutch soccer league every week (games are played each weekend). Participants either predicted without hardly any thought at all, or after conscious thought, or after unconscious thought. Participants were furthermore divided into two groups on the basis of their knowledge of soccer: Experts and non-experts. Again, unconscious thinkers made the most accurate predictions, but this was only true for experts. They could recruit relevant knowledge during unconscious thought to arrive at sound predictions. However, as the non-experts showed, unconscious thought is not helpful without having relevant information.

SPECIAL SESSION SUMMARY

Access versus Ownership in Consumer Research

Ashlee Humphreys, Northwestern University, USA

Markus Geisler, York University, Canada

SESSION OVERVIEW

This session sought to explore the distinction between access and ownership in consumption practices. We brought together three presentations that examined a paradigm shift from ownership to access organized consumer discourses, practices and theory. Within a paradigm of ownership, consumption objects are clearly defined, and the role of the consumer is circumscribed as simultaneous owner and user. Within a paradigm of access, however, property boundaries become blurred, and consumers play a more ambiguous role in constituting the consumption object by using objects that are not owned. As marketing paradigms evolve from a product-based orientation to a service-based orientation, these tensions between ownership and access have become more prominent in the marketplace (Vargo and Lusch 2005). Examining the relationships between access and ownership allows us to (1) explore the relationship between material and immaterial dimensions of consumption, (2) add to our understanding of how cultural values and interpretations are formulated and shared, and (3) document how consumers and producers collectively negotiate social and legal norms of access and ownership.

The applicability of this theoretical distinction was explored in three papers. Markus Giesler and Ashlee Humphreys examined the two conflicting paradigms in two consumption contexts: retail bookselling and music downloading. These two cases allow us the opportunity to theorize the dynamics between ownership and access, and its results at two levels of consumer-producer conflict, one cooperative and the other agonistic.

Clinton Lanier, Hope Schau, and Albert Muniz discussed the distinction's place in the consumer co-creation process in the case of three fan fictions (*Harry Potter*, *Xena: Warrior Princess*, and *Tom Petty and the Heartbreakers*). Although producers legally maintain the rights to the material aspects of mass culture, consumers co-create and disseminate the immaterial meanings and interpretations of popular culture. Who owns the "meaning" of these co-created texts is hotly contested between fans and producers. Traditional notions of ownership break down as we move from considering value as residing in the product to residing in the experience surrounding the product. The only way for producers to maintain ownership of the experience of the product is to restrict access to the product itself.

Eric Arnould, Carolyn Curasi, and Linda Price explored the interplay between access and ownership in a context in which access is historically privileged over ownership, and likewise takes precedence over ownership in several meaningful ways. In the context of Nebraska Century farms and ranches, access precedes ownership and flows uncontested into ownership. However, ownership must be earned via demonstration of guardianship skills. Ownership is a responsibility that entails considerable lifestyle trade-offs. A priority for agents occupying the guardianship role is securing access to the farm for existing and future generations of potential owners. Loss of the farm, which curtails future access, is a great ill, all guardians seek to avoid. Century farm families employ a variety of strategies to pass their farms forward into the future. A variety of economic and policy factors threaten the access/guardianship model of the Century farm.

Russell Belk then tied together the presented empirical work and drew conclusions using a framework of sharing and owning and contrasted them to previous work on material possessions. All three

presentations use the access/ownership distinction to theorize social relations between consumers and producers and between consumers themselves. By convening this session we tried to advance the understanding of these two modes of consumption and their interrelation in the marketplace.

EXTENDED ABSTRACTS

"Tensions between Access and Ownership in the Media Marketplace"

Markus Giesler, York University

Ashlee Humphreys, Northwestern University

When and why will a social actor use a framework of access over one of ownership? To answer this question, we examine ownership/access dynamics in the context of media consumption and production. Media products present us with a valuable opportunity to study the conflict between access, a viewpoint generally taken by the consumers of media that entails the sharing of goods and services, and ownership, the viewpoint more commonly taken by producers of media that entails placing restrictions on the circulation of goods and services. This paper seeks to organize and explain the tensions that arise between media producers and consumers based on divergent perspectives of the marketplace in two consumption domains, books and music.

Two ethnographic field studies of book and music consumption were undertaken including depth interviews, archival data, and extended experiential participation in a cultural context (Pettigrew 1990; Arnould and Wallendorf 1994; Stewart 1998). In the case of the bookselling industry, the transition from ownership to access, while on-going, has been relatively smooth and takes place through a process of continual gifting between company and consumer. In the case of the music industry, the transition from ownership has been contentious, heavily debated in popular and industry circles, and has taken the form of a social drama (Turner 1969).

In the case of bookselling, consumers have the option to read or 'access' titles in the store rather than to buy them outright. They view this access as a free service offered by the bookstore and use the service to read things they would not otherwise buy. Book producers, on the other hand, are structurally oriented toward selling media in material form. While they may offer free access to materials, they do so in order to entice consumers to buy and 'own' the book. The tension between access and ownership plays out as consumers try to maximize 'access' while producers try to place barriers on access in order to promote ownership.

In the case of music, downloaders, who are access-oriented, and music producers, who are ownership-oriented, are drawn into dramatic presentation efforts to legitimate their own cultural standpoint (Goffman 1959; Turner 1969). Members of each dramatic stakeholder group exert a moral demand upon their rivals and cultural bystanders to accept the cultural standpoint encoded in their dramatic performances as the most desirable, proper, or appropriate. Through their dramatic performances, consumers and producers invest themselves and others into a particular music marketplace ideology, legitimate their divergent cultural standpoint on music access and ownership, and reinforce their own sources of cultural identity and power.

In summary, this presentation contributes to our understanding of the access-ownership distinction in marketing in three

important ways. First, we profile media access and ownership as two fundamentally different perspectives in the marketplace. Second, we develop how these fundamental but abstract perspectives serve as a springboard for the construction of divergent dramatic narratives, roles, and behaviors. Finally, we show how marketplace stakeholders seek to manipulate the relationship between access and ownership to guide media consumption in particular directions. In summary, the two cases allow us to examine the multiple ways in which the tension between access and ownership can be negotiated, with more or less conflict between producers and consumers.

“Write and Wrong: Ownership, Access and Value In Consumer Co-Created Online Fan Fiction”

Clinton D. Lanier, Jr. University of Nebraska-Lincoln

Hope Jensen Schau, The University of Arizona

Albert M. Muñoz, Jr., DePaul University

This presentation specifically addresses issues of ownership and access in relation to fan community appropriation and alteration of media-based products through the writing of fan fiction (Bond and Michelson 2003; Caudill 2003). As marketing continues to evolve from a goods-centric to a service- and experience-centric dominant logic (Pralhad and Ramaswamy 2004, Vargo and Lusch 2004), the role of consumer involvement in the value and meaning creation process takes on greater importance. This active participation by the consumer exposes many of the limitations of our traditional understanding of property rights in marketing. It also raises many questions and concerns about the nature of products, consumer engagement, and the boundaries of consumer participation as they relate to access and ownership.

Copyrights protect intellectual property and lead to a legally legitimate and authenticated genealogy, but what happens when the protected property is subject to “textual poaching,” or the process in which people write around and through the “meta-text” of the protected property to meet their unique desires (Jenkins 1992)? The most common form of textual poaching by consumers is the writing of fan fiction. Because fans write stories that are based both on the primary text and the consumers’ imagination, we consider the writing of fan fiction as a form of active co-creation analogous to Vargo and Lusch’s (2004) new paradigm of marketing where consumers create both value and meaning, and are considered inextricable from the firm’s offering. Combining aspects of both the producers and consumers, the writing of fan fiction is considered a co-creation phenomenon in which consumers use the focal texts of mass culture as “cultural resources” to co-create the cultural meanings of popular culture (Fiske 1989). We interrogate the implicit assumption in this consumer orientation towards mass and popular culture, asserting that popular culture cannot be unilaterally produced or owned. We posit that media producers manufacture mass commodities (e.g., television programs, movies, music, fiction) and consumers turn them into popular culture through a co-creative process of access, interpretation, and identity negotiation (individual and collective).

In order to explore issues of ownership and access associated with the phenomenon of fan co-creation of media-based products, we examine three organically formed fan communities (Harry Potter, *Xena: Warrior Princess*, and Tom Petty and the Heartbreakers) and their interaction with three different types of media “texts” (i.e., novels, television shows, and music). We monitor ten online forums that contain fan fiction in a manner analogous to naturalistic observation: four devoted to Harry Potter fan fiction, four centered on *Xena: Warrior Princess*, and two related (directly and indirectly) to Tom Petty and the Heartbreakers. We analyze the content of the fan fiction on each site, the manner in which it is disseminated,

and discussions surrounding its interpretation and meanings to the fan communities and their various factions.

Through examination of these three fan communities, we find that fans engage in co-creation of meaning and value through the writing of fan fiction that involves the focal texts of the community. We find that this access-oriented form of co-creation is a transformative process that converts the commodities of mass culture into meta-texts of popular culture. That is, although producers legally maintain the rights to the “material” aspects of mass culture, consumers co-create and disseminate the “immaterial” meanings and interpretations of popular culture. Who owns the “meaning” of these co-created texts is hotly contested between fans and producers. We also find that the success of fan co-creation is based on the richness of the focal text, what is left unwritten in the focal text, and the degree to which the focal text can be appropriated and reconstructed by the consumer. Harry Potter, *Xena* and Tom Petty fan fiction writers all adore the focal texts, are intrigued by what is not contained in these texts, and engage in poaching and refashioning these texts to create broader meanings that meet their individual needs and the needs of the fan community.

We also find that the writing of fan fiction allows consumers to mitigate the cultural tensions between mass culture and popular culture. Although the products of mass culture are often described as the primary hegemonic tool of capitalist society to oppress and pacify the masses (Adorno and Horkheimer 1979), this co-creative process allows consumers to alleviate their feelings of being exploited and alienated by actively engaging these “texts” to produce the meanings of popular culture. Interestingly, although consumers are able to carve out a separate cultural space (i.e., popular culture) in which to create their own symbolic meanings and build their own communities, they replace one form of tension (mass culture vs. popular culture) for another (the tensions that exist between equally adoring fans with disparate reads of the focal storyline). In a sense, after transcending the issue of ownership, consumers wage their own internal battles concerning access and the degree of transformation of the focal text. We posit that the latter tension is preferable to consumers because it is a byproduct of the co-creation process and part of the tensions that consumers actively employ between individual and collective identities (Arnould and Price 2000; Schau and Muniz 2002).

In addition, these communities also face anxieties as some producers try to wrest control of the focal text away from highly involved fan consumers. Some producers of mediated-texts (e.g., Anne Rice) attempt to strictly control both the material and immaterial aspects of the focal text. This typically does not stop the fan community from co-creating their own texts and meanings, but usually forces them underground. Other producers attempt to put boundaries on how far the characters, meanings, etc. of their texts can be extended (e.g., many producers forbid the creation of sexually explicit stories based on their characters). A few producers actually invite consumers to suggest ways to extend the meaning of the focal text in upcoming productions. Since there are obvious advantages to producers from encouraging consumers to co-create with their products (e.g., the transformation of products from mass to popular culture), the issue of how much access and control to provide to consumers will need to be carefully considered.

We contribute to the existing literature by arguing that traditional notions of ownership break down as we move from considering value as residing in the product to residing in the experience and meaning surrounding the product. The only way for producers to maintain ownership of the “immaterial” aspects of the product is to restrict access to the product itself. Obviously, this defeats the purpose of any market offering and is almost impossible to control.

Likewise, although Holt (2004) asserts that it is the cohesive myth that binds people to a community, we find that it is precisely what is left unwritten in the focal text that inspires fans to actively engage in co-creation and form fan communities. Lastly, although the co-creation literature views this process as between producers and consumers (or consumption communities), it does not really address how co-creation goes on between consumers. Members of these fan communities not only engage the focal text (i.e., meaning creation and interpretation), but also co-create texts with other consumers (i.e., meaning development). This process generates the “meta-text,” which in turn provides consumers with more “cultural resources” to continue their creative endeavors.

“Guardianship and Access on Nebraska Century Farms”

Eric Arnould, University of Arizona

Carolyn Curasi, Georgia State University

Linda Price, University of Arizona

Nebraska “Century Farm” families have owned a farm or ranch for at least one hundred years. Perhaps paradoxically, our research with these families extends our understanding of a paradigm of object relationships highlighting access, where property is in some sense shared, and the agents involved have complex roles in constituting consumption objects imbued with relational symbolism within kinship groups (Curasi, Price and Arnould 2004; McGraw, Tetlock and Kristel 2003). Our research exposes cultural tensions agents experience between guardianship of something inalienable and loss through alienation, as well as the way these tensions shape their “curatorial” consumption (McCracken 1988). Access to and transfer of Century farms illustrate the interplay between alienability and inalienability across generations of farm families. Our paper exposes a variety of tactics for establishing and maintaining guardianship of the farm as site of production and consumption.

The Aksarben Foundation recognizes over 5000 Century Farms in Nebraska. Given the history of settlement, this often means a single family has held title to these farms since the original homesteading in the 1870s and 1880s, which was itself an access gaining process. In other words, Century farms have been transferred between four and six generations of farm family members. We conducted long interviews with over 30 families and participant observation with two of them to investigate contemporary management practices, curatorial consumption and family farm culture.

For individual agents, access to the farm precedes ownership and typically is mediated by kinship, that is, nuclear or extended family membership. It is enacted over time through expressions of interest that senior guardians recognize in more junior kinsfolk, and through their investment of productive labor in farming operations. Access may lead to increasing levels of agent’s engagement or desire for ownership/guardianship. Engagement is effortful. It is expressed through obtaining educational qualifications. It is further expressed through farmers’ commitment to what they term stewardship, care of the land and steps taken to improve it, such as sustainable management practices with a view to preserving access for future generations. In some cases, rescuing a failing family member’s farm operation may entitle one to greater say in the eventual disposition of the heritage farm removed from risk. Heirs are not simply designated, but become heirs through long-term demonstration of effort, worth, and ability.

Guardianship entails lifestyle commitments involving trade-offs between investments in the farm and additional land (rent and purchase) and consumption attractions available to city dwellers such as vacations, nice clothing, and the like (Machum 2005). Those who enjoy current guardianship/ownership make choices to

have access to the farm and the way of life it entails instead of something else (due to time, money, etc). A jack of all trades’ ethos with regard to production, and an attitude disparaging of farmers who engage in conspicuous consumption of new agricultural equipment or materialistic lifestyles was common among Century farms owners/guardians.

In this context, access has preeminence over ownership. As a necessary precursor to guardianship/ownership, access flows naturally into guardianship. Absentee owners, i.e., those without day-to-day access, even cash renters are suspect, even resented. This may be because absenteeism and alienated relationships to the land threaten the access-guardianship pathway. Access to the farm induces positive identity claims and symbolism that are shared with younger family members. Through the length of time they’re on their land, many Century farm families feel they have earned a type of distinction that resonates with the concept of ‘patina’ associated with inherited family possessions before the industrial revolution. Many informants seem to feel that Century Farm families have earned a level of distinction (good character, dependability, strong work ethic, faith, etc.) due in part to the longevity of their guardianship, and that these distinctions are lost when access is lost, but may be regained if access is renewed.

Guardians go to some lengths to preserve access for themselves and future generations (Coyné 2005). Developing niche markets and blending farm and off-farm income sources are tactics some employ (Edgcomb and Thetford 2004). A legacy of cautious innovation is common among these families. Nevertheless, market pressures lead some families to expand the scale of farmland and farm operations at the expense of other harder-pressed farm families. Guardians that are unable to actively farm the land due to financial reversals or advancing age may rent their farm to others family members preferentially but not necessarily, but resist the temptation to sell it out of the family. In these cases, they trade off their own access to the land against the responsibility to act as guardians for future generations. They express the hope that some family member will be able and willing to take over access and guardianship of the farm. Guardians also gift access of the farm to family members who have migrated to town or to other states, and encourage members of the migrants’ families to return for the agricultural summer season or important family holidays. In this way, ownership is symbolically shared and future guardians are sometimes even recruited. Those who see an off-farm future ahead express regret and misgivings.

Century farm families engage in creative strategies to retain family farms within the family and across generations. Farm transfer practices are quite complex from family to family. Engagement is expressed in an array of everyday practices such as ongoing labor commitments in the absence of ownership guaranties. This behavior is characteristic of younger family members who may hope to assume guardianship of the farm at some future point. Living trusts, intergenerational gifting, intergenerational installment purchase, investments of labor and even capital investments by younger family members in the farm to which they do not have title, are among the tactics employed to transfer guardianship between generations of farm families. Older guardians may signal progressive transfers and their change in status by moving from the main house to a secondary home either built on the property or at its margin, or in some cases in nearby small towns. Overall, progressive intergenerational transfer of limited rights characterizes these practices.

We found many cases where the burden of guardianship (Curasi, Price and Arnould 2004) had become great; farming is just “no fun” anymore, and selling out appears to be the only option.

Still, many informants indicate that an important goal is to pass the farm forward into the future, and they desire at all costs to avoid being the one who "lost the farm." These behaviors resonate with those of the guardians of inalienable wealth in other contexts (Curasi, Price and Arnould 2004). In other words, curatorial behavior is a key factor distinguishing the behavioral models of family and corporate farming in the minds of our informants.

Today, working century farm families operate within a complex and highly competitive market economy that imposes a host of threats to the guardianship/ownership model (Hassebrook 1999; Salamon and Toratore 1994). But family farms persist, and Nebraska Century farmers recognize significant distinctions between the logic of family farm operations and those of corporate farms.

SPECIAL SESSION SUMMARY
‘Fakin’ It’’: Why Do Consumers Buy Counterfeit Goods?
Sankar Sen, Baruch College/CUNY, USA

SESSION OVERVIEW

Objective. Despite a booming multi-billion dollar global market for counterfeit goods, academic research on the consumption of such goods remains sparse. Who are the consumers of counterfeit goods? Why do they engage in such illegal consumption behaviors, even when they can afford the genuine goods? And how do others view those who engage in such questionable but, at the same time, often *de rigueur* actions? These are the questions that motivate this session, the objective of which is to further our understanding of this increasingly important but largely overlooked domain of consumption behavior.

Content. This session comprises four papers that together shed light on the individual and product-specific determinants, the motivational underpinnings, and the social and product-specific consequences of counterfeit good consumption. The papers are in advanced stages of completion, each containing empirical findings from one or more studies. The session’s scope is both broad and deep: the papers draw on a diversity of theoretical and empirical perspectives to contribute towards an incipient but persuasive, coherent understanding of how the social environment interacts with individual motivations to influence the consumption of counterfeit goods.

The first two papers examine the nature and extent of social sanction for counterfeit consumption behavior. The Geiger-Oneto paper draws on social identity theory to implicate the counterfeit buyer’s social distance as a determinant of others’ reactions of such a person. While counterfeit buyers are in general evaluated less favorably than buyers of genuine brands, the former are evaluated more favorably when they are members of an in-group than of an out-group. The Chang, Keinan and Lehman paper examines the moderating role of product type on such social perceptions by undertaking a product-specific (i.e., hedonic versus utilitarian) investigation of people’s opinions of counterfeit good buyers on dimensions of morality, likeability and attractiveness as a social other (e.g., friend, fellow shopper, etc.). Interestingly, while buyers of counterfeit utilitarian goods (e.g., software) are viewed as less moral, fair and considerate compared to buyers of the genuine versions, buyers of counterfeit hedonic goods (e.g., fashion) are viewed as more moral, fair and considerate compared to buyers of the real goods.

The final two papers complement the first set by investigating the socially-driven motivations guiding consumers’ pre- and post-counterfeit good purchase psychologies. The McCabe & Rosenbaum paper draws on sociological research on delinquent behavior to examine how consumers rationalize this illegal consumption behavior. Their findings suggests that consumers of counterfeit luxury branded goods not only employ multiple rationalizations to justify their purchases but also do not, paradoxically, desire the real brands any less. The Wilcox, Kim and Sen paper draws on theories of self-monitoring and accompanying attitude functions (social-adjustive vs. value-expressive) to demonstrate a consumer by product interaction in the motivations underlying purchases of counterfeit luxury brands: the purchase decision of low versus high self-monitors is differentially influenced by the extent to which the counterfeit product is identifiable as a desired luxury brand.

Structure. Each presentation will be 20 minutes long. As with most fruitful sessions on emerging topics, this session is likely to generate more questions than answers and the final 10 minutes of

the session will be devoted to a discussion of worthy research directions in this domain of consumer behavior.

Audience. The potential audience for this session is quite broad. It will appeal to researchers interested in illegal/aberrant consumption behaviors as well as, more broadly, to those interested in consumer decision making, motivation, and social norms and influences. Equally importantly, the session will be of interest to practitioners and regulators seeking to formulate effective anti-counterfeiting or piracy policies/strategies grounded in consumer insights.

Contributions. The contributions of this session are four-fold. First, it enhances our substantive understanding of the motivational and social underpinnings of an increasingly important domain of consumption behavior. Second, it draws on relevant theories of motivation, perception, preference and groups to advance our theoretical understanding of counterfeit good consumption. Third, this session combines the internal control of experimental work with the external validity of field surveys and ethnography to yield a methodologically robust set of insights into the consumption of counterfeit goods. Finally, this session brings together a diverse set of researchers whose research efforts in the area of counterfeit good consumption complement each other in the articulation of a fruitful research agenda on this important but under-examined consumer behavior topic.

Cueing Common Ecological Behaviors to Increase Environmental Attitudes and Behavior

Gert Cornelissen, Catholic University Leuven, Belgium
Mario Pandelaere, Catholic University Leuven, Belgium
Luk Warlop, Catholic University Leuven, Belgium
Siegfried, Dewitte, University Leuven, Belgium

EXTENDED ABSTRACT

The appeal for social marketing research to serve consumers' and society's long term well-being and address sustainable consumption issues has been put forward since the early 70's (Andreasen 1995; Kotler and Zaltman 1971). The promotion of sustainable consumption behavior has shown to be an arduous task for governments and organization acting as behavioral managers, despite an increased interest of the general public in sustainable development. An often cited reason for this phenomenon is that people associate sustainable behavior with behavioral costs like money, time, effort and inconvenience (Pieters et al. 1998; Thøgersen 1994). In the present paper we focus on ecological behavior in specific and propose a technique, which aims to improve consumers' attitude towards specific environmental acts, and to increase their adoption of environmental behaviors.

Bem's self-perception theory (1972) proposed that attitudes may be inferred from previous behavior, especially when attitudes are to be constructed on the spot, or when existing attitudes are ambiguous or weak (Holland, Verplanken, and Van Knippenberg 2002). When deriving one's attitude towards pro-environmental behaviors, an individual can base his or her judgment on the availability of instances of previously performed environmental behaviors in memory (e.g., Tversky & Kahneman's availability heuristic (1973)). Increasing this perceived availability may thus render people's attitudes more favorable.

We propose that cueing people with commonly performed environmental behaviors may therefore render their attitude towards ecological behavior more positive. First, showing that they actually do perform environmental acts quite frequently in their daily lives increases the perceived availability of these behaviors. Second, cueing may render behaviors more relevant as a source of information to infer one's attitudes from. As a matter of fact, people may not perceive certain environmental acts as being informative when deriving their attitudes. This is the case when the behavior is seen as a social norm or when they attribute it to other motives than their green ethics, like financial reasons. This conjecture was supported by a first pre-study ($N=32$). From a 'logic of conversation'-perspective, cueing these behaviors as environmental acts will render them relevant as information to derive attitudes from (Grice 1975; Schwarz 1994).

A second pre-study ($N=42$) confirmed the assumption that the perceived ease with which participants could generate instances of previous environmental acts is correlated with their attitude towards environmental acts. In Study 1 ($N=160$) we examined the effect of cueing commonly performed environmental behaviors on attitudes. We constructed three sets of behaviors. One set contained *environmental behaviors which people usually perform*. These were the eight most often mentioned behaviors of this type, by participants in the second pre-study. Similarly, the second set was constructed to contain eight *environmental behaviors which people usually do not perform*. A control set contained eight behaviors, unrelated to ecology. Participants were randomly assigned to one of three groups, each of which received one of the three sets of behaviors. They were asked to indicate how frequently they engage in each of them. This way we created an *ecologically cued group*, a *non-ecologically cued group* and a *control group*. The results indicated that the ecologically cued group indeed showed more

favorable attitudes towards environmental behavior, perceived themselves more as ecological consumers and indicated a higher feeling or moral obligation to protect the environment than participants in either of the other two groups. Between the non-ecologically cued group and control group, no significant effects were obtained on any of the measures.

In Study 2 ($N=66$) we verified whether this increase in favorability of people's attitudes also renders their consumption decisions more ecologically sound. The manipulation used was identical to the one of Study 1. After the cueing manipulation, participants had to make several ecology-related decisions. First, they were asked to imagine being in a shopping environment and had to make purchase decisions. They were presented with ten product pairs: five filler pairs and five critical pairs. In each critical pair, one product was a more environmentally friendly but more expensive alternative of the other. We counted the number of environmentally friendly choices, which was higher for the ecologically cued group. A second task measured environmental conduct in a more subtle way. Participants were asked making notes for a task supposedly investigating the type of information consumers deem most important when reading product claims. We actually measured the efficiency with which participants used scratch paper. Again the ecologically cued group showed to behave in a more environmentally friendly way by using the available scratch paper more efficiently, and writing smaller than both other groups. Finally, to measure behavior in a more involving task, we offered participants to take a notepad home. They had to choose between a notepad containing the less appealing brownish recycled paper and a notepad with normal white paper. A higher percentage of participants in the ecologically cued group (81 %) and a smaller percentage of participants in the non-ecologically cued group (23 %), chose the recycled paper, compared to the control condition (52 %). On both other behavioral measures, these last two groups did not differ.

Our data suggest that drawing attention to the ecological acts people already engage in, improves people's attitudes towards ecological behaviors, with an analog effect on their behavior.

These results allow us to propose some guidelines for designing effective social marketing efforts for other sustainable behaviors as well.

Traditional campaigns are known to elicit aversive feelings towards the request, by creating guilt and using a paternalistic approach. Our technique approaches people in a more positive way, which is more likely to be accepted by the public. Second, traditional campaigns usually provide an external motivation for behavioral change, asking people to make a personal sacrifice for the benefit of society in general. However, external motivation usually results in reduced performance and reduced persistence of a behavior (Ryan and Deci 2000). To the extent that our cueing approach causes a *greener* perception of self, this might lead to internally motivated behavior, resulting in better performance and persistence of the promoted behavior.

Progressing a Taxonomy of Possible Reflexivities: Guidelines for Reflexive Practice in Consumer Research

Shona Bettany, University of Bradford, UK

Helen Woodruffe-Burton, University of Lancaster and University College of St. Martins, UK

EXTENDED ABSTRACT

Reflexivity has been identified in consumer research (Wallendorf and Brucks, 1993, Hirschman 1993, Thompson 2002) and in the wider social sciences (e.g. Wasserfall, 1993, Mauthner and Doucet, 1998, 2003) as a way to address power and control in the research encounter, to attend to the researcher/researched dynamic and to give insightful commentaries into the research process itself. The 'reflexive turn' (Weick 1999) has emerged in the social sciences largely as a response to the notion that data collection and analysis is a neutral activity, a technology of knowledge making in which the researcher can take a disinterested, objective position in relation to their research. Reflexivity instead is used to highlight the personal, interpersonal, emotional, institutional, disciplinary and pragmatic influences on the research, as well as the methodological, epistemological and ontological assumptions built in to specific approaches (Mauthner and Doucet 2003). As such, reflexivity has been seen a route to more accountable and responsible research, and as a stimulus to better accounts of the social and cultural world.

Researcher reflexivity has been conceptualised in consumer research discourse as a sub type of introspection. It is argued that there is much to recommend reflexivity as a practice in consumer research as it will 'improve our understanding of the actual research process' and act as such to develop consumer research theory (Wallendorf and Brucks 1993:355). Additionally it has been seen as a way to address the power issues in consumer research and specifically the instrumentality of the researcher/respondent relationship. For example, Hirschman (1993:551) advocates a more reflexive approach to research, and argues against the use of detached and 'objective' methods in consumer research. She exhorts consumer researchers to 'choose to abandon any method or practice that is premised on power inequalities between researcher and subject' she argues that research should be designed which recognises respondents as 'equal sentient beings'.

Although it is clear that consumer researchers have found the idea of reflexivity attractive and recognised its potentials, there is a need to develop the discourses already apparent in consumer research and formalise the conceptualisation and operation of this research approach. Currently, despite significant discourse around the issue in the wider social sciences there seems to be a lack of discourse around reflexivity in consumer behaviour research and although reflexive practice is evident in some work, the research processes around reflexive research are not articulated clearly, and a plethora of different approaches are evident. The aim of this paper is to stimulate essential new discourse around the practice of reflexivity. In order to do this it is necessary to formalise and structure reflexive practices as a foundation and basis for discussion. This work examines the many different reflexivities which might be enacted within consumer research and their concomitant implications and foundations. To accomplish this it provides a taxonomy of 'possible reflexivities' to structure the debate around this element of consumer research and to guide the potentially reflexive consumer researcher. The possible reflexivities which emerge from this study are envisaged as 'Objectivist Reflexivity', 'Experiential Reflexivity', 'Perspectival Reflexivity' and 'Multiplex Reflexivity'. The possibilities we have identified are distinguished by the dimensions of ontology and power in the research

encounter; this position, we believe, reflects closely key issues in contemporary consumer research. In terms of ontology, we reflected upon reflexivity as it has been seen as a route to better knowledge and enhanced theory building through reflection on the process of research. This to us suggested questions and challenges arising pertaining to the 'reality' of the research process, not just in terms of what 'really' happened, but the models of reality implied in different reflexive approaches. Different types of reflexivity, like different research approaches, carry their own ontological assumptions about the nature of subjects (researcher and researched) and what knowledge is and how it is constructed. These assumptions are clearly crucial to the conceptualisation of multiple reflexivities and render attempts to achieve closure around the notion of reflexivity as a singular concept highly problematic. Attending to ontology as one of the axes in our taxonomy allowed us to structure our theorising to account for this multiplicity of reflexivities and the constitutive and generated realities they imply. In terms of power, this pertains to reflexivity as a route to addressing the power imbalances and issues inherent in any research encounter, whether that be conceptualised in terms of an overt remit for an emancipatory research politics, or as a way to direct the researcher encounter towards one with less of a dominating and instrumental dynamic. For us, reflexivity is inherently political; our exposure to it initially emerged from our own engagement with feminist theory and our identification as feminist researchers. Reflexivity has been seen by feminist researchers (and other critical researchers) as a political tool for critically engaging with power issues in research (Ramazanoglu and Holland 2002). Underpinning the different types of reflexivity in our taxonomy are assumptions relating to the nature of power in the researcher/respondent relationship and these different reflexivities also generate different (and sometimes ambivalent) power relations in the research encounter. In terms of this constitutive and generative relation to power we found that the taxonomy of reflexivities was a useful tool to reflect in a more structured manner upon the shifts in the researcher/respondent power dynamic which occurred at different parts of our own research. As Wolf (1996) has argued, power differentials are an inevitable part of research, and the necessity is to critically reflect upon these inevitable differentials and the way that these shift and transform as the research progresses. Attending to power as one axis of our taxonomy allowed us to structure our thinking about reflexivity in terms of these shifting power relations.

This paper progresses the authors' recent work on researcher reflexivity which has been developed and augmented with practical guidelines for the different approaches to reflexivity. Guidelines for practical action and points for reflection are given which relate to each of the possible reflexivities outlined in the taxonomy.

Auspiciousness: Coping with Kratophany

Karen V. Fernandez, University of Auckland, New Zealand

Ekant Veer, University of Auckland, New Zealand

John L. Lastovicka, Arizona State University, USA

The sacred, described as “more significant, powerful and extraordinary than the self” (Belk, Wallendorf and Sherry, 1989, p.13) is distinguished from the merely special by the key characteristic of efficacy. Belk et al. (1989) also note that the sacred should be approached with care, because the sacred has kratophanous power. Kratophany—the simultaneous devotion to, and fear of, the sacred (Pimentel and Reynolds 2004)—is experienced by consumers because the efficacious power of the sacred is unpredictably multi-valenced: it can be manifest in a benevolent and/or malevolent way (Belk and Wallendorf 1990). Accordingly, when consumers seek the benevolence of the good-sacred, they likely also expose themselves to the malevolence of the bad-sacred (Belk and Wallendorf 1990). Consequently, consumers can simultaneously experience strong positive feelings (e.g. devotion) and strong negative feelings (e.g. fear) towards the sacred (Belk et al. 1989; Pimentel and Reynolds 2004).

Belk et al. (1989, p.8) suggest that ritual prepares profane persons to approach the sacred, and surrounds the contact of these profane persons with the sacred to forestall the unleashing of the evil powers of the sacred. We believe this implies that consumers require ways to cope, when faced with the kratophanous power of the sacred. Consumer researchers have not yet devoted much attention to discovering these coping mechanisms. Consequently, we begin to fill this gap in the consumer research literature by examining how Hindu Indians use auspiciousness to cope when faced with the tension inherent in their kratophanous reactions to the sacred.

THEORETICAL FOUNDATIONS

The Meaning of Kratophany

The term kratophany was introduced into the English language by Mircea Eliade, as a technical term meaning “an appearance of the sacred in which the experience of power dominates” (Miller 2005). Belk et al. (1989) introduced kratophany to the consumer literature as one of the twelve properties of the sacred, and explained kratophany as the *ability of the sacred* to elicit both strong approach and strong avoidance tendencies. More recently, Pimentel and Reynolds (2004) defined kratophany as the simultaneous devotion to, and fear of, the sacred. This later definition, which focuses on *consumers’ reactions to the sacred*, is consistent with the way the term has been used in more recent consumer research (e.g. Curasi, Price and Arnould 2004). Our reading of the relevant extant literature suggests that consumer researchers’ progress in understanding of kratophany may have been impeded because kratophany has been used to describe *both* the sacred, *and* consumers reactions to the sacred. We adopt Pimentel and Reynold’s (2004) definition of kratophany, and carefully distinguish between “the kratophanous power of the sacred” (a property of the sacred) and kratophany (consumers’ strong, mixed reactions when faced with the sacred’s kratophanous power), throughout this paper.

Coping with Kratophany

Although Belk et al. (1989) give different examples of sacred entities associated with the benevolent good-sacred (e.g. gods) and malevolent bad-sacred (e.g. corpses) powers respectively, they then note that consumers fear malevolence, at the same time as they seek benevolence. Although some entities may be largely seen as

benevolent, and some may be largely seen as malevolent, all sacred entities have the potential to be both benevolent and malevolent, provoking mixed feelings of awe and terror (Belk et al. 1989). We surmise from this that kratophany exists because the power of the sacred does not operate on a simple continuum. Instead, sacred power can be manifest along two orthogonal dimensions—a dimension of good-sacredness and a dimension of bad-sacredness. It is the two-dimensional nature of sacred power, coupled with its unpredictability, which generates the tension inherent in kratophany. Furthermore, even when particular sacred entities are usually perceived of as wholly benevolent, these entities tend to be approached with care, because the power of the sacred, irrespective of its valence, is understood to be dangerous to ordinary beings. It seems logical that consumers would employ coping mechanisms to deal the kratophanous power of the sacred. Accordingly, we ask what these forms these coping mechanisms might take.

Belk and Wallendorf (1990) examine one such kratophanous sacred entity—money—in depth, and suggest that money can be perceived as kratophanous by consumers because it is viewed as having both malevolent and benevolent powers. We surmise from their work that if sacred power is NOT understood or perceived as multi-valenced (for example a child’s faith in a wholly benevolent God), then kratophany may be considerably lessened. Hence it is possible that consumers could cope with kratophany by choosing to view the sacred entity is purely benevolent (leading to a pure approach orientation) or by viewing the sacred entity as purely malevolent (leading to a pure avoidance orientation). To be precise, in these situations, choosing to perceive the sacred entity as wholly positive or wholly negative collapses the good-sacred bad-sacred dialectic to a simple continuum anchored on either end by the benevolent good-sacred and the malevolent bad-sacred respectively. However, a consumer with an approach orientation to the sacred would still need to undertake further preparatory rituals such as self-cleansing, because of the danger inherent in any contact with sacred power.

Two other consumer research studies have briefly discussed kratophany using the illustration of consumers’ relationships with inherited family heirlooms (Curasi, Price and Arnould 2004) and their college football teams (Pimentel and Reynolds 2004) respectively. In both cases, consumers highly value something (the heirloom or the team’s victory) while simultaneously fearing the loss of that thing. These two examples attest to the tension caused by the simultaneous antithetical reactions to the sacred, suggesting that when consumers do perceive sacred power as valenced, it is this *uncertainty* as to the outcome in a particular instance that causes the tension associated kratophany. For example, a confident custodian of family heirlooms or a devoted fan who is aware that loss can occur but who is *sure* that loss will not occur, will likely not experience kratophany. This suggests to us that a more sophisticated coping mechanism might involve attempts to reduce uncertainty. We believe that the Hindu Indian (“Hindu”) concern with auspiciousness may shed light on how consumers cope with kratophany by reducing uncertainty.

Auspiciousness

Auspiciousness is a favorable state that bodes well for the future (Inden 1985). According to Inden, the Roman Empire practice of augury—interpreting signs from nature in order to

TABLE 1
Auspicious and Inauspicious Elements in Hindu Discourse¹

determine the will of the gods—gave us the word auspicious, which comes from the Latin noun *avis* (bird) and the Latin verb *spicere* (to look at). Although we shall use the Hindu notion of auspiciousness to illustrate our discussion, we note for the record that auspiciousness is also an important conceptual category in other Asian cultures. Furthermore, we note that in contrast to Western consumers’ idiosyncratic use of rituals designed to generate favorable outcomes (such as personalized pre-game rituals undertaken by some professional sportspeople), auspiciousness systematically pervades Hindu Indians’ daily lives. Hindu Indians’ shared understanding of auspiciousness also suggests that such rituals are more likely to be publicly employed in India, as compared to the West. Almost every thing, creature, person, act, or event can be described in Hindu discourse as either auspicious or inauspicious. Anything that predisposes the gods to favor a human undertaking is auspicious. People, events, objects, words, numbers and points in time can be more or less auspicious.

Table 1 draws on the work of Indian sociologists to present examples of auspicious and inauspicious elements in Hindu discourse. As indicated in the table, Das (1982) points out that among Hindus, marriage and other rituals pertaining to life are regarded as auspicious while cremation and other rituals pertaining to death are viewed as inauspicious. Consequently in her view, auspiciousness is defined as pertaining to life and inauspiciousness as pertaining to death. In a similar vein, Marglin (1985) suggests that auspiciousness is reflected in festivities and inauspiciousness in mourning. Narayanan’s (1985) more nuanced example of the auspicious death of an elderly man pre-deceased by his wife and survived by his progeny suggests that inauspiciousness is anything that prevents the extended family from carrying out its *dharma* or destiny of biological immortality (Channa 2000).

Every married Hindu woman, during her husband’s lifetime, is perceived to be the concrete embodiment of temporal auspiciousness, as shown in her colorful attire, jewelry and the red dot on her forehead (Carman 1985). But, as soon as she becomes a widow, she is viewed as inauspicious, and generally avoided (Srinivas 1952). Yagi explains the difference in auspiciousness between the two as a function of their ability to bear “fruit” (1999 p.275). Hence Yagi (1999) views auspiciousness as conduciveness to future prosperity, much like the concept of “lucky” numbers found elsewhere. In a

similar vein, Inden and Nicholas (1977) define the Hindu term *mangala* to mean luck or well-being. Srinivas, on the other hand, writes that “mangala [an emic term referring to the marriage ceremony which involves the tying of a sacred thread or mangala sutra around the bride’s neck] is an auspicious or good-sacred ceremony” (1952, p.74), and later implies that inauspiciousness relates to bad-sacredness. Thus, we seek to clarify the relationship of auspiciousness to the Western concept of “luck” and its relationship(s) to the benevolent and the malevolent sacred.

METHOD

We utilize data from depth interviews conducted with twelve Hindu Indian informants. Two of our informants were resident in India, two were resident in Australia, and eight were resident in New Zealand. The ten non-resident Hindu Indians we interviewed had spent the majority of their adult lives in India, had married Hindu Indian spouses in India, and continued to maintain strong ties with India after immigrating to Australasia. Our informants, eight of whom were female, ranged in age from 24 to 77. In keeping with interpretive research norms, we utilize the use of pseudonyms to preserve our informants’ anonymity. We employed the constant comparative method of analysis, engaging in open ended and axial coding of interview transcripts and fieldnotes and developing interpretations after each wave of data collection. Our emergent insights then informed and directed the next phase of data collection. Our interpretations in each phase were informed by the relevant literature.

FINDINGS

Hindus utilize as many auspicious elements and signs as possible, and avoid anything remotely inauspicious. Auspicious times, places, persons, colors, and objects seem to be valued by Hindus because they attract the benevolence of cosmic powers.

Auspiciousness is a control mechanism

Our informants found it easy to list objects, times or places that are auspicious and those which are inauspicious. We spoke to Sudha (IF 77) and her daughter-in-law Shaila (IF 39) about the meaning of auspiciousness.

- Sudha: auspicious events mean something good...
 Shaila: good
 Sudha: ...inauspicious events are the opposite of that."
 Shaila: "if we want to do something, we note it from the calendar—in India we get calendars that show certain dates that are auspicious...lucky days! It's something to do with lucky and unlucky.
 Int: lucky and unlucky?
 Sudha: we may see from the calendar which days are good.
 Shaila: we do the same with numbers too. Some are lucky and some are unlucky. Nine is a lucky number...
 Sudha: seven also.

According to these comments, auspicious bears some relationship to "lucky" and "good". However, another informant was careful to distinguish the concept of auspiciousness from that of luck. To Geeta (IF 44) an auspicious object is more than a lucky object, as luck implied (to her) something that cannot be controlled. Instead, auspiciousness was explained as something that helped a person increase the chances of a favorable outcome by increasing the probability the gods would approve of their undertaking. This seems to imply that Hindus attempt to exert control over their lives by using auspicious elements and signs. According to Geeta,

"a Hindu believes that there are definitely some things that are better than others and some times that are far better than other times, they are the auspicious times. There are definitely times that are bad or things that are bad that as a Hindu we must avoid. These are the things that have not met with God's approval. Who are we to decide for ourselves what we want to do? Inauspicious times are the worst times or things possible—yes there are 'neutral' times or things but they are avoided for the big decisions as they can be seen as just as bad as the inauspicious times. If we have three choices, have God on our side; have him against us or have him not care, I would like God on our side all the time. If he does not care about our decision either way then it is not auspicious, he is not against us so it is not inauspicious or dirty, but he is not in approval—therefore for the big decisions we cannot go forward."

Geeta's observation—that small tasks can be undertaken in neutral times, but important tasks cannot—implies to us that while it may be acceptable to risk failure with regard to trivial tasks, important tasks need every assistance possible, so as to ensure success. As Dinesh (IM 55) put it, auspicious objects are like "...runway lights for a plane—the better the light, the more chance there is that Ganesh [a Hindu god] will visit us and give us success." We surmise from Dinesh's observation that auspiciousness can serve to beckon the benevolence of the sacred.

Later Vijay (IM 25) elaborated, "...the gods are often called upon for daily as well as life altering events. However, the big decisions require far more effort and planning—the women are the 'prayer warriors' for the family and are seen as responsible for the[ir] husbands' health." As we shall show, this is because auspiciousness can be transferred from one entity to another, and hence allowing the task of generating auspiciousness to be sub-contracted to another.

Auspiciousness can protect

In traditional Hindu belief, the bride and groom ascend to a temporary elevated state, and are believed to be the embodiment of deities (in the case of Brahmins) or royalty (in the case of non-Brahmins) during the marriage ceremony (Dumont 1972). Situating a ritual performance in an auspicious space and time while employing

the use of auspicious artifacts facilitates this movement between liminal and bounded states (Das 1982). Accordingly, several of our informants described preparations for a typical wedding. First, a priest is consulted to select the most auspicious date and time for the wedding, with respect to the birthdates of the bride and groom. Prior to the wedding, the bride, groom, and any ritual objects to be used in the ceremony are purified while the selected venue is physically and ritually cleansed and decorated. Often a dais is erected in a hall or under an awning outside the home. The location in physical space that houses the birth, marriage or death acts as what Eliade (1959) terms an *imago mundi* (a representation of the cosmos on the earth). For example, during the ceremony, the bride and groom often sit on a *mandap*, a raised platform, under a canopy with four pillars. The material directly over the place where the bride and groom sit is often an auspicious red color. The Hindu bride is most often dressed in a new, auspiciously red sari, and adorned with auspicious jewelry. Other ritual attempts to generate auspiciousness are made. Vijay, recollected his own wedding day in India:

"The *hawan* [sacred fire altar] was prepared in the center of the largest room in my ancestral home. As the wedding began, Anita [the bride] and I were seated in front of the *hawan*... and we added *ghee* [clarified butter] to it when instructed by the *pandit* [priest]. He would sing *mantras* [invocations] and after each one we'd add some *ghee* and the guests would add sawdust [sweet smelling wood grains]."

Just as the central mall in Heritage Village was designed to allow its visitors to experience a time and space separate from the profane world without (O'Guinn and Belk 1989), the transcendence of spatio-temporal boundaries is also experienced at the focal point of the Hindu wedding ceremony, the *hawan*. The perfumed smoke of the fire, the burning of incense and the chanting of *mantras* all serve to transport the participants to the liminal zone of the axis mundi, where they may commune with the sacred. The *hawan* is sacralized by the addition of *ghee* [clarified butter] which is considered the most distilled essence of the cow which is revered as sacred by Hindus (Korom 2000).

Sudha explained to us that the date for a marriage is fixed after checking that it is an auspicious date for both groom and bride (as determined from their respective birthdates). However, she elaborated "Fate picks the date of death but within that you can pick your timings [for the cremation]. But if possible they do the cremation on the day of death. But they can pick mornings or evenings depending on which is more auspicious.." We learnt from Sudha that since the date of births and deaths cannot usually be chosen, special care must be taken to removed auspiciousness e.g. by engaging a religious leader to engage in special prayers in order to "stop bad things from happening".

We surmise from Sudha's comments that during dangerous times of transition such as birth, marriage and death, auspicious symbols do more than just attract the benevolent attentions of the good-sacred—they also serve to repel the malevolent attentions of the bad-sacred and/or protect from the danger inherent in sacred power.

Auspiciousness can be sub-contracted

Many Hindu marriages involve the tying of a sacred necklace made of gold and black beads, called a Mangal Sutra—literally "auspicious thread"—(in North India) or a tali (in South India) around the bride's neck. Maya (IF 44), a medical professional now residing in Australasia, was asked about her Mangal Sutra. Maya told the interviewer that she was planning to buy a bigger and more expensive one when she made her next trip to India. This more

elaborate Mangal Sutra was to be purchased to serve as evidence of her now improved financial status. When asked how she would dispose of the old one, she reacted in surprise, “Oh you can NEVER [emphasis present] sell it, you have to melt the old one and use the gold to help make the new one. If not the new one will not be genuine...it will not be auspicious”. It appears that the sacred powers contained in the Mangal Sutra reside in the gold and black beads it is made of, and can be transported by incorporating said gold and beads into another Mangal Sutra.

This ability to transfer auspiciousness from one element to another, coupled with Vijay’s remark that “women were the prayer warriors of the family” led us to ask whether auspiciousness be transferred between individuals as well. Can auspiciousness be generated by one party, while its benefits are enjoyed by another? Further probing elicited that Hindu women’s responsibilities extend well beyond the modern Western notion of women ensuring their husband’s good health by managing their nutrition and medical care. Hindu women are also expected to pray, fast and wear auspicious symbols in order to ensure their husbands’ longevity.

This “sub-contracting” of auspiciousness-generation to the women of the family begins at marriage. One informant, Tara (IF 42) explained that once married, a bride’s new focus was expected to be the well-being of her husband. According to Tara,

“These glass bangles ...are rings of glass with a bit of silver. They are a symbol for matrimony... after marriage, in India, glass bangles are a must for every married woman. And you must be very careful that you don’t break them...glass bangles give long life to your husband...The toe rings as such, that is also part of married...uh...uniform that you have to wear... this Mangal Sutra [pointing to the gold necklace she was wearing] is another thing that every Indian woman wears, these black beads are what we call a symbol of marriage. Every married woman wears these... This ...is also for the longevity of your husband.... everything for the husband, so we... we’re happy.”

The tinkling sounds made by jewelry such as bangles and anklets are believed to be pleasant to the gods. According to Shukla (2000), a bride not wearing the marriage jewelry of toe rings, anklets, and most importantly, bangles, can become a bad omen for the husband. Wearing the jewelry does not just generate positive outcomes for the husband, it avoids the negative outcomes generated by not wearing the jewelry. We surmise from this that auspiciousness simultaneously functions to approach the good-sacred and repel the bad-sacred.

The relationship between auspiciousness and sacredness can be further unpacked by looking at the kratophanous power gold jewelry such as the Mangal Sutra. These strong, ambivalent reactions inherent in kratophany, are evident when we consider the reversal of the rituals involved in marriage when a woman becomes a widow. During the marriage, the adorning of the bride with auspicious gold jewelry prepares the bride to join the groom in a temporary elevated state, as they are believed to be the embodiment of a god/goddess (in the case of Brahmins) or royalty (in the case of non-Brahmins) during the ceremony (Dumont 1972). While the couple is in this common state of elevation, the bride is incorporated into her husband by virtue of the marriage rites which usually include the groom or the officiating priest tying a golden thread bearing the Mangal Sutra pendant around her neck. Since Hindus view the wife as incorporated into her husband’s body, his death means that she is permanently associated with death and bad-sacredness. Thus the voluntary removal (Srinivas 1952) or forcible stripping (Firth

2001) of auspicious wedding jewelry from a widow, is an obvious reversal of the adorning of the bride, to prevent attracting the attention of bad-sacred powers.

The new bride is adorned by the groom’s family with auspicious jewelry to anchor her to her new identity. Once the bride is absorbed into the groom’s self, she does not need to transcend the boundaries of the groom’s extended family but enters it as part of the groom. Consequently, the extended family’s boundaries are maintained intact throughout the process—the groom ascends to a higher cosmic plane temporarily and returns to the extended family augmented with the bride as his “half-body.”When the new wife utilizes auspicious symbols to attract the benevolence of the gods for the benefit of her husband and his extended family, she is also helping to ensure her own favorable destiny since she is now as one with them. Thus selection of auspicious dates, times, and spaces, and the use of auspicious symbols are motivated by the desire to attract the benevolent attentions of the good-sacred while repelling the malevolent attentions of the bad-sacred.

DISCUSSION

Hindus believe in karma—that one’s present social status is prescribed by one’s actions in a previous incarnation (Channa 2000). Thus Hindus are commonly thought of as fatalists and perceived to be very different from North American societies where the majority of individuals are believed to seek to control their own destiny. Yet, Hindus’ concern with generating auspiciousness is second only to their concern with attaining and maintaining purity. When we recognize that purity is viewed as the absence of pollution, which in turn is viewed as “essentially that which cannot be controlled” (Hershman 1974, p.290), we begin to understand that the Hindu attempt to be pure and auspicious is an attempt to control one’s condition by avoiding or removing that which cannot be controlled.

Hindus are concerned with using auspicious symbols to attract the benevolence of the gods and avoiding inauspicious symbols to avoid attracting the attention of malevolent beings. We note that this concern with auspiciousness is heightened at times of birth, marriage and death—all dangerous transitions where we are forced to face the kratophanous power of the sacred. We view this concern with auspiciousness as an attempt to indirectly control (via the superior powers of the gods) what one cannot control directly. Thus, Hindus are, after all, concerned with control. The need to exert control over one’s destiny is universal- and it will find expression in some way, despite the constraints of society and religion. Consequently, even those in the West who seek to exert personal control over their lives, may seek to indirectly control those aspects of their lives cannot be directly controlled. For example, the popular media abounds with stories of people fighting a terminal disease who seek to dominate the uncontrollable by using science, litigation, religion or even, magic. Like purity and pollution, science and litigation operate on a social plane. Like the sacred gods, religion and magic operate on a cosmic plane. Our Western equivalents of auspicious symbols, such as lucky numbers, prayerbooks, magic crystals, and inalienable jewelry, are used to attract benevolent cosmic powers to control what we cannot control, on our behalf. Thus marketers are increasingly faced with consumers who seek to control every aspect of the consumption experience but then may be dissatisfied when the product, service, or experience consumed is not exactly what they had anticipated. For example, while awaiting the discovery of a magical weight-loss pill or elixir of life, some consumers seek to transform their bodies or regain their youth with the aid of a surgeon’s scalpel (Schouten 1991) in an attempt to control their appearance, and perhaps, their destinies.

How does the Hindu conceptualization of auspiciousness inform consumer research on luck, chance, and negotiation? Our realization that consumers employ auspiciousness in attempt to indirectly control their destiny offers insight into the krataphonous power of the sacred. Krataphony may explain the revulsion and vindictiveness consumers experience when omnipotent surgeons and revered ballplayers fail to provide them with the favorable outcomes they seek. We call for research that looks at if, and how, science, religion and magic inter-relate in the lives of postmodern consumers actively seeking to participate in production and consumption processes (Firat and Venkatesh 1995).

Thus our explication of auspiciousness sheds light on the distinction between the good-sacred and the bad-sacred. Sacred powers, whether benevolent or malevolent, cannot be controlled by mere humans. Hence the use of auspiciousness represents a way of manifesting attempts to attract benevolent powers and the removal of inauspiciousness is an attempt to forestall malevolent powers while also protecting oneself from the danger inherent in sacred power. What other coping mechanisms do consumers employ, when faced with the kratophany of the sacred? Research into these coping mechanisms may shed further light on the nature of the krataphonous power of the sacred, and the impact kratophany on consumers.

One or Many?: Examining Consumption Experiences from the Lens of Multiple Selves

Shalini Bahl, University of Utah, USA

George Milne, University of Massachusetts Amherst, USA

EXTENDED ABSTRACT

This paper explores multiplicity in consumers' self-concepts and their relationship with consumption experiences. It builds upon recent streams of consumer research that recognize multiplicity in self concepts and examine multiple selves in different consumption contexts. It addresses the question, what is the meaning of consumption experiences from the perspective of multiple selves? More specifically, does a consumption experience entail one set of attitudes and feelings that are consistent across selves or does it involve many sets of attitudes and feelings that vary across selves?

This research draws from dialogical self theory, which views multiple selves as narrative voices that occupy multiple self-positions (Hermans and Kempen 1993; Raggatt 2000, 2002). This theoretical perspective relies on people's life stories centered on important attachments to people, historic events, beliefs, and consumption activities as the basis for their self-positions. This theory assumes a natural state of multiplicity and allows multiple selves to enter into dialogical relationships. By grounding our study in this theory we are able to gain a broader understanding of the consumer selves, which then can be applied to better understand consumption experiences from the perspective of the different selves.

In this paper, the term multiple selves is used to mean multiple voices that speak from different positions, which is very different from schizophrenia or multiple personality disorder. Moreover, we choose to use the word "multiple selves" instead of "self positions," "multiple voices" or "dialogical self" as it is a more generic term that is consistent with current marketing literature on self-concept.

The dialogical self differs from other more commonly used perspectives in consumer behavior. It is different from the situational self (Schenck and Holman 1980) in that the focus is on the position from which the person is narrating an experience, which is not necessarily tied to a particular situation. Dialogical self is more of an internal perspective based on affective attachments as opposed to a self image that is desirable in a particular situation. It also varies from identity theory, and social identity theory. The dialogical self is a broader construct that subsumes roles and social memberships. While social identities gain salience through positive affirmations, dialogical self emerges from positive and negative attachments. Dialogical self also differs from other conceptualizations as it allows for dialogical relationships. Consequently, the consumption choices would be different from what they would be in the absence of dialogical relationships.

This study employed a mixed-method approach in order to understand consumers within a larger context over and above current explanations of multiple selves as role identities, social identities, and narrators of consumption stories. Raggatt's (2002) personality web protocol, comprising narratives and multi-dimensional scaling, was adapted and used in combination with metaphors in order to discern multiple selves. Metaphor analysis was used to get a further understanding of the feelings attached to the selves discerned and to understand informants' consumption experiences at the overall and self levels.

There were 12 hours of data collection for each of the study's six informants. In this paper we report data from two individuals.

The findings illustrate that the same consumption object or experience can evoke different sets of feelings for different selves. This has significant implications on how we study consumer behavior and also for market researchers in their endeavors to understand consumers' attitudes and opinions. Further, by examin-

ing positive and negative consumption experiences from the lens of multiple selves, this research contributes to current literature in post purchase evaluation.

Current research suggests that products that evoke primarily positive emotions during the consumption experience are positively evaluated (Oliver 1993; Stokmans 1998; Westbrook and Oliver 1991), which was also found in our study. However, when understood from perspective of certain selves, even positive experiences could involve primarily negative emotions. More interestingly, some products and experiences that were considered negative and evoked overall negative feelings were described as very positive experiences when understood from perspective of certain selves. These findings suggest that researchers would benefit from examining consumption attitudes and feelings from perspective of the consuming selves in order to understand complex consumer processes such as post purchase emotions and evaluations.

The findings in this study, consistent with dialogical theory, suggest that decisions are not based on overall feelings or attitude towards a product, but based on feelings of the self that is dominant at the time. The idea of dominant self is similar to that of identity salience (Arnett et al 2003; Dimofte, Forehand, and Deshpande 2003; Forehand, Deshpande and Reed 2002; Kleine et al 1993; Laverie et al 2002). Yet, an importance difference is that the sphere of influence for the dominant self extends beyond that of salient identities, which are primarily concerned with identity-related consumption behaviors. Further, we found that the dialogical self perspective allowed us to study products that are not clearly related to any identity and may be outside the purview of identity studies.

We also found that overall metaphorical feelings were different from feelings expressed by the different selves. This reveals limitations of research methods that do not take into account feelings and attitudes of the different selves. By looking through the lens of multiple selves as a dialog between multiple self positions, we can gain a richer understanding of consumption patterns in consumers. Instead of relying on compensatory reasoning as is done in multi-attribute models, we see that consumption is often based on dominant feelings of one self which may not be congruent with other self perspectives.

The findings in this paper reiterate the importance of studying consumer behavior from the perspective of multiple selves. Other research programs can adapt the methodology used in this study to examine multiple selves in other consumption contexts such as brand loyalty. Further, this study demonstrates the use of dialogical self theory, which can also be used to understand other consumer topics such as ambivalence, conflict resolution, addictions, and self-control.

Lines in the Sand: Using Category Widths to Define and Pursue Self-Control Goals

Cait Poynor, University of South Carolina, USA

Kelly Haws, University of South Carolina, USA

EXTENDED ABSTRACT

Much of the recent media attention on issues such as obesity in children and adults (Brownell and Yach 2005), rising bankruptcies caused by overextension of credit (Fetterman 2005), and the lack of savings by Americans (Colvin 2005), focuses on individuals' inability to regulate their own behavior. That is, many people seem to repeatedly give in to temptations in an impulsive manner (Baumeister 2002). While this lack of control may well account for many societal ills, lack of control alone does not tell the full story. Rather, failure to properly categorize alternatives is likely a contributing factor to the problems associated with such issues as obesity and consumer debt. In fact, the road to addressing many of the dark issues associated with today's society begins with individual consumers setting goals and creating plans to achieve those goals. One of the first steps in creating such plans is to define the category of goal-consistent options and behaviors. For example, a consumer embarking on a dieting plan needs to determine if buying a McDonald's hamburger should be categorized as a goal-consistent alternative or not. Similarly, a consumer creating a plan to reduce personal debt will need to determine if "buying groceries" using credit should be categorized as an appropriate expenditure that constitutes an acceptable or unacceptable behavior. Ill-defined plans in this early categorization phase can contribute to self-control failure in a variety of consumption domains.

Categorization theory provides insight into the ways that individuals define and group stimuli in their environment. However, despite the realization that self-control goals are contingent upon delineation of target behaviors and outcomes (Gollwitzer 2003), little research has focused on the goal-consistent and goal-inconsistent option categorization process as it relates to goal pursuit. Specifically, category width has long been viewed as an individual difference factor (Huang 1981; Pettigrew 1958), such that individuals are chronically either broad or narrow categorizers of various stimuli in their environments. In this tradition, neither goals nor beliefs about one's own self-control ability should normatively impact the way in which a given set of options is categorized. More recent research has demonstrated that category width can be altered by situational factors (Ulkkümmen, Morwitz and Chakravarti 2006).

In the present research, we are primarily interested in exploring the relationship between self-control goals, individuals' perceptions of their ability to meet self-control goals, and the widths of their categories of goal-consistent and goal-inconsistent alternatives. Importantly, we are interested in the ways that categories of goal-consistent and goal-inconsistent options are subjectively defined by individuals. Options included in the goal-consistent category are, conceptually, those alternatives the individual feels will facilitate the accomplishment of her/his goal(s). On the contrary, goal-inconsistent options are potential choices that hamper efforts toward goal achievement, based on the individual's interpretation. Our research illuminates issues involving category construction and self-control by showing that variation in the construction of goal-consistent and goal-inconsistent option categories can be explained by examining individuals' trait level self-control as well as their particular consumption goals. Furthermore, we demonstrate that the construction of these categories can differentially impact subsequent choice behavior.

Stress and Eating: Disentangling the Effects of Psychological, Autonomic and Endocrine Components of Stress Response

Zhenfeng Ma, University of Toronto Institute of Technology, Canada

Aida Faber, McGill University, Canada

Laurette Dubé, McGill University, Canada

ABSTRACT

Using a psychophysiological approach to stress, this study examines the joint effects of psychological, autonomic and endocrine reactivity on consumer food preference under stress through a randomized controlled study. Stress was manipulated using guided mental imagery technique. Consumer showed increased preference for high energy-density snack foods in the stress vs. control condition. The changes in food preference were jointly predicted by psychological, autonomic and endocrine responses. A model comparison approach shows that the inclusion of autonomic and endocrine responses contributed incrementally to the prediction of food preference. Theoretical and practical implications are discussed.

Beating Back that Triple-Chocolate Cake: Mental Accounts as Instruments of Self-Regulation

Parthasarathy Krishnamurthy, University of Houston, USA

Sonja Prokopec, University of Houston, USA

EXTENDED ABSTRACT

One of the vexing conundrums in everyday life is our inability to say “no” to actions that we would ideally like to say “no” to. It is common for people to profess ‘healthy eating’ goals and yet repeatedly succumb to temptations in the form of foods high in calories, fat, sugar etc. Such instances of goal-behavior inconsistency represent failures of self-regulation (Heatherton and Baumeister, 1996).

Research in consumer behavior has long been interested in strategies aimed at reducing self-regulation failures (Hoch and Loewenstein, 1991). In this research, we examine whether having mental accounts (Thaler, 1980, Thaler and Johnson, 1985; Tversky and Kahneman, 1981), defined as self-specified allowances for action, will lead to improved self-regulation. Why should mental account influence self-regulation? According to Baumeister (2002), effective self-regulation depends on three principal factors which are (a) clear standards for the behaviors to be regulated, (b) ability to monitor one’s status with regard to the standards, and (c) capacity, i.e., resources to alter one’s own behavior should it be warranted.

Mental accounts appear to satisfy all the three criteria outlined by Baumeister (2002) that are necessary for self-regulation. First, mental accounts are set around active goals (Brendl, Markman, and Higgins, 1998), so they inherently provide the necessary standards/goals for behavior. Second, mental accounts enable a person to evaluate current choice in terms of previous choices (Kahneman and Tversky, 1984); therefore, mental accounts enable one to monitor one’s own behavior. Finally, mental accounts have been thought of as instances of categorization (Henderson and Peterson, 1992), which results in resource-efficient decision-making. Thus, having a mental account leaves the decision-maker with more resources to exert self-control. Although the connection between mental accounts and categorization has been made, its connection to the amount of resources needed for decision-making has neither been demonstrated nor been made before in the literature. Since the capacity to change behavior, i.e., having enough resources to change, is a critical element without which having standards or monitoring is less likely to be useful (Baumeister, 2002), we believe it is important to assess whether having a mental account renders decision-making more efficient. Based on the notion that speed of decision is an index of the efficiency, we hypothesize that people with a mental account will make quicker decisions regarding actions relating to the mental account than people without a mental account.

Does this mean that whenever people have mental accounts, they will be able to achieve improved self-regulation? We argue that mental accounts are likely to facilitate self-control only when the task frame adopted by the decision-maker, choose versus reject (Shafir, 1993), is compatible with the goal. Specifically, if the goal is to limit behavior, we argue that a reject task is more compatible with the goal, allowing the mental account to exert its influence. A choose task, on the other hand, orients the person to look for reasons to adopt the behavior, and therefore is less compatible with the goal of limiting the behavior. Based on this reasoning, we suggest that there is reason to expect that the effect of mental accounts in limiting indulgent behaviors will be more pronounced in a reject task rather than in a choose task.

Two studies were conducted as part of a program of research focused on the self-regulatory effectiveness of mental accounts. The first study manipulated presence of mental accounts and task frame, and found that decision time was considerably faster when the decision-maker had a mental account. However, this study found only directionally consistent effects on self-regulation on account of limited variability in the dependent variable. The second study involved the same manipulations and found that mental accounts are successful in facilitating self-regulation only when the task was compatible with the goal of the mental account. Thus, having a mental account significantly reduced the likelihood of engaging in indulgent behaviors, but only when the participant was in a reject task, not in a choose task.

The contribution of this research is threefold. First, we investigate this phenomenon in a non-monetary context, in contrast with the vast majority of the research on mental accounting which focuses on monetary decision contexts. Second, we let the participants estimate the size of their mental account. Majority of the research in mental accounting examines this phenomenon by presenting participants with scenarios that involve pre-set mental accounts (both in terms of size and context). Third, and most important, the connection with self-regulation situates mental accounting as a factor that shapes the cognitive process underlying decision-making rather than as an evaluation frame that affects economic outcomes.

In summary, mental accounts offer an ecologically relevant way of exerting self-control when faced with tempting choices. However, they do so only when the task adopted by the decision-maker is compatible with the goal of the account. We believe that one of the salient features of this research is that it bridges the knowledge from three well researched genres, mental accounting, self-regulation and task framing, to indicate conditions under which people can bring their behavior in line with their own goals.

Making Prudent vs. Impulsive Choices: The Role of Anticipated Shame and Guilt on Consumer Self-Control

HaeEun Chun, University of Southern California, USA
Vanessa M. Patrick, University of Georgia, USA
Deborah J. MacInnis, University of Southern California, USA

ABSTRACT

We examine the differential effects of anticipating shame vs. guilt on choice likelihood of a hedonic product. The results demonstrate that when offered a hedonic snack (chocolate cake) consumers who anticipate shame are significantly less likely to choose to consume it compared to those who anticipate guilt. Anticipating guilt also has a more circumscribed effect, impacting choice likelihood only for those consumers who are not attitudinally inclined toward the hedonic product. The results also show that anticipating guilt versus shame has different effects on anticipated happiness after lapses in self-control.

INTRODUCTION

Maria was dismayed at how much weight she had gained. It seemed that no matter how hard she tried, she just couldn't resist indulging in high calorie desserts. Vowing to remember how bad her overeating made her feel, she put a note on the box of left-over cake from her daughter's birthday party that reads "if you eat this, you will feel bad."

Two powerful negative emotions of self-condemnation are shame and guilt. While commonsense knowledge reminds us that these emotions are reactions to self-control failures, little is known about whether *anticipating* these emotions as a consequence of consumption will impact self-control. Hence, one objective of this paper is to examine whether anticipating shame and guilt from lapses in self-control influences actual self-control. Although a limited body of literature has examined the impact of guilt on self-control, knowledge of the impact of anticipated shame is lacking. Thus, a second objective of this research is to assess whether shame and guilt exert differential effects on consumer self-control. Finally, while many consumers are beset by problems of self-regulation as evidenced by overeating, overspending, compulsive shopping, gambling, smoking and drug use, not *all* consumers experience problems with consumer self-control equally. Thus, the third and final objective of this research is to examine whether shame and guilt have a differential impact on consumers whose personality or preferences make them differentially vulnerable to self-control lapses.

THEORY AND HYPOTHESES

Anticipated Affect and Self-Control

Recent work in psychology and marketing has begun to examine anticipated or forecasted emotions and their impact on choice. Anticipated emotions (also called affective forecasts) refer to the prediction of the emotional consequences of decision outcomes (Gilbert *et al.* 1998; MacInnis *et al.* 2005), in this case, to the affective consequences of giving in or not giving in to an impulse.

Though research on anticipated affect and self-control is limited, the little that exists is intriguing. Bagozzi *et al.* (1998) found that anticipating positive emotions (including pride, joy and satisfaction) from self-regulatory success and negative emotions (including guilt, regret and sadness) from self-regulatory failure predicted dieting intentions, plans, and dieting-related actions. Other studies have addressed the relative impact of anticipated positive emotions associated with achieving a goal (e.g., delighted,

happy, proud) versus negative emotions from not achieving a goal (e.g., guilty, regretful, sad) on impulse control (Bagozzi *et al.* 2003; Perugini and Bagozzi 2001; Giner-Sorolla 2001).

An interesting and relevant extension to this literature concerns the impact of anticipated emotions of the same valence on self-control. As Lerner and Keltner (2001) point out, little work has been done to differentiate emotions of the same valence—and this is particularly true in the context of affective forecasting. Relevant here are negative anticipated emotions presumed to arise from the failure to control impulses and consume a hedonic product. Although Bagozzi *et al.* (1998, 2001) found that anticipating negative emotions like shame and guilt can facilitate impulse control, they did not assess whether each emotion can itself impact self-control. Because both are negative emotions induced from moral transgressions, one might expect that either shame or guilt can impact self-control compared to not anticipating any emotions.

H1: Compared to consumers who do not anticipate the emotions presumed to arise from a hedonic choice, those who anticipate the (a) shame or (b) guilt from hedonic consumption will be more likely to exert self-control (and less likely to choose (consume) the hedonic product).

The Differential Impact of Shame vs. Guilt on Self-Control

Lack of understanding of the potentially differential impact of shame vs. guilt on self-control is perhaps understandable because the two emotions are sometimes used interchangeably (Tangney and Dearing 2002). This lack of distinction is likely due to the fact that both are negative self-conscious emotions of self-condemnation that result in response to a moral transgression.

Notably though, cumulative empirical studies reveal that these two emotions are distinct. Shame is evoked from a perceived transgression of the 'self' (e.g., *I am a horrible person*), whereas guilt is evoked from a perceived transgression of one's 'behavior' (e.g., *I did that horrible thing*) (Lewis 1971). Shame evokes counterfactuals of the self ("If only I weren't"), whereas guilt evokes counterfactuals for actions ("If only I hadn't" for guilt) (Niedenthal *et al.* 1994). Finally, shame induces a behavioral motivation to hide, escape, sink or disappear from others and the situation (Lewis 1971). Guilt, on the other hand, induces a behavioral motivation to restore or make amends or atone for transgressions (Wicker *et al.* 1983; Tangney *et al.* 1996).

Notably these differences between shame and guilt are with regard to an experienced emotion. We theorize that these differences between shame and guilt manifest themselves even in anticipation, differentially influencing self-control. Past research finds that shame is a more powerful and intense emotional experience than guilt (e.g., Tangney *et al.* 1996; Roseman *et al.* 1994). Shame is often associated with a stronger physiological response and is more powerful by its implication of the self as the reason for the transgression. Guilt on the other hand involves a less potent physiological response and is a result of an appraisal that implicates one's behavior in the transgression. Furthermore, while guilt evokes the possibility of atonement for one's wrongdoing, shame evokes no such potential, and indeed further implicates the self for one's weakness. Hence, we predict that anticipating the accusation of the

self is more likely to keep people from transgressing than anticipating the blame of a specific behavior. Shame may also induce more self-control by virtue of the fact that it is viewed as a more public emotion, whereas guilt has been viewed as a more private affair (i.e., reaction of one's internalized conscience to a breach of one's personal standards) (e.g., Ausubel 1955; Benedict 1946; Gehm and Scherer 1988). By virtue of its power, lack of atonement potential, and public element, we hypothesize that:

H2: Consumers who anticipate shame from consuming a hedonic product will be more likely to engage in self-control (e.g., choose to forego the consumption of a hedonic product) than will consumers who anticipate guilt from consuming the hedonic product.

Attitude toward Consuming the Hedonic Stimulus

Notably, exerting self-control may be more or less important depending on consumers' apriori predisposition to engage in hedonic choice. The same hedonic choice (e.g., eating chocolate cake) may be extremely appealing to some consumers and less appealing to others given apriori attitudes toward the hedonic product. Hence, an interesting extension to H1 and H2 concerns whether shame and guilt exert an equivalent impact on self-control for consumers with positive vs. neutral attitudes toward the hedonic product.

We predict that for consumers for who have neutral attitudes toward the hedonic product anticipating either shame or guilt will impact self-control. Because the consumption item induces limited attraction, anticipating either negative emotion should induce greater self-control than not anticipating these negative emotions.

H3: For consumers with neutral attitudes toward consuming the hedonic product, anticipating either shame or guilt from consumption will have a greater impact on self-control than will not anticipating either emotion.

However, for consumers who are most vulnerable to self-control lapses—those with a positive attitude toward consuming the hedonic product—shame may exert a greater impact on self-control than will guilt. Because attitudes are more positive, the allure of the product is greater, requiring a strong emotion like shame to induce self control. We thus hypothesize that:

H4: For consumers who have a positive attitude toward consuming a hedonic product, anticipating shame from consumption will have a greater impact on self-control than will anticipating guilt.

Anticipated Happiness from Self-Control or Lack Thereof-

Self-control in the context of hedonic choice involves a trade-off between short-term vs. long-term happiness. This notion is consistent with the idea that preferences can be time inconsistent (Hoch and Lowenstein 1991; Metcalf and Mischel 1999; Giner-Sorolla 2001). Lapses in self-control brings about short-term happiness as impulses are indulged—though longer-term consequences like shame and guilt may be subsequently experienced. On the other hand, engaging in self-control often sacrifices short-term pleasures for longer-term happiness. Delaying gratification in the present can induce a larger and bigger reward—which presumably will induce greater happiness than would succumbing to short-term gratifications.

An interesting question regarding anticipated shame and guilt is whether they evoke similar effects on anticipated happiness in the short term as a consequence of giving in to impulses and engaging

in hedonic consumption. Once consumers decide to commit themselves to indulge even after anticipating guilt associated with consumption, it is more likely that they justify their decision to consume with inflated anticipatory happiness. The fact that guilt implicates the transgression of the specific behavior also implies the motivational readiness to discount their transgression as a one-time, transient incident. As the term, guilty pleasure (Giner-Sorolla 2001), signifies, anticipating guilt, once committed to indulge, may inflate anticipated happiness about consuming the impulse-laden product as a (consequence of) post-decision justification.

On the other hand, since shame is a more intense emotion that arises from the appraisal of the transgression of the self (Lewis 1971), it is likely that one's decision to indulge cannot be easily justified. Moreover, the transgression is less easily discounted as a one-time, fleeting misbehavior since it implicates the self, tarnishing one's self-image. Therefore, we predict that consumers who anticipated shame, but still consume the hedonic product, are likely to anticipate less happiness from consumption than are consumers who anticipate guilt.

H5: Consumers who anticipate guilt from consuming a hedonic product will be more likely to anticipate happiness following hedonic consumption compared to consumers who anticipate shame.

Individual Differences in Impulsivity

Self-control is more difficult for consumers with chronic tendencies toward impulsive behavior. Consumer impulsivity has been widely regarded as an important individual difference variable in self-control (Puri 1996). The impact of shame and guilt on the effects noted above would be noteworthy if they remained robust even after controlling for individual differences in impulsivity.

EMPIRICAL INVESTIGATION

Method

H1-H5 were examined in a 3 (anticipated emotion: shame, guilt, no emotion control) X 2 (attitude toward the hedonic product: positive vs. neutral) experiment. Ninety-one participants were randomly assigned to one of the three anticipated emotion conditions. Attitude toward the hedonic product served as a measured variable.

Respondents were shown a delicious-looking chocolate cake at the start of a computer-based questionnaire and were asked to imagine that it was placed in front of them. To manipulate anticipated emotion, respondents were then told that although they wanted to reach out and take a bite of the cake, they stopped for a moment to anticipate how guilty (vs. ashamed) eating the cake would make them feel. The control condition was not given any instructions to anticipate emotions.

Respondents then completed a set of questions designed to measure how likely they were to eat the cake (1=not at all likely; 9=very likely), their anticipated happiness from eating the cake (1=not at all; 9=very much) and manipulation checks for anticipated shame and guilt (1=not at all; 9=very much). Individual differences in attitudes toward eating chocolate cake were also measured using a 3-item 9-point scale (favorable, positive, good; Cronbach's $\alpha=.92$). The three items were averaged to yield a scale of attitude toward eating cake. A median split divided participants into positive vs. neutral attitude conditions (Median=6.33; M=7.99 for positive and M=4.38 for neutral). To control for individual differences in consumer impulsivity, a scale adapted from Puri (1996) was used as a covariate in the results presented below.

FIGURE 1

The effect of anticipated emotion and attitude toward consuming the hedonic product on choice likelihood

a,b,c Means with different superscripts are different at $p < .05$.

Results

Manipulation Check. The results confirmed that participants in the experimental conditions anticipated the emotions they were instructed to anticipate (M 's=4.58 and 4.61 for anticipated guilt and shame respectively) in the context of eating the cake.

Choice Likelihood. A 3 (anticipated emotion) X 2 (attitude) ANCOVA on the choice likelihood as the dependent variable and consumer impulsivity as a covariate revealed a significant main effect for anticipated emotion ($F(2, 84)=4.77, p < .05$) and a significant main effect for prior attitudes toward cake ($F(1, 84)=18.50, p < .001$). As expected, the main effect of attitudes showed that consumers who had positive attitudes toward eating cake were more likely to choose it (and forego impulse control; $M=6.93$) compared to consumers who had a neutral attitude toward consuming the hedonic product ($M=4.65$). The main effect for anticipated emotion showed that anticipating shame ($M=4.66$) resulted in greater self-control than anticipating either guilt ($M=6.04$) or the control condition ($M=6.68$). These results support H1a and H2.

However, we observed no support for H1b. Consumers who anticipated guilt did not show greater self-control ($M=6.04$) than consumers in the no emotion control condition ($M=6.68$).

Post-hoc contrasts showed that for consumers with neutral attitudes toward the hedonic product showed reduced choice likelihood when they anticipated guilt ($M=4.55$) or shame ($M=3.62$) compared to consumers in the no emotion control condition ($M=5.78$). These results support H3.

The results also support H4. For consumers with positive attitudes toward consuming the hedonic product, anticipating shame had a greater impact on self-control ($M=5.7$) than did anticipating guilt ($M=7.53$) or not anticipating emotion ($M=7.57$).

Collectively, these results suggest that while anticipating shame has a consistently positive effect on self-control, the anticipation of guilt impacts self-control only for consumers who have a neutral attitude toward the hedonic product and are thus less predisposed to making an impulsive choice.

Predicted Happiness. Respondents who experienced a lapse in self-control and decided to choose the cake were asked to predict how happy they would be after eating the cake. A 3 (anticipated emotion) X 2 (attitude toward eating chocolate cake) ANCOVA with consumer impulsivity as a covariate revealed a significant main effect for anticipated emotions ($F(2, 48)=4.29, p < .05$) and a significant main effect for prior attitudes toward cake ($F(1, 84)=7.55, p < .01$). The results were replicated in a regression analysis which used a continuous measure of attitudes (vs. a median split).

The main effect of anticipated emotions showed that consumers who anticipated guilt anticipated feelings significantly happier ($M=7.34$) after consuming the cake than consumers who anticipated shame ($M=5.86$) or control consumers ($M=6.36$). These effects support H5. The main effect of prior attitudes toward cake showed that consumers who held a positive attitude toward cake ($M=7.13$) anticipated feeling happier following hedonic consumption than consumers who held a neutral attitude toward cake ($M=5.91$).

Post-hoc contrasts shown in Figure 2 revealed several interesting effects. First, consumers who anticipated guilt from consumption also anticipated greater happiness from consumption than did consumers who anticipated shame—regardless of their prior attitudes toward cake. Second, for consumers with neutral attitudes toward cake anticipating guilt led to higher anticipated happiness from consumption than did not anticipating any emotion. Third, and most interestingly, even consumers who were not favorably disposed toward the hedonic product but who anticipated guilt showed just as much anticipated happiness from consumption as those who were favorably disposed toward the product. The fact that both consumers with favorable and neutral attitudes toward cake anticipated equivalent levels of post-consumption happiness from hedonic consumption suggests a potential association between guilt and pleasure (Giner-Sorolla 2001). The results are also consistent with the recent finding that showed the association between the concepts of “unhealthy” and “tasty” operates on an implicit level (Ragunathan *et al.* 2006).

FIGURE 2
Anticipated Happiness for Consumers Who Decided to Consume the Hedonic Product

DISCUSSION

Although prior research suggests that anticipating the emotions that might result from consumption impacts choice of hedonic products, our results extend this research by suggesting that two negative emotions of the same valence (shame vs. guilt) have different effects on both self-control and anticipated happiness from self-control failures.

We find that compared to conditions where consumers do not anticipate emotions from choice, those who anticipate shame are significantly less likely to make a hedonic choice (and hence are significantly more likely to engage in self-control). The impact of anticipated guilt on self-control, however, appears to depend on whether consumers have positive or neutral attitudes toward the hedonic product. Anticipating guilt seems to facilitate self-control, but only for those consumers who need it least—those who have neutral attitudes toward the hedonic product. For those who are pro-attitudinally inclined toward the hedonic product, anticipating guilt has no effect on self-control.

From the standpoint of happiness from consumption, we find that for consumers who chose to engage in hedonic consumption anticipated happiness with this decision varied as a function of both anticipated shame/guilt and attitudes. Consumers felt least happy with their decision to engage in hedonic consumption when they had a neutral attitude toward the hedonic product and anticipated feeling shame. Consumers who anticipated feeling guilty anticipated they would feel just as happy as consumers who did not anticipate any negative emotions when their attitudes toward the hedonic product were positive, and anticipated feeling even happier than those who did not anticipate any negative emotions when their attitudes were neutral. Therefore, anticipating guilt does not appear to deter anticipated happiness from choice for those who chose to engage in consumption.

The results provide an opportunity to revisit the conceptual distinction between experienced and anticipated emotions. We should note that affective forecasting is distinct from experienced affect. Anticipated emotions are cognitions about how one is likely

to feel in the future. A rather constructive consequence of experienced guilt (e.g., motivation to undo the error) may exert less influence when anticipated. In the same way, shame can exert a more powerful influence when anticipated than when experienced in the context of self-control. Anticipating negative consequences of shame such as passivity and desire to escape and hide can serve as a more powerful means to regulate impulses. We weigh the emotional consequences of the events and direct our motivation and behavior in line with our affective prediction.

Interestingly, while shame is a far more intense negative emotion than guilt, anticipating future feelings of shame could potentially decrease the likelihood of experiencing future negative feelings by increasing self-control. Notably though, one wonders about the effects of anticipating shame on outcomes like depression or self-hatred when hedonic choice is rendered despite anticipated shame. In this sense, anticipating shame from consumption may make consumers more vulnerable to negative feelings and self-hatred.

Another limitation concerns the fact that we did not assess how much guilt or shame consumers in the control condition anticipated. It is possible that consumers in this condition naturally anticipated guilt (or shame). This might explain lack of difference in results between the control and the anticipated guilt conditions.

The results of our study provide several opportunities for extension. Anthropologist Ruth Benedict (1946) classifies cultures according to whether they use shame or guilt to regulate the social activities of their members. She posits that some Asian cultures are considered shame cultures whereas European and modern American cultures are considered to be guilt cultures. Future research might investigate cross-cultural differences anticipating shame vs. guilt has on self-control.

The results of our study, while intriguing, are limited by virtue of the fact that self-control was assessed in terms of self-reports of choice likelihood. A stronger test would examine whether the effects we observe here are observed in the context of actual choice. On the other hand, these results were obtained even though a

relatively non-powerful inducement—a photo of a chocolate cake (as opposed to an actual real-life temptation) was used as the stimulus (see Shiv and Fedorikhin 1999). Future research might examine the impact of anticipated shame and guilt in the context of real stimuli and actual choices. By comparing respondents' behavioral responses of the current study with those using actual stimuli, we can tell how far off people can predict the behavior as a result of anticipated shame vs. guilt. Another interesting extension concerns the long-term impact of anticipated shame vs. guilt on self-control. Prior studies showed that self-regulatory strength can in fact be “worn out” like a muscle when mental efforts are prolonged (e.g., Muraven and Baumeister 2000; Schmeichel and Baumeister 2004). Considering that shame is a more powerful and intense emotion than guilt, anticipating shame over time may wear consumer's self-regulatory resources out more easily than anticipating guilt. One wonders whether a greater self-control ability induced by anticipating shame in the short-term can be extended to the long-term. Anticipating shame may make one more vulnerable to relapse over the long term due to its intense mental efforts. The future research should examine the long-term impact of anticipated shame and guilt.

Building Customer Relationships: A Comparison Across Multiple Service Encounters

Hung-Chang Chiu, National Chung Hsing University, Taiwan

ABSTRACT

The purpose of this study is to investigate the impacts of relational bonds on customer loyalty in various service encounters. Data were obtained from a sample of 621 Taiwanese customers in the securities industry. The findings are threefold. First, financial bonds have little impact on customer loyalty, social bonds create an intermediate impact on customer loyalty, and structural bonds have the greatest impact on customer loyalty. Second, social bonds influence customer loyalty more in person-to-person encounters than in interactive voice response systems or Internet encounters. Third, structural bonds affect customer loyalty more on the Internet than in person-to-person or interactive voice response system situations.

INTRODUCTION

Relationship marketing has emerged a critical tool in the current marketing climate, where managers must seek new ways to create sustainable competitive advantage (Dibb and Meadows 2001). By emphasizing a focus on the ways that companies can build, develop, and maintain successful relational exchanges, relationship marketing represents an important means to build customer loyalty to an organization (Morris et al. 1999). Recently, a body of research surfaced that attempts to discern the types of bonds that enhance relationship marketing (e.g., Berry 1995; Peltier and Westfall 2000; Williams et al. 1998). These bonds have been categorized as financial (e.g., price incentives), social (e.g., interpersonal relationships), and structural (e.g., services that are designed into the system). However, despite the increasing importance of relationship marketing, the effects of these three relational bonds on customer loyalty have not been sufficiently studied empirically.

Service encounters, defined as the moment of interaction between a customer and a firm, are increasingly critical in all industries and may take place in an actual service setting, over the telephone, through the mail, or over the Internet (Bitner et al. 2000). Prior studies have recognized the importance of service encounters in creating and maintaining good relationships between service firms and their customers (e.g., Haring and Mattsson 1999). As customers and businesses interact over time, the opportunity rises for this aggregation of encounters to transform into an exchange relationship (Morgan and Chadha 1993).

Although it is increasingly evident that technological advances will continue to be critical components of customer-firm interactions, little is known about how interactions with such technological options affect customer evaluations and behavior (Meuter et al. 2000). In different service encounters, the ways that customers interact with a business may also differ. For example, customers must personally visit some service facilities and engage in interactions with employees for person-to-person encounters. Therefore, developing buyer-seller relationships through interpersonal interactions or friendships between customers and employees may be more useful for these customers. However, for Internet encounters, customers can easily access high-quality information from the Web site (Detlor 2003). Using a service-delivery system, rather than relying on the relationship-building skills of individual service providers, allows firms to customize their offerings and

may also give customers greater satisfaction. Accordingly, to produce results that can be interpreted at a theoretical level, investigations must encompass a range of interfaces and consider the effectiveness of customer relationships in different encounters. In this study, we attempt to determine whether the impacts of relational bonds on customer loyalty differ for customers in person-to-person, interactive voice response system, and Internet encounters.

THEORETICAL ISSUES

Customer Loyalty

In Oliver's (1999, p. 34) study, loyalty is defined as "a deeply held commitment to rebuy or repatronize a preferred product/service consistently in the future." Customer loyalty is considered one of the several means by which a firm can build a sustainable competitive advantage. Loyalty plays an important role in influencing consumers' repeat purchases (Jacoby and Kyner 1973) and creating substantial income for companies (Jones and Farquhar 2003). From a business perspective, structuring consumer retention mechanisms to enhance profits has become more important than ever.

Relational Bonds

Previous literature has indicated that a customer retention strategy can focus on three types of bonds: financial, social, and structural (Berry 1995). Subsequent studies, including Berry (1995), Peltier and Westfall (2000), and Williams et al. (1998), have adopted this typology to discuss the effects of such bonds.

Researchers have argued that one motivation for customers to engage in relational exchanges is money savings (e.g., Berry 1995; Gwinner et al. 1998). However, although financial bonds seem useful in securing customer loyalty, some researchers have suggested that these bonds belong at the lowest level of the relationship hierarchy because price is the most easily imitated element (e.g., Peltier and Westfall 2000; Zeithaml and Bitner 2003).

Social bonds are defined as personal ties pertaining to service dimensions that include interpersonal interaction, relationship building (Wilson 1995), and identifications (Turner 1970). From the customer perspective, a social bonding strategy benefits them significantly through strong service relationships (Gwinner et al. 1998). These social bonds positively influence customers' emotions or feelings associated with the service experience and contribute to the formation of the affective component of attitude, all of which are salient aspects of intimate, high-quality relationships (Thorbjørnsen et al. 2002). Therefore, though social bonds alone may not bind a customer permanently to a company, they will ultimately prove more difficult for competitors to imitate (Zeithaml and Bitner 2003). Some researchers (e.g., Berry 1995; Peltier and Westfall, 2000) in turn suggest that social bonds sit at the intermediate level in the relationship hierarchy and help companies protect against competitive pricing pressures.

Finally, Berry (1995, p. 241) suggests that marketers practice relationship marketing, which depends on structural bonds when "the solution to the customer's problem is designed into the service-delivery system." The structural bonds "offer target customers value-adding benefits that are difficult or expensive for customers to provide and that are not readily available elsewhere" (Berry

1995, p. 240). From the industrial marketing perspective, Turnbull and Wilson (1989, p. 233) argue that effective structural bonds “create value to the customer and either require investment by the buyer that cannot be salvaged if the relationship ends or may be expensive if the buyer must supply this service themselves if they change sources.” Accordingly, structural bonds refer to the value-adding services that are contained in the service-delivery system, including knowledge and information about the industry and product customization; that are not readily available elsewhere; and that are expensive for customers to supply if they terminate the relationship.

In addition, because customers regard the provision of information, knowledge, and goods/services by the business and their participation in this provision as a mutual relationship investment and adaptation, these valuable services forge customer loyalty by creating a psychological barrier to terminating the relationship (Wilson 1995). In turn, some studies suggest that structural bonds belong in the highest level of the hierarchy of relational bonds (Peltier and Westfall 2000). Accordingly, we propose that:

- H1:* The impacts of financial, social, and structural bonds on customer loyalty differ.
- H1_a:* The positive impact of social bonds on customer loyalty will be greater than that of financial bonds.
- H1_b:* The positive impact of structural bonds on customer loyalty will be greater than that of social bonds.

The Role of the Type of Service Encounter

Prior studies have demonstrated the importance of service encounters to businesses. For example, encounters affect critical outcomes such as customers' intention to repurchase, relationship quality, and loyalty (Bitner et al. 2000). A service encounter, defined as a period of time during which customers interact directly with a service (Lovelock 2001), may take place in an actual service setting, over the telephone, through the mail, or even over the Internet (Bitner et al. 2000).

Prior research about service encounters focused on person-to-person encounters or interpersonal interactions (Morgan and Chadha 1993). However, to reduce costs and improve customers' convenience, many companies have redesigned their customer flows. Instead of encouraging situations where customers deal with the company representative in a person-to-person setting, these companies encourage lower contact levels where customers have remote contact with company representatives (Lovelock 2001). Accordingly, recent research has investigated person-to-machine encounters (e.g., Bitner et al. 2000; Meuter et al. 2000).

In all of these settings, the same three types of bonds may apply to the company's attempts to retain its long-term customer relationships. Because financial bonds are easily imitated and do not offer any differences with competitors in the long run (Peltier and Westfall 2000), we omit any discussion of their effects on customer loyalty across service encounters.

Social bonds, however, may affect customers in these types of encounters (i.e., person-to-person, interactive voice response system, and Internet) differently. In person-to-machine encounters, customers obtain services primarily through self-service technologies, which, according to Sauer and Burton (1999), are hard-to-reproduce social elements. In Donthu and Garcia's (1999) study, they reveal that Internet shoppers' socioeconomic, motivational, and attitudinal characteristics differ from those of non-Internet shoppers; furthermore, decreased pressure from salespeople contributes to why consumers make online purchases (GVU 1997). In this context, interactive voice response systems are easily accessible and provide timely information, but they seldom offer inter-

personal interaction or friendship elements to customers. Similarly, in a virtual environment, though the interactivity of the Internet can initiate a two-way conversation, online shoppers are hampered by the lack of personal contact inherent in remote transactions (Croft 1998). In summary, though e-retailers may build social bonds with individual customers through personalized e-mails or customer-to-customer interactions and friendships (Zeithaml and Bitner 2003), many consumers may still prefer the social component of a service encounter.

Because repeated interactions between customers and service suppliers help customers assess the service firm's credibility and benevolence (Donney and Cannon 1997), more interactions may lead to an emotional attachment through the customer's developing a sense of mutual trustworthiness. Therefore, social bonds that stress interpersonal interactions may be more useful for customers in person-to-person encounters than in person-to-machine encounters. In turn, we posit that

- H2:* The effect of social bonds on customer loyalty is moderated by the types of customers in the service encounter, such that the effect is greater for customers of person-to-person encounters than for those of Internet and interactive voice response encounters.

Finally, structural bonds also may affect customers of the three types of encounters differently. The development of electronic technologies has dramatically reduced the time and cost of information exchange, effectively linked processes, and enabled close integration of different parties in the value chain (Tang et al. 2001). Through the Internet, customers may receive personalized services (Wilson 1995). By building fast, well-structured hyperlinks with Web sites of strategic partners, businesses can also provide more integrated services to their customers, which may lead to improved customer loyalty.

In addition, online customers generally want to access product specifications, usage instructions, warranty information, and lists of products on sale (Burke 2002). They also want to be able to receive an e-mail message confirming that the order was received and shipped, and then track their shipment on the Web.

Compared to an Internet encounter, salespersons offer some similar benefits as they visit customers regularly to provide product information and resolve customer concerns, particularly in industries like financial services. From the customer's perspective, however, structural bonds developed through salespeople are probably less timely and less convenient than Internet encounters. Similarly, though interactive voice response systems are easily accessible and provide timely information, they are not customized for each customer and are therefore likely to offer a weaker structural bond. Accordingly, we propose that the impact of structural bonds on customer loyalty is lower for customers in person-to-person encounters and interactive voice response systems than for those in Internet encounters. In turn, we posit that:

- H3:* The effect of structural bonds on customer loyalty is moderated by the type of customers in service encounter, such that the effect is greater for customers of the Internet encounter than those of person-to-person and interactive voice response encounters.

METHODOLOGY

Sample

To examine H1–H3, we conducted a field study in the securities industry in Taiwan. Questionnaires were distributed to one

thousand securities customers who experienced person-to-person, interactive voice response systems, and Internet encounters. To recruit respondents we used customer lists obtained from sponsor securities companies and employees of high-tech or service industries with experience in stock exchanges. A total of 621 responses were gathered, which represents a response rate of 62.1%. T-test results reveal there are no significant differences across these demographics between these two samples.

Each respondent was asked to select one of the three encounters he or she confronted most frequently. Then the respondent selected one securities company in the context of this type of encounter that he or she had patronized previously to purchase the good/service. Finally, the respondent indicated his or her perceptions of the company.

According to the received questionnaires, the sample of respondents consists of approximately the same percentage of women and men (50.1% and 49.9%, respectively), who range in age from 15 to 60 years. The sample sizes for the three types of encounters were as follows: 387 person-to-person encounters, 116 interactive voice response system encounters, and 118 Internet encounters.

Measures

We conducted three separate in-depth interviews with two entry-level managers in the securities industry to determine how they implemented their relationship strategies. From these investigations, we identified 20 measurement items that we categorized as financial (4 items such as “The company provides cumulative points programs” and “The company offers more rebates if I trade beyond a certain amount.”), social (7 items such as “The company is concerned with my needs,” “Service providers help resolve my problem even if it is not related to the business,” and “The company sends me greeting cards or gifts on special days.”), or structural (9 items such as “The company suggests suitable investment options according to my records and assets,” “The company integrates services from other sources to solve my problem,” and “The company provides professional knowledge in the financial area.”). Each item was scored on a seven-point Likert scale (1=strongly disagree; 7=strongly agree).

We refined the instrument through a pilot test. We applied an item-to-total correlation analysis to find any items that needed to be dropped at this stage, but because we could not improve any alpha coefficients in the financial, social, or structural dimensions by deleting any items, we did not remove any.

The loyalty construct often is gauged by the relative attitude that a consumer has toward a company and his or her intention to purchase again from the same company (e.g., Jones and Farquhar 2003; Peltier and Westfall 2000). To measure the dependent variable of customer loyalty, we adopted three indicators in accordance with the literature: “I am willing to repurchase” (Peltier and Westfall 2000), “I am willing to purchase other products or services from this firm” (Sirohi et al. 1998), and “I am willing to recommend this firm to others” (Peltier and Westfall 2000). Again, respondents used a seven-point scale to respond to these items.

DATA ANALYSIS

Reliability and Construct Validity

To investigate the reliability of the scale, we computed the Cronbach’s alphas for the financial, social, and structural bonds as .85, .93, and .94, respectively. For the dependent variable of customer loyalty, the coefficient alpha was .83. These values suggest reasonable internal consistency.

To test the construct validity of the three relational bonds, we conducted a confirmatory factor analysis (CFA) using LISREL

8.54. Although the χ^2 values of the CFA models of the three relational bonds were 408 (d.f.=167, $p<.05$), the χ^2 /d.f., CFI, GFI, SRMR, and RMSEA were 2.4, .87, .86, .05, and .06, respectively. These latter values suggest an adequate fit of the model to the data.

Furthermore, convergent and discriminant validity should be examined for construct validity, which is supported when the average variance extracted (AVE) between the constructs and their measures is greater than .50 (Fornell and Larcker 1981) and the loading on the hypothesized construct is significant. Here, the AVEs for the financial, social, and structural factors were .59, .64, and .68, respectively, and the factor loadings were all significant at $p<.05$. Thus, convergent validity is supported. The AVE value also can be used to assess discriminant validity (Fornell and Larcker 1981); discriminant validity is supported if the AVE for each factor and its measures is greater than the square of the estimated correlation between factors. Discrimination was evident in this study because the largest shared variance among the three factors (.46) was less than the lowest AVE value for each factor and its measures (.59).

Relationship between Relational Bonds and Customer Loyalty

To investigate the impacts of the three relational bonds on customer loyalty, we calculated composite scores for each bond by summing its measurement items. These composite (or simple factor) scores often are highly correlated with factor scores obtained by the more complex least squares and regression methods (Johnson and Wichern 1992). In addition, the variance inflation factors (VIF) values were much below the threshold of 10. Therefore, the effects of multicollinearity can be ignored in this study. We then conducted a regression using customer loyalty as a dependent variable and the three relational bonds as predictors. The results indicate that the structural bond and the social bond significantly influence customer loyalty ($\beta=.50$ and $.18$, $p<.05$), whereas the financial bond has an insignificant impact on customer loyalty ($\beta=-.05$, $p>.05$). Therefore, H1_a is supported.

To further investigate whether the unstandardized regression coefficients of structural bonds and social bonds (which were significantly greater than 0) can be treated as equal, we conducted a t-test. The results indicate that the coefficient of the structural bonds is significantly larger than that of the social bonds ($t=3.81$, $p<.05$), in support of H1_b. As we have already discussed, the insignificant financial bond effect may reflect the ease with which competitors can imitate a financial bond strategy (Berry 1995). Virtually every securities company provides financial bonds to its customers, which decreases their effectiveness. In addition, we find that structural bonds are the most effective in enhancing customer loyalty, in line with Berry’s (1995) suggestion that structural bonds create strong foundations for customer relationships.

Furthermore, to examine the moderating effects of the service encounters, we tested H1–H3 through hierarchical regression analyses, with customer loyalty as the dependent variable and a specific relational bond as the predictor. We employed hierarchical regression analyses in which we mean centered all the variables to reduce the risk of multicollinearity. If there is a significant change in R² when the interaction between a relational bond and the encounter is added, moderation is supported (Arnold 1982). In this study, because our service encounter variable has three levels (i.e., person-to-person, interactive voice response system, and Internet), we code two dummy variables that provide qualitative information.

In table 1, we report a series of hierarchical models for H2–H3. Moderation is supported for social ($\Delta R^2=.012$, $p<.05$) and structural ($\Delta R^2=.01$, $p<.05$) bonds; moderation is not supported for financial bonds ($\Delta R^2=.002$, $p>.05$).

To further investigate whether a specific relational bond has a differential impact on loyalty for a specific encounter, we tested

TABLE 1
RESULTS OF HIERARCHICAL REGRESSION ANALYSES

Step	Independent Variable	Total R ²	ΔR ²
1	Financial bond and service encounters	.109	.109*
2	With financial bond x service encounters	.111	.002
1	Social bond and service encounters	.287	.287*
2	With social bond x service encounters	.299	.012*

three separate regression models with customer loyalty as the dependent variable and each type of relational bond as the predictor for three different encounters. To avoid the issues related to high levels of multicollinearity among independent variables, which make it difficult to draw inferences about regression estimates, we determined whether the data fit the condition of multicollinearity prior to the regression. The variance inflation factors values ranged from 1.52 to 2.29 and thus are below the suggested threshold of 10. Therefore, the effects of multicollinearity can be ignored in this study.

Table 2 also indicates the relationships between the three relational bonds and customer loyalty during different encounters. The social bond has a significantly positive impact on customer loyalty only in person-to-person encounters ($\beta=.26, p<.05$), in support of H2. The structural bond has the greatest impact on customer loyalty in Internet encounters ($\beta=.63, p<.05$). To investigate the significance of H3, we also compare the unstandardized regression coefficients between structural bonds and customer loyalty across service encounters (Arnold 1982). The results indicate that the impact of structural bonds on loyalty is significantly higher in Internet than in person-to-person ($p<.05$) or interactive voice response system ($p<.05$) encounters in one-tailed tests. H3 is therefore supported. Because the Internet provides an inexpensive means to search, organize, and disseminate complete, relevant, timely, up-to-date, and accessible information, it may be more effective for companies to deliver structural bonds to customers through Internet encounters.

DISCUSSION

Service encounters constitute critical moments of truth where a firm leaves an indelible impression on the customer (Bitner et al. 2000). Recently, because growing numbers of customers are inter-

acting with self-service technologies rather than employees to create service outcomes, Meuter et al. (2000) suggested that research should compare the underlying differences in how customers respond to telephone- versus Internet-based self-service technologies. We responded to this suggestion by investigating the impacts of the three relational bonds on loyalty for customers in different types of encounters.

The empirical results indicate that financial bonds have no significant impact on loyalty for customers in any type of encounter. Social bonds, however, have a significantly positive impact on customer loyalty, but only in person-to-person encounters. Finally, structural bonds are effective in gaining customer loyalty in every type of encounter, though they are more useful in Internet situations than in other types of encounters. This finding suggests that e-tailers should leverage structural bonds to strengthen their customers' loyalty.

Managerial Implications

Loyal customers buy more, are willing to spend more, are easier to reach, and act as enthusiastic advocates for firms (Harris and Goode 2004). The results of this study therefore provide some key strategic implications for managers, especially those in the securities industry, who seek to build customer loyalty.

Identify the nature of the bonds between consumers and businesses. When there is effectively none or little difference between suppliers, customer switching is very possible because one service or supplier is essentially equivalent to another (Turnbull and Wilson 1989). If, as recent research argued, the main purpose of managing customers is to improve long-term profitability, businesses must identify their most profitable customers and strengthen those relationships through relational bonds. Therefore, understanding the key factors that bond customers to firms is important for

customer loyalty efforts and, in turn, for businesses' profit. Managers and employees must be aware of the three types of relationship strategies to enhance customer loyalty. According to the results of this study, structural bonds are the most effective and financial bonds are the least effective ways to enhance customer loyalty overall.

Differentiate relational bonds in service encounters. Traditionally, research about service encounters has focused on person-to-person encounters. However, to reduce costs and achieve greater customer convenience, many companies have turned to person-to-machine encounters. The results of our study indicate that customers in person-to-person encounters find both social and structural bonds useful; however, the structural bond is the most effective for those in the Internet encounters. According to Garvin (1987), managers tend to employ only a few strategies in their drive to compete with other companies, so these findings should help companies identify attributes that they should prioritize in their encounters with their customers.

Develop marketing investment and training programs that lead to customer loyalty in different encounters. The careful development of a relationship investment strategy makes a company more vulnerable to attack from competitors (Turnbull and Wilson 1989), but careful allocation of the marketing budget can be planned according to the results of this study. For example, a business might use the measurement items developed in this research to benchmark its relationship activities with those of competitors and identify comparative strengths and weaknesses from a customer standpoint. The company then could develop a bonding strategy based on the customers that appear in each type of encounter. For example, customers in person-to-person encounters place a great deal of importance on personal ties, so the company should invest more to develop personal ties with this group. However, for customers in an Internet situation, value-added services should constitute the primary investments the company uses to manage its customer relationships. The business might focus on building technologies that record customer preferences and then provide detailed information and customized services to them.

Future Research Directions

Additional research might take some of the following directions. First, further research might study the problems of cross-channels in different buying stages. To enhance customer loyalty, firms likely use a combination of relational bonds at different customer decision stages. For example, customers may use the Internet to search for information but eventually make the purchase from local brick-and-mortar stores. Alternatively, a salesperson might send an e-mail to a customer to provide relevant information before his or her visit to the store, or Web sites might offer contact information for service/sales personnel, which interested customers can use. Therefore, research should investigate the effects of a combination of relational bonds and service encounters at different buying stages.

Second, some studies have suggested that organizations should analyze the position of their customers according to a continuum of transactional to collaborative exchanges and then apply transactional or relational marketing to those customers on the basis of their orientation (e.g., Garbarino and Johnson 1999). Therefore, further research might examine the relationship between the three relational bonds and customer loyalty for low versus high relational customers. For example, might social bonds be more effective in developing customer loyalty than using structural bonds for newer customers?

Third and finally, Hofstede (1980) proposes four dimensions of culture: power distance, uncertainty avoidance, individualism/collectivism, and masculinity/femininity. The primary characteristic

of Chinese culture appears to be a more collectivistic orientation, whereas North American culture is typically characterized as individualistic (Hofstede, 1980; Williams et al. 1998). According to Williams et al. (1998), structural bonds have a greater influence on customer commitment in individualistic countries than in collectivistic countries, whereas social bonds are more significant for collectivistic countries than for individualistic countries. Although this article sheds light on how different types of relational bonds affect customer loyalty in the Taiwan securities industry, additional research should also examine the generalizability of our results to other countries—possibly those considered more individualistic—and compare the results with this study.

Switching Barriers in the Four-Stage Loyalty Model

ABSTRACT

Oliver (1997) suggests a four-stage loyalty model proposing that loyalty consists of belief, affect, intentions, and action. Although this model has recently been subject to empirical examination, the issue of moderator variables has been largely neglected. This article fills that void by analyzing the moderating effects of switching barriers, using a sample of 589 customers of a large do-it-yourself (DIY) retailer. The results suggest that these moderators exert an influence on the development of the different stages of the loyalty sequence. Specifically, switching costs, social benefits, and the attractiveness of alternatives are found to be important moderators of the links in the four-stage loyalty model.

INTRODUCTION

Numerous studies have linked customer satisfaction to financial outcomes (Anderson, Fornell, and Lehmann 1994; Anderson, Fornell, and Rust 1997; Bernhardt, Donthu, and Kennett 2000; Ittner and Larcker 1998; Keiningham et al. 1999). However, in moving from a transaction orientation to a relationship orientation (Berry 1995; Grönroos 1995; Morgan and Hunt 1994), contemporary marketing thought acknowledges that gaining and sustaining customer loyalty as the ultimate goal may be more important than achieving customer satisfaction (Agustin and Singh 2005).

Obviously, the link between customer satisfaction, customer loyalty, and financial outcome is not as straightforward as it may seem (Carroll 1991; Carroll and Rose 1993; Reinartz and Kumar 2000). Yet researchers and managers acknowledge that small changes in loyalty and retention can yield disproportionately large changes in profitability (Reichheld 1993; Reichheld, Markey, and Hopton 2000; Reichheld and Teal 1996).

Despite this obvious managerial relevance, earlier research primarily analyzed the link between satisfaction ratings and repurchase intention. Few studies have examined the link between satisfaction ratings and repurchase behavior (Mittal and Kamakura 2001; Zeithaml 2000). Adding to that stream of research, Seiders et al. (2005) summarize and extend the literature by proposing that the relationship between satisfaction and repurchase behavior is moderated by customer, relational, and marketplace characteristics. Only recently, has Oliver's (1997) four-stage loyalty model been subject to more extensive empirical testing (Evanschitzky and Wunderlich 2006; Harris and Goode 2004; Olsen 2002). Our study adds to that stream of research by (1) discussing the links between the four loyalty stages and (2) identifying switching barriers as potential moderators of these links.

In the following article, we briefly discuss earlier conceptualizations of the loyalty construct. Oliver's (1997, 1999) framework of the four-stages of loyalty is then introduced. The focus of analysis is on switching barriers as moderator variables which affect the links between the adjacent loyalty stages. A set of hypotheses is derived and subsequently tested, using a sample of 589 customers of a large DIY retailer. In the final section of the article, we discuss implications of our findings, with a focus on generating a deeper understanding of loyalty.

CONCEPTUAL FRAMEWORK

Until the 1970's, loyalty was understood as repeat purchase behavior, primarily considering repeat purchase cycles (Bass 1974). Following that, a behavioral approach toward explaining purchase patterns emerged. Among the first proponents of such a behavioral approach was Jacoby (1973, 1978). Loyalty was defined as a biased (nonrandom) repeat purchase of a specific brand (from a set of alternatives) over time by a consumer, using a deliberate evaluation process (Jacoby and Kyrner 1973). Later, Jacoby and Chestnut (1978) note that the belief, affect, and intention structure of a consumer must be examined in order to analyze loyalty.

Despite these seminal works, there is still no universal agreement on the definition of loyalty (Dick and Basu 1994; Jacoby and Chestnut 1978; Oliver 1999; Uncles, Dowling, and Hammond 2003). According to Uncles et al. (2003), three popular conceptualizations of loyalty exist: loyalty as an attitude that leads to a relationship with the brand; loyalty expressed mainly in terms of revealed behavior; and buying moderated by the individual's characteristics, circumstances, and/or the purchase situation.

We use Oliver's (1997) definition, because it includes both attitudinal and behavioral aspects of loyalty. Oliver (1997) defines loyalty as a deeply held commitment to rebuy or repatronize a preferred product or service consistently in the future, thereby causing repetitive same-brand or same brand-set purchasing, despite situational influences and marketing efforts that have the potential to cause switching behavior. He introduces a four-stage loyalty model, implying that different aspects of loyalty do not emerge simultaneously, but rather consecutively over time (Oliver 1999). More than a clarification, this model extends the loyalty sequence "cognitive-affective-conative" by including an observable behavior, for example actual purchase behavior. At each loyalty stage, different factors influencing loyalty can be detected.

Cognitive Loyalty

At this stage, consumer loyalty is determined by information relating to the offering, such as price, quality, and so forth. It is the weakest type of loyalty, since it is directed at costs and benefits of an offering and not at the brand itself. Therefore, consumers are likely to switch once they perceive alternative offerings as being superior with respect to the cost-benefit ratio (Kalyanaram and Little 1994; Sivakumar and Raj 1997). Cognitive loyalty is influenced largely by the consumer's evaluative response to an experience, in particular to the perceived performance of an offering relative to price (= value).

Affective Loyalty

Affective loyalty relates to a favorable attitude towards a specific brand. Attitude itself is a function of cognition (e.g., expectation). Satisfaction is a global affect evaluation or feeling state which can be predicted from perceived performance as the cognitive component of the evaluation (Oliver 1993; Phillips and Baumgartner 2002; Westbrook and Oliver 1991). Expectancy confirmation leads to satisfaction, which in turn effectuates affect-

tive loyalty (Bitner 1990). Oliver (1997) defines satisfaction as “the consumer’s fulfillment response, the degree to which the level of fulfillment is pleasant or unpleasant.” Affective loyalty is also subject to deterioration, caused primarily by an increased attractiveness of competitive offerings (Sambandam and Lord 1995) and an enhanced liking for competitive brands. This can be, for instance, conveyed through imagery and association used in competitive communications (Oliver 1999).

Conative Loyalty

Conative loyalty implies that attitudinal loyalty must be accompanied by a desire to intend an action, for example repurchase a particular brand. It is stronger than affective loyalty, but has vulnerabilities as well. Repeated delivery failures are a particularly strong factor in diminishing conative loyalty. Consumers are more likely to try alternative offerings if they experience frequent service failures. Even though the consumer is conatively loyal, he has not developed the resolve to avoid considering alternative offerings (Oliver 1999).

Action Loyalty

Action control studies imply that not all intentions are transformed into action (Kuhl and Beckmann 1985). The three previous loyalty states may result in a readiness to act (in this case, to buy). This readiness is accompanied by the consumer’s willingness to search for the favorite offering despite considerable effort necessary to do so. Competitive offerings are not considered as alternatives.

Despite the many attempts to consider selected links between different loyalty phases, relatively little empirical research has been conducted on testing the total four-stage loyalty model. Our study tries to fill that void by empirically testing Oliver’s (1997) loyalty model and possible moderators affecting the links between the loyalty phases in a retail setting.

SWITCHING BARRIERS AND CUSTOMER LOYALTY

In the last decade, a substantial body of research has been conducted to investigate moderating variables influencing the formation of customer loyalty (Bloemer and Kasper 1995; Homburg and Giering 2001; Homburg, Giering, and Menon 2003). In this context, some studies focus explicitly on the moderating effects of switching barriers (Bell, Auh, and Smalley 2005; Jones, Mothersbaugh, and Beatty 2000; Lam et al. 2004). Switching barriers are defined as “any factor, which makes it more difficult or costly for consumers to change providers” (Jones et al. 2000). In line with the literature (Caruana 2003; Jones et al. 2000), we examine the following switching barriers: social benefits, attractiveness of alternatives, and perceived switching costs.

Social Benefits

Customers build interpersonal relationships with service personnel. These bonds between the customers and the firm result in the former receiving social benefits (Berry and Parasuraman 1991). The same interactions can lead consumers to develop strong personal relationships with the company (Grönroos 1990; Parasuraman, Zeithaml, and Berry 1985) and bind customers (Bateson and Hoffman 1999). As interactions between provider employees and customers are repeated over time, the motivation for the development of a social aspect to the relationship necessarily increases (Czepiel, Solomon, and Suprenant 1985). In addition, the more customers rely on the personnel, and the more trust the customers develop, the less risky customers perceive variations in quality.

Therefore the customers will not seek alternatives to their current provider, even if quality varies. Hence, consumers with higher social bonds rely more on past experiences with a particular retailer as a key information cue. Since it is riskier to switch a provider and to try something new, customers with lower social bonds should be less likely to remain affectively loyal if their satisfaction levels change. Empirical evidence in the context of loyalty shows that social benefits moderate the relationship between various aspects of satisfaction and selected measures of loyalty. For instance, Jones et al. (2000) found that the relationship between satisfaction and repurchase behavior is moderated by social benefits. Similarly, Crosby, Evans, and Cowles (1990) offer some support for such a moderating effect. They were able to demonstrate that the quality of the relationship between salesperson and the customer determines the probability of continued interchange. Holloway (2003) discusses social bonds as switching barriers, which especially influence the relationship between the perception of service quality and satisfaction. Based on these findings, a moderating effect of social benefits on the four-stage loyalty model can be assumed.

H1: As perceived social benefits increase, the link between cognitive and affective loyalty will become stronger.

Attractiveness of Alternatives

Depending on the quality of competing alternatives, the customer perceives a benefit in changing the provider (Oliver 1997). The more attractive the alternatives are, the higher the perceived benefits when switching (Jones et al. 2000). Therefore, consumers are likely to switch once they perceive alternative offerings as being superior with respect to the cost-benefit ratio (Kalyanaram and Little 1994; Sivakumar and Raj 1997). There is also empirical evidence from Rusbult, Zembrodt, and Gunn (1982), reporting that the quality of alternatives is associated positively with exiting and negatively with loyalty. In addition to possible direct effects of attractiveness of alternatives on loyalty, moderating effects can be anticipated: In line with Oliver (1997), it can be expected that the link between cognitive and affective loyalty will be stronger under the condition of unattractive alternatives. Hence:

H2a: As the attractiveness of competing alternatives decreases, the link between cognitive and affective loyalty will become stronger.

Furthermore, the deterioration of loyalty at the conative stage of Oliver’s (1997) model is caused primarily by an increased attractiveness of competitive offerings (Sambandam and Lord 1995). Conversely, the less attractive the alternatives, the more favorably customers perceive the offers of its current provider (Jacoby, Speller, and Kohn 1974). Consumers who generally prefer shopping at a certain retailer might therefore differ in their intention to repurchase, depending on the perception of the attractiveness of alternatives. In line with Oliver (1997), we conclude:

H2b: As the attractiveness of competing alternatives decreases, the link between affective and conative loyalty will become stronger.

Perceived Switching Costs

In many instances, customers are loyal to a provider, because of the difficulty of changing to a different firm. In accordance with Jones et al. (2000), switching is likely to involve various behavioral and psychological aspects, given that switching costs include the time, money and effort the customer perceives, when changing

trolled, fit-indices and the proportion of variance explained were almost unchanged in both models, and all path coefficients remain significant. Therefore, we conclude that CMB is not a significant issue in our study.

Analysis

We use multi-group structural equation modeling to test our hypotheses. Median-splits based on the values of the moderator variables were used to create the groups. Testing for moderation, we first looked at a non-restricted model and then restricted three paths in the four stage loyalty model so that they are equal across subgroups. Chi-square differences with three degrees of freedom (critical chi-square value ($df=3$; $p=.05$): 7.81) were assessed. After confirming a general moderating effect, we compared two models that only differ in one effect of one loyalty stage to the next, as suggested by our hypotheses. One model restricts the parameter so as to be equal across groups, while the second model allows variation in one of these parameters across groups. The restricted model has one more degree of freedom than the general model. A moderating effect would be present when the improvement in chi-square, moving from the restricted to the non-restricted model is significant, meaning the chi-square difference between the two models (and one degree of freedom) is larger than 3.84 ($p=.05$).

Measures

A conceptualization and items for measuring the constructs were developed, drawing on prior research in the loyalty literature. Except for attractiveness of alternatives, multi-item seven-point Likert scales (anchored at 1=strongly agree, 7=strongly disagree) adapted from previous studies were used.

Cognitive Loyalty. Cognitive loyalty was defined and measured as evaluation of perceived value associated with the retail outlet. In accordance with the operationalization of Verhoef, Langerak, and Donkers (2004), Sirdeshmukh, Singh, and Sabol (2002) and Baker et al. (2002), the respondents were asked to rate the perceived value.

Affective Loyalty. Affective loyalty was defined as a person's global affect evaluation or feeling state. As proposed by Oliver (1997), we used "Overall Satisfaction" and "Liking" to cover affective loyalty.

Conative Loyalty. Conative loyalty was defined as a customer's behavioral intention to continue buying at a retail store in the future, accompanied by a deep commitment to that store. The scale used was adapted from the behavioral intention battery developed by Zeithaml, Berry, and Parasuraman (1996), and included the items: willingness to recommend, and repurchase intention.

Action Loyalty. Action loyalty focuses on (purchase) behavior. Hence, we do not focus on attitudes such as an intention to purchase or intention to overcome an obstacle. In accordance with Harris and Goode's (2004), we operationalize "action loyalty" as displayed choice preference, and not as "overcoming obstacle." The most common assessments of behavioral loyalty are repurchasing patterns or behavioral frequency like word-of-mouth behavior, purchase frequency, and actual money spent per year, as used here.

Attractiveness of Alternatives. The attractiveness of alternatives was measured with one item, accounting for the evaluation of existing alternatives. Research in the field of neuron science has shown that the first choice is a good indicator for evaluating the attractiveness of alternative brands (Deppe et al. 2005).

Social Benefit. The social benefits measure was adapted from Henning-Thurau, Gwinner, and Gremler (2002), measuring the social benefits resulting from interpersonal relationships with the service personnel.

Switching Costs. Finally, the switching costs measure, adapted from Jones et al. (2000), captures costs across a variety of dimensions and focuses on the overall perceptions of time, money, and effort associated with changing providers.

Measurement reliability was examined through confirmatory factor analysis and Cronbach's alpha coefficient.

It can be noted that the coefficient alpha exceeds .7, the threshold generally proposed in the literature (Nunnally 1978). Also, composite reliabilities exceed .6 for all constructs (Bagozzi and Yi 1988). The discriminant validity of the constructs was assessed using the criterion proposed by Fornell and Larcker (1981) and this criterion was met. Therefore, reliability and validity of the constructs in this study are acceptable.

RESULTS

Firstly, it is evident that the links between the various stages of the loyalty model are all significant ($p<.01$) and the model displays a good overall fit ($\chi^2/df=4.312$; CFI=.941; TLI=.926; SRMR=.073; RMSEA=.078). Therefore, we can continue analyzing the moderating effects.

After confirming the influence of the main effects in the model, we tested for moderator effects. A chi-square difference test was conducted for the three possible moderator effects, comparing a restricted and a non-restricted model. As can be seen, "attractiveness of alternatives" (at .01-level) and "switching costs" (at .05-level) have a significant, general moderating effect on all links in the loyalty model, whereas "social benefits" displays only a weak moderating effect at .1-level. Nevertheless, we continue analyzing the specific moderator effects suggested by our hypotheses.

As can be seen from table 4, each moderator only moderates one link in the loyalty model. "Attractiveness of alternatives" moderates the link between affective and conative loyalty, "social benefits" moderates the link between cognitive and affective loyalty, and "switching costs" moderates the link between conative and action loyalty.

Hence, three of four hypothesized moderating effects in the four-stage loyalty model were supported by these findings. It only seems that only "attractiveness of alternatives" fails to moderate the link between cognitive and affective loyalty as hypothesized in H2a. Furthermore, a smaller random sample of 250 respondents confirmed these results.¹

DISCUSSION, LIMITATION, FURTHER RESEARCH

Gaining customer loyalty is less straightforward and more complex than several previous studies have suggested. Using Oliver's (1997) model of loyalty, it is not until a customer shows high consistency through the four distinct stages that loyalty is achieved. In such case, customers possess not only a stable disposition but also a stable, routine purchase pattern, making them relatively resistant to competitive offers. Therefore, examining moderator variables of the links in the four-stage loyalty model leads to a clearer understanding of how to build loyalty.

The results of our empirical study suggest that there are indeed moderator variables that display conditions under which a customer moves from one loyalty stage to the next. In particular, high perceived social benefits from a relationship with a retailer are likely to turn cognitively loyal customers into affectively loyal customers. If the attractiveness of alternatives is relatively low, a customers liking (affective loyalty) of a particular retailer can be

¹We thank one anonymous reviewer for suggesting this test.

DESCRIPTION OF ITEMS USED TO MEASURE THE CONSTRUCTS

Scale/Item	Coefficient Alpha	Composite Reliability	Variance Extracted
Cognitive Loyalty (Baker et al. 2002; Sirdeshmukh et al. 2002; Verhoef et al. 2004)* 1. How would you rate your overall shopping experience at this store? 2. The quality/price ratio with the dealer is good (merchandise). 3. The quality/price ratio with dealer is good (service). 4. For the time you spent in order to shop at this store, would you say shopping at this store is highly reasonably/highly unreasonable? 5. For the effort involved in shopping at this store, would you say shopping at this store is not at all worthwhile/very worthwhile? 6. The store is attractive. 7. For the prices you pay for DIY-items at this store, would you say shopping at this store is a very poor deal/very good deal?	.862	.869	.571
Affective Loyalty (Bettencourt 1997; Oliver 1997)* 1. Based on all my experience with this store, I am very satisfied. 2. My shopping experiences at this store have always been pleasant. 3. Compared to other stores, I am very satisfied with this store.	.883	.885	.720
Conative Loyalty (Zeithaml et al. 1996)* 1. Repurchase intention 2. Word-of-mouth intention	.804	.802	.670
Action Loyalty (De Wulf, Odekerken-Schröder, and Iacobucci 2001) 1. How often do you buy DIY things in this store compared to other stores where you buy DIY things?*	.850	.858	.673
2. What percentage of your total expenditures for DIY do you spend in this store?*** 3. Of the 10 times you select a store to buy DIY at, how many times do you select this store?***			
MODERATORS			
Switching Costs (Jones et al. 2000)* 1. In general, it would be a hassle changing DIY-retailers. 2. It takes me a great deal of time and effort to get used to a new company.	.863	.932	.870
Social Benefits (Henning-Thurau et al. 2002)* 1. This store offers high-quality service. 2. Customers could expect to be treated well in this shop. 3. Employees of this store could be expected to give customers personal attention. 4. This store's employees would be willing to help customers. 5. Employees of this store would not be too busy to respond to customers' requests promptly.	.848	.958	.635
Attractiveness of Alternatives* 1. This store will be my first choice for my DIY needs.	n.a.	n.a.	n.a.

* Measured using seven-point Likert scales anchored by 1=strongly agree; 7=strongly disagree.

** Measured in percentage of total expenditures.

*** Measured in times of selection.

transformed into a strong intention to repurchase. If retailers are able to create switching costs, those customers intended to purchase, are very likely to do their actual purchase at that retailer. Our results did not, however, find a moderating effect of the attractiveness of alternatives on the link between cognitive and affective loyalty. A possible explanation could be that both satisfaction and liking are still just attitudes and consumers may not consider an actual purchase situation. However, we acknowledge that more research is needed to test this link in particular.

As with all empirical studies, our study suffers from limitations. First, our object of analysis was a particular retailer from one industry. Second, we analyzed data from one point in time only. By doing so, we assume there is no time-lag between a customer's feeling of being satisfied and the attitudinal and behavioral consequences. Thirdly, we considered only linear relations between the four loyalty stages. However, as indicated in the literature (Anderson and Mittal 2000; Keiningham, Perkins-Munn, and Evans 2003), these relationships might in fact be curvilinear. Furthermore, some scholars are skeptical about the use of median split, due to the loss of information. Further research might consider alternative ways to split the sample in appropriate sub-samples. Moreover, we only use self-reported measures for the action loyalty. Furthermore, longitudinal data would further improve our understanding of the mechanisms influencing the link between satisfaction and loyalty in general, and the effect of certain moderators in particular.

Why Companies Should Make Their Customers Happy: The Neural Correlates of Customer Loyalty

Hilke Plassman, Stanford University, USA and University of Muenster, Germany
Peter Kenning, University of Muenster, Germany
Dieter Ahlert, University of Muenster, Germany

INTRODUCTION

The relevance of customer loyalty for company success is widely acknowledged in the literature as well as in practice (Chaudhuri and Holbrook 2001; Dick and Basu 1994; Gwinner, Gremler, and Bitner 1998; Oliver 1999; Reichheld and Sasser 1990). While relationship marketing approaches have emphasized the importance of building personal relationships with their customers, the affective foundations of customer loyalty has received less attention and is less understood than the cognitive or rational basis of customer loyalty (Chaudhuri and Holbrook 2001; Fullerton 2003). However, initial studies could show that for customer loyalty the relative strength of affective loyalty antecedents is more significant as compared to normative or “rational” ones (Fullerton 2003, Evanschitzky and Plassmann 2005). Given the homogeneity of most of today’s product and service markets and other characteristics that may constrict the customer’s use of “rational” criteria for product evaluation, brand-induced affect may represent a global evaluation measure more readily used by customers as empirical evidences from neighboring disciplines suggest (e.g. Bechara et al. 1997; Bechara and Damasio 2005 and also Slovic, Finucane, Peters and MacGregor 2002, 2004; Yeung and Wyer 2005).

In this paper, we attempt to expand our understanding of the basis of emotional bonds customers built with companies and brands. Past research could show that people sometimes use affective reactions to a stimulus as information about its reward value (Schwarz and Clore 1988, Yeung and Wyer 2004). As recent studies on consumer decision-making propose that most information processing and, in particular, the processing of emotions is subconscious (see for reviews Bargh, 2002; Fitzsimons et al., 2002; Woodside, 2004; Zaltman, 2003) we followed the approaches from Ambler et al., Deppe et al., McClure et al. and Yoon et al. and employed functional brain imaging techniques to investigate the neural correlates of customer loyalty (Ambler, Braeutigam, Stins, Rose, & Swithenby, 2004; Deppe, Schwindt, Kugel, Plassmann & Kenning, 2005; McClure et al., 2004; Yoon, Gutchess, Feinberg, & Polk, 2006).

The paper is organized as follows. First, we review concepts of customer loyalty and the role of emotions within these concepts. Then, we provide a review of neuropsychological literature on the neural foundations of emotion-based decision-making and offer hypotheses on their implications for customer loyalty. In the following, we describe our empirical study and present our results. We conclude with implications for managers and suggestions for future research.

CONCEPTUAL FRAMEWORK

Loyalty Concept

Historically, loyalty was understood as observable repurchase behavior. It was defined as a biased (nonrandom) repeat purchase of a specific brand (from a set of alternatives) over time by a consumer using a deliberate evaluation process (Jacoby and Kyner 1973). Jacoby and Chestnut (1978) later asserted that also psychological states of a consumer had to be examined to analyze loyalty. In accordance with this reasoning, customer loyalty has been defined by Oliver (1999) as “a deeply held commitment to rebuy or

repatronize a preferred product/service consistently in the future.” The repetitive same-brand or same brand-set purchasing would occur among loyal customers, despite situational influences and marketing efforts that could potentially enable switching behavior. Accordingly, commitment, i.e. the extent to which the customer desires to maintain a continued relationship with the firm or brand, is understood as the underlying psychological mechanism of loyalty (Allen and Meyer 1990; Morgan and Hunt 1994). Recently, customer commitment was found to be composed of different dimensions (Bansal, Irving, and Taylor 2004; Fullerton 2003). On the one hand, these are more rational aspects such as a lack of alternatives and institutional or technical requirements to use a specific product (Bendapudi and Berry 1997). On the other hand, these are affective aspects understood as an emotional attachment customers built with companies and brands (Fournier 1997; Fullerton 2003; Thomson, MacInnis, and Park 2005).

In contrast to traditional studies we attempted here to gain complementing insights by separating behavioral and psychological aspects through the use of two different data sources. Firstly, we extracted “real” purchasing behavior from a club card database of a department store including customers’ monthly spending and number of purchase days within a period of 6 months. Secondly, we investigated the underlying psychological states by means of functional brain imaging. In the neuropsychological literature a great body of studies is devoted to the impact of emotions on behavior and decision-making (for reviews, see for example O’Doherty 2004; Schultz 2006). In the following we attempt to give an introductory overview about these studies.

Neuropsychological Background

One initial common conclusion relating to the neuropsychological foundations of decision-making refers to the role of emotion in human decision-making (e. g. Bechara 2004; Bechara and Damasio 2005; Bechara, Damasio, and Damasio 2004; Paulus 2005). It is suggested that “rational” or advantageous decision-making depends on prior emotional processing related to the specific decision parameters (Bechara et al. 1997). This notion is based on neurobiological evidence that seeking rewards and avoiding punishments guides the behavior of both, humans and animals (for reviews, see for example O’Doherty 2004; Schultz 2006). In constantly changing environments, it is necessary to adapt decision-making strategies by updating changes of reward contingencies. Thus, central to the organization of such behavior is the ability to estimate the reward value of stimuli, predict when rewards will occur and integrate these predictions into decision-making strategies.

Two areas found to be involved in the representation of rewards and punishments are the orbitofrontal cortex (OFC) and the amygdala. Human (O’Doherty, Kringelbach, Rolls, Hornak, Andrews 2001) and animal (Rolls, Sienkiewicz, Yaxley 1989) studies have confirmed the role of OFC in coding for stimulus reward from a variety of sensory modalities, such as taste (Kringelbach, O’Doherty, Rolls, and Andrews 2003), olfaction (Gottfried, Deichmann, Winston, Dolan 2002), somatosensory (Rolls, O’Doherty, Kringelbach, Francis, Bowtell McGlone 2003), auditory (Blood, Zatorre, Bermudez, Evans 1999), and vision

(Aharon, Etcoff, Ariely, Chabris, O'Connor, Breiter 2001) as well as for more abstract rewards such as money (Elliott, Newman, Longe, Deakin 2003) or sports cars (Erk, Spitzer, Wunderlich, Galley, Walter 2002). Furthermore, various studies have revealed that the amygdala is involved in the processing of aversive (Morris et al. 1996) and pleasant (Canli et al. 2002) stimuli.

In most consumption decision situations, however, rewards are not received immediately, but at a later point in time and can be understood as a consequence of the decision. Thus, the ability to predict future rewards is crucial for consumer decision-making. Neuroimaging studies have found brain regions such as the amygdala, OFC, and striatum to be correlated with reward predictions (Gottfried, O'Doherty, and Dolan 2003; Knutson and Cooper 2005; O'Doherty et al. 2004; Schultz, Dayan, and Montague, 1997).

Then, the learning of stimulus-reward-response associations is required to integrate anticipated and experienced values into the decision-making process. Neuroscientific studies in this context have revealed that the dorsal striatum might play a crucial role in processing contingencies between responses and rewards (O'Doherty 2004; Zink et al. 2005). Additionally, areas of emotional memory such as the ventromedial prefrontal cortex (VMPFC) need to be involved in order to retrieve rewarding memories and relate them to the stimulus (Bechara and Damasio 2005; Paulus 2005). In the context of consumption decisions an initial study by Deppe et al. could show that an activation network linking the ventromedial prefrontal cortex, the striatum and anterior cingulate cortex (ACC) is involved in brand preference judgments (Deppe, Schwindt, Kugel, Plassmann, Kenning 2005). Deppe et al. (2005) described the network as an affective and self-referencing path during brand choice. Against this background our hypothesis was that the underlying neural activation patterns of reward attribution to stimuli customers feel emotionally attached to would be similar to Deppe et al.'s findings.

Thus, we hypothesize:

H: During brand choice, loyal customers as compared to disloyal customer will show a greater activity in the striatum, VMPC and ACC.

In the following, we describe our empirical study to test this hypothesis.

EMPIRICAL STUDY

The empirical study was designed to investigate differences in brain activity of loyal customers as compared to disloyal customers of a department store.

Participants and Study Design

A total of 300 customers of a local department store were chosen randomly from a department store's club card database of which 22 (9 females, 13 males, median age 46) were recruited, after several screening procedures, to participate in an fMRI study. Exclusion criteria were relating to fMRI safety (e.g., metal or implanted devices in the body, claustrophobia), factors known to affect brain organization, function, or blood flow (such as handedness, pharmaceutical / drug use, psychiatric, neuropsychological and medical disorders). Furthermore, participants were selected to proceed to the fMRI task only if they were either classified for the last six months as "A" customer (monthly spending of 250 EUR or more for clothing and 5 or more monthly shopping days) or "C" customers (monthly spending of 50 EUR or less for clothing and 1 or less monthly shopping days).

All participants were healthy, right-handed and, gave their written consent to participate in the study in accordance with the

guidelines of the University Medical School Ethical Committee. The sample size is smaller than in typical in behavioral studies, however, it is representative of fMRI studies (see e.g. Desmond and Glover 2002; Murphy and Garavan 2004).

Experimental Procedure and Design

Participants were imaged during one functional run while making choices between two out of four department stores where they would buy different types of clothing. The experimental paradigm was designed to investigate systematic differences of neural processing during purchase decisions in the presence or absence of the specific target department store (T, the department store from which we extracted the subject pool), in contrast to three other department stores, which were classified as diverse (D_1 , D_2 , D_3). Nine different pieces of clothing (P1, P2; ... , P9) were chosen, that could be bought in all four department stores. They were neutral in the sense that no brand name or other criteria that allow an identification of a special brand were visible. The stimuli were presented as follows. In middle of each stimulation, a piece of clothing (P1, P2, ... , P9) was shown. Slightly above that piece of clothing, on the left and on the right side, the logos of two department stores were presented. These were either the target store brand (T) and one of the diverse store brands (D_1 , D_2 , or D_3), or two of the diverse store brands, resulting in sequences of TDPz and DDPz stimuli (or simplified TD and DD). The order of the stimuli was randomized referring to brands as well as to pieces of clothing. Each subject had to make a total of 120 decisions (60 TD and 60 DD).

We employed a one-factorial event related design (Bandettini & Cox, 2000; Buckner, 2003; Dale, 1999; Friston, Zarahn, Josephs, Henson, & Dale, 1999) with an inter-stimulus-interval (ISI) of 5 seconds each and a randomized stimulus presentation. In order to avoid response-related activations and movement artifacts we did not request for any feedback during scanning (Deppe et al. 2005).

The subjects were instructed to choose between two stores, according to where they would prefer to buy the piece of clothing shown on the screen. Thus, the store brand itself functions as the only selection criterion. After the fMRI scan, participants were asked to provide general personal information. Then, participants were compensated EUR 25 per hour, thanked and debriefed.

Data Acquisition

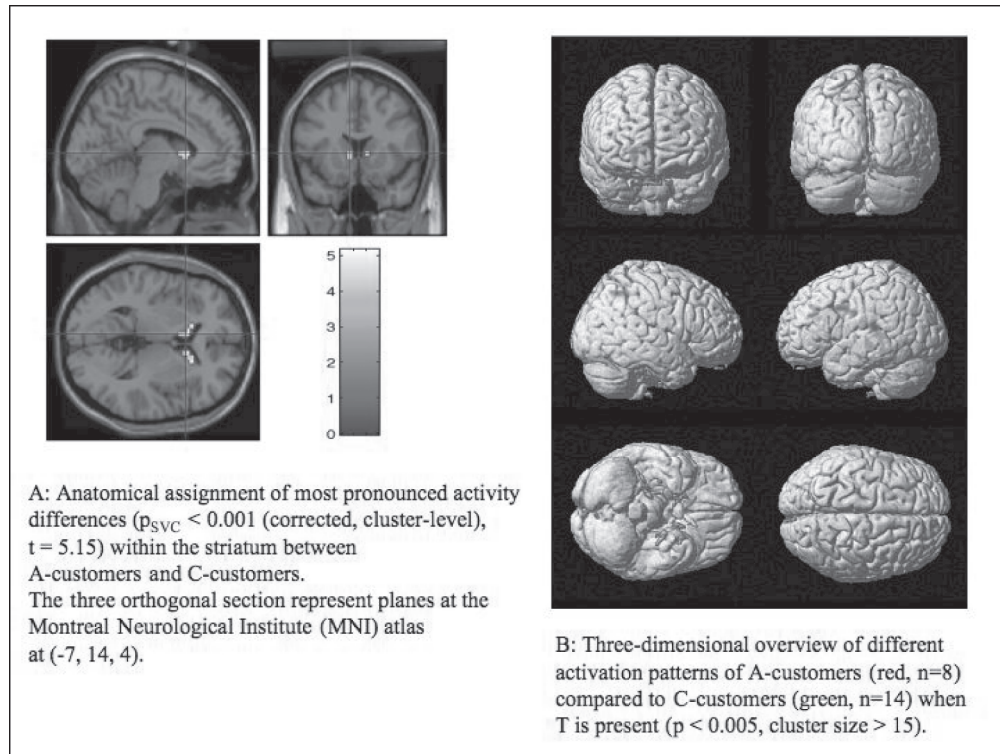

All fMRI data were acquired from a 3.0 Tesla whole body scanner (Intera T30, Philips, Best, NL). Prior to the functional data acquisition structural T1 weighted datasets were acquired for anatomical identification. The functional T2* images were acquired using single-shot gradient echo-planar imaging (EPI) sequence that covered nearly the whole brain. The data set consisted of 36 transversal slices of 3.6 mm thickness without gap. Images were acquired every three seconds (TR).

In combination with the fMRI measurement, data about the subjects' monthly spending at the target store and the number of shopping days per month in the fashion segment, were extracted from the department's store club card database.

Data Analysis

All acquired fMRI data were preprocessed using Statistical Parametric Mapping (SPM2; Wellcome Department of Cognitive Neurology, London, UK). For the statistical analysis, we specified regressors of a General Linear Model (GLM) according to our experimental design at the single-subject level. We then calculated contrast images for the events when T was present (TD) compared to when the T was not present (DD). These single-subject contrast images were used for a random effects analysis at the group level.

FIGURE 1
Results from random effects group analysis

The sample was divided into two groups (A- and C-customers) based on a customer value index (monthly spending and number of monthly shopping days). A two-sample t-test was calculated on the group level to compare neural activations patterns of the two groups when T was present.

Results

The most pronounced increased activation in the presence of T in the group of A-customers compared to C-customers was found in the striatum (see Figure 1A). This area was revealed to be involved in the representation of reward prediction (Gottfried, O'Doherty, and Dolan 2003; Knutson and Cooper 2005; O'Doherty et al. 2004; Schultz, Dayan, and Montague, 1997). Zink, Pagnoni, Martin, Dhamala, & Berns (2003) found increased activity in the particular part of the striatum that we are reporting here, in response to the prediction of behaviorally relevant rewards, as compared to "only" unexpected rewards which are represented in other parts of the striatum.

Furthermore, other areas involved in the TD decision of A-customers as compared to C-customers, confirm to Deppe et al.'s First-Choice-Brand activation pattern (Deppe et al. 2005, see Figure 1 B).

The brain areas shown in Figure 1 are the activation network linking VMPFC, striatum, and ACC. Deppe et al. (2005) described the network as an emotion-based and self-referencing information processing mode during brand choice. This network was found to be involved in decisions when the subject's first choice brand was present. Conversely, where only second or lower-ranked brands were available, the underlying neural network represents an analytical weighing of alternatives, mathematical calculation, strategic thinking and object recognition (Deppe et al., 2005). In particular

in the present study, both the latter and areas involved in semantically processing such as reading and speaking were found to be activated increasingly.

DISCUSSION

In this paper, we attempt to expand our understanding of the basis of emotional bonds customers built with companies and brands. We conducted an fMRI study to assess differences in neural activations between loyal and disloyal customers of a department store. Based on prior findings in the literature, we assumed that for loyal customers the store brand would modulate the underlying information processing via an emotion-based decision path, as compared to disloyal of the respective store.

As a result, we were able to replicate Deppe et al.'s neural correlate of brand preference for the particular case of store brands (Deppe et al., 2005). In addition to Deppe et al.'s findings (Deppe et al., 2005), we linked the neural activation patterns to the actual buying behavior of the subjects. We showed that, for customers with a high monetary customer value (A-customers) the presence of the specific store brand acts as a rewarding signal during the choice task, whereas customers with a low monetary customer value (C-customers) do not reveal such a rewarding activation pattern.

Implications for relationship management

Our findings offer some important insights for management. It can be noted that for a company, it is not sufficient to concentrate on 'bounding' customers for instance with technical requirements (e.g. hard- and software which is only compatible with specific operating systems) or general price promotions, but encourage customers in creating affective bonds to the company or its brands. This could be achieved by for example personalizing the commu-

nication with the customer and provide the basis for emotional events the customers links to the company or brand.

Limitations and future research

The interpretation of our empirical findings are based on binary decision making tasks conducted in a controlled laboratory environment and thus, do not reflect the richness of brand choices in a real-world shopping situation. Hence, further refinement of the experimental design, such as integrating more mobile brain imaging methods, will be needed in the future.

Furthermore, we focused only on the link between one department store and their customers' loyalty. Future studies should broaden our findings by investigating multi-brand-loyalty linkages.

In addition, we linked the neural activation patterns to past buying behavior. In following studies it might be useful to investigate whether the rewarding store brand effects can also predict future purchasing behavior. This could be implemented either by a panel data analysis over a longer period of time before and after the fMRI scanning or by including customers' purchasing intentions (i.e. attitudinal loyalty).

In conclusion, we could deepen the understanding of the psychological states underlying customer loyalty by providing initial neurobiological evidences of "the tie that binds" customers to companies and brands.

Optimizing Variety in Mass Customization: A Theoretical Perspective

Sanjay Puligadda, Pennsylvania State University, USA

EXTENDED ABSTRACT

Markets today are fragmenting with individual needs and wants increasingly prone to shifts and changes (Hart 1995) necessitating products that are mass customized and customerized (Simonson 2005; Wind and Rangaswamy 2001). Although considerable literature has examined mass customization from a production perspective (e.g., Papathanassiou 2004, Jiao, Ma, and Tseng 2003), it is only recently that marketing scholars have begun to examine this phenomenon (e.g., Murthi and Sarkar 2003; Simonson 2005; Wind and Rangaswamy 2001).

Typically, in mass customization, customers are provided varying options of a product's attributes to select and thus "build" their product. A major managerial challenge in such cases is to determine the optimal variety of options to offer (Simonson 2005). Too many options would be expensive, and confusing to customers, while too few options may annoy the customers who may be unable to configure the product based on their true preferences (e.g., Huffman and Kahn 1998).

We build on the work of Sherman et al. (1984) on human qualities to classify product attributes as *universally* or *variably* evaluated. According to Sherman et al (1984), for universally-evaluated qualities, there is consensus in a population about whether a particular level is good or bad, regardless of individuals' preference for the level. For example, people would agree that being honest is good and being dishonest is bad whether they themselves are honest or not. In contrast, there is more variability and person-specificity in variably-evaluated qualities. For example, opponents of abortion may think of a pro-choice political candidate as undesirable ("low quality") whereas pro-choice individuals may find that candidate very appealing. Thus, for universally-evaluated qualities there exists a widely accepted evaluation basis, whereas for variably-evaluated qualities, the evaluation schemes are more individual-specific.

Similarly, in a consumption context, universally-evaluated product attributes (universal attributes), such as battery life in cell phones, would have a common and widely accepted evaluation, whereas the evaluation schemes for variable attributes, such as exterior color of cell phones, would be more consumer-specific. In laptops, consumers would generally agree that 40 Giga Bytes (GB) of hard disk space (a universal attribute) is better than 20GB of hard disk space. In contrast, the color kit options in laptops (a variable attribute) are likely to be evaluated based on personal preferences—'Charcoal Leather' maybe evaluated positively by one while another consumer may prefer 'Mediterranean Blue.'

We suggest that this difference in evaluation schemes would result in consumers using different strategies for evaluating the two types of attributes.¹ Specifically, we suggest that, since consumers'

knowledge of the product category would influence how they search and utilize attribute information, consumer knowledge would affect the processing of information related to variable attributes. In particular, we examine the moderating effects of two constructs related to consumer knowledge, i.e., (1) objective knowledge, (Alba and Hutchinson 1987), and (2) knowledge function of attitudes, (Katz 1960, Grewal, Mehta, and Kardes 2004), for the influence of the levels of universal and variable attributes on consumer satisfaction with mass customization platforms. Objective knowledge refers to how knowledge with respect to the object (e.g. cell phones) may influence attribute processing. The knowledge function of attitudes pertains to the most basic function of attitudes that enables individuals to make better sense of their world (Shavitt 1989). While the former refers to the use of knowledge with respect to the object (e.g. cell phone), the latter refers to the use of the object (cell phone) as a means of knowledge. Thus these two knowledge related constructs represent two sides of a coin concerning consumer knowledge. We suggest that, since a variable attribute is more personal and more likely to serve as a peripheral cue than a universal attribute (Huffman and Houston 1993; Park and Lessig 1981), variable attributes would be more important for novices than for experts such that the positive effect of increasing variable attribute options on satisfaction with the customization platform would be stronger for novices than for experts. Further, we posit that if a product serves the knowledge function of attitudes (Katz 1960; Locander and Spivey 1978), consumers are likely to have a stronger personal relationship with the product, thereby increasing the importance of variable attributes such that the positive effect of increasing variable attribute options on satisfaction with the customization platform would be stronger when the product serves the product knowledge than when it does not.

We test these propositions with two experiments set in the context of customizing cell phones. In the first experiment, we examine the moderating role of objective knowledge and find that variable attributes are more important for novices as opposed to experts. In the second experiment, we study the moderating role of the knowledge function of attitudes towards cell phones and find that variable attributes are likely to generate higher satisfaction with the mass customization platform if cell phones perform the knowledge function of attitudes than if the cell phones do not perform the knowledge function of attitudes. The results of the two experiments also suggest, as hypothesized, that objective knowledge and knowledge function of attitudes do not influence the evaluation of universal attributes.

There are several important theoretical implications of this research. We distinguish between universal and variable attributes and show their differential effects on consumer evaluation of a mass customization platform. Future research might study the criticality of this categorization in other consumption contexts, such as evaluation of competing offerings of durable goods. It would be also worthwhile to examine how this attribute classification influences satisfaction with the product or service. Additionally, we have identified important moderators (objective knowledge and knowledge function of attitudes) in consumers' assessment of universal and variable attributes. From a managerial standpoint, our

¹Customization platform represents an interface where the product options are presented as attributes and options of those attributes are also listed. For example, a hypothetical customization platform can have two attributes—color and quality, with three options for color—red, green, and blue, and two options for quality—high and medium.

results should help marketers in deciding the number of attribute options that would provide the optimal variety in customization platforms. Also, the moderators we have identified, (namely, objective knowledge and knowledge function of attitudes), offer insights for segmenting the customers for design of mass customization platforms.

Temporal Sequence Effects: A Memory Framework

Nicole Votolato Montgomery, Ohio State University, USA

H. Rao Unnava, Ohio State University, USA

EXTENDED ABSTRACT

While much attention has been given recently to studying temporal sequences of events, few have offered explanations to account for how people integrate these events into a holistic evaluation of the experience, and virtually no attention has been given to the underlying mechanism involved. A temporal sequence refers to an experience that consists of a series of outcomes spaced over time. The findings from the temporal sequence literature indicate that people form global retrospective ratings of an experience using salient characteristics of the experience, such as the peak intensity, the end intensity, and the trend (Ariely, Kahneman, and Loewenstein 2000). The current explanations that have been proposed to account for temporal sequence findings (e.g., Ariely and Carmon 2000; Baumgartner, Sujan, and Padgett 1997) tend to be ad hoc in nature and are limited to explaining reported findings rather than offering a comprehensive account of the findings in the literature. We propose that adopting a memory-based framework can provide a parsimonious explanation for the findings on retrospective evaluations of temporal sequence.

Retrospective evaluations inherently require that people recall aspects of the experience. Past research suggests that information that is easily accessible in memory will impact judgments the most (e.g., Hamilton and Gifford 1976; Tversky and Kahneman 1973). Accessibility of information has been studied in the memory literature using a free recall task in which people are presented with a list of words that they may recall in any order (Ashcraft 2002). Findings from this research show that respondents have higher recall performance on early items on a list (primacy) because these items receive sufficient rehearsals to transfer them to long-term memory and final items on a list (recency) because these items are temporarily available in short-term memory. Though a temporal sequence is affective in nature and a free recall task is cognitive in nature, we suggest that there are parallels between an affective experience and the experience of learning a list. Thus, memory findings on free recall are expected to explain current findings in the temporal sequence literature and predict findings that would otherwise not be predicted by the temporal sequence literature.

In studies 1 and 2, we test whether a memory-based framework, utilizing primacy and recency effects, can account for the impact of the beginning, end, and trend of an experience on retrospective evaluations of the experience (e.g., Ariely 1998; Redelmeier and Kahneman 1996). Specifically, we argue that assuming that a memory-based structure is responsible for temporal sequence findings, then introducing a delay between an affective experience and evaluations of the experience should diminish the impact of the end of an experience and enhance the impact of the beginning of an experience on retrospective evaluations, reversing consumer preferences for improving versus declining trends. Consistent with expectations, in study 1 we show that an improving vacation experience is evaluated more favorably immediately than after a delay. Consistent with primacy and recency effects, recall of the early instances was not affected by the delay; however, recall of the final incidents declined following a delay. Study 2 replicates the findings from study 1 using both an improving and declining vacation trend and demonstrates that the differential memory for events is based on their temporal location, not their valence. Consistent with a memory-based explanation, the final events in the vacation are heavily weighted when the experience is evaluated

immediately, replicating the findings from Redelmeier and Kahneman (1996). However, the initial events are heavily weighted when the experience is evaluated following a delay, resulting in higher evaluations for the improving trend immediately but a preference for the declining trend following a delay, a finding which is predicted by proposed framework but contrary to previous findings in the temporal sequence literature (e.g., Ariely 1998; Redelmeier and Kahneman 1996).

Studies 3 and 4 further confirm the role of memory by manipulating the uniqueness of one event in a vacation experience to test whether a memory-based structure can account for the impact of the peak of an experience on retrospective evaluations of the experience (e.g., Kahneman et al. 1993). Uniqueness is examined because past research using diary studies suggests that intense emotional experiences are unique (Bower 1981), leading to the expectation that peak intensity incidents are more accessible than other incidents because they are uncommon, consistent with the von Restorff effect in memory (Wallace 1965). We argue that if a peak intensity event occurs in a temporal location of an experience that impedes memory, such as the center or end of an experience that is evaluated following a delay (Ashcraft 2002), then making that event unique will facilitate recall of the event and result in that event being heavily weighted in retrospective evaluations of the experience. Consistent with expectations, study 3 shows that making the peak intensity final event in an improving vacation experience atypical enhances the recall of this event following a delay relative to a common event with the same affective intensity, demonstrating a recovery of the recency effect previously shown to diminish after a delay. Additionally, study 3 shows that evaluations are based on the peak intensity final event when the event is unique, consistent with Kahneman et al. (1993), while evaluations are based on the initial events when the peak intensity final event is common, contrary to previous findings (e.g., Fredrickson and Kahneman 1993). Study 4 further confirms these findings by replicating the results with the peak incident in the center of an experience and by demonstrating the robustness of the effects for both positively and negatively-valenced peak incidents.

In sum, the findings from this research demonstrate that a conventional memory-based framework appears to provide a coherent structure to account for consumers' use of specific aspects of a temporal sequence when forming retrospective evaluations of an experience. In addition to accounting for past findings such as a preference for improving over declining temporal sequences and the important role of peak (both high intensity and unique) experiences, our findings demonstrate that imposing a delay prior to retrospective evaluations can create a preference reversal due to the reduced accessibility of final or common instances.

Mood and Comparative Judgment

Cheng Qiu, National University of Singapore, Singapore
Catherine W. M. Yeung, National University of Singapore, Singapore

EXTENDED ABSTRACT

Previous research has shown that consumers' affective experience, regardless of whether it is a genuine integral affective response to a target, or a feeling arising incidentally from a transient mood state, can influence their evaluations of products (e.g., Adaval 2001; Pham 1998; Schwarz and Clore 1996). While we know mood can influence consumers' absolute judgments of products, we are less clear about how it would influence consumers' comparative judgments and choices among products. Consider a consumer who is choosing among a number of options. Suppose s/he happens to be experiencing a mood state when s/he receives information on each of these options one by one, would mood influence his/her evaluations of each of the options to a similar extent, and hence have no *net* effect on choice? Alternatively, would mood influence evaluations of only one of the options, and lead to changes of his/her choice? If so, which particular option would be influenced? Our research provides answers to this series of questions.

We suggest that mood can have a differential effect on comparative judgment because consumers are likely to incorporate their mood into the first evaluation being constructed during the comparison process. Moreover, once incorporated, mood will cease to influence evaluations of the latter options because its informational value for these options will be discounted. Note, however, consumers may form the first evaluation at different points in time during the comparison process. When the timing of the first evaluation varies, the influence of mood on comparison may vary accordingly. Suppose consumers evaluate the very first option from a set (e.g., the item shown on the first page of a catalog) right away when they encounter it, before they see the other options. Their mood is likely to be incorporated into the evaluation of this first option rather than into those of the subsequent ones. Alternatively, suppose consumers deliberately wait until they encounter the last option before beginning their evaluation and take a perspective focusing on the last encountered option. In this case, the evaluation into which mood is incorporated may "shift" to the last option. As such, we expect mood to influence the evaluation of the last option, rather than those of the preceding ones.

We further show that the timing of constructing the first evaluation may vary systematically as a function of choice set characteristics. For example, it may depend on whether the alternatives are differentiated by descriptive features or by their global appearance. When consumers choose among options that have similar descriptive features but differ in external appearance, they are likely to form an evaluation of the first option very quickly once they come across it, without waiting to see the comparison options. Consequently, their mood is likely to influence their evaluations of the first encountered option, and hence their choices of this option. In contrast, when consumers choose among options that are differentiated by descriptive features, they tend to wait until they have encountered all the options and to know about their features before making any comparison. Consequently, their mood is likely to influence their evaluations of the last encountered option, and hence their choices of this option.

Three experiments were conducted to test the above predictions regarding (a) how the influence of mood on comparison may vary as a function of the timing of the first evaluation and choice set characteristics and (b) the underlying mechanism through which the influence occurs.

Experiment 1. We examined the influence of mood on choices among options that only differed in global, aesthetic aspects. We induced participants' mood by asking them to write a piece of happy or unhappy personal experience. Then they moved on to the second (ostensibly unrelated) task where they saw pictures of three mango-flavored desserts sequentially. After that, they indicated their choices and absolute evaluations of the options. As predicted, the choice share of the first option was higher when participants were happy than when they were unhappy. Absolute evaluation data confirmed that happy participants liked the first option more than the unhappy participants did.

Experiment 2. In experiment 2, the timing of the first evaluation was delayed to the last option due to changes in choice set characteristics. The procedure was essentially the same as experiment 1. However, participants chose among three desserts that differed in flavor (which is presumably an important descriptive feature for desserts). Consistent with our prediction, choice share of the last option was higher when participants were happy than when they were unhappy. Happy participants also liked the last option more than their unhappy counterparts.

Experiment 3. In experiments 1 and 2, we assumed the timing of the first evaluation would change as a function of choice set characteristics. While the literature provides theoretical supports for the assumptions, we validated these assumptions empirically in experiment 3 by manipulating the timing of the first evaluation through experimental instructions. This experiment had a 2 (induced mood: positive vs. negative) by 2 (flavor: same-flavor vs. different-flavor) by 3 (instruction on the timing of the first evaluation: no-instruction vs. immediate-judgment vs. deferred-judgment) factorial design. Participants either received no instruction or an instruction as to when to start making their evaluations before they saw pictures of two desserts. After seeing the two options one by one, they indicated their relative preferences. As predicted, happy participants in the immediate-judgment group of conditions (i.e., the "no-instruction, same-flavor" condition and the two "immediate-judgment" conditions) had a stronger preference for the first option, whereas their unhappy counterparts had a weaker preference for the first option. A reversed pattern was observed in the deferred-judgment group of conditions (i.e., the "no-instruction, different-flavor" condition and the two "deferred-judgment" conditions).

In combination, findings from experiments 1-3 support the notion that mood is likely to be incorporated into the first evaluation consumers make during a comparison process, and this evaluation could be the evaluation of the initial option or the final option of a choice set.

Complexity Effects on Consumer Choice Consistency

Benedict Dellaert, Erasmus University Rotterdam, The Netherlands

Bas Donkers, Erasmus University Rotterdam, The Netherlands

Bernard Conlon, TNS Australia, Sydney, Australia

Arthur Van Soest, Tilburg University, The Netherlands

EXTENDED ABSTRACT

The consistency with which consumers make product choices has important consequences for organizations interacting with consumers. If consumer choices are not very consistent (i.e., if consumers do not make the same choices in otherwise identical choice situations), the impact of changes in marketing mix variables on choice will be lowered. This situation may be harmful to for example innovative producers that develop products that are superior to existing alternatives. The reason is that if consumers do not respond consistently to the new product's strengths in their decisions, market share of the new product will be lower than it could otherwise have been. For consumers also it may be undesirable to make inconsistent choices, for example if it leads them to ignore beneficial product attributes in making product purchase decisions.

In this study we focus on choice set complexity as a potentially important driver of consumer choice consistency. Recent empirical work on the relationship between effort and consistency (Haaijer et al. 2000), and on the effects of choice set composition on the level of error in consumer choice models (Caussade et al. 2005, Swait and Adamowicz 2001) suggests that consumer choice consistency may vary with complexity. We add to this research an analysis of observed consistency in consumers' repeated choices and how it is affected by task-based and context-based complexity.

Task-based complexity refers to the number of cognitive steps a consumer needs to choose an optimal product (Johnson and Payne, 1985). It is expressed as the combined effect of the number of attributes and the number of alternatives in the choice set. Context-based complexity refers to the difficulty of the trade offs that consumers have to make. We express this effect using three variables based on Shugan (1980): the variability of the attribute utilities of the products in the choice set (VAR), the covariance between the attribute utilities of these products (COV), and the difference in total utility between these products (DIF).

The effects of choice set complexity on choice consistency are not straightforward. The simulation analysis of Johnson and Payne (1985) shows that with equal effort, consumer choice consistency is inversely related to choice complexity. The effect of complexity on consistency then depends on how consumers adapt their choice strategy and their effort level. In particular, if consumers respond to increased complexity by increasing their effort, the consistency of their decisions may be stable (or even improve) if complexity increases.

Results of Haaijer et al. (2000) suggest that in general consumers' effort responses to increases in choice set complexity are not sufficient to maintain equal choice consistency. Fischer et al. (2000) analyze consumer preference judgments. They find that, if judgment tasks become more complex in terms of variance, responses take more effort and become less accurate. The latter finding suggests that increases in VAR in a choice context may also lead to less consistent choice behavior. Dellaert et al. (1999) find that logit model error increases when price based utility trade-offs increase. This effect also suggests that increases in VAR (i.e., higher price variance), and possibly decreases in COV (i.e., lower correlations between price and other attributes), lead to less accu-

rate choices. An opposing effect of increases in VAR may be that the differences between the products become larger, increasing the incentives to perform well in the choice task. Hence, VAR could also increase choice consistency as more effort is exerted. With respect to task complexity, Caussade et al (2005) investigate the effects of the number of alternatives and the number of attributes, finding a positive effect of the number of alternatives and a negative effect on the number of attributes, implying a mixed result for the effect of task complexity (TASK). We are not aware of previous research on the effect of DIF, but greater differences in utility make the best alternative stand out from the rest, we expect it to facilitate consistency in choosing the best alternative from a set.

To investigate the proposed effects of complexity on consistency, data was collected through a stated choice experiment where each one of the 1114 respondents was randomly assigned to two of twelve possible choice complexity conditions. These twelve choice conditions were composed of different numbers of alternatives, different numbers of attributes, and different attribute levels, resulting in substantial variation in task and context complexity across conditions.

To quantify context-based complexity and its effects on choice consistency we first estimate a heteroskedastic mixed logit model. The variance of the error component in the mixed logit model is allowed to vary across choice sets, permitting the level of error in the choice model estimates to vary freely on choice set composition. In the next step, we obtain individual level preference parameters. These parameters are used to compute attribute utilities for each alternative for each respondent in each condition. Based on these utilities we calculate measures VAR, COV and DIF for each choice set. TASK is a function of the number of attributes and alternatives only, and varies only across choice sets.

In our main analysis, we empirically test the effects of choice set complexity on choice consistency using a Logit model. The dependent variable is whether the repeated choice task is performed consistently, i.e. the same alternative is chosen twice or not, and the independent variables are the complexity measures introduced above. The results show that TASK complexity decreases consistency and we conclude that increases in task complexity are not sufficiently compensated by increased effort to maintain the same level of accuracy. For context complexity, we find that differences in utility between the alternatives in the choice set increased choice consistency, Variance of the attribute utilities in the choice set alternatives also increased choice consistency, and the effect of covariance between the attribute utilities in the choice set alternatives was not significant. These results suggest that increased differences in utility between alternatives and greater variability in the attribute levels raise the stakes to the decision maker, resulting in more effort being exerted in the choice task and higher choice consistency.

Recollections of Pleasure and Pain: When Losers are Motivated to Edit their Retrospective Evaluations

Elizabeth Cowley, University of Sydney, Australia

Colin Farrell, University of Sydney, Australia

EXTENDED ABSTRACT

People have unrealistically positive views of self and are unrealistically optimistic about the future (Taylor and Brown 1988). For instance, they believe they will be more likely than their peers to like their first job, earn a good salary, and have a 'gifted' child (Weinstein 1980). On the other hand, people believe that they are much less likely than their peers to be a victim of crime (Perloff and Fetzer 1986) or contract the HIV virus (Raghubir and Menon 1998). All of these examples show that people are optimistic when they predict the outcome of future events. Will the same biases occur when people reflect back on events that have already occurred? Are people motivated to make the past seem better than it was? Autobiographical memory research shows that the intensity of negative affect associated with memories fades faster over time than positive affect (Walker, Vogl, and Thompson 1997). Additionally, hedonic editing suggests that people focus on the 'silver lining' in a loss frame (Thaler 1985) to maximize their happiness. However, to date there is no evidence that people in a loss frame edit their retrospective evaluations of an experience to be more positive.

We propose that gamblers in a loss frame are motivated to hedonically edit their evaluation of the experience such that the gambling experience will be remembered more positively. We show that losers use the peak win to improve the retrospective evaluation of a gambling session. In particular, gamblers that believe that winning at gambling is a skill they possess are motivated to edit their retrospective evaluation of a losing gambling episode. We also propose that gamblers are not motivated to hedonically edit their evaluation of a winning gambling episode. Instead, we show that the retrospective evaluation of the winners is determined by the amount of cash they won, regardless of their belief that gambling is a skill that they possess.

In study 1, participants were given 30 opportunities to bet on the future outcome of a coin toss. Once each outcome was revealed, the study administrator distributed winnings and collected losses based on the outcome of the coin toss. Participants were asked to report how the outcome of the bet made them feel by marking an 'X' on a 125 mm continuous scale anchored with a happy face and a sad face. A time series cross sectional regression analysis was run on moment-by-moment evaluations with the outcome for each bet as the independent variable as an additional test of whether the current outcome explained the current moment-by-moment evaluation. To check for the independence of moment-by-moment evaluations, a lagged outcome variable and a lagged evaluation variable were included to test whether current moment-by-moment evaluations were affected by the previous outcome or the evaluation associated with the previous outcome. The results indicate that the current outcome explained the moment-by-moment evaluation, that there were no remnants of the previous outcome, and that there were only slight remnants of previous evaluations. This is an important finding because study 2 is based on an assumption that the outcome of each gamble (amount won or lost) determines the moment-by-moment evaluations.

In Study 2, 102 gamblers bet on 20 coin toss games. After the gambling experience, gamblers were asked to report their evaluations of the experience and their intention to replay the game, and the illusion of control scale.

The retrospective evaluations of winners and losers were tested with separate regressions including the amount of money

won on the peak win, the amount of money lost on the peak loss, the trend of outcomes (winning, losing), the final cash position, and their score on the illusion of control scale. The retrospective evaluation of the experience for winners was determined by the final cash position only, a larger win resulted in a more positive retrospective evaluation. The retrospective evaluation for losers was determined by the peak win. Losers appear to look for the silver lining (i.e. something positive) in an otherwise negative situation. The illusion of control score was also significant: the higher the illusion of control, the more positive the retrospective evaluation.

We also ran an ANOVA on the retrospective evaluation with final outcome (winner, loser) and the illusion of control score (high, low). The ANOVA revealed a significant interaction. It is the losers with a high score on the illusion of control scale that edit the retrospective evaluation to be more positive. The losers with a low illusion of control score were significantly less positive than the winners with a low illusion of control score. The losers with a high illusion of control were not significantly different in their evaluation of the experience.

Previous research has found that the peak moment and the final moments of an experience play an important role in the construction of retrospective evaluations of purely painful experiences. An opportunity to use an optimizing strategy in the construction of a retrospective evaluation is present when reflecting back on a mixed experience that is not available when remembering a purely painful experience. We found that when people are asked about a past gambling experience, the peak win is important in the memory of losers and the final cash outcome is important in the memory of winners: facilitating the construction of a most positive retrospective evaluation. Interestingly, we found that the illusion of control did not affect the retrospective evaluation of the winners, but it did affect the losers. It was the losers with a high illusion of control score that edited their retrospective evaluation.
