Advances in Consumer Research, Volume 35

(Duluth, MN:  Association for Consumer Research, 2008)

# Preface

The 35th Annual Conference of the Association for Consumer Research was held at the Peabody Hotel in Memphis, Tennessee, U.S.A., from October 25–28, 2007. These proceedings include papers, reports, summaries and commentaries on research and discussions presented at the conference.

The theme of the ACR 2007 Conference was "Building Bridges." Over the past decades, the field of consumer research has evolved, grown, and specialized according to theoretical paradigms, methodological interests, substantive applications, and geographies. One important goal of the conference was to provide the forum for intellectual exchanges and the building of bridges across different subgroups. Innovations in this year's program included three epistemic sessions representing each of the three areas in consumer research–Consumer Culture Theory, Information Processing, and Judgment & Decision Making. The sessions were open discussions led by a panel of experts that dissected issues central to consumer researchers such as constructs and measurements, consumer freedom, and future of the field. Guided tours were conducted at the working paper session where experts led interested scholars through select posters on various topics. And junior scholars were provided with the opportunity to meet and interact with leaders of the field at the Presidents' and Fellows' Corner.

The key to the success of any conference lies in the quality of research presented, as well as the coherence and structure of the conference program. This year we set the record for number of submissions (over 700 across all categories), acceptance rates, and attendance (over 900 in total including 330 doctoral students). We accepted for presentation 53% of the 109 symposium proposals submitted, 46% of the 408 competitive papers, 125 working papers, nine films and six roundtables. We thank all the authors, and the symposia and roundtable chairs for submitting very high quality research to the conference. We also thank our program committee, our competitive program committee, and all the reviewers for their commitment and support in helping us put forward an exceptional program. In particular, we thank the following individuals who took academic leadership of various parts of the conference program: Joel Huber, David Mick, Brian Sternthal (Epistemic Sessions), Russ Belk, Rob Kozinets (Film Festival), Simona Botti, Raj Raghunathan (Roundtables), Lance Erickson and Narayan Janakiraman (Working Papers), Rohini Ahluwalia, Russ Belk and Baba Shiv (Doctoral Symposium). And special thanks go to Donna Hoffman and Eric Johnson for organizing and co-chairing the online preconference.

In addition, several other individuals deserve our sincerest thanks and gratitude. The conference ran smoothly largely due to the tireless efforts of ACR Executive Director Rajiv Vaidyanathan, ACR conference coordinator Patty Salo Downs, local experts Balaji Krishnan and Cele Otnes, as well as the student volunteers from Northwestern University, University of Toronto, University of Memphis and York University. We also appreciate the time and efforts of Miguel Brendl, Tory Higgins, Punam Anand Keller, Lisa Peñaloza and Baba Shiv who served as expert guides at the working paper session. Lolotte Olkowski, Northwestern University, was the hand and voice behind a lot of the organizational efforts. We also owe special thanks to Alex Cherfas for his help with the ACR conference web system, and the proceedings would not have been published but for the efforts of Carol and Steve Barnett. Finally, we thank Merrie Brucks, President of ACR, for trusting us with this conference. And we are grateful to past conference chairs Susan Broniarczyk, Gavan Fitzsimons, Geeta Menon, Joan Meyers-Levy, Vicki Morwitz, Connie Pechmann, Linda Price and Akshay Rao for all the advice and support they gave us along the way.

Angela Y. Lee, Northwestern University
Dilip Soman, University of Toronto
2007 ACR Conference Co-Chairs and Proceedings Editors

# Conference Committees and Reviewers

**PRESIDENT**
Merrie Brucks, University of Arizona

**CONFERENCE CHAIRS**
Angela Y. Lee, Northwestern University
Dilip Soman, University of Toronto

**PRECONFERENCE CHAIRS**
Donna L. Hoffman, University of California, Riverside
Eric Johnson, Columbia University

**COMPETITIVE PROGRAM COMMITTEE**
Miguel Brendl, Northwestern University
Margaret C. Campbell, University of Colorado, Boulder
Darren Dahl, University of British Columbia
Susan Fournier, Boston University
Zeynep Gurhan-Canli, Koc University
Stijn van Osselaer, Erasmus University
Steve Posavac, Vanderbilt University
Rebecca Ratner, University of Maryland
Craig Thompson, University of Wisconsin, Madison
Gal Zauberman, University of Pennsylvania

**PROGRAM COMMITTEE**

Rashmi Adaval, Hong Kong University of Science & Technology
Pankaj Aggarwal, University of Toronto
Nidhi Agrawal, Northwestern University
Dan Ariely, Massachusetts Institute of Technology
Eric Arnould, University of Arizona
Soren Askegaard, University of Southern Denmark
Susan Broniarczyk, University of Texas, Austin
Frederic Brunel, Boston University
Katherine Burson, University of Michigan
Dipankar Chakravarti, University of Colorado, Boulder
Tanya Chartrand, Duke University
Amar Cheema, Washington University
Alan Cooke, University of Florida
David Crockett, University of South Carolina
Peter Darke, Florida State University
Ravi Dhar, Yale University
Sasha Fedorikhin, Indiana University
Robert Fisher, University of Alberta
Gavan Fitzsimons, Duke University
John Gourville, Harvard University
Young Won Ha, Sogang University
Scott Hawkins, University of Toronto
Christopher Hsee, University of Chicago
Jeff Inman, University of Pittsburgh
Chris Janiszewski, University of Florida
Hope Jensen Schau, University of Arizona
Susan Jung Grant, University of Colorado, Boulder
Frank Kardes, University of Cincinnati
Punam Keller, Dartmouth College

Amna Kirmani, University of Maryland
Robert Kozinets, York University
Shanker Krishnan, Indiana University
Aparna Labroo, University of Chicago
Donald Lichtenstein, University of Colorado, Boulder
Mary Frances Luce, Duke University
Tridib Mazumdar, Syracuse University
Ann McGill, University of Chicago
Meg Meloy, Penn State University
Vikas Mittal, Rice University
Vicki Morwitz, New York University
Albert Muniz, DePaul University
Dhananjay Nayakankuppam, University of Iowa
Thomas O'Guinn, University of Wisconsin, Madison
Julie Ozanne, Virginia Tech
Lisa N. Penaloza, University of Utah
Michel Tuan Pham, Columbia University
Linda Price, University of Arizona
Ratti Ratneshwar, University of Missouri, Columbia
Aric Rindfleisch, University of Wisconsin, Madison
Derek Rucker, Northwestern University
Stewart Shapiro, University of Delaware
Sharon Shavitt, University of Illinois, Urbana-Champaign
Jing Wang, University of Iowa
Klaus Wertenbroch, INSEAD
Richard Wilk, Indiana University
Catherine Yeung, National University of Singapore
Carolyn Yoon, University of Michigan
Gal Zauberman, University of Pennsylvania
Rui (Juliet) Zhu, University of British Columbia

**DOCTORAL SYMPOSIUM CHAIRS**
Rohini Ahluwalia, University of Minnesota
Russell Belk, York University
Baba Shiv, Stanford University

**EPISTEMIC SESSIONS CHAIRS**
Joel Huber, Duke University
David Mick, University of Virginia
Brian Sternthal, Northwestern University

**FILM FESTIVAL CHAIRS**
Russell Belk, York University
Robert V. Kozinets, York University

**ROUNDTABLES SESSION CHAIRS**
Simona Botti, London Business School
Raj Raghunathan, University of Texas, Austin

**WORKING PAPERS SESSION CHAIRS**
Lance-Michael Erickson, University of Arizona
Narayan Janakiraman, University of Arizona

**WORKING PAPER EXPERT GUIDES**
Miguel Brendl, Northwestern University
E. Tory Higgins, Columbia University
Punam Anand Keller, Dartmouth College
Lisa Penaloza, University of Utah
Baba Shiv, Stanford University

**LOCAL ARRANGEMENTS**
Balaji Krishnan, University of Memphis
Cele Otnes, University of Illinois, Urbana-Champaign

**PRESIDENTS & FELLOWS CORNER**
Nidhi Agrawal, Northwestern University
Catherine Yeung, National University of Singapore

**COMPETITIVE PAPER REVIEWERS**

**Friday, October 26, 2007**
**EPISTEMIC SESSIONS**
8:00am-8:55am

Epistemic Session 1: *Consumer Culture Theory and Consumer Freedom*
Epistemic Session 2: *What Counts as Knowledge in Judgment and Decision Making*
Epistemic Session 2: *Rigor in Information Processing Research*

**Friday, October 26, 2007**
**SESSION 1**
9:00am-10:15am

1.01   *Consumers' Construal Levels: Organic Manipulations and Implications for Choice*
1.02   *Bridging Cultures: Theorizing the Spaces between Disciplines, Peoples and Consumer Identities*
1.03   *"Money Makes the World Go 'Round–and Other Interesting Effects on Affect, Consumption, Goal Pursuit, and Generosity"*
1.04   *Price Perceptions: The Role of Framing and Context*
1.05   *Cross-Cultural Differences in Responses to Products and Promotions*
1.06   *Health Marketing: Understanding Consumer Response to Risk and Remedy Messages*
1.07   *Understanding the Role of Co-Creation in Fantasy and Fun*
1.08   *What Drives Word of Mouth: A Multi-Disciplinary Perspective*
1.09   *Consumer Resistance and Other Socially-Motivated Behaviors*
1.10   *Issues in Measurements: Application, Scaling and Response Bias*
1.11   *New Insights in Consumer Point-of-Purchase Decision Making*

**Friday, October 26, 2007**
**SESSION 2**
10:45am-12:00pm

2.01   *Temporal Consumption: How Time Influences our Memories of the Past, our Enjoyment of the Present, and our Preference for the Future*
2.02   *"You'll Take the High Road and I'll Take the Low Road" : The Multiple Routes of Affective Influences on Consumer Behavior*
2.03   *Understanding Collaboration and Collective Production: New Insights on Consumer Co-Production*
2.04   *Commercial Mythology and the Global Organization of Consumption*
2.05   *How Do Goals Function?*
2.06   *Consumption, Health, and Consumer Wellbeing*
2.07   *Consumption Over Time: Predictions of Future Use and Value*
2.08   *Retailing and In-Store Consumer Behavior*
2.09   *Categories in Context*
2.10   *Culture Matters: Effects on Search, Information Processing and Response*
2.11   *Is Beauty Only Screen Deep? Perceptions of Avatars in Computer-Mediated Environments*

**Friday, October 26, 2007**
**SESSION 3**
1:45pm-3:00pm

3.01   *Erroneous Lay Theories of Future Affect: Processes and Consequences*
3.02   *Consumer Motivation: Identifying Factors that Increase Goal Adherence*

**Sunday, October 28, 2007**
**ROUNDTABLE SESSION**
9:00am-11:00am

| 11.01. Roundtable Session: | *Introduction to Structural Equations Models and Lisrel* |
| 11.02. Roundtable Session: | *Defining and Exploring Exorbitant Buying Behavior* |
| 11.03. Roundtable Session: | *Philosophy and Consumption: Discussions onTtrust and Brands* |
| 11.04. Roundtable Session: | *Internet Tracking and Clickstream Data: Methodological Issues* |
| 11.05. Roundtable Session: | *Conducting Consumer Research in China & India: Issues, Challenges and New Directions* |
| 11.06. Roundtable Session: | *Interrogating Fashion: Fashion Cultures and Fashion Discourses* |

# Working Paper Abstracts

# Choices in Consumer Research: Unintended Consequences

Merrie Brucks, University of Arizona, USA

## ABSTRACT

This paper is a slightly revised version of the presidential address delivered on October 26, 2007 at the Association for Consumer Research conference in Memphis, Tennessee. In this address, I explore how individual choices shape the overall composition of literature that ACR members claim to be our unique contribution to social science. I argue that structural and psychological factors shape individual decisions in a predictable manner, resulting in systematic distortions in the amount of attention focused on various types of consumption and purchase phenomena. Finally, I will discuss some recommendations for how we might reshape our body of knowledge to achieve greater representativeness in our literature.

We gather at ACR to discuss and explore ideas about the behavior of consumers. In contrast, I am going to talk to you today about the behavior of consumer *researchers*, in particular, how we (as behavioral scholars) choose research topics. The selection of a research topic is one of the highest involvement choices you and I will ever make. For example, the choice of a dissertation topic commits you to years of extensive study and writing, as well as public presentations at conferences and job interviews, and ultimately negotiating with reviewers and editors through multiple rounds and possibly multiple journals when it comes time to publish your findings. If your chosen path turns out to be fruitful, you may even spend a lifetime exploring your topic.

Clearly, the choice of research topic has many immediate and obvious consequences to the individual. But my talk today turns our attention to the aggregate level, exploring how individual choices shape the overall composition of literature that ACR members claim to be our unique contribution to social science. I will make the case that structural and psychological factors shape individual decisions in a predictable manner, resulting in systematic distortions in the amount of attention focused on various types of consumption and purchase phenomena. Finally, I will discuss some recommendations for how we might reshape our body of knowledge to achieve greater representativeness (Shimp 1994) in our literature.

## INDIVIDUAL CHOICE PROCESSES

Think for a moment about your current research projects. How did you happen to choose these particular topics? Out of all the possible research questions one could construct, *why these*? Imagine for a moment that you could symbolize every possible research topic as a door along a hallway. Behind each metaphorical door is a path of unknown length and uncertain obstacles, with an uncertain outcome. Which door(s) do you open? Which threshold(s) will you cross? That is the question I am posing to you.

I am going to share some ideas based on my long-term interest in how researchers actually make that decision and what some of the influences are. I rely in part on my experiences with interviewing doctoral students for faculty positions, and in reading research advice columns and published interviews with young and established scholars as reported in newsletters of ACR and related organizations. Based on these materials, along with some unavoidable researcher introspection, I identified a list of easily articulated influences on choices of research topics: (1) recognition of gaps in the scholarly literature; (2) gentle or pointed influence from advi-

sors and mentors (I completed my Ph.D. over 20 years ago, and I still recognize the influence of my doctoral advisors, Andy Mitchell and Rick Staelin, as I work to define research problems); (3) consideration of substantive issues and available support to study those issues (for example, the Marketing Science Institute and ACR's Transformational Consumer Research make issues salient and provide resources to facilitate research on specific topics); and (4) the perception that a research area is "hot", which we judge by gauging enthusiasm for various topics at conferences such as this one.

### Resonance with Self

In addition to these fairly obvious factors, I see another important influence in the selection of research topics: resonance with self. From a scholarly perspective, the idea that we are attracted to research topics that resonate with us at a personal level is a natural extension of the growing literature on the relationship between self and consumption behavior (e.g., self-concept, extended self, self-brand relationships, identity projects, etc.). The conduct of scholarly research may be viewed as a consumption activity. We consume and produce ideas, motivated by implicit and explicit goals. We selectively attend to information, process it through the filter of our past understandings, make decisions on how to proceed, and respond to feedback along the way. These behaviors are embedded within social networks and institutions. Compared to other consumer behaviors we might study, choosing a research topic is relatively personal and highly consequential. Not only will you be immersed in your topic of choice for years to come, but this topic also will define your professional identity.

Think for a moment about the scholars you know and the topics they study. Do you see any connections? What about your own research? These "self-research" connections may be quite intentional on the part of the researcher (e.g., "I'm studying cancer awareness because my mother died of cancer"), or quite subtle (e.g., "I've always been drawn to the study of [insert personality trait or consumption behavior here]"). Leaders in the field often advise young scholars to pursue research topics they feel passionately about. This advice makes sense since studies have shown that scholars are more productive and impactful when internally motivated rather than externally driven (see for example, Richins 2000). Another reason for the occurrence of self-research connections is that personal observations often serve as the spark that ignites a research project. Again, it makes intuitive sense to ground literature in actual consumer phenomena (see for example, David Mick's (2005) Presidential column, "I Like to Watch") because we like to think about ourselves and the people around us. Doing so is a natural part of the human condition.

### How Pervasive is the Self-Research Connection?

While preparing this address, I received the October issue of the Association for Psychological Science's newsletter, the *Observer*, in the mail. This issue featured profiles of ten young productive, influential, and potentially path-breaking scholars in Psychology. These young researchers were interviewed about what they work on, why they work on it, and how they were drawn to the topic (*Observer* 2007). These interviews seemed like an ideal data set to provide insight on this question, since they offered access to a wide range of people not otherwise accessible to me. I analyzed

these interviews as text, coding the data pertaining to choice of research topics. My general finding was that the researchers could be segmented into two basic groups regarding the degree of personal connection evidenced in these interviews.

The six researchers in the first group articulated a personal connection to their research, which appeared to be a strong influence on their choice of topics. Here are some excerpts from those interviews:

> "I was advised to do what interests me the most. I started with self-perception because I was most interested in 'myself'." [Kwan]

> "I have been fascinated by self-improvement since I was a kid." [Kornell]

> "I have always been fascinated by the idea that reality is a mental construction." [Gallo]

> "During graduate school, I came to realize that I was most interested in the impact of relationships, past and present, on the self… That other people can play such a profound role on shaping who we are is fascinating to me." [Chen]

> "I have always had a personal interest in politics, and my focus on attitudes and attitude strength really grew out of this interest." [Visser]

> "I grew up hearing dinner table conversations about interesting language phenomena… Both the issues… and the methods excited me then, and they continue to excite me now. [Saffran]

Each of these excerpts make a statement about how these people chose a research topic based upon who they are and what they connect with.

The second group of researchers was more focused on research outcomes. They were on a problem-solving quest, as evidenced in the following excerpts:

> "Developing a formal, rigorous, and mechanistic answer to the question of how cognitive control arises in the mind and brain can be considered to be the 'holy grail' of scientific psychology and neuroscience. I find it incredibly exciting to be contributing to this quest for understanding." [Braver]

> "The potential of an integrative discipline of quantitative clinical-cognitive science remains largely untapped. This relatively unexplored niche fascinated me as an undergraduate." [Treat]

> "I was assigned to analyze data from a drug trial of a potential treatment for cognitive deficits associated with Alzheimer's disease… and I become hooked on cognitive neuroscience…As for the research questions I am drawn to now, I think they all have their roots, to some extent, in my early interest in logic and mathematics." [Thompson-Schill]

> "I was drawn to this line of work because I believed it would provide the foundation for promoting positive development among children." [Pomerantz]

The four scholars in this group appear to be motivated by solving a problem or by contributing to science. But even in this group, one can still observe a personal connection and identification with their work.

The data from these interviews pertain only to scholars in Psychology. You may be wondering whether it is reasonable to generalize to consumer research as a field of study. Both fields focus on human behavior, although there are some fundamental differences in domain. Consumer Behavior is clearly an applied field, defined by its focus on particular human behaviors (Folkes 2002). Despite the applied nature of consumer research, the institutional structure of business schools permits scholars housed in these colleges the freedom to choose topics with relatively little concern for project sponsorship. (The vast majority of ACR members are primarily affiliated with business schools). As such, we are generally not expected to bring in large grants to fund our students and ourselves. We receive summer support from our deans, and research funding is often part of our contractual package. onsequently, we are not forced to go out and obtain sponsors who believe in and buy into our research projects. In addition, if you look at the ACR Presidential and Fellows addresses over the years, you can see that we are a bit ambivalent about the importance of being "relevant". For these reasons, I assert that we have much more freedom to indulge our self interests than do our counterparts in many of the basic social sciences.

Another way I was able to gauge the prevalence of self-research connections in our field was to reflect on my experience of interviewing potential faculty candidates at the AMA Summer Educators' Conference. I have talked to approximately 400 doctoral students in that capacity. I almost always ask these faculty candidates how and why they picked their research topics. The answers are quite revealing. Typically, when I ask a consumer behavior student this question, he or she will respond with a statement about how they personally connect with the topic. It could be something they observed, something they felt, or something they wished they had understood better about their own lives or the lives of loved ones. Whether or not this was the original impetus for their topics, they typically articulate a connection to their own lives. This is in sharp contrast to the doctoral students who position themselves as "managerial" or "strategy." These students typically provide a strategic answer to my question of how they chose their research topic. They explain why the topic is important for managers or for public policy and how their line of research may help solve an important problem. They may quote trade magazines and news sources about the magnitude of the problem to be solved. In this way, they are similar to the second group of psychology scholars. Modeling students sometimes provide a strategic answer as well. But more often, they seem surprised to be asked. Why would it matter how they came to choose their topic? Last year, one student actually responded, "Why would you ask such a question?" When pressed, answers relate to data availability, advisor's expertise, or sudden insight while solving a mathematical problem. Reflecting on the patterns of responses across the set of AMA interviewers, you can see that students reflect who they are and how they think in the way they answer this question. The behavioral students connect their topics to their own experiences and observations of human behavior; managerial students adopt a strategic perspective to explain motivation; and modeling students… well, you get the idea. (For the doctoral students in the audience, the correct answer to the question is one that demonstrates your passion for the topic and your commitment to continue to work on it. It doesn't really matter where your inspiration came from.)

**TABLE 1**
FOCAL RESEARCH TOPICS OF ACR 2007

| EPISTEMIC SESSION | CENTRAL ISSUES |
| --- | --- |
| Judgment and Decision Making | Individuals' preferences and choice outcomes |
| Consumer Information Processing | Individual differences in learning, memory, attitudes, persuasion, and affect |
| Consumer Culture Theory | Power structures, agency, and freedom |

## THE CONNECTION BETWEEN FOCAL RESEARCH TOPICS AND ACADEMIC LIFE

This year's conference includes three plenary sessions, one for each of the three major sub-fields within consumer research as identified by Simonson et al. (2001). The goal of these sessions is to provide a forum for researchers within a given theoretical paradigm to raise contentious theoretical and methodological issues pertinent to their paradigm, and to debate and perhaps move towards a resolution of these issues. Given the broad aims of synthesizing and advancing scholarly knowledge, these sessions are referred to as "epistemic sessions". The title and core issues of each of the epistemic sessions are shown Table 1.

**Traits and Motives of Academicians**

Let's consider how these topics relate to the lives and motives of academics (see, for example, Brown 1984; Cavan 1970; Snodgrass 2002). I will identify four principal academic traits, and show how each is connected to the topics listed in Table 1. First and foremost, academicians value *autonomy*, both personally and professionally. We don't like to be told what to do. I see that many of you can relate to that. We become academics so that we can control how we spend our time, choosing our work hours ("any 80 hours you want, each week" one of my professors once told my econometrics class) and what we do in those hours. We are a strikingly independent group of people. This trait appears to be reflected in the topics we choose to research. As you look over Table 1, you can see an autonomy theme represented in the central issues we study in all three sub-fields: individuals' preferences, individual differences, and agency and freedom.

Second, academicians value *status among peers*. We spend many hours at work hoping to be rewarded with recognition from our peers and prestige for our own personal "brand name" (Snodgrass and Brucks 2004). The financial rewards of dedicated scholarship are few. Perversely, the honors accorded to the top scholars typically require even more unpaid work (e.g., editorial review boards, conference program committees, and promotion and tenure evaluations). In Table 1, you might see the study of "power structures" as related to this academic value. Third, a related value common to academicians is the desire to have an influence on others, to leave a *legacy of ideas*. This motive may make topics such as persuasion, choice outcomes, and power structures particularly salient to academicians.

Finally, a fourth trait of the academician is to approach the world from a *detached, analytical perspective*. We thrive in a world that centers on learning, reasoning, analysis, and thinking. As teachers, we try to develop these skills in our students. Thus, it is not surprising that many of the topics in Table 1 relate to cognitive processes and outcomes. In summary, all of the core issues listed in Table 1, with the notable exception of affect, are directly related to core values and motives of academicians.

**Agentic Versus Communal Goals in Academic Life**

The structure of academic life also exerts an influence on what is salient to academicians. Almost all of us work in universities or aspire to do so. The academic tenure system rewards the pursuit of agentic goals, typically at the cost of achieving communal goals. Three issues I will discuss are the 24/7 workweek, academic entrepreneurship, and geographic mobility.

*Working hours*. Prestige in research requires a prodigious level of scholarly output, while simultaneously meeting the short term demands of teaching and service. In combination with the academician's competitive nature, a rather compulsive work ethic has evolved. For example, Joe Alba quoted the biologist Edward O. Wilson's advice to new Ph.D.s in biology in one of his presidential columns (Alba 1999): "If you choose an academic career you will need 40 hours a week to perform teaching and administrative duties, another 20 hours on top of that to conduct respectable research and still another 20 hours to accomplish really important research" (Wilson 1998), which brings us back to that 80 hour workweek I learned about in my first semester of graduate school. This obsessive work behavior may be admirable in some circles, and might indeed speed scientific discoveries in some fields. But there is a drawback to the glorification of obsessive work behavior in consumer research, if not the social sciences in general (not to mention the obvious implications for individuals and their families). The work-obsessed scholar lives in a world where family, community, and spiritual issues are background rather than foreground issues. In this way, the professor-scholar is encouraged to lead a life that is fundamentally different from the lives of typical consumers that are the intended focus of our research.

*Entrepreneurial research style*. The ultimate success for an academic scholar requires breaking new ground, creating new conceptual frameworks, discovering new phenomena, and being recognized for doing so. There is no glory and few perceived rewards to be gained from working cooperatively as part of a team, as may be the case in a corporate research laboratory. We are expected to discover and innovate on our own, and to inspire others to follow us.

*Geographic mobility*. Geographic mobility is an accepted way of life for most academicians. Doctoral students are expected to seek employment at another university, which necessitates a move in all but the largest cities. After acquiring that first teaching position, one begins the six (or eight or ten) year job interview known as being an assistant professor. Young scholars are typically advised that the best course of action is to maximize their mobility. During this period, the possibility of having to relocate constantly looms on the horizon. From a financial point of view, this enforced rootlessness continues over one's entire career. Most universities allocate the biggest salary raises to professors who pose the highest risk of relocating to another university. Professors who put down roots in the local community lose their perceived mobility to some

degree (except, perhaps, in cities with multiple universities), and thus forfeit their opportunity to receive equal financial compensation for their work. Thus the independent orientation that draws people into the academic life is further accentuated by disconnection from the local community. Taken together, (1) the work-focused lifestyle, (2) the incentive to produce work that can be uniquely identified with the individual researcher, and (3) the disincentive to affiliate with citizens of the local community, can only intensify the salience of agentic goals at the cost of communal goals.

**Culling the Field through the Journal Review Process**

Morris Holbrook once described authors' experiences with submitting articles to journals for peer review as a form of masochism (Holbrook 1986). It takes a tremendous amount of persistence, even obsession, to keep rewriting, answering (pandering to?) reviewers who probably devote less than one percent as much effort in reviewing the paper as the authors do in creating it. Once authors have experienced this process with their first paper, they undertake every new research project with the knowledge of what will happen once they complete the project and submit it for peer review. Given the noted difficulties with the process (see also John Lynch's (1998) presidential address on reviewing), there must be a marked self-selection bias on who is willing to repeatedly subject themselves to such a process. In his ACR presidential address, Don Lehman said, "I was fortunate to get into this business when tenure was easier to obtain but I still think I would rather be a roofer or run a chain saw than endure a seven-year mental and social makeover" (Lehmann 1996). Out of the universe of people who have the ability and motivation to do high quality scholarly research, only a fraction of them are attracted to the idea of spending the bulk of their lives enduring the seemingly endless rounds of attempted intellectual makeovers. And yet, clearly, some people do successfully endure this process. And they become the gatekeepers for the creative work of everyone else, locking in their perspectives as part of the journal's screening process.

The result is apparent when you compare the content of our top journals with the subject matter of the presentations you see here at the conference. The papers presented at ACR conferences are much more diverse, more creative, and explore many more aspects of consumer life than those you see published in our top journals. One potential explanation is that more creative, more diverse topics are associated with lower quality scholarship. Another explanation is that more creative scholars have lower tolerance for the review process and its hegemonic application of intellectual criticism.

## CONSEQUENCES FOR CHOICE OF RESEARCH TOPICS

Previous ACR Presidents have commented on our choice of research topics. In his 1977 presidential address, Hal Kassarjian described consumer research of the time as an exercise in "anthropomorphism", in which we see a reflection of ourselves in the behavior of the consumers we study: "[Given the] countless thousands of insignificant decisions… made by the consumer, to assume a thinking, reasoned, attitudinally influenced decision may well be a classic example of anthropomorphism" (Kassarjian 1978). Valerie Folkes made a similar observation in a presidential column in the *ACR Newsletter*: "The body of consumer knowledge that we call consumer research reflects our own idiosyncrasies…To the extent that we are a homogeneous group, the field reflects what that segment of the population deems important, useful, and interesting" (Folkes 2002).

In fact, the bulk of ACR's presidential addresses indirectly deal with this issue. Table 2 summarizes the key points of several

of these addresses. Each one of these addresses is quite thought-provoking and I refer you to the original sources for deeper insight than I can provide here. I would like to point out the overall picture that emerges from looking at the right column in the table: the depiction of consumers as high involvement, conforming to existing theories, American, isolated from the rest of life, explained through dispassionate discourse, behaving in their own self interests, adult, thoughtful, capable, and non-social. The overall picture that emerges describes the stereotype of a professor!

At the aggregate level, the concerns of Hal Kassarjian and Valerie Folkes appear to be right on target. The body of consumer research does not reach the goal of "representativeness" as set out by Terry Shimp (1994) in his presidential address. As stated by Shimp, the fundamental and abiding purpose of consumer research is to acquire understanding and knowledge of consumer behavior. But much of consumer behavior is outside the everyday life experience of academics, what Jerry Zaltman characterized as "hidden events" in his presidential address (Zaltman 1983). Zaltman defined hidden events as phenomena whose existence we either doubt or deny, or do not know about at all. Hidden events are distinguished from neglected topics, which are purposefully ignored. The literature in social cognition and judgment and decision making provide many theoretical explanations for why everyday phenomena may be hidden from the view of the work-focused academician: for example, selective exposure and selective attention, perceptual biases and schematic biases in assessing meanings, goal priming, memory accessibility, and false consensus bias, to name a few. When you factor in the tendency of researchers to intentionally choose topics of self-relevance, the problem of achieving representativeness in consumer research as a discipline becomes even of greater concern.

As I was reflecting on hidden events, I was reminded of the influential paper by Holbrook and Hirschman (1982), which highlighted consumer "fantasies, feelings, and fun" as neglected topics in consumer research. I began to wonder if these topics are in fact hidden events. Perhaps consumer fantasies, feelings, and fun are on the margins of personal experience for the trend-setters in academic life, and are thus "hidden" from academic view? Maybe we overlooked these topics because, as academics, we are not having that much fun. With this in mind, I began to think how the Holbrook and Hirschman paper might be extended. What other areas of life might be "hidden events" to us, academics living in our isolated ivory mobile homes? In Table 3, I suggest additional hidden events, as possible outcomes of faculty priorities and lifestyle. Although each of these topics has received some attention in the literature, my reading of the literature suggests that the body of research that we consider "consumer behavior" systemically under-represents these issues, both conceptually and empirically.

## SUGGESTIONS AND RECOMMENDATIONS

A multitude of forces lead us to focus on a narrowed set of theoretical issues and behavioral phenomena: disciplinary institutions and culture, university structures, and individual psychology. Thus I organize my thoughts on specific actions accordingly. Some of these suggestions have been made by others in service of different goals. Other suggestions run counter to conventional wisdom.

**ACR and Its Sponsored Conferences and Publication Outlets**

I agree with Richard Bagozzi (1992) that we do not want to over-manage the field from the top-down, which puts too much power in the hands of too few gatekeepers. Instead, it makes sense to create countervailing incentives to expand the vision and resources of individual scholars by facilitating networking and direct-

TABLE 2
VIEWS FROM SELECTED PAST ACR PRESIDENTS

| PRESIDENT (YEAR PUBLISHED) | MORE ATTENTION NEEDED ON: | CONSUMERS OVERLY REPRESENTED AS: |
|---|---|---|
| Hal Kassarjian (1978) | Low involvement, mundane behavior | High involvement |
| Jerry Zaltman (1983) | "Hidden events" | Conforming to existing theories |
| Jag Sheth (1985) | Global perspectives | American |
| Russ Belk (1987) | Embeddedness in "rest of life" | Isolated from "rest of life" |
| Morris Holbrook (1990) | "Lyricism" in communication | Explainable by dispassionate discourse |
| Beth Hirschman (1991) | Dark side of consumption | Behaving in their self-interests |
| Debbie John (1997) | Perspectives from children | Adults |
| Joe Alba (2000) | Mindless, thoughtless behaviors | Thoughtful and capable |
| Marsha Richins (2001) | Big picture, social influences | Non-social |

TABLE 3
FACULTY PRIORITIES AND HIDDEN EVENTS

| FACULTY PRIORITY | HIDDEN EVENT |
|---|---|
| Analytical thought | Fantasies, Feelings, and Fun |
| Achievement | Foolishness, Futility |
| Obsessiveness, Compulsiveness | Fickleness |
| Self-Control | Freud-ish notions (sub-, non-, pre- conscious) |
| Independence, autonomy | Family, Friendship, Fellowship |
| Competence | Frailty |
| Skepticism | Faith |
| Ambition | Free time |

ing research funds to sponsor research in under-represented areas. Examples of such existing efforts are the Sheth dissertation proposal grants to fund research on public purpose and international topics and David Mick's recent presidential initiative on Transformational Consumer Research.

As an organization, I'd like to see us find ways to support nontraditional doctoral students so that we get a wider representation of traits and lifestyles participating in consumer research. The call for increased representation of various demographic minorities is not new. What I am suggesting goes beyond demographic issues such as ethnicity and gender. We should strive for psychographic diversity as well, e.g., lifestyle, personality, family roles, and subcultures.

We also need to think about the institutional obstacles that hinder the transfer of the creative, diverse content typically included in the ACR conference to our top journals. One possibility is to seek more diversity (demographic and especially psycho-

graphic) among the people who serve in gatekeeper roles. We need to implement and formalize the suggestions made by John Lynch in his presidential address (1998). We might also brainstorm ideas for mentoring newer scholars who have trouble articulating how their ideas and perspectives fit into established bodies of literature. Perhaps we might consider a "pre-inquiries" section to supplement the existing "re-inquiries" section of JCR.

**Colleges and Universities**

Academic freedom must remain a high priority, since it is at the very heart of what attracts bright and creative minds to the world of academia. I am not suggesting that we discourage anyone from studying conventional topics. Personally, I enjoy and highly value the freedom to study individual information processing in choice, even though it is probably over-studied. My concern is that we somehow turn off or exclude people who might naturally be inclined to study mainstream yet "hidden events" such as consumer

**TABLE 4**
SUMMARY OF RECOMMENDATIONS

---

**Association for Consumer Research**
• Collect and redirect resources to provide incentives.
• Increase support for non-traditional doctoral students.
• Remove obstacles caused by myopic gatekeeping.
       Increase psychographic diversity in gatekeepers.
       Increase constructiveness and fairness of review process.
       Consider new ways to foster publication of innovative perspectives.

---

**Colleges and Universities**
• Reconsider doctoral screening process.
• Increase flexibility in doctoral program requirements for non-traditional students, especially at leading universities.
• Reconsider flexible tenure-track and tenured faculty contracts.
• Support faculty who are pursuing difficult or "inconvenient" topics.

---

**Individuals**
• Be aware of how judgment and decision making biases might influence you.
• Consider the people, places, perceptions, and processes that are hidden from academic view.
• Choose a topic that fascinates you, whether motivated by theory or phenomena.
• Then open that door and "Break on Through"!

---

fun, family, frailty, or faith. Perhaps we need to reconsider the screening process for potential doctoral students and junior professors. Do we inadvertently admire candidates who mirror ourselves?

We need to make an effort to understand and value our colleagues who conduct research on "hidden events." Just because the event or behavior is invisible to you does not mean the topic is not viable or meaningful. I recall one conversation about research on non-conscious affect in which my friend claimed that non-conscious influences do not exist: "I never make choices that have any unconscious or subconscious influences, so I don't think that exists. That is, not that I am aware of." Yes, indeed. We need to realize that our colleagues who conduct research on hidden events are likely to encounter such resistance, and thus have to overcome extra obstacles on the path to success. I argue that we need to be more flexible in how we provide rewards and support for people who pursue difficult and controversial topics. At the minimum, we should recognize that the resistance encountered will likely slow down the publication process.

We need to be more flexible with our doctoral student admissions and faculty recruiting. In most doctoral programs, we try to recruit students with work experience and an MBA. Thus the pool of attractive applicants is reduced to a pool of people who are in their mid-twenties or older, who have a record of high achievement, and who are in a position to drop everything they are doing for five years to work 24/7 for a minimal stipend. Obviously, this is a not a typical group of people. One might argue that they are not even the smartest group of people. We might be able to infuse our field with energy and new ideas if we found a way to attract smart, productive, and creative people to our doctoral programs while they are in a more flexible stage of life. We might also reconfigure our expectations of doctoral study to coexist with life outside the university—for example, flexible stipends for flexible work assignments.

Similar issues exist for faculty, especially at the assistant professor rank. The early years on the tenure track coincide with the years in which family responsibilities are most demanding. When I look back on the years when my children were small, I vividly recall how stressful it was. Now I see the next generation of young professors facing the same exhausting dilemmas. From my current vantage point, I do not understand why universities have to be so inflexible about the tenure path. I can imagine many alternative policies that would maintain, if not enhance, scholarly lifetime productivity without abolishing the tenure system. For example, why not allow people to opt for part time teaching (and commensurate salary) while still maintaining tenure-track (or tenured) status? Why not revisit the typical policy of stopping the tenure clock when one spends a visiting year at another university (fire up that ivory motor home)? Why not accomplish the same clock-stopping result without uprooting the professor and his/her family for a year? The professorial lifestyle is naturally attractive to people seeking flexibility (recall, you can work any 80 hours you choose). If we were better able to deliver on the promise of flexibility, we may be able to foster a more diverse and community-oriented set of scholars than we now have.

**Individuals**

Finally, let us consider what you can do as an individual. The JDM literature indicates that people are generally less subject to judgment biases when they are made aware of the potential for bias. So, my advice to you is to think carefully about all your research options. Identify the various options, the doors I mentioned at the beginning of this address, that you could open. Consider your knowledge, your experience, and your skills, and also consider where you might be able to make a unique and novel contribution. Consider the people, places, perceptions, and processes that are hidden from academic view. You may find some doors that were previously overlooked, whether in plain sight, behind a screen, or around the corner. And if you do, select the one that most inspires you to *Break on Through* (The Doors, 1967).

**Acknowledgements**

# ACR Fellows Address

Donald R. Lehmann, Columbia University, USA

When it was announced at an ACR luncheon that I had been named an ACR fellow, my first reaction was surprise. In fact, my first words were "are you kidding me?..." My next reactions were:

- Does that mean I have to give a talk?
- Who wants to hear from the last generation?
- What will I say?
- What will I say at 8 am?
- I guess this means I have to go to Memphis.

and

- I'm glad I didn't skip lunch.

Awards are subjective and often end up making far more people unhappy than happy. This is especially true after the first few recipients whom essentially everyone agrees are worthy of the honor. I can easily think of others who are at least as deserving as I am, as I'm sure many of you can. Ironically, I was part of a decision to stop naming fellows several years ago precisely because of the controversy and unhappiness they were beginning to engender. I recall Russ Belk giving a wonderful discussion of the downside of awards at an ACR luncheon several years ago which I recommend highly.

When I look at the list of past fellows, and the record of my co-inductee Kent Monroe, I see real scholars, i.e. researchers with deep knowledge of the field and sustained contributions. By contrast, I see myself as more of an engineer/problem solver who has worked on a broad variety of problems and methodological approaches. While after the fact I can tell a story about how the work is related, my research has been fairly unsystematic. Nonetheless, I am flattered, humbled, and delighted to have been named a fellow.

The talk I prepared (and for which I realized my notes were on the kitchen table in New Jersey as I prepared to deliver it) and this paper have three main parts. First I share some (mercifully) brief memories of ACR past. Next I discuss some research opinions which seem worth expressing. Third, I discuss some ideas for future research directions, not including work on fluency, regulatory theory, and networks. Note that these three areas have been major contributions to the field and will continue to be. (I certainly hope so in the case of networks since I am working on several papers in this area.) My point will be that these areas are "taken" so while they are safe paths to follow, it is hard to make major breakthroughs in them, especially when others have the lead. (To use a sailing analogy, you generally can't win by following along in the middle or back of the pack. To win, at some point you need to tack to clear air.) I then close with some more personal thank yous.

## MEMORIES OF ACR

I remember the first ACR "mass" conference held at the University of Massachusetts and attended by about 90 people including modelers, practitioners, and public policy makers. (Sadly we have driven most of the last two types away over the years.) In addition to sessions, essentially the entire conference moved to the Lord Jeff tavern to talk and consume beer. (Beer seems to be a common theme to events at ACR including Bettman, Lutz, Scott, Tybout, etc. at the "Saturday Night Live" parties and the "outsider" events promoted by Lichtenstein et al.) There was definitely a spirit of fun and informality (occasionally interrupted by hotel security). There was also a series of football games played at venues including the University of Cincinnati's practice field, parks in Atlanta and Florida, and the front "yard" of the O'Hare Hilton. In fact, the last game ended when someone ran into a cab trying to catch a pass. No one could find the "official" football the next year.

In addition to fun, the sessions were sometimes intense. I recall one night session (i.e., after a reception where beer was served) when a heated discussion emerged about, as I recall it, the Fishbein model and the halo effect, pitting the Florida school (led by Joel Cohen) against some Purdue types. Some observers were shocked both by the strength of opinions expressed and the fact that several of the protagonists proceeded to go out together for more beer when the session ended. I also recall some poor doctoral student "winning" one of my leisure suits (yes, the old polyester type, this one a fetching green and white plaid number) as a prize in a trivia contest. So my memories of ACR include both intellectual dialog and sophomoric fun.

## RESEARCH OPINIONS

Fortunately or not, I have been around long enough that many of my opinions are in print. In particular, several are contained in my 1995 ACR Presidential address which was published in the proceedings of the Minneapolis Conference (Lehmann, 1996). As I looked back at it (in "archaic" hard copy form), I found most of the points still seem relevant so I could just say "ditto".

I will not use fancy graphics (or Power Point) to make my points. My idea of visual aids is more like the stick figure cartoons I drew at midnight before leaving to give my Presidential Address when I realized I had no visuals and couldn't play the piano or show interesting pictures. (Someone decided to include them in the proceedings so you can see them if you are that curious.) In fact, I think Power Point etc. damages learning (which is why some people and organizations ban it). Consider also the following: which would be considered the cool/edgy communication medium if text based email had come before phone mail?

Punam Anand, who kindly introduced my talk, has taken to calling me a Luddite, a title I readily accept. When a current MBA student in their evaluation referred to me as "old school", I accepted that with pride. I don't get what I call generation text message/virtual reality that thinks relationships are about thumb-enabled poor grammar multitasking and public self presentation. (In the words of a song from Bye Bye Birdie, "what's the matter with kids today?"). So if you read on, do it for the ideas, not the sizzle.

### Opinion 1: Consumer/Customer Insights *are* Practical

I don't see a necessary divergence between rigor and relevance. If I am going to work on something, I prefer it to be something that might interest other people beyond a small group of like-minded researchers. Obvious sources of relevance include the MSI priorities based on company concerns, and social and public policy issues. Beyond these, however, how consumers behave is the fundamental unit of knowledge in for- or not-for-profit business. The reason much work in this area is thought to be irrelevant is that we, by either choice or inability, don't recognize, identify, and communicate its relevance.

### Opinion 2: Easy Does it on Theory

My observation is we have almost a fetish about theory. One of the most damaging comments a reviewer can make is "you have no/weak theory." Operationally, having theory generally means adopting something which has been published, preferably in a

prestigious outlet outside marketing (e.g., psychology, economics). While this has the advantage of integrating knowledge, it also stifles innovation. The first researcher in an area by definition works without a well established theory. To reviewers who ask "where's the existing theory?", one wants to scream "There isn't one. It's new, stupid".

I'm certainly in favor of understanding, explaining, and predicting. Developing or utilizing a theory to do this is an excellent goal and a desirable characteristic of research. However, it isn't a deity (notice I refer to it in lower case) and shouldn't be (and isn't) a requirement for every paper. Unless someone (Brahe) hadn't painstakingly measured (described) the movement of planets, Kepler (his student) would not have come up with his laws (aka theory). The criteria for acceptance should weight aspects such as is it interesting and will it stimulate future research at least as much as whether data fit a pre-existing theory. A particularly pernicious effect of requiring theory is that many papers are constructed after a search for a theory that matches the results. I don't see any problem with post hoc theorizing; the problem is the (at best a-ethical) practice of presenting the theory as having preceded the data when it did not.

More broadly, it is unlikely that a single theory explains the behavior of all individuals or even a single individual all the time (even F=ma has its limits). Rather behavior arises from multiple influences. Thus it would be useful if more of a competing theory/relative impact of theory perspective were adopted.

### Opinion 3: (Tear Down the) Towers of Babel

Like most disciplines, as it matures ACR is developing into increasingly specialized sub-fields. Yet innovations often come from outside a field or at the intersection between them. What we need are more studies which integrate multiple perspectives. As an example, at the 1995 ACR conference there was a session entitled "Another Cup of Coffee" which had a qualitative researcher, an ad agency person, a game theorist, an empirical data modeler etc. discuss coffee consumption. The result was a much broader and deeper understanding of this common product. We need more such events.

In terms of writing and presentation, complicated does not lead to communication and is not "sophisticated". While it is efficient to use specialized language and short-hand when communicating among a small in-group of experts, this type of language essentially poses an unnecessary "barrier to entry" to others. This is exacerbated by the tendency to use words in a way that is not closely tied to their plain English (or French or Spanish or …) meaning. Put charitably, we show too little concern for potential consumers of our written and spoken output. In the limit, this means we end up talking to ourselves.

Many reasons exist for this including lack of real understanding, self presentation, and intentional obfuscation, none of which are very appealing. A particularly aggravating custom is to justify by reference rather than reason. Importantly, not everything that has been published is correct. For example, I published in a prestigious journal that the best next study in a meta-analysis would "obviously" be one which fills empty cells. It turns out this is simply wrong: basically the next best study takes the typical study and changes about half of the predictor variables (Farley, Lehmann, and Mann, 1990). Even if what was published is correct, it should be possible to give the gist of the logic along with a reference. (This affliction is not limited to CB researchers. Quantitative modelers often use phrases such as "without loss of generality" and "it is easy to show that". If it is easy, then why don't they just show it?) Further, for those extrinsically motivated, it turns out that award winning papers are slightly less complex (Sawyer, Laran, and Xu, 2008).

### Opinion 4: KISS

The field risks overdosing on complicated analyses. Generally any reasonably strong result is apparent from the means, correlations, and OLS regression. Of course one can construct cases where more complex procedures (e.g., LISREL, HLM, HB) are at least theoretically more appropriate. On the other hand, such procedures, especially when applied blindly (e.g., "I analyzed the data with PROC …"), make assumptions and slant analyses in ways that are not always recognized. For example, a structural procedure which attempts to maximize links between constructs to some extent captures random correlations in the data (aka error) and overstates the relations. Additionally, by allowing for unique weights on item–construct paths, it makes generalization difficult since the next study invariably uses different weights. There is a lot to be said for using simple averages of items to measure constructs.

### Opinion 5: In Search of Empirical Generalizations

The notion of generalizability is essential to knowledge whose progress resembles an open-source mosaic. What is the point of doing a study if the results only apply to that population, time period, setting/covariates, etc.? (As an aside, the search for "up to date" teaching materials is self-defeating; if the only thing that is relevant is what's current, then what you are learning is irrelevant for the future.) Results, even when generalized, feel incomplete without an explanation (i.e., theory). On the other hand, theory without generalized results is, well, just theory. Meta-analysis (defined as the cumulation and integration of results and not as a formulaic procedure to be applied in a rigid manner) is the epitome of empirical generalization. It allows one to "test" theories and their limits and facilitates making new theoretical conjectures (e.g., predicting behavior in a combination of conditions which have not been studied previously). Since no single study (or paper with multiple studies) can "prove" anything given the myriad covariates involved, the goal of research can be essentially viewed as to prepare for future meta-analyses.

### Opinion 6: Seven Years Before the PhD?

When I entered the field, there was limited marketing literature. *The Journal of Retailing*, *The Journal of Marketing*, and three years of the *Journal of Marketing Research*. Consequently I was able to go from bachelor's to PhD in under three years, and through the 1980's three years was the norm for Columbia PhD students. Obviously the field is now much more complex so it is natural for programs to be longer. Still I see no reason why a motivated student can't write a dissertation in four years. If students choose to stick around for an additional year to work on research, prepare for teaching, etc. as a post-doc, fine. Just remember that a) there is diminishing marginal learning going on (at least from me, after four years you are unlikely to learn much new), b) the longer the program, the fewer highly motivated students will be interested in it (the price effect), and c) our job is to create independent researchers, not research dependents.

## BIGGER IDEAS

Progress toward knowledge definitely includes so-called incremental studies, without which empirical generalizations would not be possible. Still there is much to be said for big ideas (discontinuous innovation) even though most of them will fail, at least in the short run. (Translation: don't expect it will be easy to get them published.) Here are five potential ones.

### Idea 1. Basis of Utility

Generally we measure utility in monetary units, partly because they are convenient. Yet Bentham and others define utility as the

pursuit of pleasure and the avoidance of pain, making money at best a means to the end. Why not, echoing Becker's work decades ago, define utility in terms of quality time, i.e., time when you are healthy (something of increasing interest as one ages)? Clearly time is more important than money. Consider the following: if I have infinite time, I can work long enough at even minimum wage and earn infinite money. On the other hand, infinite money will not lead to infinite time/life. Reconceptualizing utility this way could produce some fascinating new insights.

### Idea 2. Consumers as Multiple Selves

Recently there has been considerable interest in assessing heterogeneity (cf. Hutchinson, Kamkura, and Lynch, 2000), partly due to the availability of hierarchical Bayes and hierarchical linear modeling software. However, with exceptions (e.g., work on variety seeking), within consumer variation has received less attention. Yet consumers often behave in inexplicable ways (Bass, 1974). Understanding what triggers a consumer to act differently seems fertile ground for both a grand theory and specific research.

### Idea 3. Generalization Shifting

While some generalizations endure, many shift over time and place. Consequently it may be worth studying what makes an empirical generalization stable and what tipping points exist that require its modification.

### Idea 4. Linking Firm Decisions and Consumer Welfare

Generally quantitative modelers focus on optimal firm decisions (e.g., to maximize profits) while many consumer researchers are concerned about consumer welfare (surplus) per se. Yet the two are clearly linked. Why not at least measure and report the welfare implications of firm and market decisions? For example, with Praveen Kopalle, I linked optimal new product claims to public policy implications about when regulation might be needed (Kopalle and Lehmann, 2006), and we are currently working to see the impact of competition on ad claims, prices, and product quality (Kopalle and Lehmann, 2008). Adding a "customer impact statement" can enhance the value of many modeling oriented papers.

### Idea 5. Choice under Restrictions

In June, 2007, a fairly diverse group met for several days at the Wharton Choice Conference to attempt to examine an interesting perspective, the impact of restrictions on decisions (Botti et al., 2008). We came to realize that restrictions are endemic to all that we do. They come in a variety of forms (e.g., rigid vs. soft suggestions, internally vs. externally unposed, widespread vs. targeted, short vs. long run, and conscious vs. not). Furthermore, restrictions interact with both individual characteristics (e.g., reactance) and goals. The resulting behaviors include grudging compliance, "creative bending" (interpreting a constraint either literally or based on its spirit in order to maximize flexibility), rebellion, and goal alteration (e.g., the child sent to his room who, before slamming the door, shouts "Good. I've been wanting to play in my room"). We put these concepts together in a broad-range flow chart model in the spirit of the model of Howard and Sheth (1969). Overall this seems to be a rich and fruitful area for both theoretical and empirical work.

### THANK YOU

So far I have reminisced, ranted, and predicted. In closing I want to give thanks.

The study of both consumers and careers is about people. None of us would be where we are today without lots of help from many sources, some of which is not recognized by either us or the sources.

Family, friends, teachers, neighbors, and random strangers have all contributed to who we are and what we have.

I would not be an academic if Professor Thimm at Union who, as I was preparing to accept a job writing software for GE in Pittsfield, Massachusetts, hadn't told me about fellowships available for attending graduate school and urged me to go to Purdue. (A big part of my support was from a National Defense Education Act fellowship designed to promote education and science in the post-Sputnik era. How much safer that makes one feel is unclear.) I would not know what I know without the teachers at Purdue and my doctoral committee (Bass, Pessemier, Schendel–who suggested I interview at a school I was not seriously considering, Columbia - and Jacoby). I would not have been as productive as I have been, had I not arrived at Columbia (after close to a coin flip decision) and found Farley, Howard, and Morrison there. I am extremely fortunate to have had a sensational set of colleagues at Columbia over the years and at the schools I have visited (Dartmouth, Cornell, Michigan, NYU, Wharton). I have been strongly influenced by my time at the Marketing Science Institute and the various professional associations I have belonged to. And I have a special place in my mind and heart for the doctoral students I have been privileged to work with. They have motivated me, taught me, carried me on projects (notice I still work with them), and become my friends.

I thought of closing my address by putting up a slide which listed the people who have helped me. I did not for three reasons:

First, I'm lazy and it was a difficult task
Second, I did not want to leave someone out
Third, I realized that to put all the names on a slide would make the print so small that it would be illegible.

So in closing, let me ask each of you to perform a thought experiment. Close your eyes and start to construct your own slide of who you would thank. Don't limit yourself to just academic colleagues. I think of family members, in particular my wife who for over 45 years has typed my manuscripts and who was the entire (unpaid) administrative support staff for Marketing Letters during its first seven years.

When possible, build the slide into a collage of pictures, sounds, and sights as well as names. Look at the result and realize how extremely fortunate we all are and that it is people (and not papers published or emails) that matter.

Pass it on.

# ACR and ME
Kent B. Monroe, University of Illinois at Urbana-Champaign

In this paper, I will sketch my involvement with consumer behavior research and the Association for Consumer Research throughout my career. This presentation is divided into three time periods that represent stages of my research career.

## EARLY RESEARCH

As background, my undergraduate degree from Kalamazoo College was in economics although I had an undergraduate minor in psychology along with an undeclared major in mathematics. As a doctoral student at the University of Illinois (1963–1968) I was interested in the emerging area of quantitative marketing. Thus, my doctoral training was as a modeling researcher. In fall 1963 my first marketing graduate course was in Marketing Models and we had a term paper assignment: develop a model of a marketing phenomenon. I told the professor that I would like to develop a model of consumer behavior. However, at this time there were no published models of consumer behavior as we know them in 2007. The consumer behavior or buyer behavior models of Howard and Sheth or of Engel, Kollat and Blackwell did not come until the end of the 1960s! He recommended that I could start by looking at a recent dissertation at the University of California–Berkeley by Franco Nicosia. Anyway, undaunted I proceeded with the project and did complete the paper by the end of semester. Two years later, 1965, on my marketing comprehensive examination, one of the questions asked me to compare and critique three models of consumer behavior. Obviously, I passed, but not without some trepidation and wondering what I had gotten myself into.

Consistent with my orientation, my doctoral dissertation was a model for product-line pricing (Monroe 1968). It has no data, which is strange for a marketing dissertation as the field is so empirically oriented. While developing the model I was struck by the number of behavioral assumptions that I had to make explicitly. (My advisor insisted that I list every assumption that provided a foundation for the model.) Indeed, mid-way through the dissertation I even thought about doing several experiments rather than finish the model building. Fortunately, David Gardner kept me on track by advising me to do the experiments later.

### Buyers' Logarithmic Subjective Price Scale

One of my characteristics as a researcher is to discover relevant knowledge outside my discipline that could be useful in my research. While working on the dissertation, my reading led me to psychophysics and learning about how people respond to physical stimuli, the underlying functional relationships of the measures of the intensity of the physical stimuli, and people's responses to them. In my dissertation and the article based on the dissertation (Monroe 1971a), I proposed that the functional relationship of price acceptability was logarithmic based on Weber's law and Fechner's adaptation of it. The implication of this proposition for understanding buyers' perceptions of prices and price differences is that the underlying *subjective price scale of buyers is logarithmic*. This proposition was the basis for my early post-doctorate research.

### Validity of the Acceptable Price Range Concept and Estimating Reference Prices

I accepted an offer as an Assistant Professor of Marketing from the University of Massachusetts-Amherst beginning September 1968. They had just completed building a behavioral research lab in the business school and had hired M. Venkatesan as a marketing faculty member. He had studied at the University of Minnesota under Bob Holloway, who was a pioneering marketing experimental researcher. Ven helped me with my first set of experiments. When I arrived at UMass I learned that Harry Helson was in the psychology department. He also helped me with my first experiments applying his adaptation-level theory (Helson 1964) to behavioral pricing research.

As mentioned earlier, I was not trained in experimental techniques or procedures. When we conducted our first experiment, I learned a first rule in research: "Make sure the participants know 'how' to respond, not what they should say or do." We had a simple study to determine how people's reference prices change (adapt) with successive exposure to prices for a product. So we developed scenarios for products that college student participants were to assume they were interested in buying. Using a slide projector, we showed them a price of a product on the screen, and they were to do three things: (1) write the price down on the response sheet, (2) evaluate that price for the product on a seven-point scale of expensiveness, and (3) indicate whether they would be willing to buy at that price, yes or no. The first time we ran the experiment, the students were very confused as to what they were supposed to do. So, we started each session with a "training" procedure and guided them through three trials. The way we set it up became what is known today as "priming," although I was not aware of that term until years later.

We then ran the study at low and high prices for eight products, in three series of prices: descending (i.e., prices became sequentially lower with each trial), ascending (i.e., prices became sequentially higher with each trial), and random. We later repeated the study adapting the own-category sorting experimental method with high school students. These two experiments empirically established (1) that the concept of acceptable price ranges was valid and (2) that we could estimate participants' reference prices (adaptation levels) across the products. The results show that we obtained similar upper and lower acceptable price limits for the different products using two psychophysical analytical techniques and the own-category sorting experimental method (Monroe 1971b).

### Effects of Sequential Exposure to Prices

We used adaptation-level theory as the foundation for our reference price research. Adaptation-level theory postulates that individuals' responses to stimuli represent modes of adaptation to three classes of cues: focal, contextual (background), and organic. This adaptation process results in behavioral responses to the stimuli that may range from rejection to acceptance with a neutral area of indifference in the transitional regions between rejection and acceptance.

In the context of the research we did, the theory leads to the hypothesis that if a series of prices are presented for judgment in order of increasing magnitude, the stimuli in the series will tend to produce higher categories of judgments than if the series were presented in order of decreasing magnitude. Consequently, extreme prices (high or low) presented first in a series of price stimuli anchor price perceptions, thereby pulling the reference price (adaptation level) toward the extreme end and resulting in depressed or accentuated price judgments for the ensuing prices that the individual sees.

The sequential results—ascending vs. descending—established that the same price for a specific product would be evaluated as less expensive if participants had evaluated higher prices first than if participants had evaluated lower prices first. This study and analysis was submitted to the *Journal of Marketing Research.* However, the reviewers did not understand the multivariate technique we used—profile analysis—and thought that using repeated measures meant we had non-independent observations. Of course, that was the research objective. Eventually, we presented the findings at the 1973 Association for Consumer Research Conference (Della Bitta and Monroe 1973).

### Association for Consumer Research (the beginning)

Going back to 1969, research in consumer behavior was gaining strength and many researchers were feeling frustrated at the perceived lack of outlets for their research. So Jim Engel organized a meeting of consumer researchers at Ohio State just before the AMA Educators' Conference in Cincinnati. Two important results of that meeting was the resolution to form a new association and to hold a conference on consumer research in August 1970. Since the AMA Educators' Conference was in Boston it was decided to hold the first open ACR conference at the University of Massachusetts immediately preceding the AMA conference. Venkatesan had attended the Ohio State meeting and was persuaded to be the conference chair. I attended that first ACR conference, and the first business meeting of the new association. Since then I have missed only one national (North American) conference.

### *Journal of Consumer Research* Begins

As noted above, consumer researchers were frustrated by what they perceived as a lack of opportunity to publish their research. Another initiative was to begin a new major research journal. The first issue of the *Journal of Consumer Research* came out in June 1974 and I published my first *JCR* article a year later (Monroe and Guiltinan 1975).

### The Effect of Brand Knowledge and Brand Familiarity

At the same time, I was learning another lesson about conducting experiments. In 1970, relying on women from local organizations as participants, I conducted research exploring the role of familiarity and knowledge on price perceptions and preferences. Using a paired comparison methodology, the mixed design was a 3 (products) × 6 (brand familiarity and knowledge) × 21 (prices, repeated measures). Using pre-measured brand familiarity and knowledge ratings, we ended up with some very unequal cell sizes. At the time there was no computer software available to analyze such a data set! So I designed the analytical procedures and hired a Fortran programmer to write the program for the analysis. It worked out, but it was seven years from beginning to publication! The article that documented the findings was the first in consumer behavior to consider the role of prior knowledge and brand familiarity on preferences and how price influenced these choices (Monroe 1976). The lesson here was to keep your experimental designs simple and not get into difficult data interpretation issues.

### Buyers' Subjective Perceptions of Price

In the early 1970s, Hal Kassarjian and Tom Robertson were preparing for the second edition of their consumer behavior readings book: *Perspectives in Consumer Behavior*. They asked me to write a chapter on perception with consumer behavior applications. So with the help of an undergraduate student I wrote a review of behavioral research in pricing: "Buyers' Subjective Perceptions of Price." The first draft was 90 manuscript pages long! (Keep in mind

that there was very little extant research at that time!) Anyway, they liked it and suggested that I cut it in length and send it to *JMR,* and they would get permission to reprint it for their book. That article (Monroe 1973) laid the foundation for behavioral research in pricing, which has grown from that beginning.

## BROADENING THE BEHAVIORAL PRICING RESEARCH PROGRAM

### Comparative Price Advertising

I moved to Virginia Tech in 1977 to establish a marketing department there. In 1979 I was asked by the Federal Trade Commission to design a national study on the effect of comparative price advertising on consumers. After meeting with officials in Washington we designed the study and the procedures. However, in 1980, the FTC research budget was cut and most of the research funds went into the children's and TV advertising project and the national study was shelved. However, we conducted the study and a replication at Virginia Tech (Della Bitta, Monroe, and McGinnis 1981). The comparative price advertising research forced us to recognize the distinction between an internal reference price and an external reference price supplied by the seller: "Regularly sold for $xxx, now on sale for $yyy" type of ads. Another idea emerging from this research was the recognition that consumers' behavioral intentions after exposure to a comparative price advertisement were mediated by their perceptions of value.

### 1980 ACR Conference

While the Department of Marketing at Virginia Tech was taking shape, I was the program chair of the 1980 ACR national conference in Washington, D.C. The Dean insisted that I become the head of the department beginning July 1980 and the ACR conference was in October. This was the first time that I realized that I was not immune to stress and its effects. That conference was noteworthy for several reasons. We had over 400 attendees at the conference and the first two ACR fellows, John Howard and James Engel were officially recognized and they gave the first fellows' talks at the conference.

### Integrative Research Reviews (Meta-analysis)

In 1982 I began reading about integrative research reviews, often referred to as meta-analysis, because I wanted to learn about this technique. Now, one of my strategies to broaden my knowledge and skills is to do it. Together with a doctoral student, R. Krishnan, we decided that there were a sufficient number of the price-perceived quality studies for us to do a meta-analysis. We read all the price-perceived quality studies we could find, coded them, often arguing about some of the ways to interpret what the researchers had done. We concluded that despite the number of studies that had been conducted on the price perceived-quality relationship, the construct was not well conceptualized and there was a need for a conceptually based program of research (Monroe and Krishnan 1985; Monroe and Dodds 1988; Rao and Monroe 1989).

### Price-Perceived Quality-Perceived Value

Another doctoral student and I presented our first price-perceived quality-perceived value paper at ACR in 1984. We presented a simple conceptual framework: perceived value is the result of the tradeoff between what consumers perceive they receive relative to what they perceive they give up (Dodds and Monroe1985). As noted earlier, our recognition that consumers' perceptions of value mediated their behavioral intentions emerged from the comparative price advertising research and the meta-analysis of

the price-perceived quality research studies. If buyers use price as an indicator of quality and also an indicator of sacrifice, then price has both a positive effect and a negative effect on perceived value. Valarie Zeithaml was the discussant at that session and she borrowed our model slide to summarize her remarks on the papers that had been presented. The model was later used in her award-winning article on perceived quality (Zeithaml 1988). Dodds tested the model in an elaborate experimental design and empirically estimated the relative strength of brand name, store name, and price on buyers' value perceptions (Dodds, Monroe and Grewal 1991). And the same model was used by another doctoral student in his dissertation. His JCR dissertation article was a Ferber award winner (Rao and Monroe 1988).

Thaler's work on mental accounting extended prospect theory and has influenced behavioral pricing research (Thaler 1985). In that article Thaler developed the concept of transaction utility. He argued that overall utility to a consumer is the weighted sum of acquisition utility and transaction utility. In an ACR paper, we translated his notions into the concepts of acquisition value [buyer's reservation price (maximum willingness to pay)-the selling price] and transaction value [buyer's reference price-selling price] (Monroe and Chapman 1987). Initially we accepted the notion that these two value concepts were independent constructs. However, on closer thinking it became clear that they cannot be independent since the selling price is a part of each concept. Dhruv Grewal's dissertation supported our arguments showing that perceived transaction value is an antecedent to perceived acquisition value (Grewal, Monroe and Krishnan 1998).

### Memory for Price Information

At the same time research on memory of price was getting attention. Earlier (and also later) research had primarily relied on recall tests to measure "price awareness." However, I did not believe that recall tests were the best way to get at this issue, particularly since most of the research was on grocery products. I felt that in the situation of groceries, especially, incidental learning rather than intentional learning was more likely and that a recognition test would be more appropriate than a recall test. Working with a student on her master's thesis we presented these ideas at the ACR conference in 1985 and her thesis actually showed that the recognition test provided more indications of price awareness (Monroe, Powell, and Choudhury 1986). A doctoral student who was working with me then was intrigued with these ideas and in his dissertation he administered recall, recognition and rank order tests to housewives in a simulated grocery shopping situation (Mazumdar and Monroe 1990; 1992).

### RECENT AND CURRENT RESEARCH

### Price Fairness

Returning to the University of Illinois in 1991 brought me back to my research roots. No sooner had I arrived in my new office and in the midst of a sea of boxes for both *JCR* and myself, a doctoral student appeared asking for advice for a research paper on price fairness. Among the questions we asked was when do perceptions of price unfairness occur and how do they influence behavioral intentions? Consistent with the price-value model discussed above we postulated that a price that was perceived to be unfair would lead to an increase in consumers' perceptions of sacrifice, thereby reducing their perceptions of value and their behavioral intentions. During a session at the 1993 ACR we presented a paper outlining the rationale for this proposition. A lively discussion ensued and in her dissertation we obtained empirical proof supporting our arguments (Martins and Monroe 1994; Martins 1995). Since then we have pursued a research program on price fairness that has led to several ACR presentations and other publications (e.g., Xia, Monroe, and Cox 2004; Monroe and Xia 2005; Herrmann et al. 2007; Kukar-Kinney, Xia, and Monroe 2007).

### Conscious and Non-conscious Processing of Price Information

During August 1993, the University of Illinois hosted AMA's doctoral consortium. One evening after a long day of sessions I quietly tried to leave the after hours social to go home and get some sleep. However, as I was leaving a doctoral student from the University of Toronto approached and asked if she could talk with me for a few minutes. Angela Lee, the co-chair of the 2007 ACR conference, introduced me to the concept of implicit memory. As I fought the urge to close my eyes and go to sleep, her passion for the concept resonated and I realized that there was an opportunity to do some new research on memory for price information. Our collaboration led to an important article on the processing of price information (Monroe and Lee 1999).

In many respects, this research on price memory and numerical cognition reignited my early research on consumers' price perceptions. This expansion followed two paths. In one path we further explored issues related to nonconscious perceptions and awareness including the effects of subliminal processing of price information (Adaval and Monroe 2002; Xia and Monroe 2007). The other path expanded our continuing inquiry into how consumers' process price information and make value judgments (Suri and Monroe 2003).

### Compulsive Buying

Ostensibly, I "retired" from the University of Illinois and moved back to Virginia to be with family, July 2005. The University of Richmond offered me an appointment of Distinguished Visiting Scholar. There I have continued to work on research projects that had started at Illinois, but I also began a research program on compulsive buying. The early results of this program have been reported in recent ACR and EACR conferences (Ridgway, Kukar-Kinney, and Monroe 2006) and hopefully will soon appear in journals.

### MENTORING DOCTORAL STUDENTS

As might be apparent from the above overview, much of my published research over the years has been with colleagues that began when they were doctoral students. Indeed, in my first year at Massachusetts as an assistant professor I was approached by a doctoral student to be his dissertation advisor. Today, I warn doctoral students and assistant professors not to become involved early on in supervising doctoral research as it is time consuming and in some cases it is similar to one apprentice guiding another apprentice. Fortunately, no one advised me about these dangers of supervising doctoral students and their research.

As of this writing I have guided 36 completed doctoral dissertations with two others in process. It has been one of the most satisfying, and at times frustrating, professional activities that I have had. It has led to two university-wide teaching awards: the W.E. Wine Teaching Excellence Award at Virginia Tech and the Graduate College Mentor of the Year Award at Illinois. After receiving the award at Illinois, I was asked to share my approach and principles for mentoring graduate students. These principles are based on taking a positive approach even when criticizing or pointing out flaws in a student's work. (Similarly, when I was editor of the *Journal of Consumer Research* submitted manuscripts were "not acceptable for further consideration," "not acceptable in their

present form," or "acceptable for publication". They were never "rejected.")

The principles that I have tried to follow when mentoring doctoral students are:

1. *Each student is a unique person; therefore, no one approach would be adequate across students.* Some students are relatively fragile in their mental state and others are relatively headstrong. The first type of student needs frequent encouragement and should be given small steps that can be taken successively to build confidence. The second type of student can be given more flexibility in pursuing the project, but at times will need a relatively stronger set of guiding statements to get them back on the correct path when they inevitably stray.

2. *Always be positive and encouraging even when criticizing.* Always try to explain what was not correct or what would be a better approach when something is not done correctly or at the level of the student's capability.

3. *Supervise rigorously and quickly.* When I was a doctoral student the initial draft of my dissertation proposal was in my advisor's hands for almost four months before I received feedback. I resolved that my students would never be delayed because I did not provide quick and detailed feedback on their submitted work. Sometimes they would deliver a manuscript to me during the night and then go to bed. I would try to get the material back to them with detailed comments by the next day. Before email, they would drop the material at my door while I slept and I would read while they slept!

4. *Help each student to recognize and achieve his or her talents.* Somehow I have developed an ability to sense when I have pushed a student to his or her limit of capability. One student once asked me if I had ever pushed beyond that limit, or how did I recognize when it was time to stop pushing a particular student. To the best of my knowledge, I do not think that I have pushed any student beyond what he or she was capable of achieving. Partly, knowing when a student has achieved to the best of his or her talents is reflected in the next principle.

5. *Each student is a colleague and a friend.* I view each student being supervised as a current and future colleague as well as a friend. That means that I need to know not only their intellectual talents but also personal and emotional events that may impinge on their performance. Sometimes a meeting will not be about the research but about family or personal situations, or about the career they are preparing to pursue. These meetings may be in the office, at my home, over lunch, dinner, or coffee, traveling to or at a conference. Overtime, I will learn not only what their intellectual talents are, but also when to push, when to pull back, when to be demanding.

## CONCLUSION

For my annual review in 1974, the department head suggested that I move away from pricing research as I had done about all that could be done in this area. I politely, but strongly disagreed. Hopefully, this quick historical review of some of the behavioral pricing research that I have done supports my view. While my research has primarily been about how consumers respond to price information, the approach has been programmatic and has a firm foundation in various areas of human psychology. Now, 33 years after the suggestion to leave pricing research, I still firmly believe that we have a lot more to learn about how price information influences consumer behavior.

I have often been asked where I get my research ideas. Looking across the various research projects that I have mentioned in this paper, the simple answer is–from many sources. Some ideas have come from reading research articles both in consumer research and in other disciplines. Other ideas have come from observing an event or from someone asking whether I might know why something does or does not occur. Sometimes an idea comes from listening to colleagues talk about their research. Behind any research effort is an underlying desire to discover new knowledge and to consider how that information might be applied to further the well-being of various constituents of that knowledge.

Overall, my career as a researcher and teacher has been very rewarding. The friendships of colleagues at the universities I have served, in the professional associations to which I belong, and the students I have taught are highlights. As I write this paper just before the beginning of 2008, the cards, emails, and phone calls that I have received this holiday season, like holidays past, are heartwarming and cherished. I especially thank my ACR colleagues for this award and being named a Fellow in Consumer Behavior.

# Consumer Freedom from Consumer Culture Theory Perspectives

David Glen Mick, University of Virginia, USA
Ashlee Humphreys, Northwestern University, USA

## SUMMARY

Freedom is among the most significant and most complex topics in human societies and personal life. It is widely believed by philosophers to have two primary conditions. First, the individual has the ability to select an option from a set of alternatives (i.e., there is indeterminacy as to the outcome of the selection process). This applies in consumer behavior to selecting brands, consumption experiences, and the entire gamut of consumer practices and actions. The second condition is that the person is the ultimate source of his or her will. In consumer behavior, the meaning and conduct of freedom is likely to vary in a number ways, along a number of dimensions, from culture to culture, from situation to situation, and from person to person. Consumers have an array of desires, wishes, intents, plans and will power, but sociocultural settings and marketplace agents also facilitate, guide, limit, and block consumers in various manners. Freedom, whether it is considered objectively or subjectively, is essential to the well-being of human beings, including their will to survive and their hope for a life worth continuing to live.

This epistemic panel at the 2007 North American Conference of the Association for Consumer Research involved a distinguished panel consisting of Robert Kozinets (York University), Lisa Peñaloza (École des Hautes Études Commerciales du Nord), and Tom O'Guinn (University of Wisconsin), and was moderated by David Mick (University of Virginia), with assistance from Ashlee Humpheys (Northwestern University). The session was organized to address the following questions:

How essential or not is the question of freedom in consumer behavior?

- What is the nature of consumer freedom?

- To what extent are consumers free, and does it change according to personal or socio-situational factors? Why? How?

- Is consumer freedom increasing or decreasing? How? Where? For whom? Why?

- What are the most important questions that remain unanswered (but are potentially answerable) in the study of consumer freedom?

A rich discussion of these questions took place on the ACR Knowledge Exchange website prior to the session. Craig Thompson approached the question by discussing theories of the dialectical relationship between human agency, and the legal, cultural, and social institutions that both enable and constrain action. Russ Belk inverted the question of consumer freedom by detailing a class exercise in which he prompts students to think about the sometimes desired limits of consumer freedom. Eric Arnould commented that freedom is a historically and culturally situated concept, and must therefore be understood within the context of an advanced market-mediated consumer culture. Nik Dholakia pointed out that the framing of consumer "freedom" may be problematic, as marketing communications often attempt engender feelings of freedom, mak-

ing true freedom illusory, and added that the critical question is whether consumers are free not to choose.

In the session, Rob Kozinets began by outlining the ways consumer research has posed the question of consumer freedom and by problematizing concepts in the question of consumer freedom such as consumers, choice, freedom, and escape. He argued that a firmer semantic grounding is needed in the form of situated definitions of these terms in order to illuminate our understandings of consumer freedom and recast the concepts of the "consumer" and "market" in the light of the classic paradigm of the individual versus society. He further argued that people may have different levels of freedom according to a variety of situational, economic, and cultural variables. Is someone as rich and famous as Paris Hilton, for example, as free as someone in poverty? The notion of escape from the market, in fact, might be peculiar to one not fully allowed access to it. People living in a commercial society thus have varying degrees of freedom and varying degrees of constraint. From this situated semantic grounding, Kozinets argued for these very big questions to be taken to a more engaged micro-question. Rather than asking if consumers are truly free, we might ask questions about the cultural and structural elements that cause us to, for example, eat genetically modified food. This grounded empirical approach, he argued, would lead us to think not only about the flow of materials and services, but also the flow of information about the behind-the-scenes production and material resources. Further examining the flow of information about the origins of commercial goods and services would draw us towards thinking about information flows and blockages in consumer culture and the extent to which an actively engaged, participatory citizenship could be efficacious in the consumer sphere. He concluded by suggesting that this approach would move consumers and researchers toward thinking in terms of consumption literacy.

Tom O'Guinn began from a populist perspective, arguing that consumer culture has been, on balance, a positive force. While acknowledging that markets can produce negative effects, he noted that markets also enabled freedom in many domains. He further remarked that concerns about consumer freedom are often rooted in paternalism, the natural effect of the third person effect in communications research. Specifically, researchers may be likely to think that they are not affected by advertising, but that it has a strong effect on others. The third person effect, he noted, is heightened by disparities in social and economic class; the larger the class disparity, the more people are likely to overestimate their own freedom and underestimate the freedom of others from lower socio-economic classes. Drawing from Michael Schudson's work, O'Guinn discussed advertising as "capitalist realism," a medium that works within the ideological framework of achieving certain ends (i.e. to encourage private consumption and sell products) just as socialist realism worked within an ideological framework aimed at inspiring collective public achievement. Advertising as capitalist realism, then, is only effective to the degree in which the ideology of capitalism is activated and accepted.

Lisa Peñaloza discussed the relationship between the ideal of consumer freedom and American nationalism and positioned consumer freedom as a modernist, individualist ideal. She noted that consumer freedom philosophically presupposes the capacity to

imagine a self-contained subject position and subjectivity that thinks of oneself in *separate* terms and as able to act with individual volition and directedness stemming from that position. Where then does this need to be free come from? Free from what? Who is deploying consumer freedom? Many immigrants from Mexico and other countries, she noted, come to the United States to pursue the very consumer lifestyle that others consider constraining. Consumer research should therefore study how people reproduce social distinctions in consumption discourses and practices to develop Transformative Consumer Research implications to potentially mitigate these distinctions. The problem of consumer freedom also poses several ideological challenges: Do consumers identify as consumers? Does US culture equal consumer culture? How far are U.S. consumers willing to go to maintain their "freedom?" Is this not what the U.S. war in Iraq is about? Future researchers, she argued, should look into our own views of consumer autonomy and the market, turning national and institutional interests and biases of the free market into questions . Peñaloza concluded by enumerating the challenges that consumer freedom poses for future work in Consumer Culture Theory, and emphasized the need for consumer culture research to situate the consuming subject both historically and culturally in studying in-group and out-group distinctions and in order to better appreciate the vast differences in consumer freedom and agency.

In the discussion portion of the session, Sid Levy then remarked on the simultaneity of freedom and determinism, using particle/wave dynamics in physics as an example. Consumers are both free and determined, he argued, because their very freedom is enabled by constraints. As an example, he cited the oppression of the 19th century Russian Czars as presenting his ancestors with the choice to move to the United States, thus further enabling him to pursue his own actions within a new structure of constraints. Determinism and freedom are thus deeply and dialectically intertwined. Social scientists, he argued, must believe in some degree of determinism because they study the effects of certain variables on human behavior. Conversely, they must also believe in some degree of agency because there is enough variation in human behavior to make it interesting to study.

Several other questions centered on the potential differences between the concepts of agency and freedom and the question of consumer desire to be free. Do consumers in certain cultural contexts seek freedom within particular constraints? When do consumers want constrained versus enabled choice? Panelists generally agreed that the optimal place to study these issues and answer specific questions about freedom is on the level between the macro study of institutions and micro study of specific consumer practices within these institutions. They also urged researchers to challenge traditional 19th century thinkers like Weber and Marx in order to develop new theory based on contemporary rather than previously existing institutions and practices of production and consumption.

Consumer freedom will continue to be among the most crucial topics explicitly or implicitly associated with continuing projects in consumer research. Ralph Waldo Emerson once remarked that life is essentially a series of ongoing selections. Few things that consumers and marketers do can avoid being a matter of choice, and thus also a matter of freedom. Moreover, as Existentialist philosophers emphasized nearly a century ago, freedom has deep ethical roots. To be free, or to affect someone else's freedom, has imposing responsibilities. Researchers need to consider more thoroughly the nature, extent, and ethics of consumer freedom in terms of the changing and unchanging conditions of our world, not the least of which involves the rise of the Internet, the emergence of new vigorous economies (e.g. China), the continuation of abject poverty in many regions, and a marketplace ideology that endorses increasing consumption in the midst of limited natural resources.

EPISTEMIC SESSION
# What Counts as Knowledge in Judgment and Decision Making?
Joel Huber, Duke University, USA
Chris Hsee, University of Chicago, USA
Drazen Prelec, Massachusetts Institute of Technology, USA
Jay Russo, Cornell University, USA
Kelly Goldsmith, Yale University, USA
Cassie Mogilner, Stanford University, USA

## SUMMARY

The objective of this epistemic session was to identify where the field of judgment and decision making currently is and in what direction the field will and should be going. Joel Huber (JH) chaired the session and Chris Hsee (CH), Drazen Prelec (DP), and Jay Russo (JR) served as panelists. Kelly Goldsmith and Cassie Mogilner served as scribes to help prepare this summary.

- *What is judgment and decision making (J/DM)?*

*JR*: The J/DM process begins with evaluation–and that evaluation has to involve some kind of multi-dimensional criterion, and it has to be personal. It is not objective, as in the objective functions of operations research. When there's a single option, we call it judgment. When there are multiple options, we call it decision making, which means picking the best one, or a subset of items, out of a group.

*CH*: There are three characteristics of J/DM: 1) about the dependent variable, 2) about the independent variable, and 3) about the finding. The *dependent variable* is usually about judgment or choice-it's obvious. The *independent variable* is close to the construct it is supposed to study. Typically J/DM study does not involve very high level constructs (e.g., self or self esteem), instead it looks at what is objective and easy to operationalize. It is elegant in its simplicity. Finally, the *finding* is usually counterintuitive or counter-normative. By the way, although some criticize that J/DM is about phenomena rather than being theoretical, I think that it is a contribution if one identifies a robust, counterintuitive and generalizable phenomenon.

- *Give examples of important J/DM findings.*

*JR*: The overconfidence phenomenon: When you ask people to give you a 90% confidence interval around some value, you find that the true answer falls outside of that confidence interval about 50-60% of the time. An economist would say that is a "problem" and would try to fix it by giving participants money to try harder to do the right thing. However, when you pay people it gets worse. In their 2006 JMR article, Meloy and Miller found that participants get worse when paid because receiving money puts them in a good mood, which in turn makes them overconfident. But that only leads to another question: why does mood influence overconfidence?

*DP*: Some striking examples are Khan and Dhar's (2006) work on anticipating a second choice, as well as Read's (2001) hyperbolic discounting. Thaler and Bernartzi's (2004) "Save More Tomorrow" takes a number of different tricks from the J/DM tool box and applies them directly to the

problem of increasing savings. In all real world cases, employees are presented with the option of joining a savings plan. The employees who were presented with the option of joining the plan were living pay check to pay check and not saving. The experiment manipulates features, where each feature is tailored to a reason why employees might make mistakes. For example, bounded rationality (don't know what the interest rate is), hyperbolic discounting (nothing happens immediately), loss aversion (reluctance to cut back on consumption), and passive procrastination (don't take action). The researchers tailor each feature to an independent problem that has been identified, which leads to increased savings and employees sticking with their plans. This is an example of how J/DM research might proceed. It may not be good science because it is impossible to say on theoretical grounds what has happened. It is more akin to what happens in a design school: tailor principles to unique situations without being able to say whether it's decisive. Thaler and Bernatzi go against the assumption here that despite the literature on biases, there is one "correct" way to save, against the fundamentalism arguing that there is a "right" decision path. However, it is hard to figure out what that right way is. Unfortunately, it is difficult to get academic credit for this type of research, but if enough prestigious people do it, then it might get picked up.

Itamar Simonson (2007) has recently been arguing that there may be "real preferences." However, then the challenge is to figure out what those true preferences are. Can the field identify true preferences? Can we do research that is consistent with the fundamentalist assumption?

*CH*: Some key J/DM constructs include loss aversion, variety seeking, Huber, Payne and Puto's (1983) asymmetric dominance or attraction effect, and Shane Frederick's (2007) X-effect showing that people predict others are willing to pay more than they are actually willing to.

- *Where is the field going, and where would you like to see it go?*

*JR*: In the 50's and 60's the field was dominated by optimal models from economics and statistics. Since around 1970, especially with the work of Kahneman and Tversky on heuristics and biases, anomalies have dominated J/DM. Parallel to this has been the process paradigm that seeks to explain the underlying causal mechanisms of phenomena like anomalies. Over time this deeper level of analysis (this process work) has become more important and will continue to be. Things that will have a bigger role in the future will be automatic vs. conscious processing (including the

distinction between what is often called System 1 and System 2), goals as drivers of decisions (including decision process goals like saving effort, being confident, avoiding regret, etc.), emotions and mood, neuroscientific approaches (both the level of analysis and methods), and process tracing methods. That is, our scientific effort will dig for deeper reasons and find more general explanations for behavior. Ideally when a phenomenon is explained at the process level, there is something that generalizes and illuminates the causes of other, related phenomena. So, J/DM research won't be just deeper; it will also be broader.

*DP*: J/DM is not an isolated discipline. Other disciplines are in areas of huge ferment and uncertainty. Psychology may be swallowed up by neuroscience. Economic theory is our basis, but what if that theory changes? The theory is very provisional because it doesn't know what is going to happen. But it is possible that neuroscience will change it. There will be more emphasis on design or craft when using the principles discovered. This emphasis on craft has been neglected, but I think it will get more attention. J/DM might start to try to understand and to map out preferences. We've ignored this mapping because we looked at preferences as a list or as not being there at all. It has not been treated as an interesting subject per se. As far as the normative question of what the field should be doing? It should be helped by neuroscience.

*CH*: First, J/DM has traditionally been "destructive." It has looked to find "faults" in normative models. J/DM should be more constructive. It should gain a better understanding of how and why people make decisions, and continue to establish general phenomena and robust patterns of behavior, regardless of whether they are anomalies or not. Second, J/DM should produce research for the real world and not just for other J/DM researchers. It's not enough for only the journal editor to like your paper. It also should have some real world relevance. Third, in terms of implications, rather than just helping marketers take advantage of consumers and make more profits, we should focus more on how it can help consumers increase their welfare, for example, increase their hedonic experience, happiness, and satisfaction. Fourth, J/DM should join other fields, including neural activity research, social psychology, etc.

• *Questions from the audience:*

**Professor Russo, what is an example of the process tracing methods you mentioned?**

It's any method that observes what happens between the input and output, and that preserves the time course of what happens. For example, verbal protocols, eye movements, hand movements and other forms of information search, etc. There is even a "joy stick" method used to evaluate reactions to TV commercials in which two joy sticks are moved, one by each hand, to reflect the positive and negative affect to the commercial moment by moment. Of course, we need to develop new methods that can offer more insight into changes in the J/DM process over time.

**What is the role of quantitative modeling and game theory in J/DM?**

*DP*: Those models that are not connected to normative notions have a precarious future. I say this by looking back at the history of math psychology and economics. Math psychology has had a problem of gaining accumulative progress because the knowledge is local and is not connected to the same tree, not associated with general principles. By contrast, consider economics and other normative disciplines. They have an easier time creating second and third generation research, with new research correcting the previous ones. This suggests the importance of later generation modeling in game theory. It's hard to turn down, but it's not clear how long a life it will have.

*CH*: It's important to train students and oneself to be able to understand math. But people should not model for the sake of modeling. You should only include modeling if it adds something to the precision of the description. In psychology in general and in BDT more specifically, we do not have to imitate economics models to build a model that can explain everything. Our field may not be ready for this. For the time being, it is fine to have various "islands" of knowledge that are true, rather than to have a big empire that is false. There is no shame in an island.

*JH*: In making a conceptual point it is important to use models, but they can be complex and get in the way of understanding. Consider putting the math in the appendix so that your argument has precision and credibility, but feature your key results in a 2x2 table or a simple graph that everyone can understand. Witness, for example, the enduring power of Tversky and Kahneman's S-shaped value function.

**How can we reach consumers? We are always seeking to appeal to marketers because that is who reads our papers.**

*CH*: We are all consumers, even marketers are. It is important that our research gets publicized and becomes known to the public. This is beyond my expertise, but I don't know whether it is possible for more practitioners and media people to attend ACR conferences, so that they can bring our research to the real world.

*DP*: Thaler's Smart Plan, "Save More Tomorrow" is a good example of how to impact consumption. Industry tries to get people to save more. If we know something then we should be able to use those principles to help design things that are better. If we know something then we should be able to beat the corporate world to the punch. The Smart Plan did.

**Joel Huber's Summary:**

J/DM is not owned by consumers, finance, operations or managers, but cuts across many fields. Its weakness is that it does not build from one positive theoretical base. As our panelists have indicated it has traditionally focused on uncovering surprising judgment heuristics and violations of economic precepts. These deviations from normative principles arise from various psychological and processing causes that are too often indeterminate. But J/DM's atheoretical nature can be turned to its advantage as it becomes more prescriptive. It can help people make deci-

sions that they are happy with, that solve their problems. That way, the findings of J/DM can be used to make the world a better place. The cost is that without a single coherent theory its papers may be harder to publish. I personally pledge as editor of *Journal of Marketing Research* to work to reduce that cost.

# Rigor in Information Processing Research

Miguel Brendl, Northwestern University, USA
John Lynch, Duke University, USA
Valerie Folkes, University of Southern California, USA
Lora Harding, Northwestern University, USA
Brian Sternthal, Northwestern University, USA

## SUMMARY

Information processing research is conducted and evaluated on the basis of a set of beliefs about the strategies and procedures needed to achieve rigor. These beliefs are not universally held and they are seldom exposed to scrutiny. The goal of this epistemic session was to discuss how to achieve rigor in information processing research by addressing three main questions:

- *What do measures measure?* Do dependent variables measure processes or states? What are direct versus indirect measures and which is preferred? Is there a single best measure of a construct that should be sought or is such a goal unachievable?

- *What is the best approach to document an explanation for data?* What is the better approach to explanation: moderation or mediation, or are these approaches substitutes for each other?

- *What is the goal of reporting multiple studies in a paper? When is enough, enough?* Most journal submissions in consumer behavior now report multiple studies. What is the goal of this enterprise? And what are the stopping rules for publication? Are there philosophical grounds on which to make such judgments or are they largely a matter of taste?

Brian Sternthal moderated the session, soliciting insights from three panelists as well as questions from the audience. Each panel member took responsibility for making the initial commentary on one of the three questions. Miguel Brendl led the discussion of measures, John Lynch directed the discussion of moderation and mediation, and Valerie Folkes initiated the discussion of multiple studies. Lora Harding summarized these discussions, including the comments made by other panelists and audience members.

### What Measures Measure

Researchers and reviewers often characterize dependent measures as being one of two types–those that measure end states and those that measure process. However, psychological "process" measures are in reality only snapshots or cross-sections of causal processes and thus do not fully capture processes themselves. In this sense, all psychological measures are measures of state–states which may be proximally or distally related to the root cause. It is from these states that researchers make inferences about the underlying process. As Douglas Medin once stated, "there are no free peeks at the mind." Furthermore, it is important to note that because measures do not tap mental states "directly," process and end-state inferences are subject to measurement error and interpretive bias.

Although no measure can tap directly into the process by which individuals are responding, this does not imply that some measures are not better than others. Indeed, the best measures fully capture the construct of interest with minimal noise. However, all

measures are errorful, capturing either too little or too much information. The best measures of unconscious processes, for example, may fail to fully capture the unconscious state or may inadvertently include conscious influences. Because all measures are imperfect in some way, it is incumbent on the researcher to take steps to bolster construct validity. Thus, rather than assuming certain measures are superior to others, researchers should triangulate on constructs using multiple measures and manipulations (convergence) and distinguish their constructs from others with evidence of unique antecedents and consequences (discrimination).

Misconceptions surrounding so-called process measures also apply to manipulation checks. The purpose of manipulation checks is to gain confidence that the psychological state a manipulation was designed to induce was indeed achieved. Measures that merely confirm that research participants were exposed to the stimulus do not qualify as manipulation checks. Thus, participants' recall of a message can serve as a manipulation check for message repetition, whereas participants' specification of the number of times they were exposed to a message does not.

The analysis of measures implies that measures being developed by neuroscience researchers are no more direct than other indicators that have been used traditionally. Researchers who use neuroscientific methods must still make assumptions about the meaning of the observed brain activity and use these assumptions to make inferences about the mind. The usefulness of these measures, like psychological measures, is to converge on the construct of interest, not to serve as definitive evidence.

### Moderation and Mediation

Moderation and mediation are different methods for testing hypothesized causal processes. Moderation is an experimental technique that manipulates the mediating construct (M) in order to observe the resulting relation between distal cause (X) and the downstream or criterion effect (Y). Mediation is a regression technique that examines correlations between predicted links in the causal chain, X, M, and Y to test whether there is a partial effect of X on Y when controlling for M. Both moderation and mediation are useful methods for examining causal processes; yet, the field has come to revere mediation as the more rigorous standard based on the enormously influential paper by Baron and Kenny (1986). However, prior to the publication of Baron and Kenny, many classic articles were published in psychology and consumer research that used some clever experimental design to provide evidence of some underlying psychological process (See, e.g., Garner, Hake, and Eriksen 1956). An example of this strategy in consumer research comes from Mitra and Lynch (1995), who argued that advertising increased price elasticity through a mediator of consideration set size and decreased price elasticity through a mediator of strength of preferences. They tested theory by manipulating conditions that should moderate each of these links. For example, when choosing from among physically present brands, there is no scope for advertising to increase consideration set size, so only the strength

of preference mediator should operate and advertising should therefore decrease price elasticity even though the same advertising increased price elasticity when consumers needed to remember alternatives in order to choose them. Recently, Spencer, Zanna, and Fong (2005) have provided a general critique of the use of mediation analysis, arguing that in many circumstances, it is superior to use moderation designs like those of Mitra and Lynch to show underlying process rather than using the Baron and Kenny measurement of mediators approach that dominates our journals. Specifically, they argued that when the mediating construct is easy to manipulate but difficult to measure, researchers must rely on experimental techniques (moderation) to test their causal predictions. Insistence on mediation, therefore, has the unfortunate effect of precluding research that does not lend itself to this technique–as when the mediating process is nonconscious and not easily measurable.

Furthermore, in order to demonstrate causal processes convincingly using mediation analysis, the analysis itself must conform to certain standards. For instance, many published articles fail to adequately discriminate between the distal cause X and the mediating construct M, or between M and the criterion Y (lack of discriminant validity). In such cases, evidence of mediation can be misleading because it may be an artifact of the co-variation between measures of the same construct rather than between measures of different constructs. This is often the case when manipulation checks of the distal cause are entered into the regression model as mediators–a practice that has become fairly common. A more rigorous approach is to demonstrate that X and M (or M and Y) have unique antecedents and consequences, and thus are indeed separate links in the causal chain. Only then do mediation analyses contribute something new and informative to the research.

**Multiple Studies**

According to an informal sampling of the *Journal of Consumer Research*, the mean number of studies reported in information processing articles has risen dramatically over the past 20 years. In 1986, these articles contained an average of 1.3 studies–a number that has now more than doubled to 3.1 despite a relatively constant page length (around 12.4 pages). Although the research and the reader often benefit from additional studies, this may not always be the case. Thus, the benefits and costs of such a standard warrant scrutiny.

Additional studies may serve many desirable functions for all parties involved in the publication process. They may allow the researcher to address alternative explanations for the data, thereby bolstering the credibility of the advocated position. Additional studies may also allow the researcher to demonstrate construct validity, using converging methods to triangulate on the constructs of interest while distinguishing them from other like constructs. Editors may favor multiple studies because they desire strong evidence for the claims espoused in their journals and feel this strength is best tested with multiple falsification attempts (i.e., more chances to fail). They may also believe these studies improve the article's contribution-to-length ratio (as mentioned earlier, the number of studies has risen while article length has stayed the same). Finally, readers may benefit from multiple studies to the extent that they facilitate understanding of abstract, complex issues.

The number of studies reported, however, should not be interpreted as a heuristic for rigor. Often it seems additional studies serve no other purpose than to increase the study count of the article–a practice that in fact hurts the article's contribution-to-length ratio. As a safeguard against such practice, researchers, editors, and reviewers should consider the extent to which each additional study makes a novel, interesting contribution to the program of research. In this regard, simple replications that make no unique contribution to the paper are difficult to justify. So too are flawed first studies that are later corrected by a subsequent study. Furthermore, it is worth considering the consequences a multiple-studies standard may have for intellectual creativity. In some cases, the novelty of the findings may be sufficient to warrant publication in the absence of exhaustive evidentiary support. By inflexibly enforcing our norms for rigor, we may prevent interesting and important findings from reaching a desirable forum. Some of the most cited papers in our literature have a single very interesting study; indeed the most recent winner of the JCR best paper award (Aaker, Fournier, and Brasel 2004) reported only a single study.

**Conclusion**

The discussion in this session focused on the analysis of measurement, moderation versus mediation and the appropriate number of studies. The analysis of these issues was based on a common understanding of what constitutes rigor in theory testing research. The goal of such research is to enhance understanding of consumers' behavior by representing theory in data. This involves selecting independent variables to represent the construct of the cause and dependent variables to represent the construct of the effect. These constructs are linked in a nomological network that specifies the relationship among constructs (Cronbach and Meehl 1955). To achieve rigor in testing such theoretical representations requires the demonstration that for the moment one explanation is better than its rivals, where better implies that the preferred theory accounts for all of the data without introducing greater complexity than other explanations (Sternthal, Tybout, and Calder 1987), or when the preferred theory has a higher posterior probability given all the data compared to other theories that could explain a particular phenomenon (Brinberg, Lynch, and Sawyer 1994) . Manipulation checks, mediation measures and moderation as well as multiple studies are introduced in the service of this goal. All of these devices can contribute to rigor, but none is essential. They represent alternative and complementary means of advancing understanding.

The focus of this session on rigor in designing information processing research is not intended to suggest that this is the only criterion in designing and evaluating consumer research. Research that introduces new phenomena is also of value in its own right, and as a starting point for rigorous tests of theory.

## SYMPOSIA SUMMARY
# Consumers' Construal Levels: Organic Manipulations and Implications for Choice
Kelly Goldsmith, Yale University, USA

## SESSION OVERVIEW

In the last decade Construal Level Theory (CLT) has emerged as a major development in social psychology, enhancing our understanding of how people represent and evaluate options (Trope & Liberman, 2003). More recent work has begun to explore the implications that CLT has for consumer choice (Dhar & Kim, 2007). While the original CLT research focused on temporal distance (Trope & Liberman, 2000), it soon expanded to encompass manipulations of psychological distance more generally, showing that variations in psychological distance cause consumers to form different representations of the same stimuli (e.g., products). CLT posits that when psychological distance is greater consumers will have a more abstract construal of a stimulus, forming a higher-level representation focused on central features. Conversely, reducing psychological distance can lead to more concrete construals, characterized by lower-level representations enriched with details (Trope & Liberman, 2003). While the first generation of research questions focused on extending what was known about how psychological distance influenced judgment or simple choice situations, the next generation extends these now established findings into the emerging areas of consumer choice and explores natural environmental variables that can prompt these different construals. For example, consumers often choose among non-comparable options or choose from products in adjacent categories. In these circumstances, factors such as the date or an event's probability may exert a natural influence on consumers' construals. As CLT has implications for the decision processes consumers use, CLT allows us to better understand these common consumer choice experiences which have yet to be explored in choice research.

In keeping with the theme of this year's conference, this session unites papers which approach this issue from different perspectives to explore how CLT can deepen our understanding of consumer choices. At a general level, these papers aim to broaden what is known about the ways in which CLT pertains to consumer choice and encourage researchers to question when our understanding of consumer phenomena may be deepened by incorporating considerations of consumers' construal levels. At a more specific level, these papers will attempt to answer three questions: How does construal level affect choice among non-comparable options and what is the consequence for deferral? Will the construal level affect adjacent category purchase likelihood? And lastly, what organic factors might manipulate construal levels in a consumer context?

The first two papers directly explore how consumers' construal levels affect choice. Kim, Khan and Dhar show the effects of CLT on choice satisfaction and deferral rates of consumers across categories (i.e., noncomparable options) and within categories (i.e., comparable options). Through a series of studies, they demonstrate that an abstract construal level decreases no-choice or choice deferral rates and increases choice satisfaction for noncomparable choices and yet has the reverse effect on comparable choices.

In the second paper, Goldsmith and Dhar address an extant void in the literature by exploring how consumer decision processes can change purchase considerations in adjacent product categories (e.g., toothpaste and mouthwash). Specifically, their research explores how a consumer's construal level of a purchase decision influences the number of items that a consumer purchases when presented with multiple adjacent category offerings. The authors find that having an abstract construal increases the number of adjacent category purchases which consumers made.

However interesting, the effect of consumers' construal levels on their choice behavior would be meaningless without ecologically valid examples of how their construals might be organically manipulated in an actual decision context. The last two papers in the session bridge this gap by demonstrating two such examples. The third paper by Kim, Malkoc and Zauberman demonstrates that the date can organically influence consumer construals. These authors find that if a date has a special meaning (e.g., Feb 14th) consumers will have a more concrete representation of outcomes to occur on that day. They further show that this change in construal level affects consumers' inter-temporal preferences and impacts impulsivity.

Lastly, Trope and Wakslak extend what is known about the practical ways in which construal level can be applied to a consumer context exploring probability as psychological distance. As probability may be an organic concern to consumers (e.g., How do I evaluate a restaurant when I have a 5% [95%] chance of getting a reservation?), this manipulation lends itself to consumer applications. In a series of studies, the authors demonstrate that consumers form more concrete representations of high probability events and more abstract representations of low probability events. After presenting his work, Yaacov Trope, one of the founders of CLT, will prompt a discussion aimed at facilitating a broader understanding of the relationship between construal level and consumer choice which we anticipate will be insightful and engaging.

This special session is aimed at furthering current interest in this area and will identify promising directions for future research. Using multiple, yet related, theoretical perspectives these four papers extend what is currently known about when and how consumers' construal levels can affect their choices. These papers employ a variety of methods and dependent variables (evaluations, choices, matching tasks and categorization tasks) to uncover how consumers' construal levels can affect choice as well as how construals can be organically manipulated. We anticipate that this session will be attended by consumer researchers in general and by members of ACR who have a particular interest in CLT, consumer inference making, and processing styles. Each of the papers to be presented is grounded in theory and includes multiple completed studies with supporting results.

# EXTENDED ABSTRACTS

## "Choosing Apples vs. Oranges: Role of Construal Levels in Non-Comparable Choices"

*Eunice Kim, Yale University*
*Uzma Khan, Stanford University*
*Ravi Dhar, Yale University*

Most consumer research has focused on how consumers make choices among comparable—within product category—items. However, in the everyday life, consumers make choices between items that cannot be directly compared (e.g., a box of Chocolate vs. a CD). Non-comparable choices are intrinsically different from choices between comparable items, which can be easily evaluated on shared features and attributes. Because non-comparable options have fewer or no shared attributes, a choice between them is more effortful and requires an abstract holistic valuation of each option (Johnson, 1984; 1988). The key difference may be the ready availability of decision criteria versus the need to create a general one (Bettman & Sujan, 1987). Consumers too, add difficulty and complications to their choices by focusing on the local context of their choices rather than on the more global context (Dhar et al, 2000). In fact, we know that when individuals cannot compare and distinguish among product attributes consumers' preference for choice deferral or no-choice increases (Dhar, 1997).

But past research has shown that construal levels can systematically affect consumer choices (e.g., Trope et al, 2007) by altering the way in which individuals process and form representations of stimuli such as a product. Construal level theory (CLT) posits that depending on psychological distance, individuals will process stimuli differently and form different representations of the same stimuli. As psychological distance increases, individuals will take on a more abstract and holistic approach to the stimuli, and as psychological distance decreases, individuals will adopt a more concrete and detail oriented approach to the stimuli (Trope & Liberman, 2003). However, all the research in this area has remained focused on choices between comparable choices. We seek to examine the consequences of choosing between non-comparable options through the lens of CLT. The present research suggests that construal levels impact choice between non-comparable options by affecting consumers' ability to form an overarching decision criterion on which to compare non-comparable items. Specifically, we predict that compared to a concrete construal, an abstract construal, by focusing the individual on higher level representations of the stimuli, will facilitate a choice between non-comparable options.

While an abstract perspective can facilitate choosing between non-comparable options, approaching comparable choices with a high level abstract perspective could inhibit one's ability to compare the options on their low level attributes. Evaluating comparable products on an abstract level can make them look less distinct (e.g., the "usefulness" of two boxes of chocolate is likely to be more similar than the "number of pieces" in each box) and reduced differences between alternatives can lead to increased choice deferral (Dhar, 1997).

Study 1 tests our main proposition by manipulating construal levels to show the effects on choice deferral for non-comparable options ($20 Starbucks gift card and $20 DVD of their choosing). Participants made a hypothetical choice between these two items; the choice deferral option was presented as a cash option (Simonson & Tversky, 1992) worth half the value. The selection of a cash option would mean that an individual was avoiding having to choose between the two non-comparable options. Participants imagined they would receive their chosen option either tomorrow (near construal) or a month later (distant construal) (Liberman &

Trope, 1998). Consistent with our prediction, participants in the abstract construal were less likely to choose cash (7%) and more likely to make a choice than those who imagined receiving their selection the next day (24.1%).

Study 2 shows construal levels have an opposite effect on comparable and non-comparable choices. Participants either wrote down a goal they wanted to achieve by the end of the week (near construal) or by fall 2007 (distant construal). After the goal priming, half of the participants in each condition chose between two non-comparable options as in Study 1 and the other half chose between two comparable options (two DVDs). All participants also had a $10 cash option. As predicted, results showed a significant interaction between the construal level and type of choice (comparable or non-comparable) (p=0.01). In the non-comparable condition choice deferral was lower in the abstract (20%) than in the concrete construal (52.6%); however, in the comparable condition, participants in the concrete were less likely to defer choice (21%) than participants in the abstract construal (52.6%).

As the ability to form a holistic, overall decision criteria to compare non-comparable items is enhanced or depressed through construal manipulation, the post-choice satisfaction individuals feel may also change. Zhang and Fitzsimons (1999) found that participants' satisfaction with their choices increased as their abilities to process non-alignable differences was enhanced. Therefore in study 3, we predict and show that an abstract construal increases people's satisfaction with their non-comparable choices, but decreases satisfaction for comparable choices. We find an interaction effect on choice satisfaction between construal level and choice types and a main effect of construal on satisfaction in the non-comparable condition. Participants gave higher post-choice satisfaction ratings in the abstract (M=7.5) than in the concrete construal (M=6.5), p=.002. Study 3 also replicates the choice deferral findings from study 2.

Lastly, in study 4, we outline that compared to a low level construal, high level construal, will lead to decreased choice difficulty in non-comparable choices. In this study construal was primed by having participants write down either "how" or "why" they studied (Freitas et al, 2004). Subsequently, all participants were presented with a non-comparable choice (box of chocolates vs. video games) and asked to indicate how difficult the choice was on a scale of 1 (not at all) to 9 (very difficult). As predicted, participants found the same choice between two non-comparable options more difficult in a concrete (M=3.67) than in an abstract mindset (M=1.8) (p=.038).

We have shown that consumers' choice behaviors and consequences in non-comparable options can be affected through the ease with which general decision criteria can be created through construal manipulations.

### "The Role of Abstract and Concrete Mindsets on the Purchase of Adjacent Products"

*Kelly Goldsmith, Yale University*
*Ravi Dhar, Yale University*

Most choice research has looked at how consumers choose in isolation (e.g., within one category at a time). In contrast, real world consumer choice often involves making a series of choices within adjacent categories that are considered together (e.g., a consumer in the oral care aisle may consider buying one or more items among toothpaste, mouthwash, floss, etc). Although many brands are widening their within-category product lines to take advantage of this phenomena (e.g., Varadarajan 2007), such extensions into these adjacent product spaces are more likely to generate incremental sales if consumers see such products as complementary rather than as substitutes for one another. Despite its ecological relevance, relatively little research has been devoted to exploring how consumer decision processes may change purchase considerations of other products in adjacent categories.

This project develops a goal theoretic framework to understand how the consumer's mindset, whether abstract or concrete, influences the likelihood of purchase from adjacent product categories. Specifically, the authors compare the number of adjacent products selected in an abstract mindset to those selected when the consumer is in a more concrete mindset. The recent literature on goals demonstrates that abstract mindsets conjure higher order, super-ordinate goals (Fishbach, Zhang and Dhar 2005, Freitas, Gollwitzer and Trope 2004, Pennington and Roese 2003, Trope and Liberman 2003), whereas concrete mindsets are associated with comparatively low order concerns (Pennington and Roese 2003, Trope and Liberman 2003). As the mindset of a consumer differentially affects attention to higher order goals, we argue that in an abstract mindset goal activation will spread from the higher order goal (e.g., oral care) to its related sub-goals (e.g., whitening one's teeth and freshening one's breath) which will ultimately lead to greater consideration of their associated means (e.g., white strips and breath mints). We propose this pattern of activation results from the cognitive structure of goals (Kruglanski et al. 2002). Conversely, a concrete mindset, which draws attention to lower level concerns, will cause consumers to focus more narrowly on the specific sub-goals themselves. As a consequence, purchasing from a single product category may be sufficient to satisfy their activated narrow goal and consumers will not feel inclined to purchase products from adjacent categories.

This hypothesis is tested in two studies. In the first study, participants' completed a mindset manipulation (Freitas, Gollwitzer and Trope 2004) then moved on to a shopping task where they were given the opportunity to purchase products from three categories (hair care, oral care and skin care). Within each category, participants first made an initial choice (e.g., a choice between toothpastes in oral care). Next, they were presented with 5 additional items from adjacent categories (e.g., mouthwash, floss, etc.) and told to purchase any additional items which they would like from that set of options. In line with our prediction, within each category participants put in an abstract mindset purchased more additional items than participants in a concrete mindset (average: $M_{concrete}=1.7$; $M_{abstract}=2.4$; $p<0.05$; pattern replicated and was significant for all categories individually).

Our second study was designed to extend the findings from Study 1. As in Study 1 respondents chose a central item from the category (e.g., toothpaste in oral care) before considering additional purchases, one account for the results could be that respondents in an abstract mindset might have had greater commitment to the goal of oral care after making an initial successful choice (Fishbach, Zhang and Dhar 2005). Thus, first choosing a toothpaste made respondents subsequently more likely to pursue the goal of good oral care through related means (e.g., additional purchases). The next study controlled for this account by offering all adjacent category items simultaneously. Specifically, after completing a mindset manipulation, participants were shown one category of products (e.g., oral care) containing twenty different items and asked to indicate which items from that category they would like to purchase. In support of our hypothesis, respondents placed in an abstract mindset made significantly more adjacent category purchases (oral care: $M_{concrete}=4.7$; $M_{abstract}=6.3$; $p<0.05$; results were replicated with an additional product category).

We use the relationship between consumer mindsets and regulatory focus to further clarify the process behind why this spreading activation generates greater motivation to purchase in an abstract mindset. An abstract mindset engenders a promotion focus, which is characterized with eagerness towards maximum goal attainment (Keller, Lee and Sternthal 2007, Pennington and Roese 2003). Conversely, a concrete mindset facilitates more balanced thoughts of promotion versus prevention, the latter characterized by attention to "bare necessities" or minimal goal attainment (Higgins 1997, Pennington and Roese 2003). As such, we predict that an abstract mindset will not only facilitate greater activation of adjacent products as related means to the higher order goal, we propose specifically that the promotion focus triggered by this mindset will be the mechanism underlying the effect of mindset on the purchase of adjacent products. Study 3 tests for this using a written protocol design to examine how mindset affects regulatory focus. The results of Study 3 support our prediction. In support of our hypothesis, participants in an abstract mindset purchased more adjacent products ($p<0.05$). Further, participants in an abstract mindset mentioned more promotion than prevention related thoughts relative to participants in a concrete mindset ($p<0.05$). Finally, using regression analysis with both mindset and a composite measure of regulatory focus included in the model, we find the composite measure fully mediates the effect of mindset on purchase. This pattern of results is supported by Study 4 where we directly manipulate regulatory focus and demonstrate that participants in a

promotion focus purchase more adjacent products than participants in a prevention focus (hair care: $M_{prevention}$=3.8; $M_{promotion}$=4.9; $p<0.05$, *one tailed*).

At present, this research achieves several goals: we demonstrate how one's mindset can affect the number of purchases which one makes when presented with multiple adjacent category offerings. Further we identify an underlying shift in regulatory focus as the mechanism behind this effect. As how consumers make choices when they consider adjacent categories simultaneously has not yet been examined, we believe this research makes an important contribution to the extant research on consumer choice. Finally we believe that as the factors which influence product perceptions are of critical interest to firms these findings have clear practical implications.

### "The Role of Special Dates on Intertemporal Preferences"

*B. Kyu Kim, University of Pennsylvania*
*Selin A. Malkoc, University of Minnesota*
*Gal Zauberman, University of Pennsylvania*

Many consumption decisions involve timing considerations. Extant literature demonstrated that consumers often act impulsively (i.e., their preferences imply high discount rates), overweighing the current outcomes and underweighting the future ones (for a review see Frederick, Loewenstein, and O'Donoghue, 2002). Prior research has documented that one source of impatience is the level of concreteness in which the outcome is represented. That is, impatience is increased if the outcome to be forgone is represented concretely (Metcalfe & Mischel, 1999), and that this level of representation could be triggered by the framing of the decision. For instance, Malkoc and Zauberman (2006) have demonstrated that delay frames lead to more concrete representations than expedite frames.

In this work, we suggest that whether the date used in describing delays is special (e.g., February 14th) or non-special (February 15th) would also affect the concretes of outcomes and have consequences for consumer impulsivity. We argue that using special dates to describe deferrals would give meaning to that consumption timing, providing a context to imagine the outcome. Imagining outcomes more concretely would then affect consumer's impulsivity.

We investigate the role of special dates in consumer impulsivity, in the context of recently demonstrated date/delay asymmetry-higher discounting in delay than in date frame (LeBoeuf 2006; Read et al., 2005). We argue that while the date/delay asymmetry holds for non-special dates, when special dates are used, consumers' impatience is significantly altered. We predict that if the sooner (later) of the temporally separated outcomes happen on a special date, the impatience will increase (decrease). In particular, if the special date is the sooner of options, this description would make the outcome in the near future more concrete, leading to an increase in impulsivity (compared to non-special date). However, if the special date is the later of options, this description would make the outcome in the distant future more concrete (relative to the near outcome), decreasing impulsivity. Results from two experiments support these predictions.

In study 1, the special date was presented as the sooner of options and thus we expected an increase in discounting with special dates, approximating the delay frame. The study was run three weeks before Valentine's Day. Participants imagined receiving a coupon for a French restaurant that was redeemable either in three weeks for $75 or in eight weeks for an unspecified amount. We manipulated whether the time was framed as delay (3 weeks vs. 8 weeks), as a non-special date (February 15th vs. March 22nd), or as a special date (February 14th vs. March 21st). The main task was to indicate the matching value of the coupon in eight weeks with the $75 coupon in three weeks. Replicating the date/delay asymmetry, results showed that participants in delay condition indicated higher value for the delayed coupon ($M$=126.54) than those in non-special date condition ($M$=86.92). More importantly, we found predicted effect of the special date, with higher matching values for the special date ($M$=118.59) than for the non-special date. These findings suggest that when temporal distance is described in terms of special dates, the greater discounting of delay versus date is significantly reduced.

To test our second prediction, in study 2 the later of the temporarily separated outcome happened on a special date. We predicted to find a decrease in impulsivity on the special date condition (compared to delay frame and non-special date). This study used 4th of July (Independence Day) as the special date. Participants imagined receiving a certificate to a local grocery store, redeemable either this week for $75 or in 5 months for a different (unspecified) amount. We manipulated whether the time was framed as delay (this week vs. 5 months later), as a non-special date (February 10th vs. July 5th), or as a special date (February 10th vs. July 4th). Main task was to indicate the matching value of the certificate in 5 months with the $75 certificate this week. Results replicated the date/delay asymmetry with higher matching values for the delay frame (M=156.59) than the non-special date frame (M=119.41). However, as expected, when the time was framed with a special date, the matching values decreased significantly (M=94.00) compared to the non-special date condition.

In conclusion, we show that providing meaning to the timing of consumption (with the use of special dates) has important implications for intertemporal preferences. Specifically, we suggest that special dates provide a context to imagine the outcome, increasing the concreteness in which it is imagined. Depending on the outcome the special dates help represent (sooner or later), consumers can be more or less impulsive in their preferences.

## "Seeing the Forest When Entry is Unlikely: Probability as a Psychological Distance"

*Yaacov Trope, New York University*
*Cheryl Wakslak, New York University*

Postulating that improbable events are psychologically distant and probable events are psychologically near, we draw on construal level theory (Trope & Liberman, 2003) to propose that decreasing an event's probability leads individuals to represent the event by its central, abstract, general features (high-level construal) rather than by its peripheral, concrete, specific features (low-level construal). A series of studies looked at the relationship between probability and mental construal. For example, one study used a categorization task, in which participants grouped objects related to each of four scenarios into as many groups as they deemed appropriate. Participants were asked to imagine that they were either highly likely or highly unlikely to engage in the scenario. As expected, participants in the low likelihood condition created fewer, broader groups out of the objects than participants in the high likelihood condition.

The effect of probability on mental construal emerged on identification measures as well. For example, participants in one study received a flyer advertising a paid research assistant position described in broad, general terms (e.g. helping behavior research) as well as in specific, low-level terms (e.g. dropping a book in front of participants). Participants in the high probability condition were told that they would be almost certain to get the position if they signed up for the post, while participants in the low probability condition were told that they would be unlikely to get the position if they signed up for the post. Participants signed up for consideration, and then completed a separate, unrelated study. At that study's conclusion, they were given a surprise "recall test" where they were asked to indicate the nature of the research assistantship that had been advertised earlier. Participants in the high probability condition were more likely to provide specific than general descriptions of the assistantship; this tendency was significantly lower for participants in the low probability condition.

Visual structure measures also revealed construal differences as a function of probability. Participants who came for a computerized study of visual perception were asked to first complete a paper and pencil practice version of the study task. During this "practice session" each participant completed two different tasks, one of which they believed they were likely to later complete in the actual experiment, and one of which they believed that they were unlikely to later complete in the actual experiment. The two tasks were the Snowy Pictures Test, which asks participants to name a picture hidden beneath visual noise, and the Gestalt Completion Test, in which participants must name an object presented in fragments. While different, both tasks involve abstracting visual information, and thus performance on both should be greater when associated with low, as opposed to high, probability. Indeed, this was the case. Participants' performance on each task was better when they believed that they were unlikely to later complete the task then when they believed that they were likely to later complete the task. Further, a follow-up study revealed the opposite pattern of results when the task content was replaced with a picture completion test in which participants had to name an element missing within a coherent whole (Wechsler, 1991). If abstracting information allows one to better close the gestalt in a picture, this should make it harder to recognize individual missing elements; in accord with this prediction, participants performed less well on the task when they believed they were unlikely (as opposed to likely) to later complete the task in the actual experiment. Thus, the effect of probability on performance is dependent upon the nature of the task: when abstraction facilitates performance, thinking of something as unlikely leads to better performance; when abstraction hinders performance, thinking of something as unlikely leads to diminished performance.

Taken together, these findings suggest that low likelihood events are indeed represented at a higher level of construal than are high likelihood events. Accordingly, decisions made about low likelihood events should be influenced by higher level aspects of those events. For instance, when an outcome has multiple features, we would expect that the lower the probability of receiving the outcome, the greater will be the weight of central, defining features of the outcome relative to weight of its peripheral, non-essential features (Todorov et al., 2007). For example, in choosing a course, students would assign greater weight to the quality of the instructor (a high level feature) and less weight to the location of the course (a low level feature) when the likelihood that the course will be offered is low rather than high. Thus, a course given by a good instructor in an inconvenient location would be more attractive when the course is unlikely to be offered than when it is likely to be offered, whereas the reverse should hold for a course given by a mediocre instructor in a convenient location.

# Bridging Cultures: Theorizing the Spaces between Disciplines, Peoples and Consumer Identities

Laurel Anderson, Arizona State University, USA

## SESSION OVERVIEW

The goal of this session is to advance research and stimulate multi-disciplinary debate on current issues in cross-cultural consumer behavior that have emerged in relation to dramatic changes in society at large. Market globalization, ethnic conflict, massive population upheaval and displacement, and the deconstruction of national cultures characterize the 21st century and demand a rethinking of a broad spectrum of acculturation models of consumer socialization (Hirschman 1981; Wallendorf and Reilly 1983; Deshpande', Hoyer and Donthu 1986; Stayman and Deshpande' 1989; Askegaard, Arnould and Kjeldgaard 2005; Oswald 1999; Peñaloza 1994). By bridging differences between various units of analysis, theoretical frameworks, ethnicities and 'contact zones,' this symposium proposes a multi-dimensional approach to cross-cultural consumer behavior that defies reduction to an oppositional in-group against out-group–"us against them" model. The four papers strive to account for multi-directional movements of meaning, material, and power between and among consumers and consumer groups.

The authors shift the focus of cross-cultural consumer research from the study of ethnicity *per se* to the fluid and dynamic process joining/separating ethnic groups in various material, figured and virtual zones which serve to structure social interactions, activities, and institutions such as networks, media, organizations, and markets. This approach foregrounds the complexity and fluidity of cultural identity, socialization and consumer behavior (Berger, Berger and Kellner, 1973: 77; Bell, 1980: 243) and the strategies consumers employ to navigate these complex and ever-changing social spaces.

The likely audience for this session includes marketing and public policy researchers and practitioners interested in:

1. the sociology of consumption at large, focalizing on the dialogical deployment of products in mainstream-minority market and social negotiations (e.g., value conflicts, cultural capital elaboration, construction and deconstruction of social boundaries);
2. consumer ethnic studies, covering theoretical domains such as postassimilationist, cross-cultural and international research on consumer behavior, identity, transculturation.
3. transformative consumer research, since the evolution of ethnic and cultural studies suggests implication in terms of consumers' quality of life and community development.

- In the first paper, Anderson articulates a "third space" in the dialogue/bridge zones forming and differentiating ethnic cultures. She also examines the fluidity of acculturation and "reculturation" strategies across generations and at developmental points in consumer's lifetime.
- In the second paper, Visconti documents cultural alternating identities of Egyptians rooting in the Italian socio-economic context. If alternation enforces win-win logics of acculturation processes and supports multiculturalism and individual flow experience, it also makes harder immigrants' categorization, leading to possible subjective uncertainty and social distrust.
- Next, Oswald examines ways the minority experience engages

multiple stakeholders in a complex, bi-directional dynamic of sharing, borrowing and bartering back and forth across ideological lines formed by race and ethnicity.
- And finally, Peñaloza reverses the direction of the usual ethnic research in examining the dialogue and impact of mainstream consumers' consumption of Mexican-American cultural artifacts on the development of Mexican American community.

## EXTENDED ABSTRACTS

### "Dynamic Inbetweeness: Ethnic Consumer Dialogue Zones"
*Laurel Anderson, Arizona State University*

Disparate and contrasting ethnic cultures with their collective voices play a part in the development of multi-voiced consumers. Consumer researchers have discussed aspects of moving between ethnic cultures (c.f. Stayman and Deshpande' 1989, Peñaloza 1994, Oswald 1999, Askegaard, Arnold, Kjelgaard 2006). This research focuses on the process dynamic of going between cultures and finds a dialectic that illuminates an inbetweeness space–a third space. Inbetweeness is the space at the bridge, the crossing and intersection of two cultural worlds, two points of view, two sets of evaluations, two voices trying to talk over each other–a dialogic collision. The people that operate in this third space at the margins of two cultures deal with conscious agency, sometimes irreducible differences between cultures, constant dynamism. Thus this research focuses on the bridging space between two ethnic cultures.

Regarding ethnic inbetweeness/ a third space, one informant says:

> "There is a group of us, and it's not small anymore, that go through that. Only those that go through that understand …what you feel like because of the choices you made. That group has evolved into a subgroup of us…"

This ethnographic research focuses on Mexican-American professionals whose careers exist in the mainstream world. These consumers must operate competently in both the mainstream culture and the Mexican-American culture. Photo essays developed by participants, in-depth interviews and observations were used to explore these dialogue zones between the Mexican-American culture and the mainstream culture. Extensive improvisation is found (Bakhtin 1987, Bourdieu 1997), creativity and resourcefulness by the individuals that inhabit this space. Improvisation creates new social competences in newly figured worlds at the margins of culturally regulated space and time. The resources of the two original cultural worlds are used opportunistically–yet sometimes without the regulations of the overarching cultural structure of those worlds. It is this component that is unpacked in this research. Improvisation commands our attention because without this attention to it we may miss the back and forth of engagement with different ethnic cultures. Furthermore, it celebrates consumer agency.

This data finds in particular:

1. Dynamic inbetweeness occurs at different levels and is especially pronounced in three different dialogue zones: between home and work, at different developmental points in life and between generations.

2. Creativity and improvisation often occur in these dialogue zones through the consumption of symbols/products. Two creative uses of symbols are especially pronounced: utilization to ensure that others that enter their dialogical zones are "comfortable;" and utilization as triggers or pivots to enter one or the other of the cultural worlds.

3. This process is often one of conscious agency. The cultural and cognitive heuristics of one cultural world that allows an individual residing in that culture to be a cognitive miser are not available in the inbetweeness space. There is a vivid consciousness that one must be making choices. The social structure of the cultural worlds is made more vivid along with an implication for change.

### "The Social Construction and Play of Ethnic Minorities' Identities: Antecedents and Epiphany of Cultural Alternation"
*Luca M. Visconti, Bocconi University*

The multicultural stream is smoothing the stony definition of nation, and marketplaces are arenas where ethnic minorities and mainstream consumers, together with marketers, negotiate their identities through artifacts cross-consumption (Grier, Brumbaugh, and Torton 2006). In this light, my ethnographic work on Egyptians in Italy acknowledges the idea of ethnic identity as: (i) situational (Stayman and Deshpande 1989), (ii) diasporic and hybrid (Askegaard, Arnould and Kjeldgaard 2005; Lindridge, Hogg and Shah 2004; Oswald 1999), (iii) socially embedded, and (iv) controversial as a result of problematical processes of migrants' self/social categorization. Relying on this basis, the work aims to bridge the micro and macro contributions in the field of ethnic acculturation through the specific lens of cultural alternation (Berry, 1980). As such, the paper discusses the way ethnic consumer identity and practices (Peñaloza 1994) are intertwined with the socio-cultural patterning of consumer acculturation (Üstüner and Holt 2007).

(Trans)cultural psychology has long confirmed how cultural adaptation may lead to multiple exits (Berry 1980; LaFramboise, Coleman and Gerton 1993), including acculturation, assimilation, rejection, deculturation, and cultural alternation. Alternation stems from a state of migrants' double cultural competence/consciousness (DuBois 1961), which endorses a win-win logic of cultural encounters. Dynamically, it hypothesizes that migrants can combine or switch to different cultural identities according to situations, social ties, emotions, goal-achievement tactics, rituals, etc.

Reverting to the consumer literature, assimilation and acculturation have been largely described, whereas cultural alternation has remained almost at the margins. Postassimilationist ethnic studies have elaborated close constructs, such as those of border crossing individuals (Peñaloza 1994), cultural swappers (Oswald 1999), or diasporic (Lindridge, Hogg and Shah 2004) and pendulum identities (Askegaard, Arnould and Kjeldgaard 2005). Recently, Üstüner and Holt have unpacked the social conditioning to creolized identities when discussing the case of Turkish women living in a squatter in Ankara (2007).

If the more micro approach has been labeled "postmodern consumer acculturation" and opposed to the socio-centered, macro view defined "dominated consumer acculturation" (Üstüner and Holt 2007), this work aims to reconcile the micro/macro lectures. Consequently, it explores the antecedents and play of culturally alternating identities so to: (i) untangle the subjective impact of the socio-cultural forces on migrants' life/market experience; and (ii) appreciate the resources and individual strategies that migrants deploy to cope with these supporting/oppositional social forces.

Data are the result of a two years field observation on a purposive sample of 21 Egyptian immigrants, selected according to variety and contrast principles (Miles and Huberman 1984). Food, linguistic and media preferences, family and social ties, personal elaboration of cultural conflicts, migration projects, and life-stages have been cross-analyzed relying on the tenets of interpretative ethnography.

Findings support a melted overlapping of individual and social dimensions, and deeply discuss:

1. *cultural alternation's antecedents*, which explain why and how certain Egyptian migrants acquire multiple identities. Individual as well as socio-cultural resources are illustrated;

2. *cultural alternation epiphany, both in market and social contexts*. The interplay between social and individual forces is mirrored by the high variety of alternating patterns (e.g., hybridized vs. polarized manifestation; instrumental vs. terminal relation to culture; subtractive vs. additive dynamics between cultures);

3. *finally, cultural alternation living experience*. Antecedents and play impact migrants' life/market experience. Data document how migrants negotiate social identities in terms of their (i) means of conflict elaboration (tragic vs. comic), (ii) principles of identities reconciliation (self-to-self vs. self-to-context) and (iii) rates of autonomy in adapting to the new cultural environments.

Evidence on Egyptians in Italy confirms the relevance of the social pattering of consumer acculturation and its interplay with the resource-basis of individuals. The ongoing debate about the threat of Islamism to Western cultures is almost ignored in consumer literature, with the main exception of Üstüner's and Holt's recent contribution on Turkish consumers, whereas it has received much more emphasis within the psychological realm (e.g., Florack et al. 2003). My data sheds light on the way informants have modified their socialized sense of self after September 11th. Furtherly, Italy-as part of the overall Mediterranean culture-offers Egyptians a kind of meta-ground where autochthonous and migrants share the same Meridian core cultural values (Cova 2005).

On this empirical basis, cultural alternation is not a static consequence of adaptation praxes, but it serves as an active and deliberate strategy immigrants dispose of in order to contest, confirm and question their own identities both within and across minority/mainstream groups.

### "The Role of Consumption in Cultural Co-Existence Strategies"
*Laura Oswald, University of Illinois Champaign-Urbana*

Sociologists stress that successful minority socialization depends on the acquisition of the cultural capital—including education, tastes, values, and consumption rituals—of the more powerful mainstream group (Bourdieu 1977; Bourdieu and Passeron 1977; Dimaggio 1992; Simpson 2001). In this paper I propose a Cultural Co-Existence model of minority socialization that emphasizes the two-way flow of influence between underprivileged African Americans and the dominant society as they negotiate the racial divide that currently perpetuates a cycle of poverty, isolation and despair in the inner city. Findings demonstrate that multicultural contexts engage multiple stakeholders in a bi-directional dynamic of sharing, borrowing and bartering back and forth across ideological lines formed by race, gender and ethnicity. This approach extends the consumer

acculturation literature (Penaloza 1994, Oswald 1999; Askegaard, Arnould and Kjeldgaard 2005; Üstüner, and Holt 2006) by interpreting the mainstream/minority dialectic in terms of a dynamic of push and pull between informal sociality at the level of the subculture, and the formal organization of society-laws, public policy, and institutions at the level of the mass culture.

America has been the ancestral home to African Americans much longer than most Americans of European origin (1805/1840s), but they continue to constitute a separate cultural entity because of prolonged racial segregation. Furthermore, the population under study has lived on the West Side of Chicago for over 40 years and do not plan to leave (Crocket and Wallendorf 2004). Findings from an ethnography conducted on the West Side of Chicago between 1998-2001 illustrate how African Americans living in the inner city leverage local networks and cultural identity–grounded in custom and charged with meaning-to negotiate with the dominant social and political establishment for the satisfaction of basic needs for safety, employment, housing, and transportation. Isolated from the mainstream by race and economic disadvantage, the subjects of this study struggle to maintain social order, economic survival and personal dignity by means of informal, voluntary activities such as street gardening (LaGuerre 1994). These activities both contribute to the neighborhood's social capital by building community networks (Bourdieu 1984/1979, Glover 2004), and also create a kind of collective cultural capital that empowers the group in relation to the dominant social order (LaGuerre 1994).

The author bridges the research streams of cross-cultural consumer research, public horticulture, and minority socialization by taking a pluralistic approach to the interpretation of urban gardening as a site for consolidating ethnic identity and solidarity, for producing cultural capital, and for circulating goods, services and favors between minority and dominant sectors of society. As previous studies on community gardens show (Coley, and Sullivan 1997; Rishbeth 2004; Glover, Shinew and Parry 2005), the West Side community gardens engage the individual at personal, social, and symbolic levels of consumer behavior. Gardeners are initially moved to action out of a need for personal control over their neighborhoods, which are plagued by street crime and urban decay. Gardeners hold fundraisers and bake sales to buy plants and materials and socialize with their neighbors.

However, most of the community gardening literature is published in journals on leisure and recreation, while the informants in the present study garden to survive in the face of extreme social conditions produced by gang activity, violent crime, drug traffic, general poverty, and high unemployment that do not exist in the settings studied by previous researchers. The current study extends the research on community gardening by 1) focusing on inner city African American communities rather than predominantly white communities, 2) taking a cross-cultural view of the community garden as a site for the circulation of goods, services and favors between the community and the dominant social system, including City Hall, social services agencies, and private organizations, and 3) showing how gardens and gardening not only bring people together (a form of social capital), but become symbols for group identification and ethnic identity (a form of cultural capital).

On the West Side, volunteerism evolves into social activism, as the informal social connections forged through gardening develop into organized networks. Gardeners encourage their neighbors to apply for social services and vote in elections, and train children in the arts of horticulture. In the course of cleaning up abandoned lots, cultivating the land and planting flowers and vegetables, they engage with City Hall to tear down abandoned buildings, build sidewalks and increase police protection. Further-

more, over time residents have claimed the gardens as sites for perpetuating their unique cultural heritage, growing collard greens, okra and black-eyed peas reminiscent of the rural South. Grounded in African American folk culture and reconstructed in the form of cultural capital (Bourdieu 1984/1979), the gardening effort contributes to the social distinction of the group in relation to the dominant culture at both social and political levels. To celebrate Black History month on the West Side, gardeners commemorate the legacy of residents whose ancestors either worked on plantations or, after Abolition, worked as sharecroppers on large estates in the Mississippi Delta (Lehman 1992). In one garden, residents cultivate cotton and tobacco as symbolic reminders of their southern roots. Over time this cultural distinction has acquired 'social sacred' status (Durkheim 1995/1912). Informants repeatedly stated, "green space is sacred." Even the gangs in this distressed community "respect the gardens and leave them alone." In other words, the community garden becomes a symbolic treasure that binds the minority community internally and enables residents to garner material benefits–in the form of services and goods–from City Hall.

Finally, there is an interdependency between the gardening community and City Hall, since the gardeners–as social activists-have the power to organize the local community, influence the vote, and ease the way for the implementation of public policy.

### "Consuming Community: The Impacts of Mainstream/Margin Social Relations on Community Development"
*Lisa Peñaloza, EDHEC, France and University of Utah*

This presentation continues the project of theorizing the spaces between disciplines, peoples, and consumer identities in shifting consumption and community as alternatively phenomena and domain in better understanding the place of consumption in community development. Over the past decade consumer researchers have produced a stream of work concerned with the forms and processes whereby consumers make community. These researchers extrapolated insights from ethnic/racial and religious subcultural communities in making sense of the social bonds they observed in the consumption of brands of products and services (Muniz and O'Guinn 2001; Kozinets 2001). In doing so, this work shifted attention from the phenomena of consumption within the domain of community to the phenomena of community within the domain of consumption.

This research reinstates the community as domain of study, specifically a Mexican American community in South Texas, in investigating various consumption phenomena and tracing their impacts on its development. Importantly, this community does not exist in a vacuum; as part of the minority Latino/a subculture in the U.S., fundamental are its relations with the White mainstream. As I will show, consumption plays a key role in community development in the ways it reflects and potentially alters social relations between the two groups. That is, these social relations serve as the raw material from which consumers produce cultural meanings, at the same time consumers are able to renovate extant social relations in their consumption meanings and practices.

The research employs an ethnographic design comprised of interviews and participant observation. The 48 informants were selected to vary by generation in the U.S., age, sex, social class, color, neighborhood residence, and language. Questions examine consumption patterns for transportation, communication, food, fashion, and holidays; together with ethnic identity and subjective understandings of being in a targeted subgroup, and relations with other social groups in and outside the market. Participant observation took place in homes, stores, neighborhoods, marketplaces, tourist sites, churches, and public parks and public transportation.

Findings contrast the colonial history of people of Mexican descent in the U.S. Southwest with dramatic market growth since

the mid 1980's. As the nation's largest minority, Latinas/os currently number over 43million persons (U.S. Census Bureau 2006), with over $650 billion in annual expenditures (Conference Board 2004). Community characteristics include common activities and values, intense interactions, loose and volatile organizational forms, socio-economic composition, and relations with other social groups and the market. To highlight, the median income for Mexican Americans is in the mid 20k range as compared to the high 40k range for non-Hispanic Whites (U.S. Census Bureau 2006). Interactions and intermarriage with Whites are increasingly common; juxtaposed with greater tolerance on the job and as consumers, continued pressures for assimilation, and persistent White dominance in local government. The community exhibits a complex, layered, dialectical market genealogy. Mexican American consumers commune in their use of products and services and constitute their culture in deploying symbols and offerings provided by marketers at home, in their neighborhoods, and in tourist sites where they are joined by Non-Latinos/as who outnumber them in reproducing distorted forms of the culture in restaurants, bars, and souvenir shops.

Discussion elaborates various forms of consumption in relation to minority/majority group status in tracing their impacts on the development of the Mexican American community. As Non-Latino/a consumers consume Mexican American culture at many of the sites, they exert profound social legitimizing effects supporting and validating Mexican American cultures. Yet the forms of Latino/a culture they consume are geographically and culturally distanced from the Mexican American community in San Antonio, and as such, contested by many cultural members. This market distancing and distortion reflects and impacts relations between the two groups, and in turn affects the development of Mexican American community. Theoretical implications discuss 1) how cultural consumption takes place in and outside the market and 2) how community is produced in cultural consumption by members and nonmembers; while research implications argue for the importance of social relations in consumer research to render it more appropriate to U.S. multicultural society and the global economy.

SYMPOSIA SUMMARY
# Money Makes the World Go 'Round–
# and Other Interesting Effects on Affect, Consumption, Goal Pursuit, and Generosity
Kathleen Vohs, University of Minnesota, USA

## SESSION OVERVIEW

**Objective:**

Money is at the heart of many consumer interactions and yet has received precious little attention from the experimental scholarly world. Moreover, the concept of money has not been examined in the manner in which the proposed speakers study it: These speakers manipulate the form of money or its presence or absence, novel methods that have not been used previously to investigate money. This session brings to the forefront the notion that money is an essential component to being a consumer and deserves more attention from consumer scientists.

This session illuminates the way in which money affects a variety of consumer responses ranging from levels of consumption to emotions, from goal-strivings to interpersonal sensitivity. Money's centrality to consumers' lives is a foundational issue that bridges myriad subgroups. This topic provides an ideal jumping off point for lively debate, inquiry, and (we hope) future research endeavors highlighting the fascinating effects of money on consumer behavior.

**Issues and Topics:**

The first paper, by Vohs and colleagues, examines the most basic of effects relating to money: How does activating the concept of money change people's behavior? In 9 experiments, Vohs et al. demonstrated that priming money led people to become more motivated in the sense that they worked harder and longer on difficult tasks (which is a good outcome). On the other hand, priming money also led people to become less sensitive toward others' needs (obviously a bad outcome). Hence, the mere activation of money produces divergent responses, both positive and negative, which may well explain people's love/hate relationship toward it. The second paper, by Mishra et al., picks up thematically where Vohs et al.'s conclusion leaves off, by detailing three experiments that investigate the effect of money on purchase decisions. Mishra and colleagues found fascinating evidence that money in large denominations (or crisp new bills) leads consumers to feel highly positive affect, whereas smaller denominations (or used bills that appear tattered and worn) elicit weaker affect. Furthermore, Mishra et al. when the product is hedonic and the denominations of money are small, consumers report high willingness to pay, whereas low WTP is found when the product is utilitarian and denominations are large. These findings reveal intriguing effects about the meaning of money and emotions that could impact a wealth of research (no pun intended) in the consumer realm. Last, Ariely et al. present a new twist on the quintessential question of how prices affect demand. Their research compares pricing products positively (i.e., above $0) to pricing products at $0. Positive pricing has the predictable effect of diminishing demand but when the product is priced at $0, more consumers partake in the free product (in accordance with supply/demand predictions) but each individual consumes less of the product–an unexpected effect from a monetary market standpoint. Ariely et al. note that a social market perspective neatly explains both sets of results.

## EXTENDED ABSTRACTS

### "Money Changes the Self"
*Kathleen D. Vohs, University of Minnesota*
*Nicole L. Mead, Florida State University*
*Miranda R. Goode, University of British Columbia*

Scholarly and other discussion about the effects of money on people's behavior range from the positive to the severely negative. On the positive side, some prize its ability to motivate behavior; on the negative side, academics and lawyers decry money's role in harming social relationships. We wondered whether both accounts of money's effects could be true, and we set out to test this idea empirically. The results of 9 experiments indicate that both types of outcomes follow from the mere activation of money in people's minds. We have called the process responsible for this effect the self-sufficiency effect of money (Vohs, Mead, and Goode 2006).

Although money has been widely debated as to its effects, it has rarely been experimentally studied in the laboratory. Most of the social science research on money has focused on factors that are related to money, but that are not money itself. Nonetheless, important insights about the consequences of money on people's behavior can be gleaned from this work. Materialism, for one, has been shown to disrupt interpersonal harmony because people high in materialism tend to value the goods that money can buy more than being close with others (Burroughs and Rindfleisch 2002). On the other hand, having money helps buffer people from the environmental shocks that naturally occur across the years of life. We thought it crucial to test the downstream associations of being reminded of money to understand the effects of money, per se, rather than related factors (e.g., income or materialism).

In six experiments, we tested for the effect of money on helping behavior. Would reminders of money lead people to become less helpful? We found that they did. In experiments 1-2, reminders of money were manipulated by asking participants to first play the game of Monopoly with a confederate. This allowed us to create a high money condition by leaving these participants with $4000 of play money and a no money control condition in which participants were not left with any play money. The next task further strengthened the conditions by asking participants to write about what life would be like with abundant finances (high money condition) versus their day tomorrow (no money condition). Afterwards, as participants walked across the lab, a second confederate dropped a bag of small pencils in front of participants and we measured how helpful they were in gathering them. We found that participants in the high money condition were less helpful than participants in the no money condition. Experiment 2 used the same manipulation, with the helping measure being amount of time participants volunteered to help the experimenter code data for her honor's thesis. Again, high money participants were less helpful than no money participants. Experiments 3-4 used a supraliminal phrase-descrambling task to prime the concept of money nonconsciously. In this task participants either descrambled phrases relating to money (e.g., answer: "she got a raise") or neutral phrases (e.g., answer: "it is cold outside"). Experiment 3 participants were

then asked for help by a confederate seated in the same room; in experiment 4, participants were given an opportunity to donate money to a university student fund. In both experiments, participants who were reminded of money earlier were less helpful in time (experiment 3) and money (experiment 4), relative to participants who were not reminded of money.

A second set of experiments asked whether participants who were reminded of money would be self-sufficient or selfish when faced with a difficult task with which they could receive help. In experiments 5-6, participants were given a challenging but solvable task (experiment 5) or an impossible puzzle (experiment 6) to work on, and both times they were offered help. Participants in experiment 5 were reminded of money or not via the descrambling task described above, whereas participants in experiment 6 read aloud essays written ostensibly by a student who grew up in an affluent family (high money) or a family whose finances were only just enough to make ends meet (low money). In both experiments we found that participants reminded of money were reticent to ask for help. In experiment 5, the money-primed participants worked longer before asking for help, and in experiment 6 the high money participants worked longer before asking for help, in comparison with their counterparts in the control conditions.

A third set of experiments tested wider implications of the effect. Experiments 7-9 primed money in participants by visually exposing them to pictures of currency while performing another task, whereas control conditions either had no pictures or pictures of nature. We found in experiment 7 that participants reminded of money put more distance between themselves and another participant with whom they were going to have a get-acquainted conversation (an implicit sign of social distance), as compared to participants who saw fish and those not given a visual prime. In experiment 8, we found that participants reminded of money overwhelmingly preferred to work alone on a task rather than with another participant, whereas participants in control conditions preferred to work with another participant. Last, in experiment 9, participants reminded of money preferred leisure activities that would be performed only by the self, rather than those that friends and loved ones could perform with them.

In sum, being reminded of money makes people behave self-sufficiently. Participants who were subtly reminded of money were less helpful–but also asked for less help, relative to participants who were not reminded of money. Moreover, money-primed participants also preferred to be physically further from an unacquainted interaction partner relative to participants and desired to work alone and play alone. This research opens the door for discussions on the role of money in egotistic as well as goal-directed behavior.

### "Money, Product, and Individual: The Influence of Affective Interactions on Purchase Intentions"

*Himanshu Mishra, University of Utah*
*Arul Mishra, University of Utah*
*Dhananjay Nayakankuppam, University of Iowa*

Marketing researchers have extensively documented the influence of affect on consumer decision-making. The study of affective influences on judgments and choices has moved in two distinct directions; one investigating the influence of product induced affect and the other exploring the individual's affective traits such as hedonism and utilitarianism. The product can have hedonic attributes and hence generate a higher level of affect or have utilitarian attributes and engender a lower level of affect. The individual, on the other hand, could have a personality trait that seeks either more hedonic or more utilitarian outcomes, which consequently controls how one reacts to affective cues.

However, along with the product and the individual, money plays a critical role in any purchase decision. While past research enriches our understanding of the role of product induced affect and an individual's affective traits in consumer decision-making, it is relatively mute on how affect arising from money could interact with product induced affect and individual's affective traits. The study of such interactions becomes pertinent considering the findings that over and above its real value, money has acquired an affective meaning, which causes it to be desired for itself. Recent research has also shown that equivalent amounts of money can possess different levels of positive affect, highlighting the finding that money can have affect that is independent of its economic value (Mishra, Mishra and Nayakankuppam 2006).

In the light of these findings, the following questions remain unanswered: How do the varying levels of affect in money influence the purchase decisions of hedonic versus utilitarian products? How do the affective traits of an individual impact purchase decisions when money induces high versus low affective responses? This research is an attempt to answer these questions by exploring the interaction of different levels of affect from money with product level and individual level affect and its resulting influence on consumers' purchase intentions.

To answer these questions, we adopt the interactionist perspective that suggests the study of interaction among various component of a decision task rather than studying them in isolation. We explore how monetary affect interacts with product induced affect and consumer's affective traits and finally influences purchase intentions. Specifically, we predict that when the affect generated by money is stronger than the affect generated by the product, there is lower willingness to buy. On the other hand, when affect from the product is stronger than affect from money, there is higher willingness to buy. Similarly, a higher or lower affect from money compared to an individual's hedonic or utilitarian traits moderates one's willingness to buy. These predictions were tested in a simulated shopping environment where participants were given money in an envelope and shown products with price cards kept in front of them. They had the option of spending all the money, a part of the money or no money on the products. In all the experiments, participants were entered in a lucky draw in which one participant received the products chosen plus the remaining money.

In experiment 1 we varied the levels of product affect and money affect and observed the subsequent influence on willingness to buy. Hedonic products induce higher positive affect compared to utilitarian products (Hirschman and Holbrook 1982) and bills of bigger denomination induce more affect compared to equivalent bills in smaller denominations. We observe a tug-of-war between wanting to buy the product due to product-induced affect and also wanting to hold on to the money driven by money induced affect. We find that participants were more willing to buy hedonic products with bills of smaller denominations (ten $5) compared with bills of bigger denomination ($50) since the affect coming from the former is less. Similarly, participants showed a lower willingness to buy utilitarian products when they had bills in bigger denomination compared to when they have bills of smaller denomination.

Experiment 2 demonstrates the interaction between consumer level affect and the affective reaction felt towards money. Consumers can be thought of as possessing hedonistic/materialistic-high

affect or utilitarian-low affect traits, which we measured using a trait scale. We hypothesized that because of these traits, consumers will differ on how they react to the affective cues in the shopping environment. The results indicated that participants felt the lowest inclination to buy the displayed products when they were low on the hedonism scale and had bills of large denomination and they indicated the highest willingness to buy when they were high on the materialism/hedonism scale and had bills of smaller denomination.

Experiment 3 demonstrates that money itself has the potential to generate two independent levels of affect. First, big denomination bills ($20) generate higher affect than equivalent amount of bills in smaller denomination (four $5). Second, a bill that is crisp and new has higher positive affect than an old crumpled bill. The results participants having new bills of bigger denomination, that is a new $20 bill, indicate the least willingness to buy the displayed products while participants having old bills of smaller denomination, that is old, crumpled four $5 bills, indicate the highest willingness to buy. In sum, across three experiments we study how affect from three different sources, product, individual and money, have the potential to influence the final purchase decision.

### "On the Discontinuity of Demand Curves Around Zero: Charging More and Selling More"

*Dan Ariely, Massachusetts Institute of Technology*
*Uri Gneezy, University of California, San Diego*
*Ernan Haruvy, University of Texas, Dallas*

The law of demand asserts that demand should weakly decrease as price increases. This downward sloping demand is due both to downward sloping individual demand, and downward sloping market demand. The downward sloping individual demand effect is due to diminishing marginal utility, meaning that we should expect the average demand per consumer to decline with price. The downward sloping market demand effect is due to consumer heterogeneity, meaning that the number of people demanding a product should decline with price.

While both effects in the law of demand are likely to hold for most price levels, we show that they might not hold for the price of zero–as the price of zero involves not only a specific price level but also social norms. As an illustration, consider a case of a birthday cake, left-over Halloween candy, or doughnuts brought to the office by a co-worker. Suppose the sweets are left unattended at the empty coffee room with a sign that says "help yourself." You can take as much as you like, so how much would you take? Under these conditions most people, we expect, would take only the "socially acceptable" amount, but they would take much more if the price was ¢1 per doughnut and if the offer was made by the local bakery. This example illustrate that social norms can operate when no monetary exchanges are salient, and that the inclusion of a monetary tradeoff can interfere with these norms.

The effect of payment or lack of payment on the social norms that individuals apply is apparent in Fiske's Relational Theory (1992). Those papers show that when money is not mentioned at all, transactions are considered to be in the social exchange domain, causing people to apply norms of fairness and reciprocity to the exchange (helping a friend move, helping someone to change a flat tire etc.). But when money is involved in the transaction, the norms and rules that people use relate more directly to market norms of exchange and cost-benefit analysis.

Together these ideas suggest that when monetary exchanges are not explicitly mentioned, social norms, but not market norms, are invoked and that when monetary exchanges are explicitly mentioned, market norms, but not social norms, are invoked. A set of 3 experiments showed this effect and that the combination of these two forces yields higher average (and total) amounts consumed when the price is low than when it is zero.

As shown in Experiment 1, we find that for the most part, with positive prices, the Law of Demand holds for both of these components. That is, when positive prices are raised, fewer individuals demand the items offered and on average individuals demand a lower quantity of the good in question. While the standard theory is observed for positive prices, when the prices decrease to zero social norms are invoked and we observe a discontinuity in the Law of Demand. When the price is reduced to zero, the first component of the Law of Demand still holds–more people demand the item relative to positive price. However, at the individual level, when the price is reduced to zero, the Law of Demand breaks down and individuals consume an amount that is dictated by the social norms–which in our case is substantially lower. The results of the first three experiments presented here support this idea. In addition, Experiment 1 provided initial evidence that the effect is generalized to other forms of exchange such as effort. Experiments 2 and 3 also indicated that the effect of price decrease to zero was particularly large for males–mostly because their demand at the ¢1 price condition was higher than for females.

These findings have relatively straightforward economic implications. At a micro level, firms wishing to introduce new products through samples or sales promotions may find that charging nothing will clearly increase the number of individuals who will ask for the product, which may be good or bad for the promotion (depending on whether the additional individuals are likely to become consumers). Relative to very cheap samples, free samples have a negative effect on the quantity taken by individuals. Having each individual restrict him- or herself to only one sample product might be the effect that companies are striving for, but it is also possible that from companies may want individuals to take multiple samples and try the product repeatedly over time or share it with others. Then a lower price that is not zero might be more appropriate.

SYMPOSIA SUMMARY
# Health Marketing: Understanding Consumer Response to Risk and Remedy Messages
Lisa E. Bolton, The Wharton School, University of Pennsylvania, USA

## SESSION OVERVIEW

The objective of this special session is to address an important problem in health care—how to encourage consumers to engage in health-protective behaviors, including risk-avoidance and health remedy consumption. Such research is part of a larger literature on how consumers respond to health communication messages and how to promote a healthy lifestyle. As such, audience interest at ACR should be high.

Each project offers a unique yet complementary perspective on these issues. Specifically:

1) "*Health Communication Effectiveness: Using Underlying Processes…*" investigates how health risk messages change consumers' mental maps of diseases and, in turn, risk perceptions and behavioral intentions. The research uses a dual process model to understand consumer response to health communications.
2) "*Harboring Hope and Accepting Anxiety…*" investigates how health risk messages affect emotions and, in turn, health risk perceptions. The research focuses on the role of emotions in consumer response to health communications about disease and risk.
3) "*No Pain No Gain…*" investigates how health remedy messages affect consumer beliefs about the risks and benefits of medicines and, in turn, their perceived effectiveness. The research focuses on consumer lay theories about health remedies.
4) "*… TCM versus WM in China*" investigates consumer perceptions and preference for Traditional Chinese versus Western health remedies in China. The research focuses on consumer lay theories about these health remedies in Chinese culture.

Together, these projects examine consumer response to two kinds of health marketing: health risk messages and health remedy messages. In large part, prior research in health communications has focused on the former and taken a traditionally cognitive approach to examining message effectiveness (cognitive responses, attitude change, etc.). The present research attempts to go further in developing an understanding of the cognitive schema that underlie health attitudes and behaviors—specifically, consumers' mental maps of diseases and consumers' lay theories about health remedies. Moreover, the present research argues that consumer response in the health domain is not guided solely by cognitions but also by the interplay with emotions and must be understood in a culture-specific context. By bringing together research on both sides of the health communication coin—that is, risk and remedy messages—we hope to further our understanding of the myriad factors that influence health-protective behaviors. Our discussant (a recipient of NCI and MSI awards for research on health communications) has been chosen for her unique breadth and depth of experience in areas relevant to our research—and should help bring further insight to our understanding of how to improve consumer health and welfare.

## EXTENDED ABSTRACTS

### "Health Communication Effectiveness: Using Underlying Processes to Understand the Relationship between Health Risk Attitudes and Behavioral Intentions to Follow the Recommendations"

*Yanliu Huang, The Wharton School, University of Pennsylvania*
*Sam K. Hui, The Wharton School, University of Pennsylvania*
*Barbara E. Kahn, University of Miami*

Past health literature examining the effectiveness of health communication (e.g., Becker 1974; Kahn and Luce 2006; Rogers 1975, 1983) generally assumed that health-related messages initiate people's assessments of risk and vulnerability and resulting coping strategies, which, in turn, influence intentions to follow message recommendations. Based on these models, consumers usually form risk perception attitudes and behavioral intentions to follow the recommendations in a deliberate way after assessing relevant factors in the communication. Furthermore, attitudes and intentions are generally assumed to be positively correlated. A recent meta-analysis by Keller and Lehmann (2006), however, suggests that the consistency between attitudes and intentions is not always true because some contextual factors (e.g., message framing) could affect attitudes and behavioral intentions in opposite ways. No systematic theories have been suggested to date to explain why changes in attitudes and behavioral intentions are positively correlated in some situations but negatively correlated in others. Understanding these questions has important implications for the effective design of health communication messages.

We propose that the relationship between attitudes and behavioral intentions depends on the functioning of underlying cognitive processes. First, we assume that previous findings showing a positive correlation between changes in attitudes and intentions as a result of health communication messages occurs because both are formed through a relatively deliberate process which imitates System 2 cognitive functioning that is controlled, effortful, and involves forming underlying conceptual representations of the task at hand (Kahneman and Frederick 2002; Stanovich and West 2002). On the other hand, we hypothesize that certain types of health communication messages can activate automatic attitudes by bypassing the deliberate System 2 reasoning and that these changes in automatic System 1 attitudes can thus be negatively correlated from changes in behavioral intentions that are still formed deliberately.

A 2 (information: vivid vs. non-vivid) x 2 (number of enumerated disease exemplars: high vs. low) experiment was designed to test our hypotheses. We propose that when a vivid personal story attracts people's attention (McGill and Anand 1989), they will engage in relatively deliberate integrative processing of both the enumerated disease instances and the vivid information and use them to make the subsequent judgments (Burnstein and Schul 1983; Schul and Burnstein 1985). As a result, people in the high number condition will have higher deliberate attitudes of risk and correspondingly higher intentions to follow recommendations than people in the low number condition. However, when non-vivid information is provided and the enumerated disease instances

become the primary input for the subsequent judgments, automatic risk attitudes are activated and the high number condition will lead to the lower risk attitudes than the low number condition. In this case the high number of enumerated disease exemplars inhibits people's recall of the remaining cases, and the perceived difficulty of recalling specific disease cases decreases people's health risk perception (Alba and Chattopadhyay 1985; Raghubir and Menon 1998). This memory inhibition effect has been shown to be an automatic process that happens quickly, unintentionally, and effortlessly (Menon and Raghubir 2003). Since behavioral intentions are not influenced by information vividness (Keller and Lehmann 2006), they will still be formed deliberately and intentions will remain higher in the high versus low number condition. Thus the pattern of behavioral intention changes will diverge from the pattern of changes in the automatic attitudes. Experimental results confirm our hypotheses.

Using conceptual mapping technology (John et al. 2006; Lord 1994; Stuart 1985) we map the conceptual representations underlying deliberate health attitudes and behavioral intentions, and show that concept maps are more predictive of attitudes when they are formed through a deliberate process than when they are formed through an automatic process. We also identify conceptual associations that are important in influencing consumers' behavioral intentions which can be used in the design of health communication messages.

## "Harboring Hope and Accepting Anxiety: The Role of Uncertain Emotions in Judgments of Health Risk"

*Nidhi Agrawal, Northwestern University*
*Geeta Menon, New York University*

How much am I at risk of getting hepatitis C? Does this message that presents risk factors for hepatitis C convince me that I may be at risk? Do I need to get tested for it? Raising such questions and prodding people into action is the focus of much of the communication intended to promote safe, precautionary and preventative behaviors in the context of health. One of the unique aspects of such communication is its inherently threatening and aversive undercurrent. A growing stream of research on health seeks to understand the factors that affect how people process health risk messages and to answer the question: When, why and how are messages effective in convincing people of their vulnerability? In this paper, we focus on the dual roles of *emotions* in the context of health messages: (a) when they are evoked by a health message (i.e., emotions as *consequences*), and (b) when they are incidental to the health message and thus affect the processing of such messages (i.e., emotions as *antecedents*).

A significant stream of research has examined the effect of affective states on judgments and decision-making. One such stream examines the effects of valence on responses to stimuli. Another more recent research stream examines the role of *specific emotions* (e.g., anger, sadness, peacefulness) in processing information and forming judgments (Lerner and Keltner 2000), with a focus on the effects of different emotions that share the same valence but differ on other characteristics. For example, anxiety and sadness are both negative affective states, but anxiety is a highly uncertain state whereas sadness is associated with lower levels of uncertainty. In the current paper, we identify how two appraisal dimensions of emotions, valence and uncertainty, interact to determine the persuasiveness of health risk messages. We bring together the literature on valence as a source of goals and resources

(Raghunathan and Trope 2002) and the literature on specific emotions to understand how emotions varying on valence and uncertainty interact. We report the results of three experiments in which we contrast the effects of health messages that convey more or less vulnerability to a disease.

In Experiment 1, we show that a message that communicates greater vulnerability leads to changes in uncertain emotions (e.g., hope and anxiety), but *not* certain emotions (e.g., happiness and sadness), regardless of valence. We also demonstrate that the effects of health messages that communicate different levels of vulnerability on risk perceptions are mediated through these observed changes in uncertain emotions. These results provide initial evidence that health messages influence risk perceptions through uncertain emotions, and form the basis for our theorizing in Experiments 2 and 3. In Experiment 2, we prime two negative emotions that activate a mood repair goal, and show more directly that the incidental or ambient experience of two different negative emotions varying on uncertainty affects processing of health information and perceptions of risk. When individuals experience negative certain emotions (e.g., sadness), they process the health message in more detail, presumably because such processing does not have deleterious effects on the specific certain emotion (as per the results of Experiment 1). But when people experience an uncertain emotion (e.g., anxiety), vulnerability has little effect—suggesting less message processing, presumably to protect against feelings of anxiety that would go against the emotion regulation goal of repair (Agrawal, Menon, and Aaker 2007; Zemack-Rugar, 2006). Therefore, people experiencing uncertain negative emotions are less likely to process a health message that communicates greater vulnerability. In Experiment 3, we prime positive emotions that induce people to be open to aversive information (Raghunathan and Trope 2002), and demonstrate that the message communicating greater vulnerability has more impact on risk perceptions than the one communicating lower vulnerability. Further, we demonstrate that this effect is larger when people experience uncertain positive emotions (e.g., hope) since they have a goal of uncertainty reduction and thus process the health messages to a greater extent compared to people experiencing certain positive emotions (e.g., happiness). Since processing the message increases the positive uncertain emotion being experienced (i.e., hope) as per Experiment 1, there is no incentive to resist such processing.

### "No Pain No Gain: The Use of Negative Cues as Indicators of Health Benefits"

*Tom Kramer, Baruch College, CUNY*
*Caglar Irmak, University of South Carolina*
*Lauren Block, Baruch College, CUNY*

Consumers often rely on internal or external cues, such as brand name, price, or presence of a warranty (Rao and Monroe 1989; Kirmani and Rao 2000) when inferring products' overall quality or unknown attribute values. For example, consumers may infer that a higher-priced bike helmet provides better protection in case of an accident than a lower-priced one. Indeed, consumers' intuitions or lay theories about the relationships among various elements of the marketing mix have been shown to affect inferences about missing product attributes, product choice, consumption enjoyment and actual product performance (e.g., Broniarczyk & Alba 1994, Chernev & Carpenter 2001, Raghunathan et al. 2006, Shiv et al. 2005). Extending this stream of literature, the present research examines consumers' inferences about product effectiveness in the health domain. Surprisingly, the literature is silent about the factors that influence perceptions of medicinal efficacy. Specifically, we focus on consumers' reliance on product detriments, such as the likelihood and severity of medicines' side effects, when judging their benefits, such as their effectiveness. Based on equity theory (Berkowitz and Walster 1976; Walster, Walster and Berscheid 1978), we suggest that consumers who desire to gain the health benefits believe that they need to suffer through the associated pains to get better in the end (i.e., no pain, no gain), which in turn influences their inferences about the effectiveness of health products. Additionally, we investigate the moderating role of involvement in the relationship between health risk and health benefit perceptions.

In particular, Study 1 demonstrates a three-way interaction between involvement with a health issue (low/high), frequency of side effects (rare/common) and severity of side effects (mild/severe) on perceptions of product efficacy. Specifically, those who are highly involved with the health issue (e.g., those who suffer from allergies) infer higher product effectiveness when mild side effects of the allergy medication are common than when they are rare. This effect is reversed for those who are less involved (e.g., those who do not suffer from allergies); product efficacy is perceived to be higher when mild side effects are rare versus common. A different pattern emerges when side effects are reported to be severe. When the side effects are severe, product effectiveness is rated equally regardless of involvement or frequency. These results lend support to our theorizing that individuals feel like they need to "pay" either by suffering severe side effects regardless of its rate of recurrence, or mild but common side effects in order for the medication to work. Additionally, results of Study 1 reveal an interactive effect of frequency of side effects and involvement. Specifically, allergy sufferers have a more favorable attitude toward the medicine when the side effects are common compared to when the side effects are rare. However, there is no difference in attitude toward the product for low-involvement individuals. In sum, the results of Study 1 support our prediction that consumers hold an implicit "no pain, no gain" lay theory regarding medicine and efficacy. In Study 2, we investigate whether this effect replicates using bad taste as a negative cue that may signal product effectiveness. We predict that consumers infer higher product effectiveness from cough syrups with bad (vs. good) taste. Additionally, this study seeks to shed light on the underlying process of the effects we obtained. In particular, given that in a normative sense health risks pertaining to side effects should not influence perceptions of health benefits, we predict that the inference process

consumers engage in is an unconscious one. To test this prediction, Study 2 also includes cognitive busyness manipulations. We expect that consumers will still infer efficacy of the product based on its bad (vs. good) taste when consciously focused on a secondary task (i.e., when cognitively busy).

## "Consumer Perceptions of Traditional Chinese versus Western Medicine in China"

*Wenbo Wang, Peking University*
*Hean Tat Keh, Peking University*
*Lisa E. Bolton, The Wharton School*

Traditional Chinese medicine (TCM) is an important form of health practice in China and other Asian countries. The world market for TCM is estimated at over $23 billion, with most of the growth coming from Europe and the USA. In China, TCM and Western medicine (WM) have coexisted for over 200 years, and both types of medicine are licensed and widely sold. The category is legally required to be marked on all drug labeling, and Chinese consumers are familiar with the categories when purchasing drugs for self-care. The question then arises: how do consumers perceive these drug categories, and what are the consequences for consumer behavior? Surprisingly, almost no research has examined this issue (but see Piron et al. 2000). The present research addresses this void.

*Perceptions*. We expect that consumer perceptions of WM and TCM will differ in several important ways. In TCM, medical success aims for an entire recovery and re-balance of the Yin and Yang (Science of Chinese Materia Medica 2003). In contrast, a focus on alleviating symptoms quickly seems more consistent with WM, which views diseases as cause-effect sequences (Compilation Committee 1998). Accordingly, we hypothesize that:

*H1*: TCM (vs. WM) is perceived to have (a) slower action and milder side effects and (b) greater focus on treating the underlying illness versus alleviating the symptoms.

*Preference*. We expect that these perceptions will, in turn, affect product preference. We propose that consumers will prefer the medicine that is more consistent with their treatment time-frame and goals (either symptom alleviation or cure of the underlying illness). Thus,

*H2*: Consumers will prefer a) WM when the time-frame is relatively short and b) TCM when the goal is treatment of the underlying illness.

The relationship between symptom and disease is, of course, an uncertain one. When uncertainty is low, consumers can easily identify a cause-effect relationship and may prefer WM for its precise remedy. In contrast, when uncertainty is high, the same symptom may arise from any number of causes, known or unknown. TCM's philosophic-scientific based approach tolerates more uncertainty and ambiguity (Ma 1994); thus,

*H3*: Ceteris paribus, consumers will prefer TCM (WM) when uncertainty about the cause of a symptom is high (low).

We also investigate how causal uncertainty will interact with time-frame and treatment goals to affect preference. First, we hypothesize an interaction of uncertainty and time-frame such that consumers will prefer TCM over WM—except when the cause of the illness is certain *and* the time-frame for treatment is short (H3a). Second, we hypothesize an interaction of uncertainty and treatment goal such that consumers will prefer TCM over WM—except when the cause of the illness is certain *and* the treatment goal is to alleviate symptoms (H3b).

*Healthy Lifestyle Consequences*. We also expect that the consumption of TCM versus WM will have consequences for complementary health-protective behaviors that contribute to a healthy lifestyle. In TCM, re-balance in Yin and Yang requires both the assistance of herbal and other treatments and specific health-promoting habits. In contrast, WM has been shown to undermine intentions to engage in complementary health-protective behaviors (Bolton, Cohen, and Bloom 2006). Accordingly,

*H4*: TCM (vs. WM) will enhance intentions to engage in healthy lifestyle behaviors.

*Empirical Work*: Studies 1A and 1B investigate qualitative and quantitative responses to TCM and WM for a variety of illnesses, providing a preliminary test of H1-H3. Study 2 provides further evidence for H3a with a specific symptom and drug treatments. (An additional study testing H3b is currently underway.) And finally, study 3 investigates the consequences of TCM versus WM on healthy lifestyle intentions, providing an empirical test of H4. (A follow-up study is also underway.) All studies thus far were conducted among Chinese consumers (undergraduate and graduate students at a university in Beijing). Findings of the four completed studies thus far support our hypotheses. To our knowledge, the present research is the first attempt to provide a conceptual framework to understand how Chinese consumers make health-care choices, specifically between TCM and WM. We argue for the interplay of three factors: treatment characteristics (e.g., consumer perceptions of TCM and WM remedies), symptom/illness charac-

teristics (e.g., consumer perceptions of causal uncertainty), and consumer and situational characteristics (e.g., treatment goals and time-frame). Such a framework is grounded in consumer perceptions of the decision space, thereby bringing to bear consumer lay theories and cultural knowledge that may guide health care choices (cf. Molden and Dweck 2006, Briley and Aaker 2006). Indeed, we suggest that examining consumer health care choices within such a framework represents a fruitful avenue for future research in China and elsewhere.

# SYMPOSIA SUMMARY
# Understanding the Role of Co-Creation in Fantasy and Fun
### Andrew Baker, Georgia State University, USA

## SESSION OVERVIEW

There is growing dialogue among consumer researchers relating to how consumers engage with producers to co-create meaning and value through consumption. As such, this session focuses on co-creation in contexts rich in fantasy and fun, topics frequently identified as having great theoretical importance but often underrepresented in research. Researchers interested in co-creation, online communities, fantasy, identity, online gaming, and emancipatory consumption contexts will likely find this session appealing.

As consumer researchers have become increasingly attentive to consumers as partners in the production of value, important questions arise. How and why do consumers negotiate the co-creation of fantastic and fun experiences with producers? What are the consequences and outcomes of co-creation to consumers in such contexts? Is the firm necessary for consumers to co-create valuable fantasy and fun?

Based on data and findings in four studies, this session explores such questions in four empirical fantasy contexts –video games, the digital world of Second Life, Renaissance festivals, and live action role playing communities. The collective analysis provides new insights illuminating how co-creating with both producers and other consumers is an imperative component of creating value in fantasy consumption.

Sayantani Mukherjee and Alladi Venkatesh investigate how young adult video game players actively negotiate and co-construct fun experiences by using both consumer and marketer resources through three strategies–dynamic goal-setting, limited mastery, and building intertextual linkages across media channels.

Clinton Lanier and Ronald Hampton provide a resource control perspective of consumer participation, characterizing co-creation as when consumers take the greatest control over the resources in the market offering. How consumers engage in fantasy experiences at renaissance festivals is identified with consumer participation progressing along a "fantasy life-cycle." As the consumer's involvement in consumption fantasies change, so does the level and nature of involvement with co-constructing the fantasy experience with other producers or consumers.

Gulnur Tumbat and David Horowitz explore how postmodern consumers are able to take command of the market by producing their identities with other consumers instead of creating identity through only passive consumption. In the investigation of the digital world of Second Life, the authors identify many consumers who are using this fantasy world to become the producers of tastes consumed by others–thus becoming lauded culture creators.

Andrew Baker and Carolyn Curasi investigate how the members and firms of live action role playing (LARP) consumption communities negotiate the co-creation process. During a netnographic analysis of one such LARP group, evidence suggests that tensions emerge between community and firm when consumers do not achieve co-creation. In such rich fantasy contexts, achieving co-creation of identity with the firm may be an important antecedent to satisfaction.

Finally, Dr. Eric Arnould of the University of Arizona will be the discussant, weaving together the empirical discussions and providing his own perspectives to extend the theoretical implications of co-creation in fantasy and fun.

## EXTENDED ABSTRACTS

### "Co-Creating Fun: Insights from Young Adults' Engagement with Video Games"
*Sayantani Mukherjee, California State University, Long Beach*
*Alladi Venkatesh, University of California, Irvine*

In recent years, there has been a growing prominence of the fun concept in the marketing environment. With the proliferation of entertainment products, "fun" is emerging as an important goal for product development (Norman 2004). Further, within consumer research, fun is recognized as a central element in experiential consumption (Holbrook and Hirschman 1982). Pervasive in both marketing theory and practice is the notion that consumers experience fun passively, and as an outcome of engaging in playful and leisure consumption. This has led marketers to impart fun with an objective meaning which they can effectively structure, design and control (Norman 2004). Consequently, not only do we have limited knowledge of the active role of consumers in constructing fun experiences, but we also have very little understanding of the co-creative role of producers and consumers in generating fun. Given the considerable topical relevance of consumer-centric value creation (Arnould, Price and Malshe 2006, Vargo and Lusch 2004), this gap in the literature is significant.

In this paper, we examine the practices through which consumers negotiate fun experiences. In doing so, we use insights from young adults' participation in video gaming. In recent years, playing video games has evolved from a minority activity to mass entertainment generating over $10 billion a year in retail sales. A growing number of young adults are substituting traditional media such as TV with interactive media such as video games so much so that this segment is referred as the "Nintendo generation" (Miles 2000). Consequently, marketers are increasingly using video games as an advertising platform to reach out to this segment (Guardian 2006). Moreover, enhancing the fun element in video games is critical in the success of in-game advertisements (Economist 2006).

We theoretically ground our study by drawing on research that specifically focuses on the fun concept. Existing work on fun is scant but scattered across different disciplines including consumer research, human-computer interaction and sociology. Integrating these disciplinary perspectives, we conceptualize fun as a holistic experience that is fundamentally related to elements such as play (Goffman 1961), efficacy (Celsi, Rose and Leigh1993), emotions (Desmet 2003) and flow (Csikszentmihalyi 2000). In addition, we also draw on research focusing on consumer co-creation within experiential contexts (Kozinets et al. 2004, Arnould and Price 1993). These studies provide the basis for theorizing how consumers negotiate fun within video game play.

We use a combination of projective techniques (Belk, Ger and Askegaard 2003; Zaltman 1997) and semi-structured interviews (McCracken 1988) for collecting data. Interviews were conducted with fifteen young adults between the ages of 18-24 years. The only recruitment criteria used is that participants should have played video games. We defined video games in the broadest sense as "any form of computer-based entertainment software, either textual or image-based, using any electronic platform such as personal computers or consoles and involving one or multiple players in a physical or networked environment" (Frasca 2001, 4). Using varied

forms of video games yields greater possibility of uncovering a broad range of consumer interpretations. We follow guidelines of grounded theory (Strauss and Corbin 1998) for data analysis.

Our findings suggest that young adults are active participants in constructing their fun experiences. In particular, we identify three strategies: dynamic goal-setting, limited mastery and building intertextual linkages, which highlight the diverse ways in which consumers employ marketer and consumer generated resources to co-create fun. First, the strategy of dynamic goal setting encapsulates the fact that young adults negotiate challenge, a foundational element of fun by dynamically setting demanding goals for themselves. This is manifested in consumer actions such as "modding" where players modify a pre-defined game structure. Marketer created product offerings such as video game design is vital to the success of this strategy. The fluidity and ambiguity built by designers within video games allows young adults to experiment with the game structure. The key point here is that actions such as modding implicates a creative engagement on the part of consumers to transform marketer generated resources for the purpose of constructing fun. Second, consumers employ the strategy of limited mastery to negotiate relational aspects of fun. In limited mastery, young adults reduce experimentation in the game so that they can allot time for socializing with other consumers. Although, mastering the basic skills is essential for efficient game play, more complex game features are rendered irrelevant. The limited mastery strategy suggests that consumers are selective in mobilizing market based resources (game levels) as well as their own competencies (game related skills) to negotiate fun. In addition, young adults employ the strategy of building intertextual linkages: associating content across media channels such as video games, movies and books to negotiate relational aspects of fun. On the one hand, intertextual referencing displays marketer engineered multiplicity in media channels with similar content. On the other hand, young adults deploy intertextual referents as a mediating resource for social bonding and spontaneous interactions, both central elements of fun.

Our findings highlight the importance of reformulating our notions of fun from an interior experience to a process that is inextricably linked with the concrete actions of consumers and producers. To that extent, the consumer strategies that we discuss shed light on the importance of marketer generated resources in the construction of fun. Further, our study suggests that consumer-centric resources are vital, especially when fun is jointly produced at a relational level between consumers.

### "Consumer Participation and Experiential Marketing: Understanding The Relationship Between Co-Creation and the Fantasy Life Cycle"
*Clinton Lanier, Jr., University of Nebraska, Lincoln*
*Ronald Hampton, University of Nebraska, Lincoln*

Current marketing research has focused on a shift in the dominant logic of marketing from a goods-centric logic to a service-centric logic (Vargo and Lusch 2004). While the goods-dominant logic views consumers and producers as separate entities with different goals, the service-dominant logic views consumers and producers as intertwined in the creation of value. But as both goods and services become more commoditized, marketers are increasingly adding experiential components to their offerings to increase the value proposition (Pine and Gilmore 1999; LaSalle and Britton 2003; Marconi 2005). This raises the question: what affect do these experiential components have on the co-creation of value? In previous work, we argue that consumers engage marketing experiences through a mediating fantasy (Lanier and Arnould 2006; Lanier 2007). This paper explores how consumer participation in a

marketing experience changes as customers move through the fantasy cycle.

One of the foundational premises of the new service-dominant logic is consumer participation in the value creation process (Vargo and Lusch 2004). We argue that consumer participation can be divided into three main types: 1) co-optation, 2) co-production, and 3) co-creation. Co-optation is the process in which consumers assume duties once performed by producers (e.g., self-service technologies) (Meuter et al. 2000). Co-production is the process in which consumers participate in the design/production of the product (Bendapudi and Leone 2003). Lastly, co-creation is process in which consumers extend or alter the product beyond its original and/or intended form, use, and/or meaning (Lanier and Schau 2007). These three forms of consumer participation can be thought to exist on a continuum (co-optation ←→ co-production ←→ co-creation) based on the degree of control over the resources associated with the market offering.

In order to understand how consumers participate in a marketing experience, we utilize symbolic convergence theory (SCT). SCT is a communication theory that explains the role of fantasy in collectively shared experiences (Bormann, Cragan, and Shields 2001). SCT maintains that fantasies are jointly created interpretations of experiences that give meaning to human actions. Participation in a fantasy usually follows five stages: consciousness-creating, consciousness-raising, consciousness-sustaining, consciousness-decline, and consciousness-terminus (Bormann, Cragan, and Shields 1996; Cragan and Shields 1992). We extend SCT by arguing that individuals utilize different resources as they move through and jointly participate in this "fantasy life-cycle."

This research utilizes ethnographic methods in the collection of data (Emerson, Fretz, and Shaw 1995; O'Reilly 2005). Non-participant and participant observation was conducted at five U.S. Renaissance festivals. In addition, depth interviews with both consumers and producers were conducted. We chose this context for four reasons: 1) the festivals embody all four elements (i.e., entertainment, educational, esthetic, and escapism) of a marketing experience (Pine and Gillmore 1999), 2) they are based on a rich, though broadly construed theme, 3) they are accessible to a wide range of participants who vary in terms of their participation, and 4) they encourage customer participation. To locate informants, we utilized both purposive and snowball sampling. Data were analyzed using analytical coding techniques and a constant comparative method (Miles and Huberman 1984; Spiggle 1994; Strauss and Corbin 1990).

Our findings indicate that consumer participation in the Renaissance festival experience changes depending on which stage of the fantasy life-cycle the customer is in. In the creating stage, consumer involvement is typically low as consumers learn about the festivals and begin to construct their fantasies. Because of this, consumers typically engage in co-optation by utilizing resources provided and controlled by the producer and that require little investment on the part of the consumer. In the raising stage, involvement in the experience grows as the consumers begin to work with the producers to enhance their fantasy engagement. As a result, consumers engage in co-production by utilizing resources that require a larger investment, but which are jointly controlled by the producer and consumer. In the sustaining stage, involvement has reached its peak and consumers search for new ways to sustain their fantasy engagement in the experience. In this stage, consumers engage in co-creation by utilizing resources that require a heavy investment (e.g., time, energy, money) and which are now primarily under their control. In the decline stage, consumer involvement begins to wane as consumers begin to run out of resources to keep their fantasies going. In this stage, consumers will once again

engage in co-production as they try to work with the producers (or other consumers) to modify aspects of the festivals in order to generate new resources to maintain their involvement. In the terminus stage, consumers seek to re-enchant their fantasies through co-optation in two ways: 1) the consumer becomes the producer (e.g., consumers are often asked to participate as employees of the festivals) or 2) the consumer work with other consumers to produce a new experience (e.g., medieval reenactment). It is important to note that not all consumers move through these stages. Many consumers desire to maintain a certain level of involvement and investment in the experience and thus stay at a particular stage throughout the life of their fantasy engagement.

Based on our research, we discovered that consumer participation in a marketing experience often changes over time due to the development and involvement of the consumer's fantasy. At Renaissance festivals, participation often starts as co-optation, moves to co-production, develops into co-creation, moves back to co-production, and then ends with a more evolved form of co-optation. The fantasy engagement of the experience requires a certain amount of exposure, learning, acting, modification, and control in the experience. The different types of participation in the festival allow consumers to develop their fantasies and engage the experience in new and exciting ways. Consequently, consumer participation differs significantly in each stage and requires different resources and strategies to fully participate in and engage the experience over time.

### "Culture Creators: Co-Production in Second Life"
*Gulnur Tumbat, San Francisco State University*
*David Horowitz, Sonoma State University*

While the (postmodern) consumption landscape has been characterized as a place where consumers produce meanings, identities, and experiences through co-production (see Arnould 2007, Penaloza and Venkatesh 2006), this production is typically conceptualized in the B2C sense wherein the corporation still controls the means of production to a great extent (i.e. "built-to-order," "design-to-order," "invent-to-order" (Firat and Dholakia 2006, p. 138). In their example of online games, Firat and Dholakia (2006) state that "corporate marketers are fighting hard to prevent the players and their communities from 'owning' the rights to their digital creations." Alternatively, in Web 2.0, corporations provide the platform upon which consumers produce and share their original content (and even hold the ownership). Furthermore, Holt offers the view that "consumption can be conceived as a field of social life that is organized by the expression of tastes (1997, p. 343)."

Can production then be conceived as a field of social life that is organized by the *creation* of tastes? The power of these Web 2.0 sites is that they allow consumers to produce their own narratives and myths. As culture creators (those who create media that others consume), consumers are able to forge their identity in the world in a rather more meaningful manner than they could through consumption alone. Based on virtual ethnographic data in Second Life, we examine how productive consumers liberate themselves by creating their own myths, narratives, and identities. Second Life, virtual world created by Linden Lab of San Francisco, is a place to socialize via one's avatar or onscreen graphic character. These Second Life "residents" can build just about any object from scratch, using LEGO-style building blocks from onscreen menus, and use them on virtual plots of land for sale or rental. Unlike in any other virtual world, residents own their own creations, so they can buy and sell them freely with virtual currency that is readily convertible into or out of U.S. dollars. A real economy has sprung up inside Second Life, in which more than $5 million worth of

transactions in real U.S. dollars are conducted each month among the active 900 thousand residents of the now 2.7 million population (Enright 2007). Several thousand people run real businesses inside Second Life, some making enough to earn a real-world living. As a result, this consumer driven and consumer created virtual world and its economy attracts real-life brands as well (e.g., Nike; offers virtual shoes make avatars run faster!).

It would be too much of a stretch to call what is going on in Second Life as a game because the "residents" create everything in this digital parallel universe where they fully control their avatars and other creations. Although it does not translate into consumer emancipation (Kozinets 2002), this ability of consumers to forge an identity through productive consumption is very meaningful to them even in this predominantly fantasy context. Firat and Venkatesh (1995) describe how the postmodern "consumer finds his/her liberatory potential in subverting the market rather than being seduced by it (1995, p. 251)."

We feel that this idea of marketplace subversion needs further attention. Is it only marketplace subversion that leads consumers to find their liberatory and creative potential? The methods used in order to find answers to these important questions include a virtual ethnographic study where the authors create their own avatars and interact with the other residents of the Second Life. In addition to the field notes from the "virtual field site", "virtual interviews" with avatars in Second Life and online interviews with their owners in the real world are conducted.

We support the theory and extend it such that it is not solely people's goal to undermine the market, but rather to be able to create their own tastes in it. Consumption, or expressing one's tastes (Holt 1997) is easy, but creating the tastes that others consume is relatively more difficult. When consumers are able to create tastes and have others consume these tastes, they become what we call culture creators and become not just liberated, but lauded as well. The recognition that culture creators receive from their peers makes them feel respected, admired, and as though they have forged a meaningful identity in the world. An examination of this shift in the means of production, combined with an analysis of the socio-historical context that consumers live in today provides multiple insights into how consumers are using these Web 2.0 sites to be culture creators and advance marketing theory on the relationship between production and consumption.

### "Consequences of Co-Creation in Fantasy-Based Consumption Communities: Netnographic Analysis of a Live Action Role Playing Organization"
*Andrew Baker, Georgia State University*
*Carolyn Curasi, Georgia State University*

The role of imagination and fantasy has been characterized as an essential component of many consumption experiences (Belk and Costa 1998; Kozinets 2001). Although researchers (Holbrook et al. 1984; Holbrook and Hirschman 1982) have sounded the call to investigate the role of play in consumption experiences, the extant consumer research on playful and fantastic consumption contexts remains largely uncharted.

One new stream of research that may shed light onto fantasy consumption is co-creation. Prahalad and Ramaswamy (2004) explain that co-creation transcends the traditional, firm-centric creation of intimate customer experiences. Instead, co-creation is a two-way interactive relationship that consumers and producers engage in to co-create highly personalized services and products. Others have also characterized co-creation as blurring the traditional boundary between marketer and firm as producer/consumer (Arnould 2007).

Recognizing the importance of increasing our understanding of both co-creation and fantasy consumption, our research proposes that there is an essential relationship between fantasy consumption and co-creation. We propose that the emerging logic of co-creation is in part driven by the idea that consumption is fundamental to identity creation and self-representation, key constructs for examination in both fantasy consumption (Belk and Costa 1998) and communities (Firat 1991; Schouten and McAlexander 1995). Numerous studies have explored how the consumption of marketing objects are part of consumers' self-presentation and identity projects (Kozinets 2001; Schau and Gilly 2003). We suggest that, coupled with the concept of the contemporary consumer, co-creation extends into a concept of *co-creation of identity*. The consumer is no longer merely using consumption shaped and provided by the marketer to create identity, but instead conducts the self-identity project as part of a two-way collaboration with the marketer.

This research explores how the co-creation process is negotiated between marketer, consumer, and consumption communities. A netnographic study (Kozinets 2002) was used to examine the process and outcomes of co-creation between consumer and marketer within a thematic consumption community that is deeply embedded in fantasy–the national live action role-playing (LARP) organization, ActionGame International. The research question of interest emerged from early exploration of several LARP community forums, as consistent with the constant comparative method (Glaser and Strauss 1967) and naturalistic inquiry (Belk, Wallendorf, and Sherry 1989). ActionGame was the focus of the study as the data suggest an interesting dynamic was taking place between the marketer and the community. Five ActionGame community forums were explored in detail, while several blogs and personal electronic communications further supplemented our findings.

The data provide evidence that there is tension and conflict between the community and marketer, often resulting from the community perception that the marketer is not a partner willing to engage in a desired level of co-creation required to fully achieve desired immersion in the ActionGame consumption fantasy. These findings juxtaposed other personal stories of deep, immersive successful co-created fantasy experiences that were accompanied with highly favorable responses toward marketers. The data suggest that a consumer's perception of a successful co-creation experience may be essential to satisfaction in immersive fantasy consumption.

The findings further indicated there may be consequences when a consumption community perceives the marketer to hinder co-creation. In such cases, the data revealed that negative personal characteristics were ascribed to the marketer, as though the marketer was being rejected as a legitimate member of the community. Despite such vivid sentiment, schisms or abandoning ActionGame in favor of another LARP (of which there are many) did not appear to be a dominant strategy. Our findings suggest that community members may be so passionate about co-creating the fantasy experience between other community members and the consumption object (ActionGame) that the negative perception of the marketer (ActionGame National) is simply not strong enough to dissuade most members from abandoning the strong community and brand bonds that have been developed.

The study of this fantasy consumption community offers some interesting theoretical extensions of our understanding of consumption communities and co-creation. Through the lens of co-creation we provide a potential reason for tension in the relationship between a consumption community and the marketer. We posit that community-marketer conflict may emerge when community members perceive that the marketer has violated their responsibility in an implicit co-creation contract. However, when faced with a failed co-creation experience with the marketer, communities with the proper resources and conditions may pursue strategies that allow co-creation among the community itself as a substitute or recourse. In other words, the co-creation process from consumer-to-community may create enough value to overcome the loss of the failed marketer-to-community co-creation. This may be particularly relevant in fantasy consumption settings, as the resources required for fantasy consumption may be easily accessible to consumers who desire to engage in immersive fantasy.

McAlexander's, Schouten's and Koeing's (2002) findings, as well as observations by Cova (1997) and Muniz and O'Guinn (2001), have suggested customer-community interpersonal relationships are the strongest of the consumer bonds formed in brand communities and are powerful mechanisms to retain community membership. Our findings suggest a theoretical extension: when the value and meaning of the brand can be predominantly created by interpersonal co-creation, consumers may continue passionate brand and community affiliation even during substantial perceived failings by the marketer.

# What Drives Word of Mouth: A Multi-Disciplinary Perspective

Peeter W.J. Verlegh, RSM Erasmus University, The Netherlands
Sarit Moldovan, The Technion-Israel Institute of Technology, Israel

## SESSION OVERVIEW

Word of mouth (WOM) has long been regarded an important, but hard-to-manage market force. Katz and Lazersfeld (1955) list word of mouth as the most influential source of information for consumers, and since then studies repeatedly found the importance of WOM. Faced with a rapid decline of consumer trust in traditional advertising, companies are looking for different ways to promote their products, and word-of-mouth marketing has gained ground as a powerful communication tool. Lately, practitioner interest in WOM has surged, as demonstrated by the launch of the word-of-mouth marketing association (WOMMA), and the rise of companies such as *BzzAgent* in the USA, and *Buzzer* in The Netherlands.

Researchers have examined the process by which WOM spreads and influences people at the individual level (e.g., Herr, Kardes and Kim 1991) or between consumers (e.g., Reingen and Kernan 1986). Ryu and Feick (2007) examined how marketers can use incentives to stimulate word of mouth. Some of the more recent studies have focused on online word of mouth because this medium allows researchers to better track the process (e.g., Godes et al. 2005).This symposium focuses on the factors that drive people to spread word of mouth. Although this issue has been touched upon in prior work, we believe it deserves additional attention, and have collected a set of papers that focuses on (1) product-related drivers of WOM, (2) marketer-created drivers of WOM, and (3) consumer-related drivers of WOM. Each of the papers represents multiple studies and together they provide substantial coverage of the wide array of factors that motivate consumers to talk about products. At the conference, the papers were discussed by Professor Donald Lehmann of Columbia Business School.

## EXTENDED ABSTRACTS

### "The Different Roles of Product Originality and Usefulness in Generating Word of Mouth"

*Sarit Moldovan, The Technion-Israel Institute of Technology*
*Amitava Chattopadhyay, INSEAD*
*Jacob Goldenberg, The Hebrew University of Jerusalem*

While studies agree that word of mouth (WOM) is important to new product success, there has been little systematic research that examines the drivers of WOM, in this context. In this paper we explored how the two dimensions of a new product, originality and usefulness, affect WOM and its influence on ultimate adoption. We showed that, contrary to what some have suggested (e.g. Cooper 1979; Henard and Szymanski 2001; Mishra, Kim, and Lee 1996), originality does not increase product sales, but it enhances the buzz about the product. Usefulness, on the other hand, drives the valence of WOM, i.e., whether the buzz is positive or negative. Thus, high originality accompanied by low usefulness is likely to increase amount of negative WOM, and lead to rapid failure. We report three studies that empirically explore our theses about how originality and usefulness influence the amount and valence of WOM about a new product, and how this in turn affects market size.

Research shows that more original new products elicit greater levels of WOM than less original products (e.g. Bone 1992; Feick and Price 1987). But originality will not generate only positive WOM. Originality is likely to lead to feelings of surprise, which can

lead to both positive and negative WOM (Derbaix and Vanhamme 2003). Thus, while increasing originality may lead to increasing levels of WOM, the valence of the WOM can also be negative. If so, contrary to what has been implied in the past (e.g., Henard and Szymanski 2001), originality alone may not be sufficient to ensure product success. The valence of WOM may be determined by product usefulness: Research shows that useless products are evaluated poorly and are highly correlated with failure (Dahl, Chattopadhyay, and Gorn 1999; Mishra et al. 1996). Several studies have also found that high product performance generates positive WOM (Derbaix and Vanhamme 2003; Dichter 1966; Sundaram, Mitra, and Webster 1998), while product malfunction generates negative WOM (Anderson 1998; Sundaram et al.1998).

We therefore hypothesize that product originality will lead to high amount of WOM, while high product usefulness will lead to positive WOM and low product usefulness will lead to negative WOM. Since originality and usefulness have different roles in generating WOM, an increase in usefulness will increase positive WOM, especially for original products, and a decrease in usefulness will increase negative WOM, especially for original products. We therefore expect to see an interaction between originality and usefulness on the valence of WOM. Taken together, these hypotheses run counter to current thinking, which suggests that originality per se can drive new product success (Henard and Szymanski 2001; Mishra, Kim, and Lee 1996). They qualify the accepted wisdom by suggesting that originality, when combined with low usefulness, may produce strong negative WOM, leading to new product failure.

If indeed the suggested product dimensions, originality and usefulness, motivate consumers to spread WOM, their effect should be evident in product diffusion patterns. If originality increases the amount of WOM, it will also intensify the Bass imitation coefficient (Bass 1969), which represents WOM in the adoption process. Product usefulness, on the other hand, will create positive WOM that will increase market size. The combination of high originality and high (low) usefulness will increase (decrease) sales dramatically.

In order to show the different roles originality and usefulness play in the creation of WOM, we conducted five studies: Study 1 measured perceived product dimensions and WOM intentions of 20 new products, as rated by 226 MBA students. Results supported that originality increase amounts of WOM, including positive and negative WOM, while usefulness affected the valence of WOM by increasing positive WOM and decreasing negative WOM. We also found the interaction between originality and usefulness. These results were replicated in Study 2, which used a 2X2 between subjects design and manipulated the originality and usefulness of the products. Study 3 used a similar design as Study 2 to explore the effect of originality and usefulness on perceived likelihood of product success. We found that consumers believed that product usefulness will lead to success while product originality had no direct effect. Originality, however, can amplify the effect of usefulness. Studies 4 and 5 used sales data to reaffirm that originality and usefulness have different roles in the diffusion of innovation. As we hypothesize, we found that originality increases the imitation Bass coefficient (WOM), while usefulness, by determining the valence of WOM, affects market size and, thus, product success. We did not

find the interaction between originality and usefulness on market size, possibly because we did not have low usefulness products in the data.

The literature in marketing claims that in many cases WOM is crucial to product success, as are originality and usefulness. It is therefore interesting to understand how these dimensions affect WOM and, thus, product success, and consequently learn how marketers can manage WOM to their advantage. We showed that originality and usefulness have different roles in generating WOM and in determining whether a product will be successful. While previous studies extensively examined these two dimensions separately, for the first time we explored a detailed model of (1) the two dimensions together and the interaction between them, (2) their effect on both positive and negative WOM, and (3) the consequent effect on product success. We looked at the model from the intention to spread WOM as reported by consumers, and how they are reflected in actual sales of products.

**"Opening the Black Box of Buzzing Bloggers: Understanding How Consumers Deal with the Tension between Authenticity and Commercialism in seeded Word of Mouth Campaigns"**
*Robert V. Kozinets, Schulich School of Business-York University*

*Andrea C. Wojnicki, Rotman School of Management-University of Toronto*

Faced with a rapid decline of consumer trust in traditional advertising, companies are looking for different ways to promote their products. Consumers are no longer seen as mere recipients of marketing messages, but they are increasingly solicited by companies to participate in the conception and spread of these messages. Hence, word-of-mouth (WOM) marketing has gained ground as a powerful communication tool. The strength of WOM as opposed to marketer-generated messages is that consumers are considered to have no commercially motivated reason to share information (e.g., Bone 1992). However, how is the transmission of information between consumers affected when companies induce some to act as WOM agents? In terms of the Persuasion Knowledge Model (Friestad and Wright 1994), these consumers take on a dual role, being both target and agent in the WOM episode. This duality is likely to cause internal and external pressures due to cultural contradictions between the roles of consumer and marketer–the ultimate question being: Is it an authentic recommendation or is one selling-out?

This paper takes a holistic, macro perspective to examine how consumers deal with this duality. We use the method of netnography to study a product-seeding campaign involving bloggers. Observations, over time, of what bloggers write about product and campaign, as well as analyzing their readers' comments, allows for a deep contextualization of how consumers perceive, and deal with marketer-induced WOM. Specifically, we are interested in the strategies that consumer-agents use to reconcile their credibility as an authentic consumer with their role of agent acting on behalf of the company.

We use data of a product-seeding campaign that took place in the summer of 2006 in six Canadian cities. Ninety bloggers, selected for their wide readership and urban lifestyle, received a mobile camera phone with accessories and tutorial. Bloggers in the sample are between 22-45 years old; 41% is female. Among them, we find photographers, graphic designers, writers, software programmers, consultants, and administrative personnel. We collected integral blog entries of all 90 bloggers from approximately three months prior to seeding, to approximately three months after. Our total research volume amounts to circa 2000 pages of single-spaced

text and visual data. In first instance, our content analysis has focused on the blog entries surrounding the moment of seeding. We have amassed, coded, compared, and collapsed postings to form categories of strategies that consumer-agents employ to deal with the tension between credibility and commercialism (cf., Spiggle 1994). To further our understanding of seeded WOM, we also compared data in each category with other postings in our dataset in which bloggers engage in 'natural' WOM.

Although bloggers were not obliged to talk about the seeded product, 84% mention it on their blogs. Preliminary analysis of our netnographic data reveals that the majority of bloggers is open about the fact that they received the product for free. However, disclosure is framed in various ways, indicating different strategies of coping with the duality of being consumer and marketer. Some bloggers make a statement like the following: "About a month ago, I received a free X phone. [..] I was asked to blog about my experience with the phone–what I liked and didn't like" (Lucia). Others give full information about the seeding campaign, oftentimes including links to the companies involved, and listing the requirements used to qualify as influencer. Whereas the first strategy accepts the dual role as a 'fait accompli', the second seems to be driven by two emotions: excitement and discomfort. Part of the bloggers is delighted to have been selected for the seeding campaign and to receive an (expensive) product for free: "I am thrilled to say that I am qualified! So look for reviews, photos, and videos (!!!) starting sometime next week taken on my new shiny X" (Jeremy). They happily embrace their role as marketer, and communicate details about the campaign to help their readers apply for a free product too. However, others feel the need to explain the campaign and their involvement: 'I am thankful I met the criteria, and it worked out perfectly as I was just starting to look for a new phone as well. It is all voluntary, no obligation or contracts. I don't have to do any of this, but since I usually write reviews like this anyways, I have no problem writing a voluntary review as thanks for getting a phone and gear for free, and I'll even be impartial about it." (Blaine). Consumers like Blaine show implicit discomfort with their dual role: campaign details are given to imply that one has nothing to hide. Finally, there are consumers that ridicule their role as agent: "I rarely initiate conversations about the phone, but when they start, oh then I go into celly-love gushing mode. [..] This all sounds like a carefully crafted product placement, doesn't it? I told you, I am an advertiser's dream" (Paige).

Thus, most consumer-agents *accept*, *embrace*, *ridicule*, or *apologize* for their role as semi-marketer. A few *ignore* this role vis-à-vis their readers by mentioning the product, but not the seeding campaign. Our analysis indicates that strategies are chosen for their effect on blog readers.

**"Talk, Talk, Talk: Consumer Motives for Word-of-Mouth Referral"**
*Peeter W.J. Verlegh, RSM Erasmus University, The Netherlands*
*Carolina M. Buijs, RSM Erasmus University, The Netherlands*
*Andrea Zethof, RSM Erasmus University, The Netherlands*

Word of mouth (WOM) has long been regarded as an important influence on consumer behavior. Interest in this area has recently surged, as evidenced by recent studies of, among others, Ryu and Feick (2007), East et al. (2007), and Godes et al.(2005). Most of these studies, as well as the more classic work have looked at the effectiveness of word of mouth, examining the process by which WOM spreads and influences people at the individual or market level. In this paper we focus on the question of why people engage in word of mouth. We felt there was a need for an extensive study that examines consumers' motives for word of mouth and relates these to different aspects of WOM behavior, and to con-

sumer personality characteristics such as opinion leadership and market mavenism. Our study focuses on positive word of mouth (also known as "referral"), and does not look at negative word of mouth (cf., Goldenberg, Libai, Moldovan and Muller 2007).

In a first study, we conducted about two-hundred face-to-face interviews with consumers in The Netherlands, applying the Critical Incident Technique (CIT). We asked these consumers to describe a recent instance in which they referred a service to another consumer. We also asked the consumers why they referred this particular service to the other consumer, and what triggered their referral. Interviews typically lasted between 15 and 30 minutes. The interviews were transcribed and coded by four independent coders, following standard procedure for CIT studies: Two coders developed a coding scheme on half of the data, and then two independent coders applied this scheme to the entire dataset. The coding proved to be reliable. From these analyses, four different motives for referrals emerged, namely product enthusiasm, self-presentation, helping consumers and helping the firm. *Product enthusiasm* refers to the extent to which consumers are satisfied or delighted with the service or product. *Self-presentation* includes instances in which consumers wanted to demonstrate their knowledge, expertise, or good taste. *Helping consumers* refers to situations were consumers wanted to help the other consumer make a better decision, and *Helping the firm* refers to situations were consumers felt sympathy for a firm and wanted to help them succeed. These motives are similar to the ones suggested by Dichter (1966), and the motives uncovered by Sundaraman et al. (1998) in a smaller scale study. Additional analyses of the interview data revealed that these motives relate to different attributes of the referred service, and that different motives are important in different types of customer relations.

The next phase involved preparations for a more quantitative approach to uncovering the roles of the different motives for word of mouth, which would also allow us to link the different motives to other variables, including WOM activity, and personality characteristics like opinion leadership and market mavenism (Feick and Price 1987). Based on the motives established in study one, we developed a set of scale items to measure these motives. These items were discussed with a small panel of consumers and experts in order to come to a first set of items, that was further refined in two prestudies, involving two waves of small-scale surveys.

Phase three involved the administration of our scales to a panel of consumers, who filled out a survey that related to "a recent instance in which they referred a product to others." This survey included a number of measures to gauge the consumer's WOM activity and behaviors, including the amount of word of mouth spread, the number of people that were reached, and the persuasiveness of the WOM. This survey also included measures of the consumers' innovativeness, market mavenism, opinion leadership, and product expertise and involvement. In addition, we measured the tie-strength of the relationship in which the WOM occurred and whether the WOM was initiated by sender or receiver (cf., East et al., 2007).

Our first analyses show that the four WOM motives contributed significantly to the explanation of WOM activity, over and beyond the impact of well-established factors like expertise, market mavenism and opinion leadership. We also find support for the notion that different motives affect different aspects of WOM.

# New Insights in Consumer Point-of-Purchase Decision Making

Ryan Hamilton, Northwestern University, USA

Dipankar Chakravarti, University of Colorado, USA

## SESSION OVERVIEW

Many consumer purchases are not the result of extensive pre-planning, but are instead a function of decisions made at the point of purchase. It is hard to overestimate the importance of point-of-purchase decision making, both in terms of frequency—making these decisions, in some ways, prototypical of consumer decision making—and in terms of dollars spent. Despite its importance, there has been paucity of research on factors that influence consumer decision making at the point-of purchase.

The papers in this symposium use multiple research methods to provide new insights into the consumer point-of-purchase decision-making process. The goal of this session is to provide insights into consumer decisions made at the point of purchase by examining the three most prominent aspects of these decisions: deciding whether to make a purchase from a given category, deciding which option from the category to select, and deciding whether to purchase the selected option at the offered price.

Research by Inman, Winer and Ferraro examines the first aspect of point-of-purchase decision making: choosing whether or not to make a purchase from a category. In particular, they use a hierarchical modeling approach, using a dataset of 2,800 in-store consumer intercept interviews conducted in 14 cities, to explore product category factors and customer characteristics that affect the likelihood of engaging in unplanned purchases at the category level.

Next, research by Srivastava and Chakravarti examines the influence of consumer roles on the option-selection stage of consumers' point-of-purchase decisions. In many transactions, consumers' purchase decisions are influenced by their dual roles of buyer and seller (i.e., buying a new car and selling the old one). This research examines how the role a consumer plays influences evaluations and choice at the point-of-purchase.

Finally, research by Hamilton and Chernev investigates retailer price image as a driver of the third aspect of point-of-purchase decision making: whether or not to buy a selected offering at a given price. This research examines price image formation by investigating consumer reactions to changes in the retailer's product line, such as adding an upscale or down scale extension, and how these changes impact consumer decision making.

After the presentation of the research papers, discussion was facilitated by Tom Meyvis.

## EXTENDED ABSTRACTS

### "The Interplay between Category Factors, Customer Characteristics, and Customer Activities in Point-of-Purchase Decision Making"

*Jeff Inman, University of Pittsburgh*
*Russell Winer, New York University*
*Rosellina Ferraro, University of Maryland*

Consumers often enter the grocery store with a set of purchases already in mind, but they often leave the store with a number of unplanned purchases. Inside the store, consumers are confronted with an environment of colorful displays of fruits or flowers, perfectly aligned packages of snacks on endcap displays, and even advertisements covering the floor. These are a few examples of the in-store stimuli that may trigger unrecognized needs and desires or trigger memory for forgotten needs. These in-store stimuli serve as a mechanism for need recognition and may lead to unplanned purchasing, or in other words, point-of-purchase decision-making.

Any given item in a shoppers's grocery basket may have been planned to the level of the brand, to the level of the category, or not at all planned. According to the Point-of-Purchase Advertising Institute (POPAI), over two-thirds of purchase decisions involve some sort of in-store decision-making. Manufacturers spent $18.4 billion dollars in 2004 on in-store marketing and promotion. These efforts are assumed to be effective because they have their influence at the last stage of the choice process – at the point of purchase.

The current research explores the factors driving the extent to which consumers engage in in-store decision-making. While prior research has examined various factors independently influencing in-store decision-making, we present a more comprehensive framework incorporating the product category factors, customer characteristics, and customer activities that affect this type of decision-making. We argue that these factors operate via increasing exposure or affective responding.

First, to have any impact, in-store stimuli require the shopper's attention. That is, shoppers must come into contact with and be exposed to stimuli for there to be any chance of need recognition. Therefore, factors that increase or decrease exposure to stimuli impact the level of in-store decision-making. Second, consumers often buy as a consequence of emotional arousal. Therefore, any factors that trigger affective reactions to products will increase the extent to which consumers engage in in-store decision making. We examine the role of four product category factors in increasing exposure or affective responding: coupon usage, in-store displays, category purchase frequency, and the hedonic nature of the category. Additionally, aspects of the customers themselves may also increase or inhibit in-store need recognition. We examine the role of four customer characteristics in this regard: gender, household size, store familiarity, and shopping alone versus with others.

Furthermore, we examine whether certain customer activities limit the number of in-store decisions. We argue that consumers are aware that they sometimes make unplanned purchases which may satisfy current needs but are detrimental in the long-term. Therefore, consumers initiate activities that limit in-store decision making in order to limit purchasing items they do not need, spending more money than they have allocated, or buying products that are not nutritionally healthy. These activities are use of a shopping list, number of aisles shopped, shopping frequency, time spent shopping, and method of payment.

To test the proposed model, we utilize data provided by POPAI, an association for the point-of-purchase advertising industry. POPAI periodically conducts an extensive field study of consumers' purchasing behavior. In-store intercept interviews were conducted with 2800 consumers (over 40,000 purchases) at grocery stores in fourteen geographically dispersed U.S. cities.

The results are generally consistent with expectations. Coupon use was associated with a lower probability of unplanned purchase. However, items that were on display, items with longer interpurchase cycles, and hedonic categories were associated with greater in-store decision making. Also as predicted, in-store deci-

sion-making was impacted by the customer characteristics examined. Females tended to make more unplanned purchases than did males. As household size increased so did the likelihood of making unplanned purchases. Additionally, shoppers that were accompanied by others were more likely to make unplanned purchases and greater familiarity with the store also increased unplanned purchases.

We expected that customer initiated activities would lead to a decreased likelihood of making unplanned purchases. Our findings offer useful, easy-to-enact strategies for consumers who are interested in curtailing unplanned purchases (e.g., impulsive consumers). First, consumers should use a list because it dampens unplanned purchases. Second, consumers should try to make more frequent, fewer-item trips. This helps focus the shopper on getting in, getting only the items s/he came for, and getting out. Third, consumers should limit browsing. Visiting all aisles increases exposure to stimuli and increases unplanned purchasing. Fourth, consumers should limit the amount of time spent in the store. Limiting time forces the consumer to focus on the task at hand. Finally, consumers should make the decision to pay by cash before entering the store. Paying by credit (and to a lesser extent, by check) decouples the "pain of paying" from the purchase and makes it easier to engage in unplanned purchasing.

### "The Psychology of Trade-Ins in Point-of-Purchase Decisions: Consumer Price Perceptions when Playing the Dual Role of a Buyer and a Seller"

*Joydeep Srivastava, University of Maryland*
*Dipankar Chakravarti, University of Colorado*

In making point-of-purchase decisions, consumers are often confronted with transactions that are naturally related or occur together in time. For example, new car purchases are often made in conjunction with the trade-in of an older car and a vacation involves the purchase of air-ticket and lodging. In such situations, marketers have various options in how to price and present the overall transaction. For example, a car dealer has the option to treat the purchase of a new car and the trading-in of the old car as separate transactions with different price tags or as a bundled (consolidated) transaction where the overall transaction is presented under a single price tag. The manner in which the overall transaction is priced can significantly alter consumer perceptions.

Even when the transaction is presented under separate price tags, a car dealer may create different gain (loss) scenarios from the same net transaction. To the extent that reference prices are available for both transactions, the manner in which the component transactions are priced could lead to different representations of the separate transactions and hence the overall exchange episode. For example, a car dealer can choose to provide a good deal on the new car but a poor deal on the trade-in. Alternatively, the dealer can provide a good deal on the trade-in and a poor deal on the new car, or the dealer could provide moderately good deals on both the new car and the trade-in, while maintaining the same net dollar amount for the overall transaction. Although marketers can implement these different price presentations relatively easily, there is little systematic research on the effects of such price presentation on consumers.

This research examines how variations in the price presentation of transaction bundle affect consumer perceptions. While economic theory would predict no differences in consumer preferences across the different price presentations, the mental accounting principle of segregate the gains would suggest that consumers are likely to prefer the overall transaction where the dealer provides moderately good deals on both the new car and the trade-in. Alternatively, consumers may be more sensitive to the price of the

new car as that is the focal transaction or consumers may be more sensitive to the price of the trade-in because of the general inclination to demand more for giving up something they own (endowment).

This paper reports the results of three studies that examine consumer preferences for transaction bundles as a function of price presentation. Using a scenario involving the purchase of a new car along with the trade-in of an old car, study 1 had six conditions, all with a separate price for the new car and a separate price for the trade-in. In all conditions, reference prices were provided for the new car and the trade-in such that the overall transaction would always result in a gain. The six conditions varied how the net total price was split across the new car and the trade-in. For example, in the conditions where there was a gain on one component and loss on other, the price of the new car was $15,000 and the trade-in value was $4,000 whereas in the related condition, the new car price was $18,000 and the trade-in value was $7,000. The results of study 1 (n = 158) show the different price presentations systematically affected consumer perceptions. Specifically, in contrast to the principle of segregating the gains, consumers were more sensitive to the price of the new car. The overall transactions in which the price of the new car was relatively low were preferred to the transactions in which the price of the trade-in value was relatively high. These results suggest that consumer preferences for overall transactions are affected by how the component transactions are priced.

Study 2 then adds a consolidated condition where the overall transaction is presented under a single price tag to the six conditions used in study 1 and also examines how consumer attachment (involvement) with the trade-in affects preferences for the different transactions. The results (n = 296) replicate the findings of study 1 in the low attachment condition. However, when consumers are trading-in a car that they were attached to, they prefer the overall transactions where the price of the trade-in is relatively high. In addition, the consolidated price presentation is uniformly preferred to the segregated price presentation in the high attachment condition but not in the low attachment condition. Study 3 replicates these findings in a choice study. Together the findings of the three studies show that consumers are differentially price sensitive to the component transactions and that this price sensitivity is malleable. The findings have both theoretical and managerial implications.

### "Price Image Formation and Point-of-Purchase Consumer Decision Making"

*Ryan Hamilton, Northwestern University*
*Alexander Chernev, Northwestern University*

One of the factors that influences consumers' point-of-purchase decisions is price image, the overall impression consumers form of the prices at a given retailer. Despite the importance of price image to marketing theory and practice, there has been relatively little investigation into the factors that influence its formation, antecedents, and consequences. Price image is important to consumer behavior researchers because it plays a key role in at least two types of consumer decisions. First, because price image can affect consumers' reference prices, it can influence the point-of-purchase decision of whether or not to buy a selected offering at a given price. Second, because price image is one of the factors that can determine the overall attractiveness of a retailer, it is also likely to influence consumers' decisions of where to shop. Thus, high price image can lead consumers to expect that there is a better price for comparable merchandise, and consequently, that they should shop elsewhere.

In this research, we draw on theories from psychology and decision-making to better understand the formation of price image by investigating consumer reactions to changes in the retailer's

product line. Although retailers tend to price the items they carry within a range that will appeal to the store's core segment of consumers, it is also common for retailers to season these narrowly-priced assortments with a handful of vertical extensions: products from a higher or lower price tier. For example, Best Buy, a retailer whose very name projects a low price image, has added the high price, high quality Magnolia home theater line to complement its other audio/visual entertainment products. Likewise, grocery chains that are positioned as high-priced, premium service providers will often still carry a few inexpensive, private label items in addition to higher priced national and specialty brands.

Conventional wisdom predicts that a vertical extension would push the price image in the same direction (e.g., adding a downscale extension would lower a store's price image). We argue, however, that the impact of vertical extensions on price image is a function of the way consumers process the available information. In this context, we identify conditions in which a vertical extension can move the price image in the opposite direction, such that adding a downscale extension can actually raise a retailer's price image and adding an upscale extension can lower its price image.

To illustrate, imagine a consumer standing in front of a display of cordless phones. Most of the prices are fairly similar, but there is one downscale model with a substantially lower price. The consumer takes into account all of the available options and she forms a price image. Now picture a different consumer standing in front of the same display. After looking over the available options, this consumer selects a phone he would like to buy. He then evaluates the price of the option he selected in forming a price image.

The two consumers in this illustration exemplify two ways of evaluating information in forming a price image. The first consumer evaluated all of the available information in the set without focusing on any particular option. This type of non-focal evaluation would lead the consumer to assimilate the price of a vertical extension into an overall price image. In this context, the presence of the downscale phone would lead this consumer to form a relatively low price image of this store. The second consumer focused on a single option and contrasted it with the other alternatives. The presence of the downscale extension would make the phone he chose seem expensive. Based on his focal evaluation, this consumer would form a relatively high price image of the store.

We examine the impact of vertical extensions and evaluation type on price image, and thus, on consumer decision making, in a series of three experiments. In the first experiment, participants are encouraged to make either a focal or a non-focal evaluation of a set of options that includes either an upscale or a downscale extension. We use likelihood of purchasing a chosen option at a given price as a measure of price image: Participants were shown an additional item from a different category and asked whether they would purchase that item at a given price or defer choice to look for a better price elsewhere.

The second experiment demonstrates that these findings can impact choice among retailers as well as choice deferral. Participants were asked to choose between two hypothetical stores, one where they had previously made a focal evaluation, and one where they had previously made a non-focal evaluation. When faced with two stores that both carry an upscale extension, consumers will form a higher price image of the store where they made the non-focal impression than the store where they made the focal evaluation. In contrast, when faced with two stores that both carry a downscale extension, consumers will form a lower price image of the store where they made a non-focal evaluation than they would from the store where they made a focal evaluation.

Building on the findings of the first two studies, experiment 3 examines the impact of vertical extensions on price image by using

brand loyalty as a predictor of the type of evaluation a consumer is likely to engage in. Thus, consumers that are loyal to a particular brand will tend to focus on that brand, comparing its price with the other prices in the set when forming a price image. Consumers that are not loyal to any brand, on the other hand, will tend to make more non-focal evaluations in forming a price image. We find that when given a choice between two retailers, one of which has upscale extensions and one of which has downscale extensions, brand-loyal consumers overwhelmingly prefer the store with upscale extensions, whereas consumers that are not brand-loyal prefer the store with downscale extensions.

# Temporal Consumption: How Time Influences our Memories of the Past, our Enjoyment of the Present, and our Preference for the Future

Leif Nelson, University of California, San Diego, USA

## SESSION OVERVIEW

Consumption is necessarily temporal in nature. We recall yesterday's trip to the record store, savor the experience of listening to music today, and look forward to hearing it again tomorrow. These processes are relatively easy to identify and yet incredibly challenging to describe. Consumers maintain a complicated relationship with time; our consumption memories are colored by our motives over time, our behavior and our experience changes with the progression of time, and in fact our anticipation of the future is sculpted by our ability to conceptualize time. In four papers, we pose questions and offer some tentative answers, about the role of time in consumption.

The first paper (Norton and Chance) considers how consumers recall past decisions. Quite famously, past research has suggested that following difficult decisions people are motivated to bolster the chosen option and deride the foregone alternatives (i.e., Festinger 1957). Norton and Chance show that consumers sometimes use the even simpler strategy of forgetting the original decision entirely. They demonstrate first that, in seeming violation of standard memory effects, this decision amnesia is *most* likely to occur for those decisions consumers spent the *most* time considering. Furthermore, consumers seem to fill in the missing elements of past decisions with originally absent options: The desire to maintain the amnesia is strong enough to reconstruct the fabric of memory. Though people know how to cope with post-decision regret, sometime a few well-chosen memory lapses may be even more efficient.

When given enough time, people may avoid such regrets by simply improving their consumption. The second paper (Vohs) considers self-regulation over long time periods, and show that the seasoned veterans of self-control (of the consumption of calories and the expression of emotions) are significantly better at foregoing temptations than their journeymen counterparts. Most interesting were results suggesting that a little bit of self-regulatory experience was worse than none at all, as novice dieters showed less self-control than non-dieters. In order to perfect consumption, people need to self-regulate, but it appears that people need a lot of time practicing self-regulation before they can eliminate its negative consequences.

What about the perception of time during consumption? Intuitively and empirically it is believed that time flies when you're having fun. The presence of such a strong lay theory, and the persistent ability for people to misattribute information to the wrong source, allows for an intriguing possibility: if people think that time is flying, to they actually have more fun? The third paper (Nelson and Meyvis) shows that people think an upcoming event will be more enjoyable if they are made to feel as though it will go by quickly. Furthermore, in three additional studies they also show that when an incidental cues signals that time is passing quickly (a slightly fast timer) people enjoy listening to music more, regardless of whether the songs are enjoyable or irritating.

The final paper considers how we value products and currency to be consumed in the distant future (Frederick, Read, and LeBoeuf). A commodity to be consumed "when I'm 64" is no different than one to be consumed "33 years from now", put people value the former much more than the latter. Interestingly, that effect diminishes with the age of the participant, perhaps reflecting that experi-

ence with time makes consumers more expert at conceptualizing it. Furthermore, another investigation hints that the key variable may be thinking about age, rather than merely focusing on dates and time.

Given the breadth of this research domain, these papers necessarily represent substantial variation in both methods and inferences. Thankfully, we are pleased to have an expert in temporal perception to serve as a discussant for the session. Over his career Yaacov Trope has made substantial inroads into the investigation of time in human behavior, and his work on temporal construal has brought coherence to a seemingly diverse set of findings.

## EXTENDED ABSTRACTS

### "Decision Amnesia: Why Taking Your Time Leads to Forgetting"

*Michael I. Norton, Harvard Univeristy*
*Zoë Chance, Harvard Univeristy*

Imagine having to choose between your two favorite flavors of ice cream, chocolate and mint chip. Such conflicted decisions – decisions under uncertainty – have been explored through a number of theoretical lenses: cognitive dissonance theory (Festinger, 1957) focuses on how people denigrate foregone options and inflate the value of their choices – which a host of studies have demonstrated – while other researchers have focused on how such decisions lead to counterfactual regret (e.g., Kahneman & Miller, 1986; Roese, 1997). To varying degrees, these approaches focus on how individuals engage in the uncomfortable process of rationalizing the regret such decisions induce. Our research demonstrates another viable, efficient – and, we suggest, surprisingly common – means of coping with difficult choices: forgetting them altogether. Rather than engage in complicated – and costly – post-decisional rationalization, we suggest that individuals frequently exhibit *decision amnesia* when coping with difficult decisions. In addition, because the motivation to forget is at its highest when decisions are most difficult, we predict that people are ironically most likely to forget those decisions they take the longest to make, since this greater amount of time indicates a greater degree of conflict.

We demonstrate this decision amnesia in a series of studies using a diverse array of stimuli. In Study 1, we asked participants which vacation destinations they preferred among 40 pairs (e.g., Shanghai vs. The French Riviera), while measuring their reaction time and reported difficulty; after a distracter task, we then asked them to recall which destination they had chosen. As predicted, participants made significantly more errors on pairs they had taken longest to choose between (which were also those pairs they rated most difficult). We replicated this basic effect in choices between types of death (e.g., getting bitten by a poisonous snake vs. getting strangled by a tetherball rope) as well as in choices between consumer products (e.g., an autographed James Gandolfini portrait vs. a Robosapien robot). An alternative explanation for our findings would be that the objective similarity of options – rather than the subjective difficulty of choosing – impairs recall. In Study 2, therefore, participants chose between pairs of colors and we asked them to rate both the difficulty of the choice and the similarity of the two colors. When asked to recall their choices, once again, partici-

pants forgot more difficult than easy choices; most importantly, difficulty predicted accuracy independent of and more strongly than similarity.

The strongest test of our decision amnesia hypothesis, however, is that participants forget not only which option they chose when making difficult decisions, but also forget having made a choice at all. In Study 3, participants again chose between pairs of colors at Time 1. At Time 2, however, rather than indicating the color they chose at Time 1, participants were asked to indicate if they had seen pairs of colors in the previous task or not – and were presented with pairs that had been difficult or easy, or with new pairs they had not seen. As predicted, participants were more likely to forget having seen pairs of colors for which their choice had been difficult than easy. In Study 4, we added a "lure" option at Time 2 (a 3rd color not present at Time 1). When asked to recall the earlier colors, participants were more likely to select the new "lure" option as having been present at Time 1 for pairs that had been difficult, again suggesting they had forgotten the original choice sets altogether.

Taken together, these studies demonstrate that decision difficulty impairs memory both of what options were chosen and even of having made a decision at all: the longer participants took to make decisions – and therefore the longer they were exposed to stimuli – the less likely they were to remember ever having seen them. Of course, in many real life situations, we have lingering evidence of our difficult choices: for instance, we are unlikely to forget which person we married, no matter how hard that decision may have been. There are, however, ample opportunities for decision amnesia to occur; indeed, were we to rationalize every decision we made, we would likely have little time left to think about anything else. Thus decision amnesia may be a generally efficient strategy: rather than continually coping with the agony of regret, we suggest that people simply forget.

### "Self-Regulation Over Long Periods of Time: Practicing a Controlled Activity Reduces Depletion of Self-Regulatory Resources"

*Kathleen D. Vohs, University of Minnesota*

It is now well-known that when people engage in self-regulation something akin to a reservoir of energy becomes depleted and leaves people less capable of performing a subsequent act of self-control. Tests from all around the world as documented in over 90 published articles support this limited-resource model of self-control. Despite these robust findings, it deserves noting that almost all of the experiments are conducted in laboratory settings wherein participants are instructed to engage in a self-regulatory task or they are instructed to engage in a task that is similar in scope but not in degree to which self-regulation is needed. Hence, people in the regulatory condition are presumably engaging in a task that represents some natural form of self-control (e.g., controlling one's attention while distracting words appear on the video that one supposed to be watching is similar to keeping one's eyes on a boring speaker while one's Blackberry begs for attention). Nonetheless, to understand the fundamental nature of self-control, it is crucial for the field to move beyond its current paradigm. Hence, the present research asked whether people who have been self-regulating over long periods of time show differential effects in terms of self-regulatory depletion than people who have not been devoting effort at such lengths of time.

In experiment 1, participants were experienced dieters or novice dieters who came to the lab and were seated at a chair next to or far away from several bowls of tempting candies. The candies were present to differentially activate self-regulatory processes within dieters, who would have to overcome their desire to eat them:

sitting close to the candies was designed to be more tempting – and therefore require more self-regulatory resources to resist – than would sitting far away from the candies. Participants sat next to the candies while watching a boring documentary about the lives of Big Horn Sheep. Next, as a test of how many self-regulatory resources they had exerted in the movie-watching phase, all participants were taken to a different room and asked to eat ice cream ostensibly as part of a taste and rate paradigm. Ad-hoc eating was the measure of self-control, a measure that has been used in the eating literature for more than 30 years (Schachter et al 1968). As expected, veteran dieters self-regulated better, by eating less ice cream, as compared to novice dieters. This finding suggests that time spent dieting is a significant factor in how depleting it is to self-regulate.

In Experiment 2, participants were novice dieters, experienced dieters, or nondieters. They came to the lab where they were tempted with bowls of sugary and chocolate candies. This setting was intended to active the desire to eat, which for dieters would have to be overridden but not so for nondieters who are not regulating with respect to eating (cf. Vohs and Heatherton 2000). The second task involved asking all participants to attempt to solve difficult puzzles (that were, in actuality, unsolvable), as a measure of self-control. The results showed that nondieters had the best persistence, followed by the experienced dieters, with the novice dieters showing the worst persistence. These results supported the hypothesis that practicing a specific act of self-regulation over a long period of time fails to disable people to the extent that being new at an act of self-regulation does. Note, however, that being an experienced self-regulator completely removes the need to regulate — dieters who were experienced at dieting were more depleted (and less persistent) than nondieters, who did not have to regulate while seated next to candy.

In Experiment 3, I investigated long-term efforts at self-regulating in the domain of emotion regulation. All participants completed an emotion regulation questionnaire (Gross and John 2003), which enabled me to score some participants as being experienced emotion regulators (meaning, they were frequently engaging in emotion control) and some participants to be novices at this task (meaning, they did not often control their emotions). All participants were asked to watch a disgusting and sad video under instructions to control their emotions. Later, as a test of self-regulatory resource availability, participants were given a task to perform, which was akin to the task of assembling a bookshelf that was purchased in disassembled form. Persistence at the difficult task was the measure of self-regulation. The results showed that participants who were well-practiced at controlling their emotions were better at persisting at the difficult task relative to participants who were unused to controlling their emotions.

In sum, time spent self-regulating is a meaningful component not yet recognized by current theories in self-regulation, especially work pertaining to the limited-resource model. The discussion of these experiments will revolve around conscious versus nonconscious self-regulation and how repeated attempts at self-regulating may help automatized controlled behaviors and hence free consumers to engage in other acts of self-control.

### "Time is Flying, We Must be Having Fun: The Effect of Subjective Time Porgression on Enjoyment"

*Leif D. Nelson, New York University*
*Tom Meyvis, New York University*

Time flies when you're having fun. This old adage holds that as enjoyment increases, our estimates of elapsed time will similarly decrease. Indeed, popular wisdom holds up relatively well to empirical scrutiny, as more engaging activities are judged to be faster than similar non-engaging tasks (Chaston and Kingstone

2004). Apparently, this basic relationship is strong enough to end up in the popular lexicon.

If the assumed effect of enjoyment on time perception is learned well enough, then perhaps people will rely on this lay belief to infer the cause from the consequence: Subjective changes in the passage of time could lead to corresponding changes in the enjoyment of an experience. Time is flying, I must be having fun.

There is a long history investigating the misattribution of feelings in consumer research (Schwarz, 2004). Feelings of fluency, for example, can make preferences and attitudes feel more positive and more persuasive (Muthukrishnan and Wathieu 2007; Levav and Fitzsimons 2006). Furthermore, existing lay theories (like beliefs about the relationship between time and fun) can influence a variety of human inferences, including those relating to consumption (e.g., Mukhopadhyay and Johar 2005). Given that people have a strong lay theory about the effect of enjoyment on time perception, altering the subjective time experience may lead to inferences of enjoyment. To test this hypothesis, we conducted four studies in which we manipulated the subjective experience of time and measured anticipated (Study 1) or actual (Studies 2-4) enjoyment.

In Study 1, participants thought about the upcoming weekend and listed a few activities they would engage in during that weekend. Some participants listed 2 activities whereas others listed 6. Past research has shown that, when considering future time periods, if people list more events they will perceive the time period to be shorter (LeBoeuf & Simmons 2006). We reasoned that if a known time period (a weekend) was felt to be shorter, people would feel as though the time was moving faster. As predicted, people who listed 6 activities thought the weekend would go by faster than did people who listed 2 activities. Furthermore, and most central to our hypothesis, people who listed six activities thought that the weekend would be more enjoyable than did people who listed only 2.

Since the first study only studied anticipated enjoyment, we conducted a second study to test if the effect also influences actual enjoyment of an ongoing experience. In Study 2, participants listened to an enjoyable pop song ("*Yours to Keep*" by the Teddybears) while a timer either displayed the accurate timing, or instead displayed a slightly accelerated timer (seconds are updated each 0.8 seconds). Though consciously imperceptible to our participants, the latter timer gave the impression that time was moving faster than normal. As predicted, people enjoyed the pop song more when listening with the fast counter than with the normal counter.

Perhaps fast timers merely enhance the magnitude of the typical enjoyment pattern, and negative stimuli might get worse with a faster timer? To test this alternative we had participants listen to a sample of symphonic dot matrix printers ("@.}@}.@.}@}.@.}@}.@.}" by The User) which was judged to be generally irritating (Study 3). Nevertheless, when participants listened to the sample with a faster timer they judged it to be less irritating, and a less aversive overall experience, than when it was played with a slow timer (updated every 1.2 seconds). Apparently, the perception of time flying by makes all experiences more fun, even those that are no fun to begin with.

The subjective time perception could influence enjoyment in several ways. One possibility is that people are influenced by the perceived fluency of the ongoing time progression, and attribute this surprising fluency to their enjoyment (Whittlesea & Williams 2001). Alternatively, people may be influenced by the perception of the total elapsed time, and attribute their surprise about the length of that time period to their enjoyment of the experience. To distinguish between these two possibilities, we conducted a fourth study in which we asked participants to listen to a song chosen from a list of familiar titles (e.g., "Crazy" by Gnarls Barkley, "California

Über Alles" by the Dead Kennedys, etc.) and manipulated whether the timer counted up from zero or counted down from the end. Whereas the perceived fluency of the ongoing time progression should be equally salient in both conditions (counting up or counting down), the total time elapsed should be most salient when the counter is counting up. Participants with the timer counting up showed responses consistent with our previous findings: when the timer was fast, people enjoyed the song more than when the timer was slow. When the timer counted down however, the effect was completely eliminated Participants in the fast timer conditions inferred greater enjoyment of the experience due to their surprise at the length of the elapsed experience rather than due to the suprisingly fluency of the ongoing experience.

From a theoretical perspective, these findings hint at the malleability of hedonic experience. Recent work has suggested that top-down processes only operate on preference if that information is consciously encoded prior to consumption (Lee, Frederick, and Ariely 2006), but this work suggests that preferences can shift in a bottom-up manner, even when the influential information operates outside of conscious awareness. From a managerial perspective, these findings show how a subjective sense of time can operate on explicit preferences. Perhaps if managers can create a sense of time flying by, the consumption experiences they offer will be judged as more enjoyable.

## "When I'm 64: Temporal Referencing and Discount Rates"

*Shane Frederick, Massachusetts Institute of Technology*
*Daniel Read, London School of Economics*
*Robyn A. LeBoeuf, University of Florida*

The *Beatles* song sharing our title refers to the future in two distinct ways. The lyrics begin "When I get older, losing my hair, *many years from now…*" and end "Will you still need me, will you still feed me, *when I'm 64*." Though each of authors is still many years from 64, one of us recently "recognized" that he'll be 50 in just 12 years, which didn't feel nearly long enough to bridge the psychological distance between his conception of himself and his conception of a 50-year-old.

These ruminations suggest that our conception of the future, and the choices we make regarding it, may depend on the manner in which the future is described. Thinking about a given age may make the future seem more psychologically distant than the number of intervening years suggests – something that should *increase* discounting. On the other hand, our prior research on temporal referencing (Read, Frederick, Orsel, and Rahman, 2005, and LeBoeuf, 2006) suggests that an age reference may *decrease* discounting by directing attention away from the intervening time period, and toward other things (e.g., our stereotype of someone of that age, or our speculations of what our own life will be like at that age).

We explore the effects of temporal referencing in three studies. In Study 1, respondents specified the amount of money to be received 10 years hence required to achieve indifference to receiving $40 immediately. In the *Delay* condition, temporal distance was framed as "10 years." In the *Age* condition, respondents first specified how old they would be 10 years from now, and then entered this value into the brackets (as shown below) before completing the matching task.

I would be indifferent between getting $40 right now or getting $_____ when I am [   ] years old.

Respondents were more patient when the temporal interval was marked by their future age rather than the number of intervening years; when faced with an age reference, they indicated that a

smaller future reward was sufficient to achieve indifference with $40 now.

Our second study was conducted using an on-line survey site. On the first screen, respondents entered their date of birth. On the following screen, they made twelve intertemporal choices. For respondents assigned to the *Delay* condition, the future was referenced as a number of years (e.g., $40 immediately vs. $250 in 10 years). For those in the *Age* condition, it was referenced in terms of the person's future age, generated from their previously entered birthdate (e.g., $40 immediately vs. $250 when you are 48).

Once again, respondents were significantly more patient when the future was indexed by their future age. For example, while only 20% were willing to wait 10 years to get the $250 when it was "in 10 years", 50% preferred that larger later reward if it was received when they were X+10 years old. Intriguingly, this framing effect diminished with age, and for respondents older than 60 there was no effect at all. We speculate that age becomes chronically salient for older respondents, since opportunities for retirement, for receiving social security, or senior citizen discounts all depend on individuals soon reaching specific salient age milestones.

In our third study, respondents were randomly assigned to one of four conditions, in which temporal distance was specified in one of four ways: as the *Delay* in years until the future reward or penalty, as the specified *Date* on which the future event would occur, as the *Age* that the respondent would be when the future event occurred, or as the number of *Years Older* the respondent would be at the time of the future event.

| Condition | Phrasing |
|---|---|
| *"Delay* | $Y in exactly 2 years |
| *"Date* | $Y on Sept 29th, 2008 |
| *"Age* | $Y when you are 43 |
| *"Years Older* | $Y when you are 2 years older |

Respondents were significantly more patient in the *Age* and *Older* conditions than in the *Delay* or *Date* conditions. The *Years Older* frame increased patience nearly as effectively as the *Age* frame. This is noteworthy because the numeric presentation in the *Older* frame was nearly identical to that in the *Delay* frame, arguing against a psychophysical explanation involving comparisons of the presented numbers. The words "years older" may prime (as might an "age" reference) the concept of a continuous persistent identity enduring across time demanding impartial treatment by the current self. In our fourth study, we explore whether these framing effects result from perceived temporal distance or perceived "connectedness" to future selves. We conclude by discussing the implications of this research for the marketing of financial instruments, such as IRAs, life insurance policies, and annuities.

SYMPOSIA SUMMARY
# The Multiple Routes of Affective Influences on Consumer Behavior
Jiewen Hong, Northwestern University, USA
Aparna A. Labroo, University of Chicago, USA

## SESSION OVERVIEW

Research on emotion has suggested that the influence of affect on behavior can occur through multiple routes, ranging from the rather quick and automatic "low road" that bypasses any cognitive processes, to the more fine-tuned "high road" that allows for systematic cognitive processes (LeDoux 1996). Indeed, empirical research has shown that affective reactions can occur automatically and rapidly, and exert a direct influence on judgment (e.g., Murphy and Zajonc 1993) and consumption behavior (Winkielman and Berridge 2004), which is independent of cognition. Affect can also indirectly influence consumer behavior by changing people's cognitive processes. That is, people's affective states can alter their perceptions or beliefs about the target (Pham 2004) or activate affect-consistent information in memory, which in turn impact people's behavior (Isen, Shalker, Clark, and Karp 1978). More recently, it has also been suggested the influence of affect on consumer behavior can also take a high road by going through a metacognitive process before exerting its influence. In this case, the reliance on affect in judgments and decisions is subject to the scrutiny of cognitive processes in which people assess whether or how they should use their feelings in a given judgment or decision (Avnet and Pham 2004; Pham 2004). This session takes a closer look at the multiple routes of affective influences on consumer behavior by bringing together research that examines the role of affect in consumers' judgment of novel objects, their ability to detect changes, and their financial decision making.

The first paper by Hong, Lee, and Li examines the low road of affective influences through which precognitive affective processes directly impact consumer judgment. Building on the valence hypothesis of emotional processing (Silberman and Weingartner, 1986), which postulates that the left hemisphere is specialized for processing positive emotional stimuli and the right hemisphere is specialized for processing negative emotional stimuli, this research examines how emotional lateralization processing impacts judgment. Using a paradigm where affective primes are presented subliminally in participants' right or left visual field, the author showed in three experiments that participants' judgment of a target is more favorable when the valence of the prime is positioned to match the efficient processing of the hemisphere (i.e., negative primes in the left visual field and positive primes in the right visual field); that is, the matching effect is observed even when the prime is negatively valenced. These results differ from the classic affective priming effects (Murphy and Zajonc 1993) whereby participants' judgment of the target assimilates toward the valence of the prime (i.e., positive prime leads to more positive judgment, whereas negative prime leads to more negative judgment).

The second paper by Rucker and Labroo explores the indirect influences of affect on consumers' ability to detect perceptual changes by way of changing people's cognitive processes. Specifically, they show that mood-congruent cognitions may interfere with the accurate storage and retrieval of a stimulus representation from memory. Consequently, people are more accurate in detecting change in emotion-incongruent (vs. emotion-congruent) objects. That is, happy respondents are less accurate in detecting change in a positive (vs. negative) object, and unhappy respondents are less

accurate in detecting change in a negative (vs. positive) object. Interestingly, the effect is not hardwired: simply imagining a neutral product (e.g., beer) with positive or negative associations leads to similar effects.

Finally, the third paper by Stephen and Pham investigates a case where affect influences consumer behavior through a high road. Specifically, using an ease-of-retrieval paradigm, they manipulated whether people would trust their feelings in a classic behavioral economics game called the ultimatum game. Results from five experiments show that, compared to lower trust in one's feelings, higher trust in one's feelings results in less generous offers in ultimatum games, especially in the dictator version of the game. Higher trust in one's feelings also results in greater rejection of unfair offers, with little effect on the acceptance rates of fair offers. These findings are not driven by differences in perceptions of what players see as "fair" divisions under high versus low trust of feelings. Rather, players with high trust in their feelings appear to be playing the game as if they represented it in a more literal fashion.

The session highlights a topic that has generated considerable interest in consumer research over the last two decades. We expect this session to be well attended by members of ACR who are interested in the areas of affect and emotion, as well as in consumer decision making and information processing. The session will end with a discussion led by one of the experts in the area, Mary Frances Luce, on how affect can impact consumer behavior, judgment and decision making. We hope the session will provoke discussion on how to systematically integrate the findings relating to these three types of emotion-judgment into a unified framework.

## EXTENDED ABSTRACTS

### "Bilateral Affective Priming and Consumer Judgment"
*Jiewen Hong, Northwestern University*
*Angela Y. Lee, Northwestern University*
*Wen Li, Northwestern University*

The affective primacy hypothesis (Zajonc 1980) posits that affective reactions can be elicited with minimal stimulus input and cognitive elaboration. Research in affective priming has provided strong support for this hypothesis by demonstrating that the processing of affective stimuli outside conscious awareness can also influence judgment (e.g., Murphy and Zajonc 1993). These studies show that a subliminal affective prime (e.g., a smiling or a frowning face) presented in the center of the screen can influence the affective judgment of a target (e.g., a Chinese ideograph). More specifically, targets are judged more favorably following a positive prime (e.g., a smiling face) and less favorably following a negative prime (e.g., a frowning face)

In this research, we contribute to the affective priming literature by examining how hemispheric differences in emotional processing may influence judgment. The valence hypothesis of emotional lateralization processing (Silberman and Weingartner, 1986) postulates that the left hemisphere is specialized in processing positive emotional stimuli and the right hemisphere is specialized in processing negative emotional stimuli. We hypothesize that when an affective prime is located in the visual field that allows

more efficient processing of the prime by the specialized hemisphere, people would develop more favorable attitudes toward the target. This hypothesis was tested in three studies.

In Experiment 1, affective stimuli with positive or negative valence were presented subliminally in participants' right or left visual field and participants were asked to evaluate a logo appearing in the center of the screen. The affective primes were normed pictures selected from the International Affective Picture System (Lang, Bradley, and Cuthbert 2005) and were matched on their arousal level. We found that participants' liking of the logo was enhanced when the valence of the prime matches the hemisphere specialized in processing the valence (i.e., when negative primes were presented in the left visual field, and when positive primes in were presented in the right visual field).

Affective priming studies have consistently shown an assimilation effect toward the affective primes on target liking; that is, targets following a positive (negative) prime are judged more favorably (negatively). To ensure that the effects obtained in Experiment 1 were not an artifact specific to the priming stimuli, we conducted Experiment 2 to replicate the classical affective priming effect and also to test the robustness of our bilateral priming effects. Thus, we included conditions in Experiment 2 where the primes would appear in the left versus right visual field as well as in the center of the screen, as in a typical affective priming study. We also included a control condition to examine whether the effects were due to more favorable attitudes when the valence of the prime matches the visual field for more efficient processing or to less favorable attitudes when the valence of the prime mismatches the visual field for less efficient processing, or both. To these aims, a 3 (prime valence: positive vs. negative vs. neutral) × 3 (prime visual field: left vs. right vs. center) within-subject design was used. The same IAPS pictures as in Experiment 1 were used as affective primes, and nonsensical polygons were used as neutral primes in the control condition. Chinese ideographs were used as targets. Results showed that the classic affective priming effects were obtained when affective primes were presented in the center; that is, targets were judged more favorably following a positive prime and less favorably following a negative prime. Replicating the findings from Experiment 1, when affective primes were presented in the visual fields, target liking was more favorable when the prime was processed by the specialized hemisphere, regardless of whether the prime was positive or negative. We also found that the effects were driven by increased liking in the matching condition.

Experiment 3 was designed to further understand the mechanism underlying the bilateral affective priming effects and to test the generalizability of the effects in a consumer related context. We presented participants with an ad for a brand of sunblock in the center of the computer screen as the target and affective primes disguised as banner ads were placed on either side of the screen. We replicated the findings from Experiments 1 and 2, but only when participants were not aware of the banner ads (i.e., the affective primes). These bilateral affective priming effects disappeared when participants noticed the banner ads, suggesting that these effects were driven by a nonconscious process. Further, processing fluency of the target seems to mediate these effects.

### "Noticing Change in Our World: The Role of Emotions in Stimulus Discrimination"

*Derek D. Rucker, Northwestern University*
*Aparna A. Labroo, University of Chicago*

In 1985, New Coke, a reformulation of Coke Classic, was launched. Coke had spent $4 million and interviewed 200,000 consumers to make this decision, and blind taste tests had determined that consumers clearly preferred the taste of the new product. The product failed in the marketplace and was quickly withdrawn. Did the loyal consumers, supposedly consumers having many happy feelings relating to Coke, fail to notice the improvement in flavor? Companies often introduce changes to their products or product packaging, for example, to reflect a promotion, such as a free toy inside a cereal box. What factors affect consumers' success in detecting such changes? Although an important question, research has only recently begun understanding factors affecting change detection. In the current research, we consider how consumers' emotions and the valence of associations to a product interactively affect success in detecting change in the product. For example, feeling happy, are consumers likely to be more accurate in discerning changes in a positive stimulus (*kitten*) or a negative stimulus (*roach*)? Are they likely to be more accurate in discerning change in a neutral stimulus (*beer*) when they form positive (*liked beer*) versus negative (*disliked beer*) associations with the product? Why might this happen?

Traditional models of memory suggest detecting change requires attention to the initial stimulus and storing a representation of that stimulus in memory until it is encountered again (Rensink, 2000, 2002). Importantly, any factor that interferes with holding a representation in memory, such as an increasing delay between the presentation of the initial stimulus and the target of comparison, or its retrieval from memory, such as other interfering representations, impairs people's success at detecting change.

How might emotions influence consumers' success in detecting change? Recent research suggests that emotions facilitate automatic capture of attention of valence inconsistent information (Rothermund 2003, Rothermund, Wenura, and Bak, 2001). As a consequence, consumers may not only pay less attention to mood congruent information, but may also fill in peripheral details of the mood congruent stimulus. Based on this, one might predict that consumers will be more accurate in detecting change in stimuli whose valence is inconsistent with the valence of their current mood. Notably, prior research suggests that the impairment in detecting change will occur at the time of encoding of the stimulus. However, we propose that there is also reason to believe that the impairment might occur during storage and retrieval of the representation from memory. That is, mood interferes with the storage and retrieval of mood congruent information from memory. The implication is that the effects of mood are not hardwired. Simply imagining positive (favorite beer) or negative (disliked beer) associations toward a neutral stimulus (beer) might lead to mood incongruent effects in the detection of change. That is, happy people may be more likely to be accurate in detecting whether a beer changed or not when they previously imagined it to be a disliked versus liked beer. The reverse is true for unhappy respondents. In two experiments, we tested how emotions affect people's success in detecting changes in positive versus negative stimuli. In experiment 1, we sought to establish that people are more accurate in detecting change in mood incongruent stimuli, controlling the amount of attention to the stimulus. In experiment 2, we further tested whether mood interferes with storage and retrieval of a previously encoded representation of a stimulus.

Experiment 1 manipulated participants' emotions and the evaluative associations to the target. First, participants were asked to recall a time they either felt happy or sad, a well-established mood manipulation. Participants were then exposed repeatedly to a target stimulus and their task was to indicate whether the brightness of the target changed between two exposures. Importantly, the valence of the target stimuli was experimentally manipulated to be either positive (e.g., kitten) or negative (e.g., roach). Results revealed a significant interaction ($p<.01$) between participants' emotions and the valence of the stimuli. Supporting the incongruency hypothesis,

participants in a positive (negative) mood may more errors attempting to detect change in a positive (negative) object compared to a negative (positive) object.

Whereas Experiment 1 used target stimuli that were either positive (*kitten*) or negative (*roach*), Experiment 2 used a neutral stimulus (*beer*) but manipulated whether participants' associations to that stimulus were positive or negative. This manipulation allowed us to test the idea that consumers' current emotions interfere with participants' own representation of a stimulus, rather than other properties of the stimulus itself. Specifically, prior to the change detection task participants were asked to imagine a glass of beer as a beer they liked or hated. After that, participants wrote about a happy or an unhappy life event. Thus, mood was manipulated after the initial stimulus had been encoded, and different attention to the stimulus based on a preexisting mood state was not possible. After the mood manipulation, participants then were asked to attempt to detect any change in the beer from one slide to the next. As in experiment 1, we systematically varied the brightness of the object. A significant interaction emerged replicating the results of experiment 1 ($p<.01$). Participants in a positive (negative) mood may more errors attempting to detect change when they had imagined the beer to be positive (negative) compared to negative (positive).

The present research suggests that mood interferes with the accurate storage of a mood congruent representation in memory and consequently the accurate detection of change. This is particularly interesting because the detection of change was thought of as a purely perceptual task; yet we found a conceptually-based interference effect of mood. That is, the data suggested cross modal interference: the conceptual system interfered with holding of an accurate perception. The present research calls for more research to examine how the perceptual and conceptual systems may interactively influence success in accurately assessing change in objects.

### "To Trust or Not Trust One's Feelings in Ultimatum Bargaining"

*Andrew T. Stephen, Columbia University*
*Michel Tuan Pham, Columbia University*

The effects of emotion on human decision making may not be as detrimental as generally believed. In particular, feelings and emotions appear to sustain an *ecological* form of rationality in that they often enhance people's ability to relate to their social, cultural and natural environment (Pham, 2007). As part of a broader investigation of the role of emotions in economic interactions, this research examines across five experiments how differences in how much people trust and rely on their feelings influence their behavior in a classic economic game called the ultimatum game, which provides a powerful means of studying bargaining and negotiation behavior.

In this game, one player, the proposer, has to propose a division of a sum of money between him- or herself and another player called the responder. If the responder accepts the offer, the two players are paid accordingly. If the responder rejects the offer, the two players each receive no payoff. According to standard economic theory, the optimal solution in this game is for the proposer to offer the smallest positive residual possible, which the responder should rationally accept. Empirical economics studies show, however, that this supposedly "rational" equilibrium is rarely met. Instead, proposers typically offer a substantial fraction of the money, which responders generally accept. It has been suggested that this regular empirical deviation from the supposedly rational economic equilibrium may be driven by the emotions that the players feel. However, empirical investigations of the role of emotions in this game have been inconclusive because of the inherent difficulty in isolating the effects of emotions precisely.

To obtain more insight into the role played by emotions in this game, in our experiments we subtly manipulate the players' reliance on their feelings by varying their momentary trust in their feelings. To manipulate players' trust in their feelings, we used a manipulation developed by Avnet and Pham (2007) based on an earlier ease-of-retrieval manipulation by Schwarz et al. (1991). Specifically, participants were asked to recall two or ten instances in the past in which they had trusted their feelings in making a decision and it turned out to be the "right" decision. Previous findings by Avnet and Pham (2007) indicate that those players who recalled just two examples of themselves correctly trusting their feelings would have a higher level of momentary trust in their feelings than those players who recalled ten examples—an assumption that was verified in another pretest.

Experiment 1 examined proposers' behavior in the ultimatum game, and found that proposers who trust their feelings more make less generous offers than proposers who trust their feelings less. Interestingly, while the offers made by proposers with higher trust in their feelings were less generous, most of these offers were still in a range that made them likely to be accepted. On the other hand, proposers with lower trust in their feelings tended to make offers that were slightly too generous. Also, proposers with higher trust in their feelings who made less generous and objectively riskier offers did not rate the subjective probability of their offers being accepted any lower than proposers with lower trust in their feelings who made objectively more conservative (less riskier) offers.

Experiment 2 examined proposers' behavior in the dictator version of the game where responders have no choice and are forced to accept the offers made to them. In this version of the game, proposers face no risk of rejection. This experiment yielded the same pattern of results as in Experiment 1: proposers with higher trust in their feelings made lower, less generous offers than proposers who trusted their feelings less. Compared to Experiment 1, proposers with higher trust in feelings lowered their offers more than did proposers with lower trust in their feelings. Thus, players with higher trust in their feelings strategically adjusted to the risk-free nature of the dictator game more strongly than players with lower trust in their feelings.

A possible explanation for the patterns of results in the first two experiments is that players with higher versus lower trust in their feelings might have substantively different perceptions of what constitutes a "fair" division. Experiment 3 tested this hypothesis and found that perceptions of the fairness of various divisions of the money pie did not differ across conditions. Players with high and low trust in their feelings exhibited similar perceptions of "fairness." Hence, differences in behaviors found in the first two experiments cannot be attributed to substantively different notions of "fairness." Instead, they are likely due to differences in how high-trust-in-feelings versus low-trust-in-feelings players think about and play the game.

The first three experiments focused on proposer behavior. Respondent behavior was examined in Experiment 4. Responders played the game twice, against different proposers, and were presented with a high offer and a low offer in successive rounds whose order was randomized. The results showed that responders with higher trust in their feelings were more likely to reject lower, "unfair" offers than responders with lower trust in their feelings, but equally likely to accept "fairer" offers. Players with higher trust in their feelings were more sensitive to lower offers than players with lower trust in their feelings, and would reject these lower offers even though rejection would "rationally" disadvantage them.

One explanation for the first four experiments' findings is that high trust in their feelings leads players to represent the game in a more *literal* fashion. This seems to manifest as a greater sensitivity to relative payoffs, with a distinct preference for outcomes that provide a relatively higher payoff to themselves at the expense of their opponent. Conversely, players who trust their feelings less and presumably rely more on logical, rational thought processes in playing the game tend to be less concerned with relative payoffs and more focused simply on receiving a nonzero payoff for themselves. To test this explanation, we conducted a fifth experiment in which responders were allowed to make a counteroffer. Adding this extra stage in the game resulted in a dramatic change in the proposers' behavior. Unlike in previous studies, proposers with higher trust in their feelings now made more generous offers than proposers with lower trust in their feelings, suggesting that trusting one's feeling alter how players mentally represent the game.

Finally, in terms of payoffs received, it was found that players with higher trust in their feelings did not do any worse—and in some studies in fact did better—than players with lower trust in their feelings. Trusting one's feelings and therefore incorporating affect-based information into these kinds of strategic decisions may thus be ecologically rational in that this strategy may result in higher long-term welfare for both parties.

# Understanding Collaboration and Collective Production: New Insights on Consumer Co-Production

Ashlee Humphreys, Northwestern University, USA

## SESSION OVERVIEW

The concept of co-production is central to marketing's new Service-Dominant Logic (Vargo and Lusch 2004), which has been attracting considerable recent attention from both academics and practitioners. A co-production perspective is one where "the customer becomes primarily an operant resource (coproducer) rather than an operand resource ('target') and can be involved in the entire value and service chain" (Vargo and Lusch 2004, p. 11). A better understanding of co-production activities is important not just because of recent growing interest in the phenomenon (Lusch and Vargo 2006), but also because such investigations are likely to contribute to our already extensive knowledge about how consumers interact with one another in the marketplace (e.g. Schouten and McAlexander 1995). Achieving this better understanding is the collective aim of the researchers contributing to this symposium proposal.

Across three studies, we focus on two distinct types of co-production, which have not yet been fully discussed and distinguished in the literature. The first type, which we call "collaboration," is the partnership of consumers with the company to co-produce a service (Meuter et al. 2005), a brand identity (Sherry 2006), or a product (von Hippel 2005). The second type, which we call "collective production," is the interaction between consumers to produce a brand community (Muniz and O'Guinn 2001), a narrative (Schau and Russell 2004), or product alterations (Schau and Muniz 2005), independent of company input and stewardship. Our session aims to investigate theoretical and practical issues associated with each of these types of co-production (collaboration and collective production) in order to better understand marketplace relationships (both consumer-to-consumer and consumer-to-organization), and their role in the marketing process.

Understanding more about collaboration and collective production is important for three reasons. First, co-production is becoming an increasingly visible phenomenon in the marketplace. As evidenced by consumer participation in recent Super Bowl advertisements, consumers are being more openly solicited for input into the development of marketing mix elements. And, in domains like Amazon.com and Youtube.com, the traditional consumer role has become blurred as it moves from a 'passive' receiver of value to an 'active' producer of value. Second, the analytical distinction between consumers and producers is foundational for orienting existing models of market exchange including pricing, cost structure, and division of rewards from intellectual property. What adjustments in our theories of consumer behavior are therefore required when the distinction between 'consumers' and 'producers' becomes blurred? Lastly, we know from previous research that consumers form communities around products (Muniz and Schau 2005), brands (Muniz and O'Guinn 2001), and media (Kozinets 2001), but we don't yet fully understand how this collective activity relates back to the company itself.

Three papers will explore co-production by examining collaboration and collective production. In an exploration of collective production, Andrea Hemetsberger will discuss the way in which open-source contributors negotiate and portray their roles as members of an entrepreneurial tribe. Johann Füller and Eric Von Hippel will present another study of collective production in which they examine joint innovation activities in a community of computer users and modifiers. Lastly, Ashlee Humphreys and Kent Grayson will use data from a collectively-produced online encyclopedia, to understand how conflict is managed in consumer collaboration and collective production activities. Following the paper presentations, a discussion will be led by Al Muniz, whose published work has already made significant contributions to the literature on consumer-consumer and consumer-organization relationships (Muniz and O'Guinn 2001, Muniz and Schau 2005).

This session contributes to our understanding of consumer behavior in three ways. First, by studying relatively new consumer-behavior contexts, we learn something about a novel mode of consumer-production and are able to better understand the type of value produced by this mode of consumption. Second, we enrich our understanding of company-consumer relations by moving from a dyadic model to a multi-nodal model that includes company-consumer, consumer-consumer, and company-community relationships. Finally, we gain a better understanding of the nature and direction of consumer activity, including collaboration, dissent, and production processes.

## EXTENDED ABSTRACTS

### "Between Idealism and Realism: Negotiating the Entrepreneurial Role of the Free and Open-source Movement in Contemporary Economy"

*Andrea Hemetsberger, University of Innsbruck*

From a consumer research perspective, we can approach the networked information environment as a collective form of consumer creativity, which is transpiring through interactions of networks of consumers as they communicate, share community and forge culture. Consumers are creative human actors in various consumptionscapes (Ger and Belk 1996). Yet, consumer creativity goes far beyond that. The changes in technology, economic organization, and social practices have resulted in remarkable new forms of co-production, such as the collective production of software. This is the case of free and open-source software (F/OSS). Together, consumers are creating sophisticated software–the outcome of an aggregation of collective expertise that is difficult to match elsewhere (Bagozzi and Dholakia 2002; Cova, Kozinets and Shakar, 2007). Consumers/users/co-producers passionately engage in programming, freely share their work with online friends, and build up successful businesses with free and open-source software.

This research examines the discourse of the F/OSS community, and carves out the ambivalent nature of their emerging entrepreneurial identity. It shows how co-producing tribes on the Internet negotiate, resolve, and restate contradictory motivations and tensions that arise from their common practice as successful entrepreneurs. It also contributes to our burgeoning understanding of online tribes and their role as "productive" communities. Finally, this presentation contributes to the current postmodern discussion concerning the spheres of production, consumption, and entrepreneurship.

In this symposium session I will report on an interpretive study, using public discourse data from the main newsforum of the F/OSS movement, covering the years 2000 to 2006. 10 to 15 stories are posted daily, which produce up to 5,700 replies. Posted stories with relevant topics and replies above a critical threshold of 600 to

1000 were selected. I used a grounded theory approach (Goulding, 2002) and analyzed the data for emergent themes.

I separated out four important quadrants of identity discourse. The first quadrant comprises Utopian romantic discourse which connects early altruist, gift-giving and helping behavior narratives, accompanied by discourse about highly passionate work. A second quadrant encompasses strong notions of freedom and libertarian values, resulting from a countercultural, emancipatory striving. These two quadrants reflect the political-ideological motivations for the collaborative practices among the members of the F/OSS movement. Originally thought of as a revolutionary movement, instances of political-ideological discourse are geared towards radical distinction from work in capitalist enterprises. The other two quadrants are characterized by their realist undertone. One of them is ultimately pragmatic. Pragmatic discourse is oriented towards action, emphasizes the power of factuality and 'the power of the doer'. It advocates collaboration and free sharing as the origin of collective expertise and wealth. While political-ideological discourse is directed against capitalist working practices, the goal of realists is to produce excellent software. As long as this goal is achieved, action is considered moral. Realist skeptical discourse–the fourth quadrant–challenges naïve romantic and overly pragmatic action as well. It is characterized by careful attempts to impede co-optation and hostile takeovers of free and open-source businesses by the established industry. Realist discourse enables the Collective to think and act entrepreneurial, political-ideological discourse is "the guardian of the moral conscience".

By dissociating entrepreneurial action from the domain of "the entrepreneur" as a social institution, the findings contribute to the current discussion about the producing and entrepreneurial consumer. The findings suggest that participatory cultures like the F/OSS movement are as entrepreneurial in their thinking and acting as they are romantic and activist. Contrary to countercultural movements, entrepreneurial tribes contain a multitude of stances, are pluralistic and heterogeneous; they are no amorphous masses (Cova, Kozinets and Shankar, 2007). This produces contradictions and tensions, which seem to be vital for continued identity search and meaning construction of entrepreneurial consumer endeavors. In contrast to co-optation theoretical claims, online participatory cultures like the F/OSS community sustainably pursue their radically different production and business practices through their openness to multiple stances. Their entrepreneurial common practices provide new and empowering opportunities to define the social identity of consumers: not through consumption but through contributing to a collective, productive effort. Yet consumers' entrepreneurial identity is still ambivalent; struggling to become the moral collective entrepreneur uniting idealism and realism.

### "Innovation Creation in Online Consumer Communities– How Computer Tuners jointly Develop New Products"

*Johann Füller, University of Innsbruck*
*Eric Von Hippel, Massachusetts Institute of Technology*

While existing studies demonstrate the high quality of user innovations and give insight in the characteristics and motivations of innovative users (Hemetsberger, 2001; Lakhani & von Hippel, 2003; Shah, 2006; Von Krogh & Von Hippel, 2006), little is known about differences in consumers' innovation activities in dependence on their motivation. This paper investigates joint innovation creation activities in computer case modding and overclocking communities. It especially explores the impact of community members' motivations on their specific innovation behavior and innovation focus.

Similar to hot-rodders who customize car bodies, PC "modders" or "tuners" individualize their computers. Case modding primarily deals with changes of the design. Overclocking tries to force computer components to run at higher clock rate and thereby increase the levels of performance. The field of computer tuning was chosen for several reasons. First, computer tuners often meet in online communities dedicated to innovation activities. Second, creative and technically skilled users can be found in online computer tuning communities. Third, computer tuners do not only generate and discuss ideas but indeed build their own computers according to their specific needs. Fourth, case modding and overclocking present important market segments of consumer goods, both in terms of volume and innovation lead markets. Almost all gaming computers cases are modded. Designs for high performance hardware and new cooling systems are often initiated by overclockers.

Multiple research methods have been applied to shed light on the innovative behavior of computer tuning communities such as www.extremeovercloking.com and www.casemodder.de. Netnography (Kozinets 2002) served as starting point to get an understanding of the research field, identify interesting community members, and analyze their behaviors. Interviews provided an even deeper understanding and portrayed who those innovators are. Videography (Belk & Kozinets 2005) helped to capture richer insights: emotions, gestures, and impressions of computer tuning; valuable for a deep understanding. Finally, an online survey was used to quantitatively test our derived hypothesis regarding the relation between motives, innovation activities, and the type of created innovations.

Our findings reveal that computer tuners come up with creative solutions and tend to be very skilled. While the desire for unique solutions, need for better computers, and the fun derived from the modding activity itself seem to be the primary motives for case modders, overclockers either aim for more performance necessary to better run extensive software applications or to compete with others and set new benchmarking records. Like case modders, overclockers really love what they do and spend loads of time and money for their hobby. Besides of the utility gained from their self-created solutions and the fun derived from the creative act of building, community aspects like sharing experiences and know-how with others, striving for pride and recognition present further important aspects of computer tuners' motivations. For some community members, computer tuning is not just a hobby, but a philosophy which drives their everyday life.

Depending on the motives, computer tuners behaviors and kind of innovations seem to differ. Competition oriented computer tuners for example tend to innovate more extreme solutions often lacking practical applicability e.g. because of short durability and complex handling. While competition oriented computer tuners look for help and suggestions to improve their records in communities, they tend to keep their ideas private until they take part at a tournament. For computer tuners paying more attention to social aspects, developing a new computer is less important than getting involved in community related activities. Often, they fill a moderator or administrator position in the community.

Another interesting aspect encountered in our analysis is that motives and preferred innovation activities of community members seem to change over time. While personal need for a better computer may often be the initial reason to get into computer tuning, the feeling of mastering becomes more important after a while. Afterwards, some computer tuners become more interested in competitions while others engage in community activities around computer

tuning. Finally, most experienced and known members often become community champions who hold the group together and stimulate development of the domain.

First, our results challenge the predominant view of passive consumers. They show that consumers become active and produce their own products. Consumers become producers and execute tasks in their leisure time previously considered as work. Hence, the existing definition of consumers and producers becomes obsolete. Second, motives why consumers engage in collaborative innovation activities go beyond typical values encountered in economic and consumer theory. Hence, motives that affect consumers' way of life's may be more complex than so far reflected in theory. Third, collective collaboration seems to be a complex phenomenon allowing consumers to develop in different directions, taking on different roles, and contributing to different activities depending on their motivations. Little is known about consumers' careers as co-creator. With our findings we hope to contribute to a better understanding of the emerging phenomenon of community collaboration.

### "He Said, She Said: Managing Dissent in Co-Production"

*Ashlee Humphreys, Northwestern University*
*Kent Grayson, Northwestern University*

The notion that firms gain competitive advantage by engaging customers in co-production can invoke images of producers and consumers happily cooperating. However, community interactions also inevitably involve discord. And, while previous research has noted that disputes can occur among consumers within the same community (e.g., Kates 2002; Kozinets 2001) or between producers and consumers (e.g., Kozinets and Handelman 2004), less attention has been given to the systems that consumer communities develop for handling these disputes and the strategies that individual consumers use for winning them. That is the focus of our research. We seek to understand how disputes among consumers can be managed in a way that maximizes the benefits of consumer collaboration and collective production.

To develop this understanding, we focus on disputes that occur among the consumer/producers of Wikipedia, an open-source online encyclopedia. Wikipedia offers two important advantages for our research. First, the Wikipedia community has developed specific guidelines for handling conflict, which provides uniquely tangible evidence for our study. Second, most disputes on Wikipedia are part of the public record, which offers an extensive and comprehensive population of disputes for us to sample.

We analyzed two data sets from Wikipedia.com. The first consisted of 100 Wikipedia articles (and their accompanying discussions) randomly chosen from all Wikipedia articles. The second consisted of 100 articles (and discussions) randomly chosen from a set of 1111 "core" topics on Wikipedia. Articles, discussions, and revision histories were all read and open-coded for common themes and strategies.

In line with previous research on disputes in the social construction of knowledge (Fuchs and Ward 1994; Owen-Smith 2001; Rosental 2003; Tuchman 1972), we find that the very same tactics used to assert claims can be inverted and used as tactics to contest or undermine claims. Extending previous research, we identify six tactics that are used this way. When consumers *(de)objectify* a claim, they focus on whether a statement is appropriately supported by expert or secondary sources (Tuchman 1972). When they *(de)rationalize* a claim, they focus on whether the claim meets the rules of logic or follows common sense (Tuchman 1972). *(De)proceduralizing* a claim, involves a focus on whether formal or informal procedures were followed in making or disputing the claim (Daston 1992; Porter 1995). *(De)structuring* a claim involves

addressing whether the formatting or presentation meets formal or informal expectations (Fuchs and Ward 1994; Tuchman 1972). When consumers *(de)reputationalize* a claim, they focus on whether the claimant has knowledge or biases relevant to the claim (Fuchs and Ward 1994; Tuchman 1972). When they *(de)assert* a claim, they address whether a claim is so undisputed that it does not need any tactics to reinforce it. And, when they *(de)enforce* a claim, they take a unilateral action against another claimant such as classifying certain claims as irrelevant or deleting claims altogether (Fine 1996).

We further extend previous research by providing insight regarding the power implications of each of these tactics. We group the above tactics according to whether they invoke power by referring to consensus [(de)objectifying, (de)rationalizing], to accepted rules [(de)proceduralizing, (de)structuring], or to the claimant [(de)reputationalizing, (de)asserting, (de)enforcing]. We find that gaining power by consensus and reference to accepted rules are the two most common strategies, but that references to the claimant are both more influential and more detrimental to the collaborative process. Tactics such as (de)enforcing, for example, work by defining the 'field' of a topic and thus influence what can and cannot be legitimately said about the topic, and limit the ability of other users to make contributions (Foucault 1977). Our research points to the importance of providing consumers engaged in collective production with approaches for handling conflict that may enhance the collaborative process. We also draw attention to the fact that consumer community discourse is not always harmonious and that power in these communities is often heterogeneous.

# Commercial Mythology and the Global Organization of Consumption

Eric Arnould, University of Wyoming, USA

### SESSION OVERVIEW

How does commercially-mediated mythology organize the frameworks in which consumer choices unfold? Can its influence be measured? This session aims to develop answers to these theoretical questions rendered compelling by "the proliferation of the imaginary made possible by the new" global media- and brandscapes (Savage, Bagnall and Longhurst 2005). Why myth? Myth offers a way of studying cross-cultural consumption that is consistent with CCT's distributed view of culture (Arnould and Thompson 2005). Further, ethnologists have long recognized that myth is a distributed cultural phenomenon not coterminous with geography or society (Leach 1967; 1970); and, there is some evidence of this in consumer culture (Brannen 1992). And finally although Barthes' (1970/1957) explicitly theorized the significant ordering role of myth in consumer culture, scholars have not tapped his insights to explain how myth may organize consumption on a global scale.

This symposium session delivers on the theme of spanning and bridging. The authors deploy qualitative and quantitative methodologies and theoretical orientations, representing diverse scientific traditions in consumer research to the substantive topic of consumer mythology and market outcomes. Mythology is shown to be a non-reductionist way to operationalize cross-cultural research. Mythology is shown to transcend the brand context. Still its impact on brand involvement can be measured. The session should be of interest to those scholars interested in branding, cross-cultural research, consumption meanings, and multi-method research.

What is commercially mediated mythology? It is harnessing myth to commercial purposes via the marketplace. Previous work on consumer mythology (Holt and Thompson 2004; Thompson 2004; has not always provided clear definitions of commercial myth or has used the term rather more fluidly than desirable. Thus, one purpose of this session is to contribute to the conceptual development of this construct. In general, myth may be qualified in terms of the following characteristics (Georges 1968; Leach 1967; Lewi 2003; Stern 1995):

1. A myth is a foundational story or system of related stories perceived to be age-old. Myth imposes sense and order on experience and is believed to encode time-proved verities. Actors in mythic stories face cosmic or epic challenges such as the tales of Gilgamesh, the story of Job, or the very human Jesus in *The Passion of the Christ*.
2. Myths are anonymous, shared, and to survive must be continuously re-appropriated by a social group, as in the recycling of Cinderella tales through many successful American films, e.g., *Princess Diaries*, *Ella Enchanted*, and *Maid in Manhattan*, or in the Chanel myth among fashion subculture insiders (Lewi 2003).
3. Myths integrate social groups by proposing meaning for social life and outlining appropriate modes of conduct. Myth helps people understand their place in society, as in utopian myth (Kozinets 2001), dystopian myths (Kozinets 1997), or gnostic myth (Thompson 2004).
4. People think myths compelling and "believable;" in some sense, "it could happen."
5. The heroes who populate myths tend to be monotypic, shorn of psychological complexity and nuance. They

incarnate powerful forces. Archetypes such as the man-with-no-name in Clint Eastwood's classic westerns or even James Bond fascinate us because they are absolute.
6. Myths are dynamized by compelling binaries: good-evil, high-low, nature-culture, life-death, day-night, science-nature, and so on. The male-female binary, for example is central to the mythology of Goth consumer sub-culture (Goulding, et al. 2004).

A small stream of influential research and practitioner targeted texts have tapped into the ways in which brands become mythical resources and the impact of such brands on consumer behavior and other marketing outcomes (Atkin 2004; Lewi 2003; Vincent 2002). The most thoroughgoing treatment in English is Holt (2003a). Holt outlines a general theory of brand iconicity in which brands are viewed as exemplifying classic mythic characteristics (although points 4 & 5 are not so germane to his analysis). Moreover, iconic brands, rather like totemic objects (Leach 1967) render myths more accessible, more easily appropriated, and these facts together help to explain iconic brands marketplace success. However, the myths iconic brands resolve are existential contradictions people feel between their own lived experience and society's prevailing ideologies, rather than classic mythic binaries. Perhaps more central to our session is Holt's contention that brands compete in what he calls "myth markets:"

> "a myth market is as an implicit *national* conversation in which a wide variety of cultural products compete to provide the most compelling myth. The topic of the conversation is the national ideology, and it is taken up by many contenders" (Holt 2003b, 44, emphasis added).

In contrast, in addition to clarifying the nature of global consumer myth, the second contribution of this session is to argue that myth markets play a significant role in organizing and structuring the choice-making work of consumers that transcends the brand context (paper by Pauline and Cele). Our third and final contribution (papers by Yuliya et al. and Søren and Dannie) is to argue that some myth markets are transnational globalscaping phenomena, constituent of global commercial ideoscapes (Appadurai 1990; see Tissiers-Desbords and Arnould 2005's work on beauty products in France), and thus transcend the national context central to Thompson (2004) and Holt's work (2003b).) Thus in this session we seek to build insights to extend mythic analysis of the type pioneered by Thompson (2004) and Holt and Thompson (2004) globally.

The paper by Pauline and Cele on the British Royal Family (BRF) myth explores how myth is produced and kept relevant in contemporary consumer societies, by looking at how producers shape consumers' experiences of the British Royal Family (BRF) brand. The authors' paper also illustrates the ways in which mediatized and commercialized places and events simultaneously fuel a secular myth market via particular narrative elements, and a trade in BRF merchandise and BRF sanctioned goods and services. The paper by Søren and Dannie examines one of the most fundamental myths of contemporary consumer culture, the myth of the self-actualizing consumer. The authors unpack the origins and dimensions of this mythic construct as a central organizing dynamic in consumer culture. If the paper by Pauline, Cele and Eileen focus

on the production of global mythology, and that of Søren and Dannie dimensionalizes one of consumer culture's foundational myths, the paper by Yuliya, Robin and Linda focus a S.E.M-based assessment of the impact of a global brand myth as a central tool for self-actualizing consumer identity projects and brand involvement. Eric Arnould leads a discussion of the further potential for deploying the myth construct in explaining global consumer trends and outcomes.

## EXTENDED ABSTRACTS

### "Maintaining the Myth of the Monarchy: How Producers Shape Consumers' Experiences of the British Royal Family"
*Pauline Maclaran, Keele University*
*Cele Otnes, University of Illinois*
*Eileen Fischer, York University*

The myth of the monarchy around the globe often begins in childhood, with fairy stories of magnificent castles peopled with wealthy kings and queens, Prince Charmings and Sleeping Beauties. These archetypal figures are deeply rooted in our psyches, shrouded in mystery and allure, and fuelling our imaginations. Indeed, within marketing, we can offer no higher accolade than to acknowledge the customer as "king", the notion of the "sovereign" consumer.

In this paper, we explore how the myth of the actual monarchy is kept alive and relevant in contemporary consumer societies, by looking at how producers shape consumers' experiences of the British Royal Family (BRF) brand. Our rationale for conceptualizing the BRF as a brand stems from Balmer, Greyser, and Urde's (2004) argument that the monarchy should not be regarded solely as a political institution, but is conceptually comparable to a corporate brand that offers consumers tangible benefits. These include providing consumers with a respected and shared symbol of nationalism, helping them engage in national "togetherness", and fostering a sense of identity based on a shared history, culture, and traditions. Moreover, conceptualizing the BRF among all extant monarchies is especially appropriate, because although it no longer plays any real political role in the United Kingdom, 53 countries still claim allegiance to the British Commonwealth (wikipedia.org, 2006). Furthermore, many manufacturers in a plethora of industries (e.g., tourism, film, publishing, china and ceramics) produce goods, services and experiences specifically designed to enhance consumers' knowledge and enjoyment of the BRF, and depend on consumers' interaction with the BRF brand to remain viable businesses. "By Special Appointment to HRH" is a much sought-after endorsement that gives a product or service perceived "sovereignty" within its particular category.

In 2005, we conducted depth interviews with retailers of memorabilia (who were interviewed multiple times), editors of newspaper columns and magazines devoted to royalty, and curators of royal palaces (a total of eight informants). Interviews focused on how and why these producers believed the myth of the monarchy was so compelling to consumers, and their roles in supporting and encouraging the co-creation of meanings around goods, services and experiences related to the BRF. Our axial coding and pattern recognition of the text resulted in our identification and interpretation of five key themes in the experiences that they create for consumers around the BRF brand, as they engage in maintaining and, in some instances, modify, the myth of the monarchy. These are:

### 1) Storying the Monarchy: Telling Tales of People

In making royal attractions (i.e. palaces and other venues associated with the monarch) accessible to the public, the emphasis is on the use of narrative to build a relationship with consumers and give them co-ownership of the myth. Royal buildings become repositories for stories about the relationship between monarchs and their people, the various tensions therein, and how, together, they have shaped society. A recent exhibition in the Tower of London, "Gunpowder Treason", tells the story of Guy Fawkes' plot to overthrow the king in 1605. The present BRF is seen as only one chapter in this story of the monarchy.

### 2) Keeping History Alive: Creating Links between Past and Present

This use of narrative that according to Vincent (2002. p. 19), "connects the consumer and the brand in a kind of existential bond", concentrates on bridging the past and present, juxtaposing the old with the new (Brian May playing "God Save the Queen" at the Queen's Golden Jubilee celebrations), and making it relevant for today's consumers (Guy Fawkes as the first terrorist). This helps the myth of the monarchy to remain timeless.

### 3) Event Management: Pomp and Pageantry

Keeping royal rituals alive and, in some cases, inventing new ones is importani (Billig 1992). The public celebrations that surround these events-coronations, silver and golden jubilees, birthdays, anniversaries, and marriages-present perfect opportunities to create commemorative collections and other types of memorabilia that re-enchant consumers. Like "brandfests" (McAlexander et al. 2002), these events not only offer consumers experiences that reconnect them to the core values and traditions of the monarchy, but also allow their own personal stories to interweave with those of the BRF brand.

### 4) The Role of Place: Creating a Persona for Each Palace

The creation of a unique sense of place for each of the royal symbolizes the monarch's extraordinary wealth, but also evokes different facets of the myth of the monarchy: the Tower of London is powerful, intriguing, ancient; Hampton Court is majestic, romantic, and flamboyant; the Banqueting House is dramatic, exuberant, and revolutionary; Kensington Palace is feminine, fashionable, and stylish; and Kew is intimate, domestic, and intense. These personae provide the backdrops against which various embedded stories are played out.

### 5) Creation and Sustainability of Sub-Myths

The media-centered nature of much of the storytelling aspects around the BRF often creates sub-myths, as in the case of Diana, Princess of Wales, a mythic figure in her own right with a mythic sub-text of "The Cinderella Princess". Now new sub-myths are starting to grow around her sons, Princes William and Harry. In these ways the myth of the monarchy remains a never-ending story, a still unfolding mystery.

In these various ways, producers together build the BRF brand narrative (Holt 2004), thereby re-circulating and up-dating the myth of the monarchy for contemporary consumers. According to Holt (2004), brand myths resolve key societal tensions at particular periods in history. Perhaps the real lure of the monarchy for today's consumer, confronted by the "tyranny of choice" (Schwartz 2004), is actually in the *lack* of choice that this concept offers. One does not choose a monarchy; its legitimacy is conferred from above (the divine), rather than from below (the people) (Fitzgerald 2007). Thus, despite existing within a largely secular society, producers of the BRF experience represent and reinforce the monarchy's quasi-sacred properties and mythic potential.

### "The Global Myth of "Me": Self-Actualization and Identity Practices in the Contemporary Global Consumptionscape"

*Søren Askegaard, Southern Denmark University*
*Dannie Kjeldgaard, Southern Denmark University*

This paper takes its point of departure in possibly one of the most fundamental myths of contemporary consumer culture, the myth of the self-actualizing consumer. The central narrative of this mythology is that the goal of human existence is, as formulated by Nietzsche (2005 [1888]) in *Ecce Homo* "to become what one is", through the unfolding of the true and natural self via self-actualizing activities and therapies. In this way, the myth of self-actualization unites the two core marketplace mythologies, the Romantic and the Gnostic, suggested by Thompson (2004).

Part and parcel of the project of modernity is an accelerating process of individualization as rigid social structures disappear as frames for identity. The notion of the individual becomes an institutional feature of what it means to be (a) modern (consumer). The myth of self-actualization intensified and diffused on an increasingly global scale through the combination of the popularity of psychology and new-age orientation towards Eastern philosophical and religious practices among Western cultural movements of the 1960s and 70s. Paradoxically the focus on individual emancipation and self-realization of this ostensibly anti-capitalist movement fits the core ideology of consumer culture (Jackson Lears 1983)

The commercialization of the myth of self-actualization takes two forms: a general and a specific one. The general form is the way in which all kinds of references to the role of products, brands and consumption in consumers' self-enhancement and self-actualization is prevalent in modern commercial vernacular and form the mythological basis for one of the substantial research streams of consumer culture theory, termed "Consumer Identity Projects" (Arnould and Thompson 2005). The specific form, on which we will focus here, is the huge and growing self-actualization industry communicated through self-help books, courses, coaching, personal branding etc. and, increasingly, through life style programming on TV. This could also be called the marketplace mythology (Thompson 2004) of self-actualization, a particular commercial rendition of modern regimes of self governance (Belk, Ger and Askegaard 2003).

Why do we talk about self-actualization as a myth? Because the self-actualizing industries' discourse often evokes the heroic monadic self that is trying to liberate itself from Society's constraining social norms and expectations (see elements 3,5 and 6 above). Self-actualization is thus linked to a Rousseau inspired anthropocentrism of unspoiled, immediate natural state of being as against unnatural technologized society. Of course, the modern idea of the individual is not an a-historical concept (Dumont 1980). But the basic function of the myth in society is exactly to naturalize that which is culturally instituted, thereby legitimizing it and providing it with a status of profound truth (Barthes 1970/1957). When the ancient Greeks proclaimed *Gnothi seauton* (know thyself), they did not advocate a modern concept of self-actualization but reminded the people that they should reflect on their own place in the world in relation to the Gods and the social order. Thanks to the myth of self-actualization, we understand this credo very differently.

The myth of consumer self-actualization is part of modern management paradigms and global capitalism's quest for a flexible work-force and the constant self-development of the individual as an attractive employee in a post-industrial economy. The generalized myth of self-actualization is thus found in the sphere of production as well as in the sphere of consumption. The consequence of this is a myth and identity script which promotes the idea of an unfinished self (Bauman 2004). In the myth of self-actualization the subject stands in an instrumental relation to the self-identity both in the role of employee, consumer and, one might hypothesize in the intimate sphere of family-making and procreation.

One may argue that humanistic psychology with its focus on self-actualization in the tradition of Maslow (1954) and Rogers (1961), has developed into the most prevalent popular psychology and, thus, a cornerstone of a modern lifestyle (Smith 1997). According to Brinkmann (2005), there are three major consequences of this humanistic ethic: hypostasis, therapeutization, and subjectivization. *Hypostasis* indicates that the self becomes conceived in material terms as a resource or a commodity, an object for consumption as in working with one's self through a mind- and body regimes: controlling one's caloric intake and one's exercise level or managing one's fashionability in terms of clothes, shoes, hair and make-up. *Therapeutization* refers to the degree to which life becomes a therapeutic project and is linked to consumer culture in the general idea that products and brands are there to help the consumer cope, to solve problems occurring in daily social life. *Subjectivization* is indicative of a tendency to consider moral values as inner and private rather than externally given and is reflected in the philosophy that "the customer is always right", that the ultimate judgment of the appropriate character of some kind of solution rests on the acceptance of the user/customer/client.

We will illustrate the global character of the myth of self-actualization with an example from Nepal. The example is based on a set of depth interviews with Nepalese yoga institute owners as well as yoga practitioners in Kathmandu. Furthermore, secondary data was collected in the form of advertisements for yoga institutes and magazine and newspaper articles about the local yoga market. The modernization of the Nepalese middle classes led to a sharp decrease in yoga practice since it was associated with archaic (non-modern) religious cultural practice. Today, the meaning of yoga in the context of Nepalese middle class youth is changing from a religious to a secular one. The practice of yoga is gaining renewed popularity among the Nepalese youth as a symbol of modernity, endorsed by Western celebrity yoga practitioners such as Sting and Madonna. Yoga classes are now found in the urban health and fitness centres where they are positioned and marketed as a way for the self-actualizing consumer to live a life of physical and mental health and balance not as a lived practice of a pre-modern local culture but as part of the myth of what it means to be a modern consumer.

### "Buying into the Global Myth: A Cross-National Investigation of Building Identity Through Brands"

*Yuliya Strizhakova, Suffolk University*
*Robin Coulter, University of Connecticut*
*Linda Price, University of Arizona*

According to Holt, Quelch, and Taylor (2004), consumers look to global brands to create an "imagined global identity," a transnational "global myth" of belonging anchored in consumer culture. A premise of this research is that branded products are a preeminent source of mythic and symbolic resources for consumer identity projects (Arnould and Thompson 2005; Holt 2002; 2004). In prior research, we questioned the premise that branded products are omnipresent resources for consumer identity through an examination of consumers in Hungary and Romania. We found consumers' involvement with branded products is framed by their ideological positions about consumer culture, and varied, nuanced, and socio-historically situated (Coulter, Price, and Feick 2003).

In our present research, we examine whether and how a transnational global brand myth drives consumer involvement with branded products among youth in the U.S. and Romania. Our

research in these two countries enables us to compare the ideological buy-in to consumer culture between young American consumers and Romanian consumers who recently have witnessed an explosion of branded products touted as tools of personal identity actualization. We are particularly interested in: 1) whether a belief in the global brand myth fuels the use of branded products as central tools for identity projects, and 2) whether branded products serving as tools for identity drive involvement with branded products. Our research also assesses other relevant variables that might contribute to involvement with branded products (Coulter et al. 2003). Our present work is grounded in depth interviews with young people in Romania and the U.S., but in this abstract we restrict attention to the results of survey responses of 218 American ($M_{age}$=21.01, $SD_{age}$=1.74) and 287 ($M_{age}$=19.93, $SD_{age}$=1.25) Romanian young adults.

Based upon our depth interviews, extant literature, and initial brainstorming related to content and translation issues, we developed multi-item 7-point scale measures of our constructs of interest. Items were translated from English into Romanian and then back-translated by two native Romanian speakers. We assessed global myth using three items: "Buying global brands make me feel like a citizen of the world," "Purchasing global brands makes me feel part of something bigger," and "Buying global brands give me a sense of belonging to the global marketplace" ($\alpha_{US}$=.86; $\alpha_{RO}$=.82; Holt et al. 2004). To measure consumers' use of branded products as expressions of personal identity, we developed five items each to assess self-identity, group-identity, and status. The second-order latent factor measurement model of personal identity resulted in an acceptable fit ($\chi^2$/$df$ ratio=2.24, CFI=.95, TLI =.94, RMSEA<.05, Hoelter=268 at $p$=.05), with factor loadings ranging from .86 to .98 for the countries, and indicative of configural invariance; the model exhibited full metric and partial scalar invariance (Steenkamp and Baumgartner 1998). The reliabilities for the 15-item scales were: $\alpha_{US}$=.94 and $\alpha_{RO}$=.92. Consumer ethnocentrism was measured using six items ($\alpha_{US}$=.88; $\alpha_{RO}$=.79; Klein, Ettenson, and Morris 1998; Shimp and Sharma 1987); cultural openness was measured using four items ($\alpha_{US}$=.90; $\alpha_{RO}$=.81; Sharma, Shimp and Shin 1995), and country-of-origin was measured using four items ($\alpha_{US}$=.92; $\alpha_{RO}$=.90). All scales exhibited configural, metric and scalar invariance. In addition, we computed a measure of involvement with branded products as an average of a respondent's answers about the importance of a brand name related to ten durable and non-durable products (such as, soda, chocolates, personal care items, automobiles, and TVs.)

Our measurement model yielded an acceptable fit: $\chi^2$/$df$ ratio=1.72, CFI=.92, TLI =.91, RMSEA<.04, Hoelter=316 at $p$=.05, and exhibited configural, metric, and scalar invariance. Our across-country z-test comparisons of latent means indicated that Romania had significantly higher means ($p$<.05) for global openness ($M$=5.46; $M$=4.83), country-of-origin ($M$=3.51; $M$=2.63), and involvement with branded products ($M$=5.44; $M$=4.99), whereas the U.S. had a significantly higher mean for using branded products to reflect personal identity ($M$=3.70; $M$=3.10). Strikingly, there were no significant differences between the two countries on ethnocentrism ($M_{US}$=2.53; $M_{RO}$=2.36) and global myth ($M_{US}$=3.41; $M_{RO}$=3.13).

In both the U.S. and Romania, global myth predicts the use of branded products to communicate personal identity, which in turn, predicts involvement with branded products. Additionally, across the data sets, ethnocentrism and cultural openness predict the extent to which consumers make brand choices based on their country-of-origin, and women reflect more cultural openness than men. But, the structural models differ in some respects. More complex paths between antecedent and dependent measures are present in the US

model than in the Romanian one. In the U.S., cultural openness has a stronger effect than ethnocentrism on global myth, and ethnocentrism also impacts the use of branded products to reflect personal identity. In Romania, concern for a brand's country-of-origin has a direct effect not only on personal identity, but also involvement with branded products. In our presentation we detail the implications of these findings and directions for future research.

# Consumption, Health, and Consumer Wellbeing
Jason Riis, New York University, USA

## SESSION OVERVIEW

Economic theory and common lay intuition both tell us that as consumers get more of the things that they want, their quality of life and subjective well-being will improve. But this straightforward assumption is not consistently supported by empirical research. For example, people in developing countries are much wealthier today than they were 60 years ago, but there is little evidence that they are happier (Easterlin 2003). And several studies have suggested that the impact of health on happiness is surprisingly small (Riis et al 2005). One highly cited study of identical twins concluded that life circumstances account for just 10% of the variance in happiness between people, but that genetically determined personality accounts for 50% or more (Lykken and Tellegen 1996). If that is really the case, then the prospects of achieving happiness through consumption are extremely limited. As biotechnology continues to advance rapidly, many scientists expect that pharmacological options for directly improving well-being will become safer and much more effective (Hughes 2003, NeuroInsights 2006). If genetic disposition, and not consumption and health, is what drives happiness, then such pharmaceuticals may be very appealing to broad consumer segments.

The papers in this symposium will examine these issues. Both Hsee and Irwin and colleagues look at specific kinds of wealth and consumption and their differential effects on well-being. Loewenstein and colleagues examine the effects of poor health on happiness and demonstrate an important limitation to adaptation. Riis and colleagues examine consumer demand for the pharmacological improvement of well-being.

In the first paper, Hsee proposes that certain kinds of consumption experiences are more evaluable than others. Experiences that are inherently evaluable have the same influence on happiness whether experienced on their own, or when experienced in the presence of others who have slightly better or worse experiences. Such experiences directly influence one's visceral and biological system, so one's reaction to them is largely independent of social comparison. Experiences that do not directly influence the visceral and biological system are much more susceptible to social comparison. He demonstrates this in a lab study and in a large field study in China.

Irwin and colleagues also examine the effects of different kinds of consumption on happiness. They show two important moderators of previous findings that people get more lasting happiness following purchases of experiences than following purchases of durable goods. First, the effect is only found for purchases that turn out well. For disappointing purchases, the lingering bad feelings were at least as strong for experiences as for durables. Second, materialistic people tend to get just as much lasting happiness from durables as from experiences. The recommendation that consumers could improve their happiness by purchasing more experiences may thus only be true to the extent that experiences are successful, and to the extent that consumers are not materialistic.

Loewenstein and colleagues conducted a field study to investigate the mechanisms of adaptation to health conditions. They find that people adapt better to colostomies if they know that the procedure is permanent than if they know it to be temporary. The location of the patient's intestinal blockage, and not the severity of their condition is what determines the permanence of the procedure, so differences in adaptation between permanent and temporary patients are not likely due to selection effects or bias. The results thus strongly suggest that adaptation is not merely a function of continued exposure to a negative stimulus or circumstance. Rather, adaptation is very much dependent on the beliefs that a person has about the circumstance, and on the degree to which a person accepts the circumstance.

These three studies all suggest specific limitations of the effects of consumption and circumstance on people's happiness. In the final paper, Riis and colleagues consider how people view the possibility of directly improving their happiness through pharmaceuticals. In a series of studies they show that most people do indeed wish to be happier, more relaxed, and more outgoing. And they wish to be better at concentrating and at remembering information. But controlling for the desire to be better on these various traits, people are more reluctant to enhance their happiness (and other emotional and personality characteristics) than they are to enhance cognitive abilities like concentration and memory. Concerns about jeopardizing personal identity are the source of this increased reluctance. Furthermore, advertisements that frame a drug's effects as enabling happiness, rather than enhancing it, greatly diminish people's reluctance to take it.

Together the papers bring new knowledge to the very old concept of happiness. And with evidence from experiments, surveys, and field studies, they suggest very concrete implications for consumers, practitioners, managers, and policy makers interested in increasing happiness. The session will be of interest to researchers studying consumption, hedonic experience, materialism, well-being, consumer welfare, health, and pharmaceuticals.

## EXTENDED ABSTRACTS

### "Warmth, Wealth, and Wellbeing"
*Christopher Hsee, University of Chicago*

A fundamental question in happiness research is whether increasing every citizen's wealth in a given society increases the overall happiness of that society. Much research suggests that it does not (e.g., Easterlin 2003). In this project we sought to distinguish two types of outcomes: *Inherently evaluable* outcomes are those that directly influence one's visceral and biological system, such as temperature, sweetness, amount of sleep, etc. *Inherently inevaluable* outcomes are those that do not directly influence one's visceral or biological system, such as the size of a diamond, the brand of a purse. Many outcomes lie between the two; examples include the size of a home, the power of a car, the speed of a computer, etc. Our main hypothesis is that inherently evaluable variables can affect one's happiness regardless of whether one engages in social comparison (joint evaluation) or not (single evaluation), and inherently inevaluable variables can affect one's happiness only if one engages in social comparison (joint evaluation). This is tested in a lab experiment and a field study.

The lab experiment consisted of 4 groups of participants: A, B, C and D. Each participant went through 2 stages (in counterbalanced order). In stage I, each participant in each group was presented a container of water and indicated how happy they would feel if they took a shower using water of that temperature (an

evaluable variable). In stage II, each participant in each group was presented with a diamond and indicated how happy they would feel if they wore a diamond ring of that size (an inevaluable variable). Across Groups A, B, C and D, the temperatures of the water increased linearly from 15C to 45C, and the size of the diamond also increased linearly from about 0.1 karat to about 1 karat. Critically, Groups A and B were run in the same room so they could easily compare each other's water temperature and compare each other's diamond size. Likewise, Group C and D were also run in the same room. However, Groups A/B and Groups C/D were run separately. Thus, Groups A/B resembled a poor society (with smaller diamonds and colder temperatures), in which Group A were poor citizens and Group B were rich citizens. Group C/D resembled a rich society (with larger diamonds and warmer temperatures), in which Group C were poor citizens and Group D were rich citizens. The rich society and the poor society do not know each other, but citizens within each society can compare with each other.

What we predicted and found is as follows: Water has both a within-society effect and a between-society effect on happiness, namely, Group B (rich people in a poor society) were happier than Group A (poor people in a poor society), Group D (rich people in a rich society) were happier than Group C (poor people in a rich society), and on average, Groups C/D (people in a rich society) were happier than Groups A/B (people in a poor society). On the other hand, the diamond has only a within-society effect and has no between-society effect, namely, Group B (rich people in a poor society) were happier than Group A (poor people in a poor society), Group D (rich people in a rich society) were happier than Group C (poor people in a rich society), but on average, Groups C/D (people in a rich society) were not any happier than Groups A/B (people in a poor society). An implication of these findings is that whether increasing a society's wealth increases the society's happiness depends on how the wealth is spent. If it is spent on inherently evaluable variables, it may indeed increase happiness (contrary to much of previous research); if it is spent on inherently inevaluable variables, it will not.

A field study replicated the finding in the lab study. The field study involved nearly 7000 respondents across 31 largest cities in China. Among others, we asked respondents about their room temperature in their homes and their feeling about it (the survey was conducted in the winter and many homes in China do not have sufficient heating), and also asked about the estimated value of their jewelry and their feeling toward it. What we found is as follows: For temperature, the between-city effect on happiness was just as big as the within-city effect. But for jewelry value, between-city effect on happiness was much smaller than the within-city effect on happiness.

In sum, improving an inherently evaluable outcome, such as temperature, can make some individuals in a society happier than other individuals and can also make the whole society happier; improving an inherently inevaluable outcome, such as jewelry, can make some individuals in a society happier than other individuals, but cannot make the whole society happier.

### "Happiness for Sale: Do Experiential or Material Purchases Lead to More Consumer Happiness?"

*Julie Irwin, University of Texas, Austin*
*Joseph Goodman, University of Texas, Austin*
*Leonardo Nicolao, University of Texas, Austin*

Scitovsky (1976) suggested that income does not increase life satisfaction because consumers are spending their money in the wrong way. As they acquire more money, consumers often buy "joyless" material possessions such as houses and cars that do not substantially increase pleasure. More recent writers have echoed Scitovsky's sentiments. Easterlin (2003) suggests that investment in "pecuniary" market objects has no effect on life satisfaction, and Pine and Gilmore (1999) warn that consumers have become bored with the acquisition of objects. In "How Not to Buy Happiness" Frank (2004) explains, "beyond some point, across-the-board increases in spending on many types of material do not produce any lasting increment in subjective well-being." If the extant work on happiness is correct, then purchases of material goods (e.g., cars, houses, furniture) should, overall, lead to less happiness compared to purchases of experiential goods (e.g., vacations, concerts, sporting events). We call this the "experience recommendation". In this paper, we suggest that this experience recommendation may be premature, or at least too broad in scope.

In our first experiment, we tested whether material and experiential purchases are differentially affected by a purchase's outcome valence by extending the methodology used by van Boven and Gilovich (2003). In a 2x2 between subjects design, we asked respondents to recall a positive or negative purchase (outcome valence) that was either material or experiential in nature. After the recall stage, respondents indicated their happiness with the purchase across three measures and answered control questions. We find that the effect of purchase type was significantly moderated by the outcome valence of the purchase. For positive purchases, experiential purchases induced more reported happiness than did material purchases. However, if the purchase turned out negatively, experiential purchases did not lead to more happiness than material purchases. These results held above and beyond any effects of time since the purchase, the amount of the purchase, and the residual value of the purchase. A second experiment has shown that consumers can indeed distinguish between experiential and material purchases, validating our purchase type manipulation, and that they predict the same interaction found in the first experiment.

In a third experiment we asked if there segments of consumers who might glean different amounts of happiness from purchase types in our two valence conditions. We expected materialism to have a moderating effect on the valence by purchase type interaction. The underlying rationale is that, as materialism increases, the adaptation rates for material purchases (of either valence) should decrease; material purchases should resonate longer for materialistic consumers, impacting happiness more. Indeed, we find a three-way interaction between materialism, valence, and purchase type, such that the valence by purchase type interaction grows stronger as materialism decreases.

In a fourth study, we avoided concerns about possible accessibility differences between material and experiential purchases by simply asking participants to freely recall three different purchases that turned out positively (or negatively, depending on the condition) and then allowed the participant to rate each purchase on a material–experiential scale. In a hierarchical regression model, we regressed a composite happiness measure onto the three purchase classification ratings for each participant individually, and then regressed the purchase classification slopes derived from the first model onto the valence of the outcome condition, as well as the moderators. Our results support the interactions found in the previous studies. When the purchase turned out positively, more experiential purchases were associated with more happiness compared to material purchase, but when the purchase turned out negatively there was no difference. Consistent with experiment three, this was moderated by materialism.

These studies addressed the extent to which experiential purchases actually increase the happiness of consumers. Results across four studies affirm that experiential purchases have more

variance than material purchases: when they are good, they are very good; but when they are bad, they are awful. The simplest form of the "experience recommendation" is thus not supported.

### "The Dark Side of Hope: It's Harder to Adapt When the Adversity is Temporary"

*George Loewenstein, Carnegie Mellon University*
*Dylan Smith, University of Michigan*
*Aleksandra Jankovich, University of Michigan*
*Peter Ubel, University of Michigan*

After the onset of a negative life event, such as a disability, overall well-being typically declines, but then recovers over time (though not always fully). But relatively little is understood about the mechanism by which adaptation occurs. In addition, there is considerable individual variability in how well people adapt to challenging circumstances. We explored whether knowing that a disability may be temporary, rather than permanent, would influence adaptation. We studied colostomy patients, approximately half of whom eventually have their colostomies reversed, and normal bowel function restored. Whether someone gets a reversible colostomy depends mostly on anatomy (where the surgery was and how much intestine is lost).

Given that temporary colostomies are strongly preferred—virtually all patients who can get a colostomy reversed choose to do so, one might think that people with temporary colostomies would be happier and adapt more rapidly to their condition than those with permanent colostomies. Contrary to this prediction, however, we reasoned that, because patients with a temporary colostomy know their disability is of limited duration, this would interfere with their motivation and ability to emotionally adapt to their condition. We predicted that patients whose colostomies were permanent would adapt, increasing their subjective well-being (quality of life, life satisfaction) from the time of their surgery to the 6 month follow-up. In contrast, we predicted that the patients who expected to have their colostomies reversed would show less evidence of adaptation.

We conducted a longitudinal study of 75 new colostomy patients, recruited while still in the hospital after their surgery (82% response rate). Consenting participants were mailed written surveys at one week, 1 month, and 6 months after their surgery. About half of the patients had "reversible" colostomies; six to nine months after receiving a colostomy, they typically go back into surgery and have normal bowel function restored. The surveys focused mostly on measures of psychological well-being, and included measures of life satisfaction (1-7), and overall quality of life (0-10).

We observed strikingly different patterns between the temporary and permanent colostomy groups. In the permanent group, perceived life satisfaction and quality of life increased between the one-week and 6 month time points (p<.05). For example, scores on the 0-10 quality of life scale increased from 5.4 to 7.1 over this time period. In contrast, these variables actually decreased—though not significantly—in the temporary group (on the 0-10 scale, scores dropped form 5.5 to 5.3). A between-within subjects ANOVA confirmed a significant interaction between temporary versus permanent status and time (p<.05).

Patients who expected their colostomy to be temporary did not show evidence of adapting to their condition over the first 6 month period after their surgery. In contrast, patients who knew their new disability to be permanent showed substantial increases in well-being over time. These results are consistent with our hypothesis that knowing that a "cure" for a disability is on the horizon would interfere with adaptation.

These findings are not consistent with some models of adaptation—those that suggest that negative reactions fade with time

merely because of continued exposure to the negative stimulus. Both groups in our study had the same disability for the same period of time, yet the temporary group failed to adapt. We can speculate that this occurred because the knowledge of the pending surgical reversal would represent a salient counterfactual set of circumstances. That is, these patients would be reminded of what life is like with normal bowel function, and these reminders would make it more difficult to adapt (and perhaps reduce the motivation to try to accept the disability).

Previous studies have found that people with an optimistic outlook—those who expect their illness to improve with time—are happier than those who are less optimistic. But these results could be due to dispositional differences; people who adopt optimistic attitudes about their illness may be naturally happier and more resilient. In our study, patients do not choose to expect their colostomy to be reversed—this is determined exogenously. Our findings have implications for other health conditions, such as spinal cord injury, where patients may believe that medical science will cure their condition. Our results suggest that these beliefs could actually interfere with emotional adaptation.

### "Better Living Through Chemistry: Preferences for Pharmacological Self-Improvement"

*Jason Riis, New York University*
*Joseph Simmons, Yale University*
*Geoffrey Goodwin, Princeton University*

Advances in medical technology are providing people with increasingly powerful ways to improve themselves. These technologies are not just used to restore health and youth, as increasing numbers of healthy young people are using them as well. Many healthy young people take stimulants like Ritalin and Adderall to improve cognitive performance and anti-depressants to lift mood and reduce anxiety, even in the absence of any disorder or deficit.

The biotechnology boom has many scientists and clinicians optimistic that dramatic improvements in the effectiveness and safety of such pharmaceuticals are imminent. Such improvements will presumably lead to increased demand for these drugs among non-clinical populations. Concern about these developments has sparked considerable public debate, including the publication of a report by the President's Council on Bioethics (2003). But there is little research bearing directly on the psychology of consumer demand for such pharmaceuticals.

We suggest that people's willingness to take psychological enhancements will largely depend on beliefs about whether those enhancements will alter characteristics considered fundamental to the self. In Western cultures, the belief in a fundamental, essential self is widespread. People believe that certain core traits can explain much of a person's behavior and that these traits form a person's essential self or soul (Chen, Bourcher, and Tappis 2006; Dweck 1999; Haslam, Bastian, and Bissett 2004). Moreover, people are highly motivated to express beliefs about their fundamental selves (Vazire and Gosling 2004), and to reject information that challenges these beliefs (Swann 1987; Swann, Stein-Seroussi, and Giesler 1992). In this light, we propose that people will be especially reluctant to artificially enhance themselves in ways that are believed to alter their fundamental selves.

In three studies, we show that this is indeed the case. People are much less willing to enhance traits representing a fundamental aspect of their personal identity (including well-being traits like mood) than traits that are not seen as core to the self (e.g., ability to concentrate). This is the case even though people have strong desires to improve fundamental traits like mood. Further support for our fundamentalness hypothesis comes from a study in which

we explicitly asked people why they were reluctant to enhance each of a series of 19 traits. Concern about changing the fundamental self was the most frequently cited reason for not wanting to take a hypothetical enhancing medication. Concerns about morality or risk seem to play only a minor role in determining people's willingness to artificially enhance themselves.

We also address the implications of our findings for advertising and regulation. Direct-to-consumer (DTC) advertising of psychoactive pharmaceuticals has been controversial, with some authors suggesting that the pharmaceutical companies are actually reaching out to non-clinical populations with their advertisements (Healy, 2004). This is of particular concern in light of studies showing that non-clinical individuals can easily get prescriptions for drugs like anti-depressants (Kravitz et al., 2005). We aim to inform this debate by examining factors that influence people's responses to such advertisements.

In a fourth study, we presented participants with advertisements for a hypothetical pharmaceutical, Zeltor, which was said to affect either a high-fundamentalness trait (social comfort) or low-fundamentalness trait (ability to concentrate). The tag-line of the advertisement was also manipulated to frame the nature of the self-improvement in one of two ways. One framing emphasized that taking the drug would change people's core selves (i.e., Zeltor: Become More Than Who You Are). The other framing emphasized that taking the drug would enable people to realize their core selves (i.e., Zeltor: Become Who You Are). For high-fundamentalness traits, we found that the advertisements that used this "Become who you are" framing were more effective than advertisements that use the framing that emphasized a change to the self. Interestingly, this framing effect was not observed for low-fundamentalness traits.

This result suggests that advertisers can successfully disarm the fundamentalness concerns that would otherwise prevent non-clinical individuals from seeking an enhancement pharmaceutical. Paxil, an anti-depressant sold by Glaxo Smith Kline, has used the tagline, "Paxil gets you back to being you" on its website. This tagline can, appropriately, ease the concerns of clinically depressed and anxious individuals who are considering taking this potentially helpful medication. At the same time, our research suggests that it could also increase the inclination of non-clinical individuals to seek a prescription for self-improvement purposes. It is for regulators (as well as for industry and consumer welfare groups) to decide if anything should be done about this. It is our role as market researchers to inform their decisions by understanding the psychological mechanisms underlying consumer demand for this increasingly powerful and available product category.

# Consumption over Time: Predictions of Future Use and Value
Anastasiya Pocheptsova, Yale University, USA

## SESSION OVERVIEW

Most consumer choice research does not distinguish between options that provide single-time consumption versus a stream of consumption. Many real-life choices, ranging from durable products (furniture, appliances) to more frivolous ones (CDs, vacations) provide consumers with a stream of consumption utility that can last from a few days to a few years. In a seminal paper on the topic, Prelec and Loewenstein (1998) have shown the importance of understanding consumption as a stream of utility to better predict consumer choice and payment preferences. Conceptually, evaluation and preference for such products are influenced by expectation of use and value of the product on the multiple future consumption occasions. This raises several interesting questions that have been under-researched in the literature. If people are forward-looking when it comes to extended consumption is their choice influenced by, for example, value of time now and in the future? How do consumers approach decisions that involve long-term vs. short-term consumption (e.g., buying vs. renting)? How does the expectation of leftover unused utility affect preferences? The topics examined in this session bridge research on time consumption and emerging research in the domain of extended consumption to better understand consumer decision making.

The papers in this session study three important research questions. First, Okada examines how people value time in the present and in the future. This paper shows that consumers' predictions of use and value of time in the future are ambiguous and hence lead to larger discrepancies in WTP and WTA for future as compared to current consumption of time. Next, Bolton and Alba examine consumption of products and the effects of unused utility or waste on consumer decision making. In a series of studies the authors find that consumers are less likely to accept and are less satisfied with products if they anticipate unused utility. This forward-looking waste aversion has consequences for bundling and competition among goods and services. Finally, Pocheptsova et al. compare the consequence of different consumer decision strategies for renting vs. buying products with a flexible stream of consumption. This paper shows that long-term use of a product leads to different decision mindset as compared to a temporary use of a product. As a result consumers choose to rent a product that they would not purchase, even when the purchase price is equivalent to the rental price.

All three papers in this session include multiple empirical studies. Taken together, the papers examine how predictions about time, use (and non-use), and value over time can systematically impact consumers' preferences and choices. In addition, Drazen Prelec, an eminent researcher in the area of intertemporal choice will serve as the session's discussant and will synthesize the contributions of the papers into a cohesive framework for understanding the dynamics of consumer choice in the domain of extended consumption.

Recent trend in consumer behavior research has been shifting attention towards a more comprehensive view of consumer decision making that involves multiple choices and consumption episodes (e.g., Dhar and Simonson 1999, Khan and Dhar 2006). This session contributes to this growing body of research and is expected to attract audience interest at the conference.

## EXTENDED ABSTRACTS

### "The Value of Time in the Future and Present"
*Erica Mina Okada, University of Hawaii*

Money is more valuable in the present than in the future, but we propose that with time the relative value in the future versus the present is more ambiguous. On the one hand, based on the theories of asymmetric discounting of positive and negative outcomes (Mowen & Mowen 1991) and temporal construal theory (Liberman & Trope 1998), we propound that people are generally optimistic and expect the future to be better than the present. Therefore, people put a higher opportunity cost on their time in the future than their time now. But on the other hand, the resource slack theory (Zauberman & Lynch 2005) also suggests that people expect time to be more abundant in the future than in the present. The value of time in the future is therefore more ambiguous than time now. Time would be more valuable in the future if one considered its higher opportunity cost in the future versus the present. However, time would be more valuable in the present if one considered its relative scarcity in the present versus the future. We study the effect of this relative ambiguity of future time on two types of choice patterns.

*Buying and Selling Time in the Future versus Present.* A seller's willingness to accept (WTA) for an item is generally higher than a buyer's willingness to pay (WTP), and this WTA – WTP discrepancy can be explained in part as a manifestation of conservatism on the part of both buyers and sellers in evaluating the uncertain outcomes of a prospective exchange (Okada 2006). The true value of an item to an individual: i.e. how much s/he will actually like and use it, availability of better alternatives in the future, etc., is inherently uncertain. Therefore, buyers and sellers both face uncertainties about whether they will become better off or worse off as a result of exchange. To be conservative, buyers focus more on scenarios where they become worse off for purchasing an item that ends up being low value, and are willing to pay only a relatively low price. Sellers focus more on scenarios where they become worse off for parting with an item that would have been high value, and are willing to accept only a relatively high price. The magnitude of the WTA – WTP discrepancy should therefore become greater when there is a higher level of uncertainty about the item's value.

The WTA – WTP discrepancy has been shown in the exchange of time. For example, a homeowner may mow his own lawn instead of paying his neighbor's son $20 to do the job, though he would never mow someone else's lawn for $20 (Thaler 1980). The value of time is more ambiguous than the value of money (Okada & Hoch 2004), and we present that the value of future time is even more ambiguous than the value of time now. Therefore, the WTA – WTP discrepancy should be greater when buying and selling time in the future compared to the present.

An experimental study involving 182 participants demonstrated that people were willing to do three hours of data entry work today in exchange for $30.98 on average, but were willing to pay only $21.39 to someone else to get the same task done, replicating previous studies. When the same three hours of data entry work had to be done not today, but in one week, the WTA – WTP discrepancy further widened: people were willing to accept on average $40.02,

but were willing to pay only $19.93. Even though it would presumably be more convenient to schedule something one week in advance rather than the same day, three hours of time was valued higher in the future than the present, especially as measured as WTA. In a further study with 175 participants we ruled out alternative explanations, such as dread, for the increase in the WTA – WTP discrepancy from the present to the future. We also directly measured people's opportunity costs of future time versus present time, and the extent to which they perceived time to be more abundant/scarce in the future versus the present, to corroborate our theory.

*Expediting versus Postponing.* The value of time in the future is more ambiguous than the value of time in the present. Time in the future would be more valuable if one considered the relatively higher opportunity cost of time in the future versus the present. However, time in the present would be more valuable if one considered its relative scarcity in the present. In a study involving 175 participants, we varied the context in which participants made intertemporal choices, so that either the relative opportunity cost, or the relative abundance/scarcity of time, was made more salient.

When a prospective task is firm and binding, the trade-off between spending present time versus future time becomes more explicit, and the relative opportunity cost becomes more salient. If they must expend a given unit of time, people would rather save their time in the future, which is of the greater value, and they should expedite. In contrast, when the task is more flexible and less binding, people may be less likely to spend time now when they are busy, and prefer to postpone when they expect to have more of it in the future. After accounting for alternative explanations based on the feasibility, difficulty, or enjoyability of a given task when performed now versus in the future, our study demonstrated that people tended to expedite a given task when it was required, and postpone when the same task was optional.

### "When Less is More: Consumer Aversion to Waste"
*Lisa E. Bolton, University of Pennsylvania*
*Joseph W. Alba, University of Florida*

The present research investigates how forward-looking anticipation of waste affects consumer response. For example: consumers will pay significant amounts of money to attend concerts by new artists yet buying and listening to CDs only once is deemed wasteful; buying and reading magazines once is accepted practice whereas buying socks and wearing them once is not; for the same price, renting DVDs seems more responsible than subscribing to premium TV in order to watch three television series. Although alternative explanations likely abound, one common thread runs through each of these scenarios: waste aversion is a constraint on consumers' pursuit of utility. We contend that waste aversion—a phenomenon that is largely independent of vendor behavior—exerts a significant, seductive, but largely obscure influence on consumer decision making

Aversion to waste is a matter of common, perhaps universal, experience. "Waste not, want not" is an intuitively appealing heuristic that serves us well when resources are constrained. Yet waste aversion has been virtually ignored as a subject of scientific inquiry. The primary exception has been the work of Arkes, who first broached waste as an explanation for the sunk-cost bias (Arkes and Blumer 1985; see also Arkes 1996). According to this formulation, people persist in a losing endeavor because abandonment would imply that prior investments in the endeavor have been wasted—a nice illustration of how an otherwise sensible rule can be overgeneralized to a potentially catastrophic extent. To our knowledge, extension of Arkes's insightful observation has been rare and narrow in scope, taking place almost entirely within the context of product-replacement decisions (Cripps and Meyer 1994; Okada 2001, 2006).

Although compelling in its own right, we argue that prior research understates the biasing influence of waste aversion on consumer behavior. The present investigation departs from past research in several ways that speak to broader application. First, unlike the inherently retrospective effects of sunk costs, we argue that consumers forego future utility because they anticipate waste in their purchase, consumption, duplication, and disposal of potential purchases. Second, by not constraining the investigation to replacement, which requires only a judgment about optimal point of repurchase, we are able to investigate choice among competing options. Finally, and perhaps most important, we examine different determinants of waste, showing how alternatives that are comparable in utility can evoke very different purchase intentions.

In a series of studies, we find that consideration of waste affects consumer responses in a variety of consumption settings. We first demonstrate consumer aversion to waste when judging the behaviors of others—even when the purchase scenarios were otherwise designed to be equivalent in terms of utility and price. For example, even when both deliver equivalent enjoyment, paying to work out at a nice fitness club (where the remainder of the one-month membership will go unused) is deemed less intelligent than paying to attend a professional sporting event—because seller constraints (i.e., minimum purchase requirements) in the former case give rise to waste. These results pointed to unused utility as the fundamental driver of waste aversion. Nonetheless, study 1 demonstrates that consumers' own forward-looking purchase intentions are especially sensitive to waste aversion for goods versus services. For example, participants are more likely to purchase a service than a good, when a past purchase leads to duplication. Studies 2 and 3 further demonstrate the effects of tangibility. In study 2, we demonstrate how tangible waste affects competition among goods and services, this time operationalized in terms of buying versus renting. In study 3, we demonstrate how consumer aversion to waste drives riskier choice when tangible goods "live on" and cue waste considerations. Throughout these studies, we rule out alternative explanations and provide evidence (e.g., cognitive response data, waste ratings) that waste considerations play a mediating role.

A better understanding of the role played by waste in consumer response to product offerings is important for several reasons. Fundamentally, waste aversion is another example of the limitations of value-based pricing: consumer preference for a higher-value option is reduced when the option entails unused utility. Moreover, waste can shift preference among goods and services. For example, consumers may prefer a service over a good when the good entails unused utility—even when both offer equivalent utility. Service providers may be less vulnerable to waste aversion and therefore more able to charge a price commensurate with an offering's utility. This result provides further evidence that goods and service providers (including renters) have differential competitive (dis)advantage in the marketplace (cf. Bolton, Warlop, and Alba 2003; Bolton and Alba 2006). Finally, our discussion focuses on three areas that merit further investigation: bundling, purchase versus consumption, and waste mitigation. The lesson for marketers? Finding ways to help consumers avoid waste can provide competitive advantage in the marketplace. Less is, indeed, more—when more entails waste.

### "Consumer Decisions to Rent vs. Buy"
*Anastasiya Pocheptsova, Yale University*
*Ran Kivetz, Columbia University*
*Ravi Dhar, Yale University*

Everyday we encounter choice options that provide extended streams of consumption. In consumer product domain we choose between buying vs. renting DVD players or tuxedos, in the domain of social relationships we choose between romantic partners for immediate enjoyment vs. long-term relationship. The outcome of these decisions is usually multiply determined by various factors including differences in cost, estimation of future use (and hence potential waste), and self-control considerations (for example, in the case of flat-fee vs. pay-as-you-go services).

We propose that there is a difference in mindsets that consumers adopt when making a decision that involves short-term versus long-term consumption. Consistent with this view research on relationships shows that people use different approaches when selecting long-term versus short-term partners, being more stringent when evaluating potential long-term prospects (Stewart et al. 2000). We argue that consumers think about the rental choice and purchase choice in different ways as consumers naturally match their decision strategy to the choice situation (Tversky et al. 1988). Buying decision (extended consumption) is seen as more permanent and nonreversible and thus, encourages consumer to adopt a more critical decision mindset. Therefore products are evaluated more carefully before making a purchase. In contrast, renting (short-time consumption) is seen as temporary and reversible decision and hence acceptable decision strategy is less extensive and thorough. As a result more products pass the acceptance threshold. Although such different strategies are frequently justified by higher prices for purchase than for rental, we show that they are applied even when the options are *equally priced*. Under these conditions an over application of higher acceptance threshold to purchases (compared to rentals) potentially leads to suboptimal choices. We predict that consumers will exercise more control over their purchases than rentals. This leads to lower purchase likelihood of long-term use products as compared to a short-term rental of the same products.

In a series of studies we provide empirical evidence that consumers choose to rent a product that they would not purchase, even when the purchase price is equivalent to the rental price. Similar to duration neglect found in the domain of extended affective experiences (e.g. Fredrickson & Kahneman 1993), we show that extended consumption provided by purchase option does not increase the purchase likelihood of a product. In study 1 we examined the preference for rent and buy by looking at hypothetical decisions made by college students imagining spending a semester at another university. The respondents were shown a single product (e.g., a fridge) and were assigned to either rent/no-rent condition or a buy/no-buy condition. Consistent with our predictions, the participants were more likely to rent than to purchase the option provided even though the rental price for one semester was the same as the purchase price. The results were replicated in a second product category.

The second study extended the results by ruling out alternative explanations. One alternative explanation for the results of study 1 is perceived hassle of product disposal after a short-term use. In study 2 we use a different product (movie DVD) which is unlikely to create a similar disposal problem. Another alternative explanation posits that given the same price a purchase may be perceived as inferior to a rental option. To rule out this explanation we pretested the movie DVDs and found not difference in the perceived quality for both purchase and rental offerings. Furthermore, in this study we explore a boundary condition of our effect, a situation where a product is available for either purchase or rent for the same price (within-subjects condition). Consistent with previous literature (Ariely & Loewenstein 2000), we predict that "within-subjects condition" will increase the attention that participant pay to the duration of consumption and hence more participants would prefer purchase over rent. As predicted, we found that more people preferred to rent than to purchase in the between-subjects conditions, however, the reverse was true for within-subjects condition.

The next set of studies examined the underlying process of renting and buying decisions. In study 3 we used an optional stopping paradigm (Rapoport et al. 1972) and predicted that participants in the buying condition would be more thorough in their information search and evaluation of alternatives. Consistent with our theory, we found that while evaluating different movie DVDs sequentially, the participants in the rental condition stopped on average two movie titles earlier than did the participants in the purchase condition. This indicates a less stringent decision strategy as compared to purchase decision. To further examine higher acceptance threshold for buying we used an unavailable option paradigm (Farquhar & Pratkanis 1993). Study 4 examined whether participants were willing to accept another product (a second best alternative) when their first choice was not available. We found that when the current preferred option was not available for purchase the participants were more likely to accept the second best choice for rental, but not for purchase.

The four studies have shown that participants facing a purchase (long-term use) decision are more stringent in the evaluation process and are less likely to purchase a product. Study 5 attempts to improve the likelihood of buying by priming the "spending" concept to the participants. Since the decision to rent is relatively easy and people are less frugal with their rental decisions, priming spending would have a more pronounced effect on a decision to buy than on a decision to rent. The goal of this study was to make rental and purchase decisions more comparable in consumers' mind. In this study we used a 2 (prime: spending vs. control) x 2 (mode: rent vs. purchase) between-subjects design. We find that priming spending increased the likelihood of buying, but did not affect renting. As a result, decreasing stinginess made purchase decision more similar to rental decision.

# Categories in Context

Kristin Diehl, University of Southern California, USA

## SESSION OVERVIEW

Consumer researchers have long been interested in *individuals'* spontaneous categorization of items into existing or new categories. Consequentially, categorization research in marketing has shown a strong focus on factors that are intrinsic to the consumer (e.g. expertise, risk attitude, motivation, etc.) or, if investigating situational factors, concentrated on processes inherent to the individual consumer (e.g., mood). While unveiling *differences between individuals* and their way of grouping items is instructive, this focus has also limited our understanding of other important aspects of categorization.

In particular, the effects of retailer provided categories have been largely ignored, even though contextual rather than individual differences are of particular interest to marketers. As most marketers sort their assortment into categories, externally provided categories are ubiquitous and may have important effects on consumers' decisions. As such, how the environment is structured seems to be a very important yet underresearched factor in this area. Our session bridges this gap, investigating the genesis of external categories provided in the marketplace and shedding light on how consumers are affected by different externally provided category structures.

Findings presented in this session suggest that managers' group-level interaction may lead to the creation of category schema which systematically differ from how consumers think about the grouped items. This session also suggests that consumers process information differently as a function of the categorizations and groupings they encounter in the marketplace. Finally, differences in external, marketer provided environments are shown to alter product choice and new product adoption.

The work by Hamilton, Putoni and Tavassoli investigates how teams of people develop different, more fine-grained categorization schemes when ordering options than do individual categorizers. As such, teams, representing the combined knowledge of their members, create environments that may not reflect how the average consumer thinks about the category. Subsequently, as this presentation will show, differences in categorization will affect consumers' new product adoption decisions.

Relatedly, Ülkümen, Morwitz and Chakravarti investigate how differences in the external environment can affect how narrowly individual consumers think about a category. Their work also demonstrates that external environments affect how thoroughly consumers process information and, similar to the preceding presentation, will show how such differences in processing influence new product adoption decisions.

Van Herpen, Diehl and Poynor compare two common ways in which marketers organize assortments for consumers: grouping items with either substitutes or complementary products. Like the preceding presentation, their work shows that differences in the environment can affect the extent of consumer processing and further demonstrates how differences in organization alter consumers' overall purchase experience.

The three presentations illuminate questions regarding the effects of external categories from diverse and novel angles, spanning different conceptual approaches but converging on a central theme. They investigate how external environments and particularly externally provided categorizations can affect decision pro-cesses and ultimately product choice. Taken together, this session provides new insights in the area of categorization that should be interesting to a wide range of researchers, for example, those studying context effects, new product adoption, assortment size and structure, or the effects of retail environments on consumer experience.

## EXTENDED ABSTRACTS

### "Categorization by Groups"
*Rebecca Hamilton, University of Maryland*
*Stefano Puntoni, Erasmus University*
*Nader T. Tavassoli, London Business School*

Categorization is a core psychological process (Lakoff 1987) that is central to consumer (for a recent review, see Loken 2006) and managerial decision-making (e.g., Porac and Thomas 1990). Consumers' understanding of categorization schemes helps them navigate retail environments and websites. At a more macro level, product market structure represents a social construction based on consensual categorical knowledge between consumers and producers (Rosa et al. 1999) that coordinates transactional relationships (e.g., Day, Shocker, and Srivastava 1979). Categorization shapes consumers' product evaluations (e.g., Sujan 1985), and managers rely on categorization for product development (Griffin and Hauser 1993) and product positioning decisions (Cohen and Basu 1987).

In many of the situations described above, categorization may be performed by groups of consumers or managers (e.g., a family deciding on a vacation destination or a product development team categorizing customer needs for a product) rather than by individual consumers or managers. This requires group members to integrate their potentially diverse beliefs about how constructs are related. While a substantial amount of research has been conducted to examine individuals' categorization behavior, much less is known about how groups categorize constructs. The goal of this research is to understand whether and how the outputs of group categorization processes differ from those of individual processes.

In a series of three studies comparing group and individual categorization of the same items, we find that groups and individuals systematically generate different category structures. Relative to individuals, groups with three or four members create a larger number of categories with fewer items in each category. This effect is mediated by groups' larger knowledge base and moderated by groups' ease in achieving consensus. We also show that categorizing concepts either individually or as part of a group affects the structure of individuals' memory and subsequent category membership decisions such as evaluations of brand extensions.

In our first study, sixty-one participants categorized customer needs for a new product. To compare group and individual performance, we used four measures of category breadth: the number of categories created, the average size of categories, the size of the largest category and the size of the smallest category. As predicted, groups of four members sorted the 48 customer needs into a larger number of different categories (M=10.36) than individuals (M=8.35), $F(1, 26)=6.99$, $p<.05$, resulting in a smaller average number of customer needs included in each category by groups (M=4.49) than individuals (M=5.96), $F(1, 26)=7.04$, $p<.05$. Moreover, the average size of the largest group was larger for individuals (M=12.0) than

for groups (M=8.18), F(1, 29)=11.42, p<.005, and the average size of the smallest group was directionally larger for individuals (M=2.76) than for groups (M=2.27), p>.28.

In study 2, we examined the underlying process by measuring expertise and the group members' perceived ease of reaching consensus. Working either individually or in groups of three, 211 participants categorized movies, a category in which we predicted relatively large variation in expertise. As in study 1, groups created more categories than individuals (Mg=9.32 and Mi=7.87, F(1, 108)=7.46, p<.001); created smaller categories on average (Mg=5.64 and Mi=6.56, F(1, 108)=8.69, p<.001); created a smaller largest category (Mg=11.28 and Mi=13.51, F(1, 108)=7.56, p<.001); and created a smaller smallest category (Mg=2.32 and Mi=2.67, F(1, 108)=7.13, p<.001). Moreover, providing evidence for underlying differences in group and individual categorization processes, we found that expertise mediated the effect and consensus moderated the effect. More knowledgeable participants created narrower categories than less knowledgeable participants, just as groups created narrower categories than individuals. In contrast, groups reporting greater ease in achieving consensus performed the task more like individuals, creating broader categories.

Our third study focused on the consequences of categorizing more or less integratively on memory structure and on subsequent categorization tasks such as evaluating brand extensions. One hundred forty participants completed a categorization task either individually or in groups of three. Next, participants evaluated line and brand extensions for three different brands. Because brand extensions require consumers to stretch the parent brand beyond its original product category, we predicted that groups would evaluate brand extensions less favorably than individuals. As predicted, there was no difference in the perceived fit of the line extensions across group and individual conditions (Mg=6.11 and Mi=5.96), but individuals evaluated the brand extensions (M=3.98) more favorably than groups (M=3.11), resulting in a significant extension type by social context interaction, F(1, 68)=7.01, p<.01.

The results of these studies show that whether individuals work alone or in groups systematically affects the way they categorize the same set of items. In all three studies, groups categorized less integratively than individuals, creating a larger number of narrower categories. We provide direct evidence for the mechanisms responsible for the effect of social context and provide insight into its consequences.

**"The Effect of Exposure to Narrow versus Broad Categorizations on Subsequent Decision Making"**
*Gülden Ülkümen, University of Southern California*
*Vicki Morwitz, New York University*
*Amitav Chakravarti, New York University*

In this paper we investigate the impact that externally imposed categorizations may have on choices that are made in a subsequent and unrelated decision context. We document a very simple, yet powerful effect: being exposed to a decision context with broad categorizations (e.g., movies classified as comedy or drama movies), as opposed to a decision context with narrow categorizations (e.g., movies classified as comic action, dark comedy, romantic comedy, courtroom drama, historical drama, or melodrama movies), systematically and reliably affects judgments and decisions made in a subsequent and unrelated decision task (e.g., an unrelated grouping task, or a new product adoption decision).

Through six studies, we show that this effect occurs because exposure to narrow (broad) categorizations in a decision context induces a more (less) careful and critical information processing orientation. This change in information processing style has important carryover effects on subsequent, unrelated decisions, by affecting the kind of information that people use as inputs in these decisions. In particular, it affects whether people make their decisions carefully and critically, by taking multiple factors into account, or whether they simple let the more salient cues in the environment guide their subsequent decision making. We observe these carryover effects in basic cognitive behaviors (e.g., grouping tasks, category inclusion decisions), in consumption domains (e.g., new product adoption decisions), and in general decision making strategies (e.g., susceptibility to heuristics).

Specifically, we find that people exposed to narrow categorizations become more critical and meticulous decision makers, basing their evaluations on all available information in the environment. In contrast, people exposed to broad categorizations appear to be less careful, basing their decisions on a few, highly salient dimensions. For example, we found that decision makers exposed to broad categorizations created relatively fewer categories in a grouping task (study 1a), and were more lenient in their category inclusion decisions involving a continuum of Chinese-Caucasian faces (study 1b). Likewise, their new product evaluations were also driven by attributes that were made salient by the decision context. Thus, exposure to broad categories led to relatively favorable attitudes towards new products in innovation-salient decision contexts (studies 2-5), but led to relatively unfavorable attitudes in risk-salient decision contexts (studies 4-5). In contrast, exposure to narrow categorizations, led to a more balanced consideration of both innovation and risk, irrespective of which dimension was made more salient in the decision environment (studies 2-5).

In fact, for decision makers exposed to broad categorizations, even difference perceptions were colored by the salient dimension (study 4). As new products became progressively more different from existing products in the market, each unit of increase in the perceived difference of a new product was construed either as an increase in innovation, or as an increase in risk, depending on which of these dimensions was made more salient by the decision context. For these decision makers, in innovation (risk) salient domains, differences were construed as being indicative of innovativeness (risk), and evaluations of the new product became progressively more (less) favorable as the new product was perceived to be increasingly more different from the conventional product offerings on the market. Exposure to narrow categorizations, on the other hand, led to a more balanced consideration of both innovation and risk in interpreting these difference perceptions.

More generally, we also found that decision makers exposed to broad categorizations in the first task, become more susceptible to context effects and decision heuristics in a subsequent and unrelated task (study 6). Specifically, we found that on exposure to broad categorizations in a first decision, decision makers were more likely to use the frequency heuristic, a popular consumer decision heuristic, in subsequent product evaluations and choice tasks. In contrast, exposure to narrow categorizations, led to more compensatory decisions that were invariable across contexts. Given that prior exposure to these broad-narrow categorizations (a) affected a wide variety of subsequent and unrelated tasks, (b) were unaccompanied by differential affect, mood, completion times, or feelings of task difficulty, and (c) went unreported in the funnel debriefings, it is quite likely that the carryover effects documented in this paper operate outside conscious awareness of the consumer and occur in an automatic fashion.

### "Arranged to Distraction: How Categorizing Products with Complements versus Substitutes Alters the Experience of Product Choice"

*Erica van Herpen, Wageningen University*
*Kristin Diehl, University of Southern California*
*Cait Poynor, University of South Carolina*

Websites such as www.furniture.com organize their assortment either by product type (i.e., dining tables) or by collection (i.e., full dining rooms with tables, chairs, sideboards, etc.). Likewise, clothing stores either present products in sets of substitutes or as part of entire outfits. These examples represent fundamentally different ways in which marketers organize products, in either taxonomic categories or consumption constellations. Although we know that consumers are influenced by the order and format in which alternatives are presented (Diehl, Kornish, and Lynch 2003; Drèze, Hoch, and Purk 1994), prior research has mainly focused on sets of substitutes (e.g., Bettman, Luce, and Payne 1998; Simonson 1999) or on purchases of entire product bundles (Harris and Blair 2006; Janiszewski and Cunha 2004). As a result, we know much about the influence of substitute products in an assortment, but relatively little about the influence of categorizing complementary products alongside the target item. Our research posits that external categorization in terms of consumption constellations (Englis and Solomon 1996; Lai 1994) may have both drawbacks and benefits for consumers.

Complementary products can distract consumers who plan to buy a single target product. They may complicate search, as the cluttered environment obscures rapid identification of specific target products (Bravo and Farid 2006). As such, complements may raise the effort involved in shopping simply because they compete for attention (Janiszewski 1998) and thereby increase the difficulty in remembering and comparing target products. For complements to act as distractors it is not necessary that consumers effortly search complementary products or consider them at all relevant to their purchase goals (Perruchet, Rey and Hivert 2006). We predict that the mere presence of complementary items in a display will mentally distract consumers from their target product, therefore increasing decision time and difficulty but not necessarily time spent actively processing complements.

However, organizing targets in consumption constellations may also generate positive outcomes. Compared to substitute-based organizations, consumption constellations may encourage greater visualization of product use (Dahl and Hoeffler 2004; Petrova and Cialdini 2005). Such organizations highlight how the target product can be integrated in a set of complementary products and may stimulate imagery of product use. As a result, we predict that consumers' satisfaction with the assortment as a whole should be higher when items are externally categorized with complements rather than only with substitutes.

In Experiment 1, 82 participants were randomly assigned to either a substitute or a complement organization, in a 2-group design. Stimuli were clothing brochures, with products from 8 taxonomic categories. Participants were asked to choose a shirt. In line with our predictions, participants in the complement condition experienced higher decision effort, more difficulty to grasp the selection, and more confusion than participants in the substitute condition. Still, consistent with our predictions, they thought that the assortment was more attractive.

Experiment 2 examined whether increased effort in complement organizations could be attributed to greater physical distance between target products. Does the act of flipping pages to view different consumption constellations explain this increase in effort? 92 participants were asked to select a pair of pants from an online assortment containing 8 pairs of pants. Participants were randomly assigned to one of three conditions: substitutes together (the 8 pairs of pants all displayed on 1 screen), substitutes separated (one pair of pants on each of 8 screens), or complements (8 pairs of pants displayed on 8 screens surrounded by complementary products). The computer captured time measures as well as subjective responses.

Our results suggest that the physical separation of items in complementary sets cannot explain the decision difficulty found in Experiment 1: Decision times were significantly longer in the 8-page complement than the 8-page substitute condition, where page distance was objectively equal and only the organization changed. Interestingly, differences in decision time were not driven by consumers actively examining complementary products, but rather by them spending more time looking at consumption constellations overall. As in Experiment 1, individuals shopping in complementary sets consistently took longer deciding and reported greater decision difficulty. Yet, such sets also generated greater assortment satisfaction and were seen as more inviting.

A third study investigates differences in the underlying psychological processes triggered by complement as opposed to substitute based organizations. Preliminary results suggest that complement organizations prompt consumers to engage in more extensive visualization while substitute presentations impair such thoughts.

As a whole, our research shows that in the presence of a well-defined purchasing goal, external categorizations that group complementary products alongside the target product can have both adverse and beneficial outcomes. Marketers may want to adopt such complementary sets because they seem inviting and engaging to consumers. However, they should also be aware that although consumers spend more time deciding, they do not engage in more detailed examinations of either target products or complements.

# Is Beauty Only Screen Deep?
## Perceptions of Avatars in Computer-Mediated Environments
Natalie T. Wood, Saint Joseph's University, USA
Michael R. Solomon, Saint Joseph's University, USA

## SESSION OVERVIEW

Residents of the online "world" Second Life spend approximately $12 million per month (in real money) on virtual land, products and services. To date more than 40 *RL* (real life) companies including GM, Dell, Sony, IBM and Wells Fargo are staking their claim to online real estate in computer-mediated environments (CMEs) including Second Life, Entropia Universe and There.com. They hope to lure the growing flood of consumers who enter these sites in digital forms called *avatars*. These digital representations socialize with one another, take virtual university courses, participate in corporate training programs, share reactions to new products, and of course shop. Eventually, these CME forums may rival traditional, marketer-sponsored E-commerce sites in terms of their influence on consumer decision-making and product adoption. Avatars are starting to spend big.

Despite this huge potential, we know very little about the best way to talk to consumers in these online environments. How will well-established findings from the *RL* regarding the impact of source credibility upon persuasion transfer to a situation where a "source" espousing adoption of a new product takes the form of an animated supermodel with exaggerated "attributes" or a bright green demon with fearsome horns?

We will stimulate dialogue when we bring together several teams of researchers to address different aspects of person perception in CMEs. Wood and Solomon's paper explores the use of avatars as endorsers in online advertising. Keeling and McGoldrick looks at how avatar attractiveness influences ratings of friendliness, social competence, parasocial interaction, trust and intentions. Our final paper from Malter, Rosa and Garbarino investigates the effects of consumers' self-perceptions on the creation of avatars (virtual models) to evaluate representations of body-involving products (apparel) for use on their real bodies in the real world.

In his role as discussant, Michael Kamins will synthesize these research programs and relate them to RL studies that address the impact of source appearance upon message acceptance. Kamins published some of the seminal work on the matchup hypothesis and is well-qualified to draw conclusions regarding the extent to which online person perception dynamics do or not mirror those in the more familiar offline world.

## EXTENDED ABSTRACTS

### "Digital Brand Personality: Does the Matchup Hypothesis Extend to Online Environments?"
*Natalie T. Wood, Saint Joseph's University*
*Michael R. Solomon, Saint Joseph's University*

Aaker defines brand personality as "…the set of human characteristics associated with a brand" (1997, p.347). The consumer behavior literature views brand personality as an important factor to increase consumer awareness (Tan Tsu Wee 2003), preference, usage (Sirgy 1982), loyalty and trust (Aaker 1997). Furthermore, a winning personality is a critical determinant that may simplify the consumer decision-making process (Tan Tsu Wee 2003) while it fosters long-term brand equity (Aaker 1996).

How does a marketer convey this personality? This process involves the careful manipulation of marketing mix elements, particularly those communicated visually (Tan Tsu Wee 2003). Whereas numerous researchers have examined the dynamics of brand personality in offline communications platforms such as print advertisements (cf. Aitken et al 1987; Ang and Lim 2006), virtually no research informs us as to how and if these findings apply in the virtual world. Given the web's capability to generate higher levels of user interactivity and engagement than traditional advertising media, is it reasonable to assume that what works in the offline space also will work online? The scant extant research on this topic generally adopts a holistic approach; it investigates how an entire website contributes to corporate brand image (cf. Opoku, Abratt and Pitt, 2006), rather than focusing on individual visual elements. For instance, no work to date explores how (or if) well-established findings on the role of brand endorsers in traditional (real world) advertising transfer to the role of avatars in the virtual world.

From a brand management perspective, Neumeier (2003) defines an avatar as the virtual DNA of a brand; "…an icon that can move, morph or otherwise operate freely as the brand's alter ego." Despite their growing popularity, we do not know much about the persuasive dynamics of avatars (for notable exceptions see Holzwarth, Janiszewski and Neumann 2006; Wood, Solomon and Englis 2005, 2007). Indeed, companies seem to choose the avatars that will represent them on their websites rather arbitrarily. For example, Coke's digital spokesperson-an average-looking male in cartoon form, was recently changed to an average-looking female (http://www.thecoca-olacompany.com/contactus/) in photographic form, not unlike the avatar archrival Pepsi also displays on its website (http://www.pepsiusa.com/help/index.php). We find it ironic that these companies, which spend hundreds of thousands of dollars to choose and validate spokespersons for real life (RL) advertising campaigns, appear to make parallel choices rather capriciously in online formats.

In this study we examine how avatar-based advertising influences consumer perception, attitude and behavior toward the brand in online promotional contexts (n.b., to date most applications tend to use avatars merely as "props" in e-commerce applications like the Coke and Pepsi spokespeople). We devised a sequence of empirical steps to systematically investigate the differential impact of avatar types upon advertising evaluations.

We base our theoretical approach upon prior work (in offline contexts) regarding the *matchup hypothesis*. This states that the correct "matchup" between the source and the product may have a greater influence on consumer attitudes toward the product and purchase intention than the unitary dimensions of endorser likeability or product involvement (Kamins 1990; Solomon, Ashmore and Longo 1992). We began by pretesting brands in two disparate product categories to identify a set that embodies the "Big 5" attributes Aaker and others typically use (cf. Ang and Lim 2006; Tan Tsu Wee 2003) to encapsulate dimensions of brand personality. We also pretested a large set of actual avatars to identify those that embody the same personality attributes. Finally, we empiri-

cally tested the proposition that ads pairing brands and avatars with similar personalities are more effective in generating a positive attitude toward the brand and the advertised product than are ads that pair brands and avatars with mismatched personalities.

We began by verifying that source effects are as robust in the online world as in more traditional offline communications formats. A total of 113 students viewed two avatar- based advertisements for a fictitious store. Half of the respondents viewed the ads in print format and the other half viewed the same ads online. We verified that method of delivery had no significant impact on attitude towards the advertisement or intention to visit the store.

In our next step, we identified a number of well-known yet distinct brands for two popular yet divergent product categories of interest to our student subject population: 1. Cell phones-a functional product consumers tend to evaluate along objective dimensions of performance (in addition of course to some aesthetic distinctions), and 2. Jeans-an expressive product for which consumers consider the psychological implications of selection (Okazaki 2006). We identified eight brands (four per product category) for initial evaluation.

Next, we generated a list of attributes for each brand and identified a number of existing avatars to match each brand attribute. For example, if students characterized a brand as sophisticated we tried to locate one or more sophisticated looking avatars. We obtained these avatars from a variety of online sources, including avatar developer sites, commercial websites and virtual social networking environments such as noDNA, Sitepal and Second Life.

The third phase of the study involved categorizing the collection of avatars according to Aaker's 15 attributes of brand personality, factored according to the "Big 5" dimensions of sincerity, excitement, competence, sophistication and ruggedness (Aaker 1997). Through group consensus (judges included both authors and four research assistants), we identified two avatars to embody the personality attributes we desired for each of the five dimensions (i.e., 10 avatars per brand).

In the fourth step, we validated our judgments in a pretest on a sample of 40 respondents who assigned personality ratings to each of the eight brands and 20 avatars according to Aaker's (1997) "Big 5" list. Subsequently we reduced the sample brands from four to two; we selected the two most divergent brands in each product category for further examination. We based our selection on the dominant personality attribute within each product category–sophistication for cell phones and ruggedness for jeans. For jeans we selected the Wrangler and Seven For All Mankind brands and for cell phones we included the LG 400 and the LG Chocolate brands. We also reduced the number of avatars per brand to two with the avatar that exhibited a similar personality rating with the brand (jeans: ruggedness, cell phones: sophistication) and the avatar with a mismatched rating being retained.

In the final step we examine the robustness of the match-up hypothesis when applied to an online communications format. In a 2 x 2 design (Products: jeans and cell phone X Avatar: similar and mismatch) we paired these avatars separately with each brand in a series of online advertisements. Through random assignment, each respondent viewed two ads online–one cell phone/avatar pairing and one jeans/avatar pairing. Manipulation checks confirmed that respondents rated the LG Chocolate cell phone as more sophisticated than the LG 400 phone and Wrangler jeans as more rugged than Several for All Mankind jeans. In addition they rated the "sophisticated" avatar (as determined by our pre-test data) as more sophisticated and the "rugged" avatar as more rugged than the

alternates within each condition. Our dependent measures included attitude toward the brand and purchase intent for each brand/avatar pairing. Results indicate scattered support for the match-up hypothesis. However, we also note a tendency for the brands to "engulf the field" such that their *a priori* brand personalities tend to swamp the ratings. This pattern implies that the match-up hypothesis may be more robust for new brands that have yet to establish a firm brand personality. In addition, the static nature of these initial experimental stimuli may diminish the impact of the avatar spokesperson. In subsequent studies we hope to address these issues by using brand stimuli with more ambiguous offline personalities and more realistic, animated avatars. More generally, our findings are a reminder that–just as in the offline world–source characteristics are a potentially important influence on consumer behavior in online marketing environments.

*"Keep up appearances; there lies the test;*
*the world will give thee credit for the rest"*
   *(Charles Churchill, 1731- 64)*

Interactions with customers are important, but Internet shopping provides little opportunity for such exchanges. For Gefen and Straub (2004), this deficit can be overcome by perceptions of social presence. A cue for social presence in computing is interactivity, especially when this supports a social role. An interactive animated 'avatar' on computer screens could provide a source of social presence and hence trust building capabilities (Holzwarth, Janiszewski, and Neumann 2006; Wood, Solomon, and Englis 2005). The outcome of such interactions may invoke the established social rules and dynamics from other interactions and so influence future behaviour. This invocation of social rules and dynamics could prove the most challenging and a trap for the unwary.

One social dynamic introduced is the influence of physical appearance and accompanying social attributions. The avatar is highly visual and so the 'physical' attributes such as attractiveness should be a subject of interest.

The stranger-attribution literature supports robust effects of attractiveness on the attributions or judgments people make of others at first impressions (Eagly et al 1991). Pervasive and strong though the effect of physical (un)attractiveness may be, there is evidence that first impressions based on appearance can and do change. Perceptions of competence and expertise can weaken or even reverse physical attractiveness effects, e.g., when a communicator is described as an expert (Till and Busler 2000).

Nevertheless, attractiveness effects can show remarkable persistence. Whilst Langlois et al (2000) advise that the mediating influence of familiarity on attractiveness effects is important, their results demonstrate that the advantages of attractiveness can persist even after initial interactions. Attractive adults are judged and treated more positively than unattractive adults, even by those who know them (Langlois et al 2000). Consistent with Eagly et al (1991) attractive adults were judged as having more social appeal and as more interpersonally competent than unattractive adults. Attractiveness affects attention, positive interaction, negative interaction and help-giving/cooperation (Langlois et al 2000).

Traditional theories view relationships as built on a number of contingencies and strategies including physical attractiveness but also characteristics of interactions. Attractiveness affects ongoing attention and positive interaction behaviours and there may be a halo effect of physical attractiveness on perceptions of friendliness and social competence. It is intuitive therefore that attractiveness is associated with the formation of relationships over time. The literature also suggests physically attractive people are more often chosen as friends (Langlois et al 2000).

In addition to attractiveness, the amount of similarity perceived increases interpersonal attraction and liking, facilitating communications and development of trust based relationships. However, relationships between perceptions of similarity and persuasiveness are thought to be heavily context dependent and thus difficult to predict.

As regards interaction with computers, perceptions of similarity of the 'social identity' of the computer by the human interactants are associated with higher ratings of attractiveness, trust and persuasion (Reeves and Nass 1996).

Recent research confirms that avatar presence may be associated with persuasiveness and building trust in e-tailing. It also confirms that the effects of appearance are moderated by performance, customer product involvement and motivation for interaction (Holzwarth et al 2006; Keeling, McGoldrick and Beatty, 2006; Luo et al 2006; Wood et al 2005). Some researchers warn that inappropriate avatar appearance and interaction presents a real danger of alienating customers (Keeling et al 2004; McBreen et al 2000). In advertising research, important considerations include the 'consistency' (Walker, Langmeyer and Langmeyer 1992; 'appropriateness' (Solomon, Ashmore and Longo 1992) and 'congruence' (Kamins 1990) between the copy and the visual component of the communication.

However, there is little information on the relationship between avatar attractiveness/appropriateness and interactions with other evaluations over a series of human-avatar interactions as might happen with repeated visits to a retail website. From the literature discussed above, there are five initial research questions for longitudinal human-avatar interactions, 1) can attractiveness effects be demonstrated in this medium; 2) are attractiveness effects strongest for ratings of friendliness and social competence as offline; 3) are these modified with the addition of other information gained during interactions; 4) can halo effects of attractiveness persist over time in this medium.

The fifth question is whether ratings of attractiveness will affect inclinations and intentions towards extended interactions and the development of some feeling of a 'relationship'. Relational schema theory suggests that people will attribute motivation, personality and emotion to the avatar as a result of interactions but human-avatar relationships are perhaps best designated as 'parasocial'. Parasocial relationships are formed when there is an illusion of face-to-face relationship and/or the viewer identifies with people or characters (Rubin and McHugh 1987). With strong echoes of 'real' relationship building, parasocial interaction is strongly related to likeability, perceived similarity, social and task attraction: the same cognitive constructs utilised in building actual social relationships are implicated in parasocial relationships (Rubin and McHugh 1987). Hoerner (1999) points out that some commercial web sites are already using representations of hosts, fictional or synthetic characters in order to draw customers into a parasocial relationship.

We argue, therefore, that the quality and depth of the relationship are reflected in the strength of the parasocial relationship. Further, since real salesperson-customer relationships have a strong basis in trust, there will be a potent connection between the strength of parasocial relationship and the level of trust. In the context of online retailing, where high trust may be needed to alleviate the elevated perceived risk felt by many customers, this twin dependence may have a strong positive relationship with purchasing intentions.

Over a series of studies, we examine the five research questions posed above. Initial exploratory research indicates that great care has to be taken in matching not only the physical characteristics of the avatar to perceptions of the brand, product or retailer but also to the goals and motivations of potential customers of a website. These findings informed a longitudinal study involving a panel of experienced online shoppers who undertook weekly interaction with an existing avatar. Amongst other tasks, respondents completed questionnaires regarding perceptions of avatar attractiveness, similarity, communication skills, intrusiveness, relationship quality and future use.

The results indicate that parasocial relationships can develop but the potentially ambiguous effect of attractiveness per se is

illustrated; a persistent advantage of attractiveness for ratings of sociability, similarity and relationship quality over time is not reflected in the influence of attractiveness on trust or usage intentions. However, some indirect effects can be observed. Further, the results indicate associations between higher attractiveness and lower ratings of two negative assessments, intrusiveness and offensiveness, and that negative evaluations of behavior are influential on decisions to discontinue use. Consequently, attractiveness may offset some of the negative aspects of avatar use. However, there is a weaker than expected relationship between ratings of attractiveness and ratings of social interaction competence.

## "Using Virtual Models to Evaluate Real Products for Real Bodies"

*Alan J. Malter, University of Illinois at Chicago*
*José Antonio Rosa, University of Illinois at Chicago*
*Ellen C. Garbarino, Case Western Reserve University*

The traditional view of consumer information processing is that cognitive activity takes place in the head, i.e., the mind stores knowledge, processes and integrates new information, and evaluates options in order to make optimal choices. An alternative view that is gaining acceptance in cognitive science argues that cognition involves both the brain *and* body, working together as an integrated system to support decision making and action (Clark 1997; Damasio 1994; Edelman 1992; Johnson 1987; Thelen and Smith 1994). Thus, how the human body can interact with an object or take action is fundamental to understanding the meaning of the object or situation (Glenberg 1997; Glenberg et al. 2003).

The opportunity to physically interact with products may similarly affect consumer understanding and evaluation of these products, especially body-involving products such as apparel or sports equipment (Rosa and Malter 2003; Rosa, Garbarino, and Malter 2006). Consumers perceive greater risk in purchasing such products in body-absent environments such as telephone shopping (Cox and Rich 1964), mail-order catalogs (Spence, Engel, and Blackwell 1970), and Internet retailing (Alba et al., 1997), though individuals differ in their degree of perceived risk. For example, consumers higher in need for tactile input for product evaluation make fewer Internet purchases of clothing and flowers (Citrin et al. 2003; Peck and Childers 2003) and prefer shopping for such products in environments that allow for tactile/sensory evaluation prior to choice (McCabe and Nowlis 2003).

One possible information technology solution to the lack of opportunity to directly touch products in computer-mediated environments (CMEs) is the development of "avatars", or cyberspace characters and personas. Avatars can be created by online marketers or co-created by online shoppers and used as proxies to interact with other consumers, to be spokes models for products and services, or even to represent the online shopper and virtually "try on" and "model" products such as apparel. Avatars can vary in function (decorative or proactive), action (animated or motionless), representation (photograph/illustration of real person or imaginary character), and classification (image of the real consumer using the web site, a realistic typical customer, or an idealized image of a model or celebrity) (Wood, Solomon, and Englis 2005). Increasing attention has focused on the emerging phenomenon of consumers visiting virtual worlds such as Second Life through their avatars, where they interact with other consumers and even spend real money to purchase virtual products and services for use by their

avatars. Though such avatars may appear to take on a life of their own, they are, of course, created and directed by real human users, interact with other avatars whose behavior is similarly directed by other human users, and purchase and "consume" familiar products and brands placed in the virtual world by real-world companies seeking to influence real-world behavior. Thus, the thoughts, choices and actions of avatars may more closely reflect the abilities and limitations of the bodies and minds of real humans in the physical world than is commonly recognized. The extent to which consumers perceive online avatars as realistic and authentic representations of the real world may influence the effectiveness of avatars as spokes models for real-world brands or as virtual models for apparel that will be purchased and worn by consumers in the real world.

Our research investigates the interaction between real-world (embodied) consumer cognition and the use of online avatars (virtual models) in CMEs to model and evaluate items for purchase and use by consumers in the real physical world. Specifically, we conducted a series of studies testing how consumers' self-perceptions affect their creation, perception and use of virtual models of themselves (Ives and Piccoli 2002). In this case, an avatar is designed to represent the actual online shopper (Wood et al. 2005) and can be used to virtually "try on" clothing to aid in making online purchase decisions. It is an open empirical question whether consumers will perceive a virtual model to be similar to them, and whether their evaluation of a digital rendering of an item "tried on" the virtual model will translate into actual purchase of the physical item and satisfaction in the real world.

Study 1 tests the key assumption that consumers will input accurate personal information and not embellish their dimensions to build a more ideal or flattering (i.e., taller, thinner, more toned) but unrealistic virtual model. Each participant self-reported their height, weight, and other physical features, and completed an impression management scale, then later constructed a virtual self model. We subsequently measured the actual height and weight of each participant and photographed them for comparison to their virtual model. We found a general tendency to input accurate information and build a relatively isomorphic virtual model that many participants rated as looking very much like them. Consumers who preferred a more visual style of processing perceived the virtual model to look more like them and were more satisfied with the way their virtual model looked in the digital apparel (shirt, pants, shoes) "tried on" the model.

Study 2 tests the effect of using a personal virtual model versus evaluating pictures of the same items in an online catalog (without using a virtual model). We find that the experience of trying clothes on a virtual model made consumers more confident in their online evaluation of items, and shifted their preference for how they would like to see items displayed (on a model that looks like them, compared to an ideal image of a professional model). However, the enhanced isomorphism of the virtual model did not lead to a more positive evaluation of the items or increase purchase intent.

Study 3 tests the effect of actual physical body movement on perceived accuracy of the virtual model and online evaluation of digital products. This manipulation was intended to increase participants' awareness of their full body (head-to-toe) and body boundaries (as occurs in a fitting room at a brick-and-mortar store), compared to the disembodied state of sitting at a computer terminal moving only eyes and fingertips. As expected, physical body movement by online shoppers had the strongest effect on the evaluation of shoes (cf. shirts or pants), apparently increasing participants' awareness of more distant extremities compared to a static seated body position.

# Erroneous Lay Theories of Future Affect: Processes and Consequences

Cecile Cho, Columbia University
Carey Morewedge, Princeton University

## SESSION OVERVIEW

Consumers' poor predictions of their future feelings pose a fundamental and important problem for consumer well being and satisfaction. Because consumers often make their decisions and choices based on their anticipation of how they will feel about future outcomes (Mellers & McGraw 2001; Wilson & Gilbert 2003; Novemsky & Ratner 2003), not only does this tendency lead to suboptimal decisions, the "gap" between predicted and experienced affect may engender dissatisfaction with product choices and consumption decisions. The research presented in this session will offer a unique look at people's lay theories regarding future affect, and process mechanisms that lead to erroneous predictions. For example, the papers in this session investigate questions such as the following: How accurate are people's affective forecasts about the impact of alternative products on actual enjoyment derived during consumption and under what circumstances will they be more accurate? Are people's lay theories helpful regarding how to manage their future enjoyment by shifting their standards? More generally, the three papers together present a comprehensive look at the nature of the processes that may drive the affective gap, and in doing so, offer meaningful insights into how the suboptimal tendencies may be corrected.

The first paper (Morewedge, Gilbert, Myerseth & Wilson) shows that affective forecasters tend overlook the extent to which they will attend to the consumption of experiences, rendering the alternatives to that experience irrelevant to their satisfaction with it. Five experiments demonstrate that the subsequent affective "gap" occurs due to shifting standard of comparison, whereby people's forecasts of product value is mistakenly based on the relative magnitude of difference between an experience and its possible alternatives, rather than on the absolute value of the alternative itself. The results suggest that forecasters evaluate experiences in comparison to the perceived desirability of alternatives, and underestimate the extent to which hedonic experiences of the focal alternative "consume" attention, rendering alternatives irrelevant.

The second paper (Cho & Johar) questions people's lay belief that future affect can be managed by lowering one's goal standards. Using financial products, the results show that the strategy of lowering goal standards backfires because one's forecast of what it would take to make an outcome satisfactory differs from what is in fact used as the benchmark upon receiving the outcome of the chosen set of financial products. Subsequently this shifting standard of comparison casts a negative influence on people's judgment of how satisfied they are with the outcome, holding objective outcome constant.

The third paper (Nelson, Meyvis & Galak) demonstrates that people are unable to predict their adaptation to positive experiences, and that they incorrectly believe that disruptions of positive experiences will be aversive, when in fact, it increases their overall enjoyment. Using television viewing as the hedonic context, authors show that consumers are not only incorrectly forecasting the magnitude of their affective responses, but incorrectly forecasting the valence of their affective responses. The robustness of disruption-induced increase in enjoyment is explored in three studies.

Taken together, the three papers examine lay beliefs of future affect and the consequence of these beliefs in diverse consumption domains of financial decision making, food consumption and TV program viewing. The session will provide an integrative look at the processes by which the inaccurate beliefs regarding future affective responses imparts a negative influence on people's evaluation of their experiences and decision outcomes. What emerges is a dynamic view of how affective forecasting operates, and with it, ways in which consumers may be better informed towards optimizing their satisfaction and well-being. The session as a whole should be of interest to a diverse set of ACR audiences: those interested in anticipated emotions, lay theories, inter-temporal choice, and comparison processes. Furthermore, Rebecca Ratner, the discussant of this session is a leading expert in the area of hedonic forecasting in consumer research, and will provide a cohesive perspective to tie together the three presentations.

## EXTENDED ABSTRACTS

### "Consuming Experiences Shift Standards through Attentional Collapse"

*Carey K. Morewedge, Carnegie Mellon University*
*Daniel T. Gilbert, Harvard University*
*Kristian O. R. Myerseth, University of Chicago*
*Timothy Wilson, University of Virginia*

Judgments are by nature comparative. When people judge the loudness of a tone, the heaviness of a solid, or the brightness of a light, they compare their experience of the stimulus with a standard (Helson, 1964). That standard may be a prior experience ("This mug is heavier than the one I just lifted"), a concurrent experience ("This star isn't as bright as that one"), or even a future experience ("This passage is softer than the one we're about to hear"). In many cases, the standard influences people's judgments of the stimulus by creating a contrast effect, which is why a dog looks larger when standing next to a mouse than it does when standing next to an elephant (Mussweiler, 2003). Although objective measurement can solve the problem of shifting standards for judgments of brightness, loudness, and heaviness, it cannot do the same for judgments of value. Luminosity, volume, and weight are stable properties of a stimulus that only appear to vary across time, context, and persons, but value is an unstable property that actually does vary on these dimensions. Two people may value a vacation differently, the same person may value a vacation more than she did last week, and there is no principled reason why a person should value the vacation as much as another person, or as much as she once did.

Why are shifting standards a problem for judgments of value? There is a principled reason why one should value a vacation as much when one imagines it as when one experiences it. If one values

a vacation more when one imagines it than when one experiences it, one may pay too much for it, miss the opportunity to spend one's money on something that brings greater pleasure, and end up feeling disappointed. Making good decisions requires making accurate predictions about the value of future experiences, but a burgeoning literature on affective forecasting suggests that people don't do this particularly well (for reviews see Gilbert, Driver-Linn, & Wilson, 2002; Loewenstein & Schkade, 1999; Wilson & Gilbert, 2003).

We believe that the problem of shifting standards is responsible for many affective forecasting errors. Specifically, we suggest that people tend to compare experiences to a wider range of standards when they imagine them than when they have them, and thus their actual and predicted valuations of those experiences naturally diverge (Hsee & Zhang, 2004). When predicting the hedonic benefits of future experiences, we propose that forecasters over-attend to absolute differences between experiences and their possible alternatives, and under-attend to how easily experiences and their alternatives can be compared. Why does the ease of comparison matter? Participatory experiences consume attention and may make comparison to alternative possible experiences difficult. When one is on vacation, eating cookies, or cheering on one's favorite team, one may have few cognitive resources available to compare the experience one is having to what one could have done instead. In other words, participatory experiences may constrict one's attention and focus it on the here and now rather than on what might have been.

In five experiments, participants forecasted how much they would enjoy a future experience (e.g., eating potato chips) or had that hedonic experience. Hedonic forecasts were strongly affected by the presence of a superior alternative (e.g., chocolate) or an inferior alternative (e.g., sardines), but hedonic experiences were unaffected in three experiments—experiencers were happy eating potato chips irrespective of their possible alternative. In our fourth experiment, forecasters predicted that their enjoyment of chips would be affected by dissimilar alternatives considered to be vastly superior or inferior, but unaffected by similar alternatives that were slightly superior or inferior. Conversely, experiencers' enjoyment of chips was not affected by vastly superior or inferior dissimilar alternatives (i.e., chocolate or sardines), but was affected by slightly superior and inferior similar alternatives (i.e., better and worse potato chips). In other words, hedonic experiences were affected by present alternatives only when hedonic experiences required few attentional resources.

To test whether the prior effects were caused by the constriction of attention that consummatory induce, experiment 5 tested whether experiencers with surplus attention would compare an experience to dissimilar alternatives. Thus, we instructed forecasters to imagine eating and experiencers to eat one chip every 15 or 45 seconds instead of either chocolate or sardines. We reasoned that experiencers who ate slowly would have more attention to pay to alternative experiences and would thus make comparisons similar to those made by forecasters. After consuming five chips, participants indicated how much they would enjoy or did enjoy the chips. Forecasters predicted that their enjoyment of the chips would be affected by the alternative superior or inferior food, irrespective of the pace of consumption. Whereas experiencers' reports were unaffected by the alternative superior or inferior food in the fast pace (15s) condition, experiencers' reports were affected by the alternative superior or inferior foods in the slow pace (45s) condition. Together, the results of the five experiments suggest that forecasters evaluate experiences in comparison to the perceived desirability of alternatives, and underestimate the extent to which hedonic experiences "consume" attention and render alternatives irrelevant.

### "Low-balling on Goals to Regulate Future Affect: A Functional Strategy?"

*Cecile Cho, Columbia University*
*Gita V. Johar, Columbia University*

People often set low goals in order to avoid future disappointment. Whether it is how well one performs on an exam, how wonderfully the blind date will go next week, or how relaxing the spa vacation will be, people lower their goal standards downward as uncertainty and the possibility of disappointment looms near (Kopalle & Lehmann 2001; Monga & Houston 2006). While there is ample evidence of people resorting to such "low-balling" strategy in psychology (add cites for defensive pessimism) and consumer behavior literature, no research has examined whether or not such a strategy functions as assumed.

Specifically, we question whether the strategy functions in the manner that people think it will. The assumption is that when goal standards are lowered, doing so will lower the potential for disappointment with an unknown outcome, holding outcome constant. For this strategy to work, however, the lowered standard needs to be used as the point of comparison to evaluate the outcome. If consumers spontaneously recruit their goal standards and compare the outcome to this standard, they are likely to experience positive affect and be satisfied. However, if consumers recruit a different standard of comparison than the initial goal standard, then the outcome relative to that standard will drive their affect. Various streams of literature in social psychology including social comparison theory (e.g. Tesser et al. 1988) and well-being (Diener 1984), as well as the gap model of satisfaction (e.g., Oliver 1980; Parasuraman et al. 1985) have suggested that comparing one's outcome to a higher standard has a negative impact on one's evaluation of the outcome. Hence, if the potential performance, rather than the goal standard is recruited at the time of outcome, affect and satisfaction are likely to suffer when the goal standards are low relative to the potential.

We argue that consumers are likely to spontaneously compare their performance to the potential—or "what could have been"—rather than the goal that they set themselves. Such upward comparison is especially likely when the potential range, rather than the

goal, is salient at the time of outcome feedback. Four studies mimicking real decisions made in the financial decision making domain provide support for the hypothesis that low-balling on goals has an adverse impact on satisfaction and affect, even when goals are met. This is due to a spontaneously evoked comparison standard that is higher than one's initially lowered goal standard. Participants in all experiments set a financial return goal based on a range of possible performances and then perform a stock portfolio construction task. They then receive feedback about their ostensible performance that is matched to their goal level (Studies 1, 2, and 3). Our interest lay in reported affect and satisfaction after feedback.

In Study 1 we indeed find that "low-balling" goals negatively affects satisfaction even when this goal is met, and that this is because the default comparison of performance is not to one's initially set goal, but to the potential. We vary the information that is salient at performance feedback (performance only, performance plus goal, performance plus potential) and find that those who low-balled their goals report lower satisfaction and higher disappointment with their outcome than those who set high goals for the "performance-only" and "performance plus potential" condition, whereas this difference was not found when goal was provided alongside performance.

In Studies 2 and 3 we replicate the negative impact of low-balling on satisfaction controlling for the objective level of outcome. Using simulated online trading task, we induce low (vs. high) goal setting by priming motivational orientation (Study 2) or individual's concern with managing future affect (Study 3), while shifting the range that is provided such that those who pick their target return perceive it as either high (choose 6 or 11%; range of 2-15%) or low (e.g. choose 11 or 16%: range of 7-20%) given the range that is provided. Again, the low goal setters reported significantly lower satisfaction than high goal setters, holding objective performance constant. We also rule out counterfactual thoughts as a competing process which may drive the negative impact of low-balling on satisfaction, while varying the level of confidence in future performance and salience of performance range to further buttress our proposed process.

While Studies 1, 2, and 3 test the functionality of the low-balling strategy using confirmed goals, Study 4 uses disconfirmed goals to test whether people belief about the "safe and confirmed" goal choice ensuring against disappointment is a accurate. Contrary to people's belief, results show that those who low-balled their goals and met this goal were significantly less satisfied even when compared those who set their goals high but fell short of this goal, despite the former having objectively superior outcome.

Taken together, the four studies paint a compelling picture regarding the unanticipated pitfalls of people's beliefs that they can increase satisfaction and safeguard against disappointment by "managing [their] expectation." This research ties in with the recent work on affective forecasting which suggests that people are poor predictors of their future affective states. Our findings add to this literature by showing that people not only mispredict future affective states but also mis-manage them. For consumers who base their consumption decisions and choices on this belief, the mispredictions of their future affect and their belief that they can manage this future affect incurs a double cost on their satisfaction with their consumption decisions and choices.

## "Mispredicting Adaptation and the Consequences of Unwanted Disruptions: When Advertisements Improve Television"

*Leif D. Nelson, New York University*
*Tom Meyvis, New York University*
*Jeff Galak, New York University*

People like watching television but they dislike watching television advertisements. Given that television viewing is one of the most popular leisure activities, it would seem to be a reasonable assumption that consumers have the knowledge and experience to accurately gauge which factors maximize their enjoyment. On the other hand, the decision to remove commercials requires consumers to accurately forecast the hedonic consequences of that decision, and this type of forecasting falls in the domain of a particularly common human incompetence. As we detail below, despite a universal belief to the opposite, television advertisements can actually improve the experience of watching television.

Why do people believe that advertisements worsen the television viewing experience? One possibly is that consumers cannot forecast adaptation to hedonic stimuli. Indeed, people tend to believe that they will not adapt to new stimuli (Loewenstein & Frederick, 1997), that other people cannot adapt to changes in life circumstances (Schkade & Liersch, 2006), and occasionally, that some stimuli may actually lead to sensitization (Nelson & Meyvis, 2007). Furthermore, with positive stimuli, consumers may simply prefer to take in the experience continuously rather than mitigating the positivity with disruption.

Despite this consensus, consumers may be incorrect. When experiences are meaningfully disrupted consumers take longer to adapt (Lyubomirsky, Sheldon, & Schkade, 2005), and disruptions can intensify hedonic experiences (Nelson & Meyvis, 2007). If consumers adapt to television programs, it may be the case that a disruptive advertisement may mitigate adaptation and increase enjoyment of the subsequent programming.

In four studies we examine the effect of advertisement disruptions on the enjoyment of television. Across the studies, Experiencers reported their enjoyment of either a continuous or a disrupted program, whereas Forecasters were asked to predict the results of those two conditions.

In Study 1 we recruited participants to watch an episode of Taxi and report their enjoyment of the program. Approximately half of the Experiencers watched the program as it was aired

whereas the remainder watched the same program with the advertisements edited out. Forecasters either read a description of the former condition or a description of the latter. Although Forecasters thought that people would like the show less when it was disrupted, Experiencers enjoyed the program more when it was disrupted than when it was not. Furthermore, in an effort to eliminate the possibility of contrast effects (and test the robustness of our finding), we replicated these results when we interrupted a different program with an advertisement that was judged to be as enjoyable as the program itself (Study 2).

It may be the case that the mere presence of television advertisements, rather than their disruptiveness, improves judgments of television programs. We tested this possibility using a brief documentary about ducks (Study 3). For some participants, the documentary was presented continuously, with an advertisement both directly preceding it and directly following it. For the remaining participants, the advertisements were inserted in the program itself, disrupting it at two different points. As predicted, consumers who watched the disrupted documentary judged it more positively and were more likely to donate money to a nature-related charity than were participants who watched the continuous documentary. A different group of Forecasters expected exactly the opposite result.

Our final investigation wanted to show that any disruption could have a positive effect, and that advertisements need not be the disruption (Study 4). Participants watched and evaluated two documentaries, one about the American Bison and one about deserts of the world. For some participants these were each shown continuously, one after the other. For the remaining participants the clips were spliced together such that one interrupted the other. Forecasters predicted that the two versions would be about equally enjoyable, but in fact Experiencers enjoyed the spliced version more than the continuous version.

Across these studies we illustrate circumstances in which consumers are not only incorrectly forecasting the magnitude of affective stimuli; they are incorrectly forecasting the valence. Disrupting a television program seems bad on so many levels (e.g., adding a negative event, subtracting from the gestalt of the experience, etc.), that there is a near consensus that disruptions will have a negative consequence. This faulty assumption leads consumers to spend time and money (e.g., buying DVD's, subscribing to premium cable channels) to structure experiences that may actually lessen enjoyment.

SYMPOSIA SUMMARY
# Consumer Motivation: Identifying Factors that Increase Goal Adherence
Minjung Koo, University of Chicago
Ayelet Fishbach, University of Chicago

## SESSION OVERVIEW

How can marketers, managers and other social agents motivate people to adhere to their long-term goals? According to goal research, the process of goal pursuit involves setting a goal, which then motivates the exercise of self-control toward selection of congruent actions and overcoming obstacles (e.g., Carver & Scheier 1998; Mischel 1984). This session will contribute to goal literature by identifying some important factors that determine the strength of a person's motivation toward goal pursuit. All three papers explore distinct motivators (goal commitment and lack of progress, high-versus low-construal level, and consumers' lay theories on self-control) that influence the likelihood of adhering to a long-term goal.

In the first paper, Koo and Fishbach identify two factors that increase motivation: goal commitment and lack of goal progress. They find that the focus on accomplished actions increases goal adherence by signaling goal commitment, whereas the focus on unaccomplished actions increases goal adherence by signaling lack of progress. Specifically, they show that emphasizing accomplished actions increases motivation when commitment is low and uncertain (thus when commitment is under consideration), for example it increases motivation to study for a relatively unimportant exam, and to make first-time contributions to a charity. Emphasizing unaccomplished actions increases motivation when commitment is high and certain and a person is concerned with the level of goal progress, for example it increases motivation to study for an important exam, and to make repeated contributions to a charity.

In a second paper, Fujita argues that how an event is mentally represented by consumers influences the motivation to adhere to a long-term goal. Abstract (high-level) vs. concrete (low-level) construals of events enhances the adoption of various self-control strategies and increase the likelihood of pursuing long-terms goals. For example, high-level construals promote a tendency to pre-commit one's future choices, self-punishment for failure to achieve goals and more negative evaluations of temptations.

In the third paper, Mukhopadhyay and Yeung identify consumers' lay theories of self-control as a motivator to increase goal-consistent choices of products for young children. The authors argue that people who believe that self-control is a limited resource that can be increased over time (i.e., limited-malleable theorists) are more interested in products that pursue long term goals. Across four experiments, they demonstrate that those limited-malleable theorists choose more goal-congruent products for their children: taking their children less frequently to fast food restaurants, allowing them fewer unhealthy snacks, and preferring educational to entertaining television programs for them.

Taken together, the three papers provide an overview of factors that increase consumer motivation and have theoretical as well as practical implications for goal research. Data collection in all papers is complete and the session includes a total of 11 studies. All participants have agreed to present should the session be accepted. Each presentation will be for 20 minutes, which will allow 15 minutes for discussion by Michel Pham (the discussion leader) and Q&A at the end of the session.

We expect that this session will be of interest to a broad audience of consumer researchers but of special interest to those researchers interested in issues regarding goals, self-control and motivation. The area of goals is one that has generated considerable interest over the past several years, and we hope that our presentation of recent findings on factors that facilitate goal adherence will result in active debate and generate ideas for future research.

## EXTENDED ABSTRACTS

### "Dynamics of Self-Regulation: How (Un)accomplished Goal Actions Affect Motivation"

*Minjung Koo, University of Chicago*
*Ayelet Fishbach, University of Chicago*

People often encourage themselves to work on a goal by considering either their accomplished or their unaccomplished actions. For example, students increase their motivation to study by assessing the amount of time and effort they have already invested on an academic task or by assessing the amount of time and effort required to complete the academic task. Similarly, athletes maintain their motivation to complete a long race by considering either the completed or the remaining distance to the finish line. In addition, social agents, organizations, and educators provide information about accomplished and unaccomplished actions to motivate others to act on a social goal. For example, fundraisers present information about the amount of donations they have received thus far (i.e., seed money) or the amount that is missing to complete a charity campaign goal. Whereas emphasizing accomplished and unaccomplished actions is common, the current research examines when accomplished and unaccomplished actions exert greater effect on motivation. For example, when does information about the amount of money donated thus far versus the amount required to complete a campaign goal increase the likelihood of making a pledge?

We identify two factors that affect motivation: commitment and lack of progress (i.e., discrepancy). We propose that accomplished actions increase motivation by signaling goal commitment (Bem 1972), whereas unaccomplished actions increase motivation by signaling lack of goal progress, which promotes actions that reduce the discrepancy to goal attainment (e.g., Bandura 1991, Carver and Scheier 1981; 1990; Higgins 1987; Locke and Latham, 1990). It follows that accomplished actions motivate congruent choices when goal commitment is ambiguous and relatively low thus when goal commitment is under consideration, whereas unaccomplished actions motivate congruent choices when goal commitment is high and constant thus when the pace of progress on the goal is under consideration. For example, uncommitted students would express greater motivation to study if they considered their accomplished (vs. unaccomplished) academic courses, whereas committed students would express greater motivation to study if they considered their unaccomplished (vs. accomplished) academic courses. We further assume that the focus on accomplished versus unaccomplished actions has similar effects on the pursuit of personal goals (e.g., studying) and contributing to social goals (e.g., charity donations).

Our results across four studies support these hypotheses. By keeping the amount of actual goal progress constant (approximately 50%), we find that the focus on accomplished actions (50% to date) increases the motivation to work on a goal when commitment is

low, but the focus on unaccomplished actions (50% to go) increases the motivation to work on a goal when commitment is high. Specifically, in Study 1, the focus on completed (vs. uncompleted) coursework increased the motivation to study for an elective course but decreased the motivation to study for a core course. In Study 2, the focus on accumulating (vs. remaining) stamps on a frequent-buyer card increased the motivation to use the card toward luxury rewards (e.g., sweatshirts) but decreased the motivation to use the card toward necessity rewards (e.g., textbooks). In Study 3, providing information about the proportion of students who already own (vs. do not yet own) University of Chicago merchandise increased the motivation to purchase these items when the purchase was framed as fulfilling a desire, but it decreased the motivation when the purchase was framed as fulfilling a need. Finally, in Study 4, a field experiment involving an actual fundraising showed that framing seed money in terms of accumulating progress (vs. remaining progress to complete a campaign goal) increased first-time donations but decreased repeated donations by regular donors.

We found further evidence for the underlying inferences that motivate people to act on a goal—namely, either because their commitment is high or because their progress is low. Thus, only uncommitted (but not committed) participants inferred goal commitment on the basis of accomplished actions and therefore were more likely to adhere to the goal (Study 1). In addition, only committed (but not uncommitted) participants expected more goal progress when the focus was on unaccomplished (vs. accomplished) actions, which in turn increased their motivation to adhere to the goal (Study 2). It appears that whether people infer commitment or progress depends on the available information as well as the question they ask (Trope and Liberman 1996), which can refer to their levels of commitment (for uncommitted people) or progress (for committed people).

Taken together, these studies provide convergent evidence that the focus on accomplished actions increases goal adherence by signaling goal commitment when commitment is low and uncertain, whereas the focus on unaccomplished actions increase goal adherence by signaling lack of progress when commitment is high and certain and a person is concerned with the level of goal progress.

### "Mental Construals and the Use of Counter-Active Self-Control Strategies"

*Kentaro Fujita, Ohio State University*

People often fail to do what they want to do, despite possessing the knowledge, opportunity, and skills required. Such self-control failures are pervasive and the focus of a multi-disciplinary research effort. Most models of self-control posit conflicts between automatic versus controlled psychological processes (e.g. Baumeister & Heatherton, 1992), long-term versus short-term motives (e.g. Ainslie & Haslam, 1992; Frederick et al., 2002), or impulsive affect versus rational cognition (e.g. Loewenstein, 1996; Metcalfe & Mischel, 1999).

Recently, Fujita and colleagues (2006) proposed an alternate analysis of self-control based on the tenets of construal level theory (Liberman et al., 2007; Trope & Liberman, 2003). This model posits that people can mentally represent events at multiple levels. High-level construals are mental representations that extract from a class of events those abstract, global, and primary features that are common to and defining of all cases. Low-level construals, in contrast, specify the concrete, local, and secondary features that render one case unique from others. Extensive research has demonstrated the distinction between high- vs. low-level construals and their impact on preferences, decisions, and actions (see Liberman et al., 2007; Trope & Liberman, 2003, for reviews). A construal

level analysis of self-control suggests that self-control conflicts arise when the action implications of high- and low-level construals are in direct opposition. Self-control entails making decisions and acting in accordance with high- vs. low-level construals. The activation of high-level construals should therefore promote self-control. Indeed, research findings have indicated that that high-level construals reduce preferences for immediate over delayed outcomes, promote physical endurance, and strengthen behavioral intentions to engage in activities requiring self-control (Fujita et al., 2006). That is, self-control is promoted when people see the proverbial "forest beyond the trees."

Choosing a behavioral option that reflects greater self-control is only one aspect of the self-control process. People actively shape their social environments, re-structuring decisions to enhance the likelihood of self-control success. People often engage in various strategies pro-actively in anticipation of future self-control conflicts (see Trope & Fishbach, 2005, for review). These strategies are referred to as counteractive self-control strategies, and take numerous forms, such as self-imposing penalties for self-control failures, making rewards contingent on self-control success, and pre-committing one's self to a choice prior to the decision-making opportunity (e.g. Ainslie, 1975; Ariely & Wertenbroch, 2002; Gollwitzer, 1990; Trope & Fishbach, 2000). The initiation of any of these strategies, however, requires one to recognize that there are competing concerns, and that one concern is more primary and central than the other. As such, the utilization of counter-active self-control strategies should be enhanced by the activation of high-level construals.

Study 1 examined pre-committing of one's future choices as a function of construal. Research has indicated that when people pre-commit future choices, they are more likely to make choices that are consistent with greater self-control (Read, Loewenstein, & Kalayaram, 1999). Participants generated superordinate (high-level) ends achieved by vs. subordinate (low-level) means to achieve good physical health (Freitas et al., 2004; Fujita et al., 2006). They were then told of an opportunity to participate in a future study that required attending multiple experimental sessions. They were also told that they would be provided with a snack at each session. After viewing the snack options, which included healthy and unhealthy choices, participants were asked to indicate whether they would prefer to pre-commit to all of their snack choices in advance, or decide on a session-by-session basis. As predicted, those induced to construe events at high-level construals had preferred to pre-commit their future choices. Importantly, as predicted, this effect of construals was specific to those for whom the choice between healthy vs. healthy represented a meaningful self-control conflict–i.e., those who on a follow-up measure indicated that health goals were valuable and important to them. This specific pattern of results suggests that the results indeed are attributable to strategic, goal-directed adoption of pre-commitment as a function of construals.

Research by Trope & Fishbach (2000) suggests that people strategically self-impose punishments for failures in anticipation of future self-control conflicts. Study 2 examined whether high- vs. low-level construals would promote this tendency. Participants engaged in a task entailing superordinate (high-level) vs. subordinate (low-level) categorization of objects (Lin, Murphy, & Schoben, 1997). They were then told about an opportunity to participate in a future study that would provide diagnostic personality feedback but would require waking up at 2 a.m. in the morning. Participants were asked to indicate how much they would be willing to pay as a cancellation fee if they failed to appear at the appointed hour. As predicted, those induced to high-level construals imposed higher

penalties for self-control failures. As with Study 1, this effect was specific to those for whom the study opportunity represented a meaningful self-control conflict- i.e., those who on a follow-up measure indicated that they thought the feedback would be valuable and important.

Whereas Studies 1 and 2 examined changes to the external features of future choices, Study 3 examined strategies designed to change the subjective perception of future choices. Research has suggested that people prospectively de-value future temptations to promote self-control (Trope & Fishbach, 2005). Study 3 examined whether high-level construals would promote the use of this strategy. To manipulate construal levels, participants either generated category labels (high-level construals) or exemplars (low-level construals) for a series of common objects (Fujita et al., 2006). Participants, who were all students, were then asked to evaluate a list of words, some of which were temptations that undermine the goal to study. More negative evaluations of these temptation words would represent counter-active self-control. As expected, high levels of construal led to less positive evaluations of temptations (with no differences between levels on non-temptation words). Moreover, as in Studies 2 & 3, the effect was limited to those who experienced those temptations as meaningful self-control conflicts, i.e. those who reported study goals as important and valuable. Taken all together, these three studies indicate that high-level construals promote strategic re-structuring of both external and psychological features of future decisions.

### "Building Character: Effects of Lay Theories of Self-Control on the Selection of Products for Children"

*Anirban Mukhopadhyay, University of Michigan*
*Catherine W. M. Yeung, National University of Singapore*

### Overview

The process of consumerization of young children is a relatively recent phenomenon, yet it is ubiquitous today. Given the extent of attention that marketers pay to young children, what role do parents and other concerned adults play in the interactions between marketers and children? Parents could act as strict gatekeepers regulating all consumption; alternately, they could follow a laissez-faire policy if that were more in line with their beliefs. Advocates have recommended that parents regulate television, restrict junk food intake, and control consumption choices in general so that children do not develop unhealthy habits. However, such recommendations recognize that parents need to "walk the talk", e.g., by watching less television themselves if that is what they seek to regulate. Indeed, family influences on the socialization of children as consumers may permeate more through processes of "subtle social interaction" than purposive educational efforts by parents (John 1999). People transfer values through products (McCracken 1986) and the product choices that parents make for their children are critical in fostering beliefs and values.

This research explores an under-researched mechanism via which the beliefs that adults hold influence the choices they make for young children. Specifically, we investigate how people's lay theories of self-control—their beliefs about the nature of self-control in general— influence their choices. Across four experiments, conducted in the laboratory and with parents intercepted in the field, we find that individuals who believe that reserves of self-control are limited yet augmentable are more likely to try and "teach" children to increase their self-control: by giving gifts that delay gratification or round out perceived shortcomings in character, by restricting the allowance of unhealthy foods, and by preferring educational to entertaining television programs for them.

### Theory

Lay theories, or "what ordinary men and women believe about the existence and power of individual differences in personality" have been shown to affect judgments and behavior in several domains (Ross and Nisbett 1991). Mukhopadhyay and Johar (2005) identified lay theories of self-control that varied on two orthogonal dimensions–(1) limited/unlimited, or the extent to which people believe that people in general have small vs. large stores of self-control; and (2) fixed/malleable, or the extent to which they believe these stores may be augmented over time. These lay theories are relevant in the current context because differences in beliefs about the nature of self-control may prompt differing inclinations towards trying to build a child's character. For instance, a limited-malleable theorist, namely, someone who believes that people have small reserves of self-control that may be increased over time, is likely to recognize that the amount of self-control available may not be enough to accommodate all demands, so there is a need to increase the reserves of self-control. This belief, together with the belief that self-control reserves can actually be increased, may motivate them to carry out actions that help improve self-control capability. By the same token, this person would also believe that it is worth trying to teach children to increase their self-control.

In contrast, unlimited-malleable theorists believe that people in general have very large reserves of self-control. In this worldview, people generally do not have problems of self-control, and therefore are unlikely to initiate practices that facilitate children's learning of self-control. An additional consideration arises when they are faced with options that can deliver instant gratification. To the extent that value is discounted with temporal distance, unlimited-malleable theorists may prefer products that deliver instant gratification rather than those that build self-control by delivering long-term value. Such products, that deliver instant rather than delayed gratification, are known as "relative vices" (Wertenbroch 1998), e.g., tasty but unhealthy foods, and entertainment programs such as cartoons.

Finally, fixed theorists believe that reserves of self-control can not be increased over time. Hence, in their worldview, the question of teaching children to increase their self-control should be irrelevant. Therefore, regardless of whether they hold a limited or unlimited theory, fixed theorists should be indifferent between virtues and vices when deciding for young children.

### Findings

These propositions were supported across four experiments. Experiment 1 found that parents' lay theories influenced their choices of food products—such as snacks and fast food—that are related to children's self-control. Parents who were limited-malleable theorists executed tighter control over their children's consumption of fast food and were less likely to appease them with unhealthy snacks, as compared with unlimited-malleable parents. As for fixed theorists, the frequency of visiting fast food restaurants and the likelihood of providing quickie snacks did not differ as a function of whether they believed that self-control is limited or unlimited.

Experiments 2 and 3 then showed that lay theories also influence people's tendencies to gift children products that develop self-control and build character. In experiment 2, limited-malleable (vs. unlimited-malleable) theorists were more likely to choose a gift that delivers greater long-term than short-term value. Fixed theorists did not differ in their choices of products that varied on this dimension. In experiment 3, limited-malleable theorists were more likely to choose a gift that can develop the child in a manner that is complementary to the child's current character. That is, they

preferred to gift an educational game to a child described as cheerful and happy, but an entertainment game to a child described as bright and intelligent.

Finally, experiment 4 demonstrated the same pattern of effects in parents' choices of television programs, and reversed the effect using a simple salience manipulation (cf. Mukhopadhyay and Johar 2005) that changed parents' expectancies about their children's self-control.

The convergent patterns observed across experiments, across the domains of gift-giving, television program preferences, and eating allowances, and in the lab with student participants as well as outside with real parents, provide strong support for our basic hypothesis. Other psychological and demographic variables did not explain these patterns systematically, and controlling for these factors did not affect the basic pattern of results. These results show that the actions of parents and other elders may implicitly influence how children develop, driven purely by beliefs such as lay theories that the adult holds, independent of any explicit motives.

# Sex and Consumption: Empirical and Theoretical Advances

Darren Dahl, University of British Columbia, Canada

## SESSION OVERVIEW

A Google search of the phase "sex sells" yields over two million hits. This pedestrian wisdom is an often-repeated quip when people are confronted by a particularly shocking or gratuitous use of sexual stimuli in advertising. As researchers we know that this simple causal relationship, though appealing in its parsimony, is undoubtedly a gross oversimplification of a much more complex series of inter-related behavioral variables. The objective of the session is to advance consumer behavior theory on this under-researched topic: the influence of sexual motivations and stimuli on consumption. In three presentations (each of which is based on completed papers), we provide experimental data that represent unique, substantive and theoretical contributions to the consumer behavior literature and elucidate some of the complex relationships at work when sex and consumption activities collide. All three papers address the theme of this year's ACR of bridging different theoretical paradigms by incorporating aspects of economic, biological and social role theories to study consumer cognition and choice.

The first presentation (Vohs, Finkenauer and Burger) employs a social exchange perspective to further explore sex as a commodity traded between men and women, focusing on the sellers (typically women) and what kinds of resources they are willing to exchange for sex. The second presentation focuses on the buyers (typically men) and outlines conditions under which some of those men are motivated to engage in distinct consumption behaviors (i.e., conspicuous consumption) when primed with mating stimuli (Sundie, Griskevicius, Kenrick, and Tybur). The third presentation explores the effectiveness of marketing strategies that employ sexual stimuli (i.e., in advertisements); and demonstrates that the effectiveness of sexual images in advertising is moderated by both gender and personality differences (Sengupta and Dahl). Finally, the discussant, Gerald Gorn, will integrate the findings of the three papers and provide his own insights on the area. This special session is expected to be of interest to a wide variety of consumer behavior researchers; specifically those individuals interested in human sexuality, gender differences, conspicuous consumption, advertising response, and social exchange. Each of the papers included in this session are complete.

## EXTENDED ABSTRACT

### "Sexual Behavior as Predicted by a Social Exchange Model: Three Tests of Sexual Economics"

*Kathleen Vohs, University of Minnesota*
*Catrin Finkenauer, Vrije Universiteit Amsterdam*
*Nina Burger, Vrije Universiteit Amsterdam*

This research tests new theory, entitled Sexual Economics, which seeks to predict differences in heterosexual sexual behavior as viewed from a social exchange framework (Baumeister and Vohs, 2003). The theory starts with the premise that sex is a commodity that women possess and that men want. Because women are the gatekeepers of sex (Baumeister, Catanese, and Vohs, 2001), men must offer resources (e.g., time, money, respect, attention, commitment) to obtain it from women. From this perspective, women act like sellers and men act like buyers and each gender's behavior can be understood as individual and gender-wide attempts to maximize utility. Three studies tested the model and its implications.

In the first study, we tested one of the basic, underlying premises of the model. Because men have dramatically stronger sex drive than women (Baumeister et al. 2001) and women are the decision makers as to when sex is allowed to take place, women will be attuned to the amount or quality of resources they have been given. Accordingly, women will be in an exchange mode when cued with the idea of allowing sex to occur. Specifically, we tested the hypothesis that thinking of a sexual situation heightens women's exchange (versus communal) orientation. In this study, Dutch men and women either read a scenario about a woman and a man on a first date or about an evening with friends. Both the *dating* and *friend* paragraphs were written in the second-person and included as the two main activities going out for dinner and then to a club to dance. However, the dating paragraph contained some sexual overtones whereas the friend paragraph did not. Thus, the scenes were equivalent in all ways except for the presence of a sexual connotation in the dating scene. Next participants read communal- and exchange-related statements in what was described as a proof-reading task. After a filler task, participants were given a surprise recall test for the items in the proofreading task. The results showed the predicted interaction effect between gender and scenario, such that women who read about a sexual dating scenario remembered more exchange-related (but showed no change on communal-related) items, relative to women who had read the dating scenario and men who had read the dating scenario.

A second study tested an implication of the model, which is derived from social exchange theory: when one person over-benefits relative to another, the over-benefited person will feel guilt due to this imbalance. Hence, in study 2, we tested whether women would expect to feel guiltier if they received resources from the man but did not return the exchange with sexual access. Six scenarios (2x3 between-subjects design) were presented to men and women and they made judgments of what the woman in the story would be feeling. Each scenario described a night wherein a woman and a man go to dinner. Their dinner is described as their first, fourth, or eighth, and the man either pays for the dinner (as he has on each occasion) or they split the bill (as they have on each occasion). The scenario ends in all conditions with the man walking the woman to the door, where the woman senses that he wants to come in but, being unsure of her feelings for him, she gives him a small kiss on the cheek and says goodnight. Again, the dependent measure was ratings of the woman's feelings as a function of number of dinner dates and who paid for the dinners. The results showed the predicted effect, such that participants (both men and women) believed that the woman in the story would feel more guilt when she had been to dinner with the man on multiple occasions and he had paid for each dinner each time. Participants did not, however, perceive that she would be feeling more negatively in general; rather the effect was specific to guilt–as would be predicted by a social exchange account.

Study 3 took a more direct approach to understanding guilt as an outcome of over-benefiting in the context of sexual exchange. Analogous to the findings of study 2, we predicted that when women accept a gift but do not reciprocate in a sexual fashion, they will experience higher levels of guilt than men in the same situation

or women who did not receive a gift or have sex on Valentine's Day. In the week after Valentine's Day, participants completed a survey regarding gifts given for Valentine's Day. We asked participants whether they had received a gift on Valentine's Day and whether they had sex that day. Then we assessed several negative emotional states, which the key dependent variable being ratings of guilt. As predicted, women who received a gift but did not have sex with their partner on Valentine's Day reported stronger feelings of guilt than did participants in the comparable cells.

In sum, these data support the sexual economics theory of heterosexual sexual behavior. When men want sex from women, they must exchange resources. In study 1, we showed that when women are reminded of a sexual dating situation, they become more attuned to exchange-relevant (as opposed to communal) information. We showed in studies 2 and 3 that women are expected to feel (study 2) and actually feel (study 3) more guilt when they receive a resources or a gift from a man but do not reciprocate by engaging in sexual behavior.

### "Peacocks, Porsches and Thorstein Veblen: Romantic Motivations for Conspicuous Consumption"

*Jill Sundie, University of Houston*
*Vladas Griskevicius, Arizona State University*
*Douglas Kenrick, Arizona State University*
*Joshua Tybur, University of New Mexico*

As they acquire wealth, people tend to spend an increasing amount on frivolous luxuries. The market for "new luxury" products was recently estimated at $350 billion per year, with a 10-15% annual growth rate (Silverstein and Fiske 2003). Thorstein Veblen (1899) documented displays of such luxuries over a century ago, coining the term "conspicuous consumption." Conspicuous consumption can be motivated by different forms of impression management, such as signaling competency to potential clients, or one's social class to new neighbors. Our research focuses on an underexplored motivation for engaging in conspicuous consumption—signaling to potential mates.

Costly signaling theory (Zahavi and Zahavi 1997) and sexual strategies theory (Gangestad and Simpson 2000) are employed to generate unique hypotheses about mating-related motivations for conspicuous consumption. There are well-documented sex differences in mate preferences indicating that wealth displays are more advantageous for men than women in the mating market. The present research expands on this work by drawing on two biologically-based theories to predict that other factors, such a man's sexual strategy and goal state, can also influence motivations to conspicuously consume.

In three studies we investigated how mating-related primes, participant sex, and participants' sexual attitudes may be linked to purchase evaluations and decisions (studies 1 and 2), and what mating-relevant impressions are formed by observers of others' conspicuous consumption (study 3). We provide evidence for a two-way signaling system; showing first that the propensity to send a sexual signal via conspicuous consumption is enhanced only for some individuals when in a mating mindset, and second that observers of others' conspicuous consumption interpret that signal accordingly.

In study 1, tendencies to conspicuously consume were examined under different goal states. Men that hold sexually unrestricted attitudes (reflecting an openness to sex without commitment) were predicted to be the most likely to conspicuously consume, but only when primed with mating-related stimuli. 203 participants were either primed with pictures/profiles of opposite sex targets in a campus dating service (mating), or pictures/descriptions of dormitories in a residence placement service (neutral/control). In an ostensibly unrelated task, participants then spent a $2000 budget on 36 possible items (e.g., clothing, iPod) varying in their conspicuousness (per independent sub-sample judgments). Materialism (Richins and Dawson 1992) and sexual attitudes (Simpson and Gangestad 1991) were also measured. Materialism did not significantly predict conspicuous consumption. An a priori contrast revealed that sexually unrestricted men who received a mating prime were significantly more likely to conspicuously consume than sexually unrestricted men not primed with mating stimuli, sexually restricted men regardless of prime, and women regardless of sexual attitudes or prime $F(1, 223)=12.35$, $p=.001$, providing support for the hypothesis advanced.

Study 2 employed two different scenario mating primes—a short-term (uncommitted sex) and a long-term (romantic love, commitment) prime to conceptually replicate study 1 and investigate boundary conditions on those results. Unrestricted men's conspicuous consumption was expected to be emphasized when primed with the short-term scenario, because that is a type of romantic encounter consistent with their sexual attitudes. 240 participants responded to 10 items: "Compared to the average student on campus, please indicate how much money you would want to spend on (e.g., a new car, nice dinner with your friends)?" Participants' sexual attitudes were measured. Compared to all other participants, sexually unrestricted men primed with short-term mating stimuli reported enhanced conspicuous spending, $F(1, 228)=10.30$, $p<.01$, relative to unrestricted men primed with either long-term or neutral stimuli, restricted men regardless of prime, and women and women regardless of sexual attitudes or prime, confirming our hypothesis.

Study 3 was designed to provide support for the receiving end of the signaling system—to show that observers of conspicuous consumers interpret or decode that behavior in a manner consistent with its function as a sexual signal (as documented in studies 1 and 2). Given such a system, we expected that when a person witnessed someone engaging in conspicuous consumption, he or she would form certain impressions about the target's attitudes towards relationships. Specifically, we predicted that if a man conspicuously consumes, he will be perceived as more open to short-term sexual opportunities than a man making a more conservative purchase. In study 3, 248 participants evaluated an otherwise identical male or female target who had purchased either a Porsche Boxter or a Honda Civic (MSRP, picture included). Background information (income, occupation, hobbies, target attractiveness) was held constant across conditions. The dependent measure was the set of sexual attitude items (Simpson and Gangestad 1991) as they thought their target would complete them. A priori contrasts revealed car type had a significant effect on impressions of the male target's attitudes $F(1, 197)=12.19$, $p=.001$, but not on the female target's attitudes, $F(1, 197)=2.51$, $p=.115$.

Data from three studies provide converging evidence that mating-related goals play a role in motivating conspicuous consumption, and that conspicuous consumption leads to the formation of mating-relevant impressions among observers. Rather than

finding a straightforward male-female difference in conspicuous consumption, we show that individual differences in sexual attitudes, and the person's motivational state (mating vs. non-mating) play key roles in motivating this ubiquitous consumption pattern. Conspicuous consumption was only enhanced among men who held sexually unrestricted attitudes, and only when they were primed with mating stimuli. The pattern of results fits best with costly signaling and sexual strategies theories, and less well with social role and normative explanations that focus on generalized male-female differences in consumption behavior. This research suggests that evaluations of "new luxury" products and the promotions designed to sell them may be influenced by the audience's sexual attitudes, and whether or not mating goals are salient when processing this product-related information.

## "Gender-Related Reactions to Inappropriate Sex Appeals in Advertising"

*Jaideep Sengupta, Hong Kong University of Science and Technology*

*Darren Dahl, University of British Columbia*

This research examines gender-based reactions to the use of inappropriate sexual images in advertising (i.e., when the sexual image is either unnecessarily explicit, and/or has little to do with the product being advertised). We focus particularly on reactions obtained under a high cognitive load, both in order to simulate real-world conditions whereby consumers typically process ads at a very shallow level, and also to provide insights into respondents' spontaneous reactions.

Prior advertising research has shown that both men and women tend to react negatively to sexually inappropriate ads (Peterson and Kerin 1977; Simpson et al. 1996), possibly because explicit and product-irrelevant sexual images are deemed to be unethical and manipulative (Friestad and Wright 1994). However, the current research suggests that different results might obtain under constrained capacity conditions. Specifically, we argue that ad attitudes under such conditions should be primarily influenced by spontaneous affective reactions; thus, consumers who harbor positive affect towards sexual stimuli–such as those who have intrinsically positive attitudes towards sex per se–should evaluate sex-based ads positively, in comparison to equivalent non-sexual ads.

Two experiments used this conceptualization to provide some insights into both similarities and differences between men and women in their reactions to sex-based advertising. First, drawing on the premise (which has received much support in both evolutionary

and socialization perspectives of human sexuality) that men on average possess more positive intrinsic attitudes towards sex than women, Experiment 1 tested the prediction that men will evaluate the use of inappropriate sexual appeals more positively than non-sexual ads under high load conditions, while the reverse pattern will obtain for women. A 2 (Gender: Men vs. Women) x 2 (Ad Type: Sexual vs. Non-sexual appeal) was used. All participants examined an ad booklet after being given a ten-digit number to hold in memory; thus simulating a high cognitive load. The target ad (for Chaumet watches) featured product details and a picture with either an explicit sexual image (a couple having intercourse) or a product-irrelevant non-sexual image (a landscape visual). Participants then responded to a series of questions, including the critical dependent variable–a 3-item measure of attitude towards the ad. A significant interaction of ad type and gender was obtained (p<.001). As predicted, males reported better attitudes for the sexual ad than the nonsexual ad ($M_{sex}$=5.74, $M_{nonsex}$=4.22, p<.001). Further, women followed the reverse pattern ($M_{sex}$=3.25, $M_{nonsex}$=4.54, p<.01). Also of interest were the results obtained in two control conditions, in which men and women processed the sex-based ad under a low cognitive load. Replicating past results, both men and women reported relatively poor ad attitudes under these unconstrained conditions ($M_{men}$=3.91, $M_{women}$=3.79, F<1).[1]

Experiment 2 used our conceptualization to explore intra-gender differences in evaluations of inappropriate sex-based ads, with a particular focus on women's reactions. If, as we have argued, spontaneous reactions to sexually explicit ads are driven by intrinsic attitudes towards sex per se, women with more liberal attitudes towards sex should display a similar pattern of responses as the men in Experiment 1. A 2 (Ad type: Sexual vs. Non-Sexual appeal) x 2 (Sexual Attitudes: Conservative vs. Liberal) between-subjects design was used; all four conditions were run under high cognitive load (female participants only). In addition, two male control conditions (Sexual Attitudes: Conservative vs. Liberal) were also studied; control participants were all exposed to the sex-based ad under load. The primary DV was again attitudes towards the ad. There were also two key additions: a) a standard seven-item scale tapping into liberal vs. conservative attitudes towards sex (Mercer and Kohn 1979; example item: "I approve of unmarried couples engaging in sexual intercourse"; median score=3.14 on a scale of 5); and b) items tapping into participants' cognitive deliberations about the ad (e.g., agreement with the statement "I think the ad featured an unethical use of sex") as well as items tapping into affective reactions during ad viewing–both positive (e.g., "happy") and negative (e.g., "upset")

A significant interaction of ad type and sexual attitudes was obtained (p<.01). As predicted, women with relatively conservative

---

[1]We note that our research focused primarily on the extreme cases of inappropriate sex appeals, as operationalized by both high explicitness and product-irrelevance of the sexual image. However, our theoretical conceptualization posits that, under constrained capacity, deliberations regarding product relevance are unlikely to play a part in determining attitudes induced by the ad. We would predict, therefore, that the gender difference observed in Experiment 1 should hold even if the sexual image were product-relevant. A follow-up study, in which men and women were exposed under constrained processing conditions either to the sexual ad from Expt 1 (i.e., irrelevant and explicit) or a product-relevant explicitly sexual ad (the same ad, but for condoms rather than watches), provided good support for this thesis. Men reported substantially more positive evaluations of the ad than women, regardless of product relevance.

(below median) sexual attitudes reported a significantly better ad attitude towards the non-sex ad than the sex ad ($M_{sex}$=3.44, $M_{nonsex}$=4.26, p<.05). At higher (i.e., more liberal) levels of sexual attitude, however, the opposite pattern was obtained, with female participants (like the men in study 1) now preferring the sex-ad to the non-sex ad ($M_{sex}$=5.15, $M_{nonsex}$=4.32, p<.05). Further regression analyses revealed that across conditions, ad attitude was significantly predicted by the overall affective index (p<.0001) but not by the cognitive index (ns). Subsequent mediation analyses then found that the effect of ad type on ad attitudes was fully mediated by participants' affective reactions. Finally, control group results showed that, as with women, better attitudes towards the sex ad were obtained for liberal men (M=5.73) than conservative men (M=4.23, p<.0001).

In sum, our research extends prior literature by showing that, rather than being uniformly disliked, the inappropriate use of sex in advertising can actually produce positive evaluations under constrained processing conditions–for men, as well as for women with liberal sexual attitudes. Our findings are consistent with the premise that respondents' reactions to such ads are driven primarily by their intrinsic attitudes towards sex per se. At a more detailed process level, we identify the critical role of ad-induced affect in driving evaluations of inappropriate sexual appeals under high cognitive load. Finally, by demonstrating both inter-gender and intra-gender variation in attitudes towards sex-based ads, our research provides findings consistent with modern perspectives on human sexuality, which argue against a purely gender-determined view of attitudes towards sexual stimuli (e.g., Gangestad and Simpson 2000). Additional implications of our research, as well as directions for further research, are discussed in the complete paper.

# Mindset-Dependent Consumer Decision Making

Michal Maimaran, Stanford University, USA
Uzma Khan, Stanford University, USA

## SESSION OVERVIEW

Despite decades of social cognitive research on mindsets (e.g., Gollwitzer 1990), relatively little attention has been paid to how shifts in different mindsets impact consumer decision making. The question is important and deserves attention as rather subtle cues can unconsciously activate different mindsets that can in turn have substantial effects on thought production, information encoding, information retrieval and ultimately behavior (e.g., Kray & Galinski 2003; Sassenberg & Moskowitz 2005). Such influence of contextual cues is well documented in other areas of consumer behavior research. For example, task requirements (e.g., fluent or difficult-Novemsky et al. forthcoming), consumption settings (e.g., public vs. private-Ratner & Kahn 2002) and initial primes (e.g., elderly stereotypes-Bargh et al. 1996) have all been shown to impact consumer cognitions and behavior. Moreover, as mindsets have been shown to affect tasks that are not necessarily related to the task that stimulated these mindsets (e.g., Smith & Branscombe 1987; Chandran & Morwitz 2005), examining the impact of mindsets on consumer decision making is highly important, given the multiple cues and tasks consumers face. This session presents four papers that provide an integrative look on the interplay between mindsets and decision making by examining how prior tasks and contextual cues can lead to certain mindsets, which in turn affect consumer choices and other decisions.

In the first paper, Dalton, Lynch, and Spiller investigate how an implemental mindset affects following through on decisions once made. They find that an implemental mindset facilitates following through decisions only when consumers are asked to follow a single decision and not multiple decisions. When multiple decisions are activated, implemental mindsets weakens commitment which decreases likelihood of executing decisions. For example, they show that implemental mindset facilitates the decision to carry out virtuous activities such as eating healthy, only when participants were not committed to additional activities.

Keinan and Kivetz examine consumption of unusual and extreme experiences, such as staying at freezing-ice hotels. They propose that choosing these options is driven by a productivity mindset, i.e., a desire to use time productively. In a series of studies they demonstrate the impact of a productivity mindset on choice of collectable (unusual, aversive or extreme) options. They show that priming consumers with a productivity mindset increases the choice of collectable experiences and examine the process underlying this effect.

Khan and Dhar propose a distinction between a highlighting vs. a balancing mindset that provides a framework for understanding how a prior task leads to consistency versus contrast in subsequent behavior. They propose and demonstrate across a series of studies that when an initial task activates a self-concept it leads to a highlighting mindset, which subsequently guides consistent behavior. However, when an initial task activates a self-concept *and* establishes credentials for it, it leads to a balancing mindset that causes subsequent choices to contrast from the initial ones.

Finally, Maimaran and Simonson propose an integrative framework based on a distinction between bold and timid mindsets to explain and predict choice behavior across a wide range of problems. Specifically, they propose that some options represent more 'timid' choices that are associated with no risk-taking and conven-

tional behavior (e.g., compromise, safe and standard options), whereas other options represent more 'bold' choices which are associated with standing for one's beliefs and taking risks (e.g., extreme, risky and unique options). Across several studies they demonstrate this distinction between choice options and show that the tendency to choose a more bold or timid option is affected by consumers' bold or timid mindsets.

## EXTENDED ABSTRACTS

### "Following Through on Decisions: The Costs and Benefits of Implemental Mindsets"

*Amy Dalton, Duke University*
*John Lynch, Duke University*
*Stephen Spiller, Duke University*

Seventy years of research shows that despite good intentions, most decisions are not acted on. Our main focus in this research is on a strategy that is supposed to help people do a better job at following through with their decisions–namely, forming *implementation intentions* (Gollwitzer 1999). Implementation intentions are plans that specify the procedures by which a decision will be implemented and the circumstances under which these behaviors will be executed. Research has shown that this specific planning has very large effects on following through with decisions. For instance, in one study, college students all made the decision to write a report over winter break. Some students simply committed to the decision, while other students also formed implementation intentions–they decided in advance when and where they would write the report. Even though the two groups of students said that they were equally committed to the decision, the group with an implemental mindset was much more likely to write the report (Gollwitzer & Brandstätter 1997).

The extant literature has looked at the benefits of an implemental mindset in the context of acting on a single decision. But most of us are juggling multiple commitments and jobs. This raises the question of how successful the implementation intention technique would be to accomplish multiple things we decide to do. In our research, we conjecture that it is less likely that an implemental mindset would benefit individuals who have decided to carry out a number of activities (e.g., a daily to-do list) vs. a single activity (e.g., tidying up).

To test whether decision follow through depends on the adoption of an implemental mindset, we compared participants who simply made a decision to carry out a behavior to participants who made this same decision but with an implemental mindset i.e., they went beyond committing to a decision and specified when, where, and how they would act on their decision. Moreover, some participants planned (or not) how to act on a single decision, while others planned (or not) how to act on multiple decisions. This second manipulation allows to tests whether the benefit of adopting an implemental mindset attenuate in a multiple decision context.

Several experiments support our main hypothesis that individuals are more likely to follow through with decisions in an implemental mindset, provided they adopt this mindset to act on a single decision rather than multiple decisions. Our first experiment demonstrates this effect by replicating and extending the procedures of Brandstatter et al. (2001*).* All participants made a decision

to respond particularly fast to a certain number or to a set of 3 numbers, and to do so while performing a second computer-based task. The difference between participants in the implementation intentions versus control conditions was that the former group made a resolution to respond particularly fast when their given number(s) appeared, and the latter group mentally prepared themselves by writing their number(s) down 25 times. Both reaction time data and accuracy data revealed that an implemental mindset helped participants who had decided to respond quickly to a single number, but did not help those who had decided to respond quickly to multiple numbers.

In another study, we examined decisions to carry out virtuous activities, such as eating healthily or tidying up. Some participants simply decided to carry out these activities over the course of a week, whereas others supplemented this decision with implementation intentions. Moreover, while some carried out a single activity, other participants committed to multiple activities. Again, we found that the benefit of an implemental mindset broke down among participants who adopted this mindset to act on multiple decisions. We also found that commitment mediated this effect. That is, among participants with multiple activities to carry out, adopting an implemental mindset significantly weakened commitment to their decisions, and this drop in commitment spoiled the benefits associated with an implemental mindset. Implemental mindsets also affected decision follow through by suppressing commitment to alternative activities (i.e., activities that participants did not decide to pursue in the context of the study). However, this inhibitory process was weakened when an implemental mindset was adopted for multiple decisions.

To summarize, the current studies explore two factors that influence the probability that one follows through on a decision once made. These factors are (1) whether or not one adopts an implemental mindset, and (2) the number of decisions for which one adopts an implemental mindset. We show that an implemental mindset improves decision follow-through among individuals acting on a single decision, but not multiple decisions. This occurs because implemental mindsets alter commitment when multiple decisions are to be acted on.

### "Productivity Mindset and the Consumption of Collectable Experiences"
*Anat Keinan, Harvard University*
*Ran Kivetz, Columbia University*

"Man is so made that he can only find relaxation from one kind of labor by taking up another." *Anatole France*

"Finally, a to-do list you'll really want to do." *Advertisement for Mohegan Sun hotel, casino and spa*

Recent marketing trends suggest that many consumers are attracted to unusual and aversive consumption experiences and choose vacations, leisure activities, and celebrations that provide low predicted and experienced utility. A fascinating example is the increasing popularity of Ice Hotels, where visitors sleep on beds made of ice in frigid temperature of 25° F. A similar trend is observed in restaurants that are trying to attract consumers by offering unusual entrées and desserts. Such gastronomic innovations include tequila-mustard sorbet, bacon-flavored ice cream, and chocolate truffles with vinegar and anchovies.

Why do consumers desire these unusual consumption experiences, and voluntarily engage in activities that are uncomfortable, unnecessary, and even aversive? The sensation-seeking literature

has tried to explain this as an "irrational" preference, suggesting that consumers seek unusual experiences because they provide immediate pleasure. This literature is premised on the notion that such consumption is counterproductive and reflects myopic, impulsive, and spontaneous tendencies and individuals.

We challenge the assumptions of the sensation-seeking literature and propose that there is something farsighted and purposeful in this seemingly irrational behavior. The present research demonstrates that consumers derive utility from collecting new experiences and "checking off" items on their "experiential check list" (or "experiential CV"). We explain this phenomenon by the continual striving of many consumers to use time efficiently and productively. This desire to constantly improve oneself and achieve is so powerful that it not only affects consumers' performance in achievement settings, but can also influence their consumption and leisure preferences and non-vocational choices. By collecting memorable experiences, consumers obtain a sense of accomplishment and progress, and enhance their self-worth.

Consistent with this proposition, we show that the consumption of collectable experiences is driven (and intensified) by productivity mindset. The studies demonstrate that priming productivity and time efficiency, or creating a desire to correct unproductive usage of time, enhances the preference for unusual and collectable experiences. Furthermore, the studies show that farsighted and planned consumers, who are concerned about time efficiency and productivity, are more likely to desire collectable experiences. Such consumers measure their own worth in terms of productivity and accomplishment and are inclined to see all situations (including consumption and leisure choices) as opportunities to be productive and build their "experiential CV."

A series of nine studies examined the relationship between productivity mindset and the consumption of collectable experiences. We begin with a pilot study that demonstrates consumers' tendency to choose unusual and even aversive consumption experiences. We show that consumers choose experiences that they predict to be less pleasurable. This study also provides initial evidence suggesting that such choices are motivated by a desire to create special memories.

We then report a series of studies that explain this phenomenon using the constructs of productively mindset and collectable experiences. Studies 1a and 1b examine the effect of priming productivity mindset on the choice of collectable experiences. Study 2 investigates the effect of priming the collection of physical items on vacation preferences, and demonstrates the similarity between collecting items and collecting (intangible) experiences. The study examines the conditions under which consumers spontaneously mention collectable characteristics when describing desirable vacations.

Study 3 examines the effect of a need to correct unproductive use of time on a real choice of a familiar vs. exotic restaurant. Study 4 explores how the need for productivity affects preferences for retirement activities and demonstrates that collecting experiences is related to consumers' sense of identity. We show that high achievement motivation consumers, who view productivity as central to their identity, tend to seek leisure activities that provide a sense of progress and purpose, and hence consume collectable experiences.

Whereas studies 1-4 examine individual differences that are measured using self-reports, studies 5a and 5b, employ observational measures of "productivity mindset," such as consumers' tendency to set their watch fast and use their waiting for a train productively. We find that consumers, who tend to set their watch faster or try to use their waiting time productively, are more likely

to choose consumption experiences that are collectable (e.g., memorable vacations and unusual birthday celebrations).

We conclude with a field study that was conducted at Times Square on New Year's Eve. The study explores the effect of increasing the collectability and memorability of aversive experiences. This tendency to prefer memorable but less pleasant experiences is part of a broader phenomenon that we define as "memory management." In addition to testing the proposed conceptualization, we examine alternative explanations, involving such factors as misprediction of hedonic experiences and present-oriented sensation-seeking.

### "Reconciling Consistency and Contrast in Sequential Choices"

*Uzma Khan, Stanford University*
*Ravi Dhar, Yale University*

Most consumer choices follow other choices and decisions. However, there is little consensus on when an initial task leads to consistency versus contrast in subsequent decisions. For example, recent choice research has shown that after expressing their better natures in an initial task, people are more likely to self-indulge in subsequent choices (Khan & Dhar, 2006, cf. Monin & Miller, 2001). However, these effects are inconsistent with other findings in social and cognitive psychology showing that an initial task causes people to act consistently in subsequent tasks (Bargh et al., 1996, Dijksterhuis & Bargh, 2001; Wheeler & Petty, 2001). For example, LeBoeuf et al. (2007) primed college students with scholarly (socialite) identities in initial tasks and showed that they subsequently chose scholarly (social) magazines over social (scholarly) ones.

The present research offers a framework to understand when and which prior tasks guide consistent subsequent behavior rather than lead to contrast. As per Dhar and Simonson's (1999) characterization, we propose that an initial task can lead to either a balancing or a highlighting mindset, which subsequently leads to mindset-consistent behavior. We distinguish between two types of tasks and propose that an initial task that activates a self-concept leads to highlighting mindset, which guides consistent subsequent choices. Whereas, an initial task that activates a self-concept *and* establishes credentials for it, by providing evidence of progress towards it, leads to a balancing mindset and thus inconsistent choices later. Four studies illustrate our idea.

In Study 1, participants chose between a gift-certificate to a bookstore and an equally priced gift-certificate to a restaurant in three between-subject conditions. The former was pretested to be more scholarly than the latter. In the control, prior to this choice participants unscrambled some unrelated words. The second condition primed a highlighting mindset by activating a scholarly self-concept. Specifically, prior to the gift-certificate choice, participants wrote why learning was important to students at their university. In the third condition, instead of writing about the importance of learning, participants indicated some recent activities (including classes) that added to their own learning. This manipulation primed a balancing mindset by activating a scholarly self-concept *and* at the same time providing evidence of scholarship. Consistent with our theorizing, participants were more likely to balance and choose a restaurant gift-certificate (65%) after writing about their own learning compared to the control (41%; $\chi^2$=4.2, p<0.05). However, only 35% chose a restaurant gift-certificate in the highlighting mindset, i.e., after writing about importance of learning.

Study 2 provides a conceptual replication of the role of progress in highlighting and balancing mindsets. We primed an academic self-concept by asking people to think about either their own or someone else's academic activities. Other's academic activities are likely to prime a highlighting mindset by activating scholarly self-concept without providing evidence of progress towards it and will therefore lead to scholarly subsequent choices. In contrast, thinking of one's own academic activities will not only activate a scholarly self-concept but will also provide evidence of scholarship hence leading to a balancing mindset, which will subsequently lead to less scholarly choices. Results were as predicted. Compared to the control (55.6%), significantly more chose a Cosmopolitan (less scholarly option) over a Newsweek (scholarly option) in the balancing mindset (76.7%; $\chi^2$=4.39, p<0.05). Moreover, choice of the Cosmopolitan was less than the control in the highlighting mindset (34.9%; $\chi^2$=3.79, p=0.05).

Self-affirmation research has shown that people's defensiveness (in face of a threatened self-image) reduces if they are self-affirmed in totally unrelated domains (Steele 1988). Similarly, Study 3 shows that a balancing mindset influences choices across different domains as long as the initial task provides progress on an important dimension of one's self-concept. In a between-subject design, participants either wrote an essay on a value that was most important or least important to them (Sherman et al. 2000). Control participants wrote an unrelated essay. Finally, everyone decided whether to buy/not-buy a concert ticket for $50. Results show that compared to the control (61%), significantly more participants balanced and chose to buy the concert ticket after writing about their most important value (89%; $\chi^2$=7.29, p<0.05) but not after writing about their least important value (53%; $\chi^2$=0.33, p=0.57). This study suggests that a balancing mindset initiated by progress in one domain can impact choices in unrelated domains if the initial progress is on self-relevant dimensions.

Study 4 shows that the ease with which an initial task establishes credentials towards activated self-concept determines which mindset gets activated. Our findings contribute to work on sequential choices and to research on prime-to-behavior link by proposing a framework to explain when initial tasks lead to consistency vs. contrast.

### "The Bold – Timid Divide in Consumer Choice"

Michal Maimaran, Stanford University
Itamar Simonson, Stanford University

In consumer decision making research the focus tends to be on studying individual phenomena, such as identifying conditions affecting preference for compromise options (e.g., Simonson 1989; Drolet 2002), low risk options (e.g., Thaler & Johnson 1990), or unique options (Maimaran & Wheeler, forthcoming). However, a closer examination suggests that there are some basic similarities in the options consumers face in seemingly unrelated choice problems. For example, in some respects, choosing an extreme option can be seen as related to choosing a risky gamble, a unique option, and a hedonic option. Similarly, compromise options, safe options, standard, and utilitarian options have common features and reflect related choice tendencies.

In this research we try to identify such cross-problem similarities and the manner in which they correspond to particular consumer mindsets. By doing so we attempt to offer more parsimonious explanations to seemingly unrelated phenomena and identify factors that moderate choice behavior across different problem types. Building on distinctions previously discussed in the literature, including regulatory focus (e.g., Higgins 1998; Chernev 2004), uniqueness vs. conformity motivations (e.g., Snyder & Fromkin 1977; Simonson & Nowlis 2000), and arousal seeking (e.g., Mehrabian & Russell 1973), we propose that some options represent more 'bold' choices, and some represent more 'timid'

choices. Bold options are unconventional, distinctive with respect to the choice set and are self expressive. Based on this definition of 'bold' choice behavior, we refer to extreme, risky, hedonic, innovative, unique, high-price high-quality, mixed-value and action-oriented options as the 'bold' choice options. In contrast to this 'bold' choice behavior, other choice options represent more 'timid' choice behavior, which in turn is associated with conventional, bland (i.e., dull or boring), non-expressive behavior. Timid choice options include compromise, standard, sure-gains, utilitarian, traditional, low-price low-quality, all-average and inaction-oriented options.

We further propose a parallel distinction between bold and timid mindsets, which in turn affect the type of chosen option ('bold' vs. 'timid'). A bold mindset is associated with a desire to engage in unconventional or more meaningful behaviors, and to take a stand. The 'timid' mindset, on the other hand, is associated with ordinary, conventional behavior and with a desire to fit in. Consumers' mindset, which is affected by situational cues, affects their choice between bold and timid options. When in a 'bold' ('timid') mindset, consumers are more likely to choose 'bold' ('timid') options across different problem types in order to maintain this mindset and to fulfill the goals associated with it. In five studies we demonstrate this distinction between bold and timid options and the corresponding mindsets, showing that the same situational cue has the same effect across different problem types.

In Study 1 (N=58) we ask participants to rate choices that previous participants supposedly made on four scales: boldness, self-expressiveness, timidness, and conventionality. We find that indeed the options we define as 'bold' (extreme, risky gambles, unique, hedonic, innovative, mixed-value, and HP/Q) are rated as more bold, more self-expressive, less conventional and less timid than the options we define as 'timid' (compromise, sure gains, standard, utilitarian, traditional, all-average and LP/Q).

In Study 2 (N=161), we find that priming the 'boldness' mindset leads to more bold decisions. Specifically, using sentence unscrambling task, we primed participants with 'bold', 'timid', or neutral words. Participants then made a total of 9 choices among various products (between compromise and extreme options, between sure-gains and risky gambles and between hedonic and utilitarian products). Across all problem types, we find that those primed with 'bold' words were more likely to make 'bold' choices (i.e., chose more extremes, risky and hedonic options), compared to those in the 'control' and 'timid' conditions, which in turn did not differ.

Studies 3-5 examine the effect of choosing first the choice domain on the making of bold decisions. We propose that choosing the choice domain can lead to a bold mindset by triggering a desire to express the self when making later a selection within this chosen domain. As a consequence, we predict that when consumers first choose in which domain they want to make choices, they will later make more bold choices in this domain. To test this prediction, in Study 3 (N=231), about half of the participants first chose the domain to make a choice in. Participants in the control condition only made choices within some of these domains. We find that across the six problem types, participants who chose in their chosen category were more likely than those in the control condition to choose 'bold' options, namely mixed-value, unique, risky, extremes, hedonic and HP/Q. The effect holds also when controlling for products knowledge and expertise. In Study 4 (N=346), we find that this 'choose category' effect is strengthen after a time delay, suggesting that this effect operates through a motivational route. Finally, in Study 5 (N=225) we find across four problem types that the choose-category effect is eliminated when the 'bold' option is

framed as the status quo option, and thus presumably is no longer perceived as bold.

Taken together, these studies demonstrate that certain manipulations, which induce bold or timid mindset, have the same effect on choice behavior across many different problem types. In our next studies we gain further insights into the process of inducing these mindsets and their impact on choice behavior. For example, we have preliminary data suggesting that when consumers first have an opportunity to express themselves (by drawing a picture of themselves or by writing about themselves) they are then more likely to choose bold options (risky gambles, unique options and extremes).

# Bridging the Gap between Behavioral and Humanistic Perspectives to Improve Consumer Welfare: A Focus on Communication of Prescription Drug Information

David Brinberg, Virginia Tech, USA

## SESSION OVERVIEW

Nearly 50 years ago, C.P. Snow described science and literature as "The Two Cultures" of modern society. Research derived from these two cultures involve different theoretical perspectives, methodological tools, and appropriate metrics to evaluate substantive problems. In many ways, this gap has become more pronounced because of the specialization of our research efforts. In the area of health, in general, and communication regarding prescription drugs, in particular, we can see the impact of this separation in the ways researchers approach health concerns and health issues.

The recent call for transformative research by David Mick and others reflects the growing interest in applying marketing and consumer behavior theories and methods to improve consumer welfare. Although this notion of transformative research is new, previous researchers in our field, and in related disciplines, have also called for the analysis of social issues from a wide variety of perspectives. For instance, Marv Goldberg's SCP Presidential address (1995) was a pointed commentary that consumer researchers were "fiddling while Rome burned;" that is, we were not applying our expertise to improve the human condition. The focus of his argument was the need to apply multiple theories and methods to examine a social issue. Although he did not use the metaphor of building bridges, the spirit of his position was the value in examining a social issue from multiple perspectives.

Two perspectives (or islands) he discussed were upstream (environmental barriers, policy/ regulatory-oriented issues) and downstream (theories of individual decision making, theories of persuasion, marketing-mix variables) approaches to create effective behavioral change programs. Goldberg argued that social issue (or transformative) researchers would benefit from building a bridge across these two (upstream and downstream) approaches.

A second set of methodological islands that influence our approach to health-oriented research is the application of humanistic (e.g., argumentation analysis) and behavioral (e.g., experimental) methods. These two approaches represent different conceptualizations of the value of control in the development of an empirical study.

A third pair of islands reflects the unit of analysis in the research: individual or dyad and the application of static rather than more dynamic models of behavior. Most models of persuasion focus on the individual and apply a static approach; that is, the presentation of a message that is intended to inform the individual and to motivate behavior change or behavior maintenance. An alternative approach is to treat the dyad (e.g., the health professional and the client) as the unit of analysis and examine the dynamic communication process between these two parties.

Our intent for the current proposed session is to describe research that applies these different perspectives to study communication issues associated with prescription drugs. Nakamoto et al. examine issues associated with direct to consumer advertising of prescription drugs by using a humanistic theory and method (argumentation theory) to examine the impact of the structure of DTCA content on the inferences drawn from these ads. This research is an example of Goldberg's description of "downstream research." In contrast, Pechmann presents an upstream analysis of DTCA by

examining the process used by the FDA to regulate the information contained in a DTCA. Both these papers focus on the consumer as the unit of analysis and approach persuasion as a more static process. Brinberg et al. describe a research project that examines the relationship between pharmacists and their clients by combining observational methods with an experimental study to assess the impact of health messages tailored to the stage of the relationship between the pharmacist and the client.

The proposed session will bring together scholars with different theoretical and methodological perspectives to discuss ways in which these different "research cultures" can be applied to better understand the development of health messages. The session will allow us to illustrate how scholars in the area of transformative research are able to integrate distinct methods to create a more comprehensive investigation of health messages. We expect this session to appeal to researchers involved in the study of social welfare problems and methodologists interested in the application of multiple approaches to study a social problem.

## EXTENDED ABSTRACTS

### "Argumentation in Direct-to-Consumer Advertising of Pharmaceuticals: Logical Problems and Policy Issues"

*Sara Rubinelli, Universita della Svizzera Italiana*
*Kent Nakamoto, Virginia Tech*
*Peter Schulz, Universita della Svizzera Italiana*
*Anjala Krishen, University of Nevada, Las Vegas*

There is an ongoing global debate on the benefits and risks of allowing direct-to-consumer advertising (DTCA)—the promotion of prescription medicines to the general public in the lay media. Currently, DTCA is allowed only in the United States and New Zealand; however, there is strenuous lobbying in many countries to relax national restrictions on DTCA and it can be reached via internet all over the world. Promoters of DTCA argue that pharmaceutical companies have more accurate, balanced, and scientifically based information than any other sources. As such, they are in an unique position to provide people with adequate information on the safe use of medication, as well as to create effective knowledge for evaluating the benefits and risks of drug products, and generally assisting people in managing their health autonomously and appropriately. Opponents of DTCA emphasise the financial gains of the pharmaceutical industries and the fact that DTCA enhances medicalization of normal human experience. Opponents claim that DTCA's primary aim is to create name and brand recognition with a view to increasing the use of the advertised products.

There is strong evidence that DTCA is effective in increasing sales. In 1999, the 25 top-selling medicines promoted directly to consumers accounted for 40.7% of the overall $17.7 billion increase retail drug spending. The same 25 top-selling drugs had an aggregate one-year sales growth in 1999 of 43.2%. The growth in sales for all other drugs was 13.3%. This coincides with a growth in the number of prescriptions for the 25 DTC-promoted drugs. In 1999 doctors wrote 34.2% more prescriptions than in 1998 for these drugs, while they wrote only 5.1% more prescriptions for all other prescription drugs. In addition, the US General Accounting Office

estimates that 8.5 million consumers annually request and receive from their physician a prescription for a particular drug in response to seeing DTCA.

The above data suggest that DTCA has an impact, and this evidence leads us to enquire into the reasons for this success. The persuasiveness of these ads would not per se be a critical problem. What could point to problems, however, are the data indicating that physicians are ambivalent about the treatment in half the cases in which they prescribe drugs requested as a result of DTCA, and that they prescribe the drug often because of the pressure felt, suggesting that the advertising may be inciting patients to seek and obtain a medication that is neither safer nor more efficacious.

Whatever the corporate motivation for the advertising, our interest in DTCA is the basis for its persuasive impact on consumers. In particular, we want to assess whether these ads present potentially misleading information that can lead to an overestimation of the value of the medicines advertised. We approach this enquiry by exploring the rhetorical strategies used in these ads and the way people process them. More specifically, we make use of argumentation theory as a critical tool for investigating the sources of potentially misleading information.

We report the results of a set of empirical studies examining the recognition by readers of the argumentative structure of pharmaceutical ads. We first provide an analysis of the argumentative structure of the ad and identify the specific dubious arguments it presents, using the framework provided by classical rhetoric and modern argumentation theory. We then report on our studies showing that the dubious arguments are both memorable and credible. We discuss the issue of the persuasiveness of DTCA, showing how readers can make wrong assumptions that, on the one hand, seem to arise independently from the contents of the ads, and on the other hand can promote a fallacious elaboration of the quality of the medicine advertised. The critical policy problem raised by this analysis is that prominent forms of argumentation used in DTCA, in effect, shift the burden of proof for the likely efficacy of the drug for the reader from the advertiser to the reader. Because of the potential deleterious health, as well as economic, effects of inappropriate use of pharmaceuticals, the use of these argumentative strategies could be inappropriate.

### "Analysis of the Regulatory Environment for Direct-to-Consumer Prescription Drug Ads: A Case Study of Vioxx"

*Connie Pechmann, University of California, Irvine*

The USA is the only country that permits direct-to-consumer (DTC) advertising of prescription drugs, and the practice is controversial even here. The U.S. Food and Drug Administration (FDA) regulates prescription drug advertising and labeling, and the FDA's Division of Drug Marketing, Advertising, and Communications (DDMAC) implements those regulations. The FDA Modernization and Accountability Act (1997) authorizes the FDA to collect uses fees from pharmaceutical firms. User fees are used in part to fund the FDA review of prescription drug advertising and labeling. User fees are authorized in 5 year increments so a new authorization is expected in Fall 2007. Hence, significant FDA reforms are expected to occur in the near future.

Consumer groups are concerned that the FDA's review of prescription drug advertising may be inadequate and are demanding greater FDA oversight. The U.S. General Accounting Office or GAO (2002) has characterized the FDA oversight of prescription drug advertising and labeling as "limited" (GAO 2002, page 21). A 2007 Institute of Medicine report on the FDA's oversight of prescription drugs and advertising is also highly critical of the agency.

In response to demands for reform, the FDA has proposed significant changes for 2007 and beyond. In particular, the FDA has proposed an increase in user fees, so that it can conduct quicker reviews of prescription drug DTC TV ads and can review each ad prior to airing. The industry has agreed to pay higher user fees to obtain this service and has pledged to submit each DTC TV ad prior to airing. The industry wants the FDA to review its advertising prior to airing, in part to help protect it from law suits involving failure to warn and consumer fraud.

This reform assumes that the FDA has devised an effective method for reviewing prescription drug advertising and labeling, and that it simply lacks resources to conduct the reviews. This paper assesses the validity of that critical assumption and examines whether the FDA's review of prescription drug advertising and labeling should be expanded in scope, when user fees are increased as expected, to ensure the FDA's review is thorough and protects the public from false or misleading advertising and labeling. It appears that no prior paper has addressed this issue.

The FDA's DDMAC division reviews advertising directed at consumers and/or physicians, including "advertisements in published journals, magazines, other periodicals, and newspapers, and advertisements broadcast through media such as radio, television, and telephone communication systems" (CFR 202.1.l1). DDMAC also reviews promotional labeling including "brochures, booklets, mailing pieces, detailing pieces, file cards, bulletins, calendars, price lists, catalogs, house organs, letters, motion picture films, film strips, lantern slides, sound recordings, exhibits, literature, and reprints and similar pieces of printed, audio, or visual matter descriptive of a drug and references published" (CFR 202.1.l2). FDA regulation CRF 202.1 enumerates the regulatory standards for prescription drug advertising and labeling. The general principles are: (a) must provide full and complete disclosure, (b) cannot be false or misleading, (c) must provide a fair balance of benefits and risks, and (d) must be consistent with the FDA approved drug label.

However, the FDA does not routinely review the following classes of materials that are used in pharmaceutical firms' promotional campaigns: (a) Marketing plans and strategies, (b) Marketing scripts used by sales representatives when detailing physicians, (c) Direct mail letters sent by firms in response to physicians' medical queries, and (d) Marketing research about the campaigns (e.g., tracking). The paper will discuss the pros and cons of an FDA review of each class of material. The following specific issues will be addressed:

1. Why doesn't the FDA currently review these classes of materials, that is, how does the FDA interpret its regulations and how has the agency's interpretations led to loopholes?
2. Are the nonreviewed and reviewed materials likely to contain the same or different information, that is, are they samples from the same or different populations?
3. Is it feasible for the FDA to review each class of nonreviewed material, and would the benefits outweigh the costs?

The FDA has also proposed new rules that would serve to increase the weight of DDMAC reviews in state and federal law suits. This paper will address those new rules too. Do we want FDA DDMAC reviews to continue to focus a subset of promotional materials with strong emphasis on DTC TV ads? Will that approach adequately protect public health and safety?

This paper will feature a case study involving the large pharmaceutical firm Merck and its marketing of the prescription

pain reliever Vioxx. Vioxx was sold in the USA from 1999 to 2004. Vioxx was withdrawn from the market based on studies indicating it causes heart attacks. The first study showing a potential heart attack risk for Vioxx appeared in 2000. In September of 2001, the FDA sent Merck a warning letter alleging that aspects of Merck's promotional campaign for Vioxx were "minimizing" that study's findings and were "false or misleading" because the firm "misrepresents the safety profile for Vioxx." The FDA required Merck to send correction letters to health care providers who had attended conferences in which false or misleading promotional messages for Vioxx were disseminated.

The author of the current paper obtained the Vioxx advertising and labeling materials while serving as an expert witness for plaintiffs in Vioxx law suits. This paper will examine promotional materials for Vioxx that were and were not submitted to the FDA's DDMAC division for review from 2000 to 2003. The review will assess similarities and differences between the materials that were and were not submitted to the FDA and apparent consistencies or inconsistencies with the FDA standards, using the 2001 FDA warning letter and correction letters as standards. After the April 2003 Vioxx label change that included information about Vioxx's heart attack risk potential, the Vioxx product label will be used as the standard. The aim of this case study is not to draw conclusions about whether Merck's promotional campaign was or was not misleading or deceptive in terms of conveying information about Vioxx's heart attack risk potential. Instead, the aim is to describe the contents of the advertising and labeling materials that were and were not submitted to the FDA to address the issue of whether the FDA might in the future want to review some categories of materials it currently does not review on a routine basis.

### "Motivating the Pharmacist-Client Relationship: An Integration of Stages of Change to Relationship Development"

*Chiara Maniscalco, Universita della Svizzera Italiana*
*Kim Daniloski, Virginia Tech*
*David Brinberg, Virginia Tech*

Pharmacists' role in the health care setting is shifting from product-oriented to patient-oriented, with the goal of understanding and caring for clients. To date, much of the communication between pharmacists and clients has focused on the use and value of prescription drugs to treat various medical conditions. However, the re-professionalization to a more patient-oriented role has created a need for pharmacists to identify areas where they can intervene to enhance the quality of patient care and perform their services with a particular focus on client needs. At the same time, clients need to learn how to use pharmacists as a new source of information. Given the rising complexity and costs of health care, the role of pharmacists as primary health care providers will become essential. As a consequence, research needs to examine strategies to improve the communication between pharmacists and their clients to make the information exchange more patient-oriented and focused on client needs.

Clients' acceptance of pharmacists' messages depends on the level of trust clients have in their pharmacists: in other words, acceptance depends on the stage of the pharmacist-client relationship (e.g., developmental stage of the relationship; mature stage of the relationship). The literature does not contain recommendations on strategies that can help pharmacists develop and maintain relationships with their clients.

In the following research, we develop and evaluate a theoretical model that examines the stage of the pharmacist-client relationship and applies the strategies identified in the stage of change

model to motivate a change in that relationship. We assess whether these strategies increase trust in the pharmacist and in subsequent interactions with the pharmacist concerning health needs.

We approach our research by integrating observational methods (in-depth interviews with pharmacists, survey methodology) with a field experiment to develop and evaluate our theoretical model.

Data were collected from over 1,000 clients from over 40 pharmacies in the Italian-speaking canton (Ticino) in Switzerland. In the initial phase of this research, we conducted in-depth interviews with pharmacists in Canton Ticino to identify the ways in which they currently interact with their clients and the strategies they use to strengthen that relationship. Based on the information from these interviews, and previous models developed in the relationship marketing literature, we identified three key constructs that influence trust in the pharmacist: perceived expertise of the pharmacist, perceived benefits of the pharmacist-client relationship, and the stage of the pharmacist-client relationship. We viewed the stage of the relationship as both a predictor of trust and as a moderator of the perceived expertise and perceived relational benefits–trust relationship.

All the main effects were significant predictors of trust. More interestingly, the stage of the relationship moderated the relations between the other predictors and trust. Specifically, we found perceived relational benefits and perceived expertise had a stronger effect on trust in the developmental stage of the relationship and neither had a significant impact on trust in the more mature stage of the relationship.

Based on this finding, we hypothesized that stage appropriate messages were more likely to increase client trust. We then conducted a field experiment in which we created two types of messages–one that focused on perceived relational benefits and perceived expertise and a second that focused on a standard message communicated by the pharmacist. We identified 9 pharmacies and randomly assigned them to either the control group (no message), the standard message group, or the experimental message group. We measured trust four months after the client received the message.

Contrasts of the simple main effects at the developing stage of the relationship revealed that the experimental message resulted in significantly higher levels of trust than both the standard message and the control group (t=2.2; p<.05 and t=3.9; p<.01, respectively). The standard message's impact on trust was also significantly higher than the control group (t=2.2; p<.05). None of the simple effects were significantly different at the mature stage.

In contrast to the papers presented by Nakamoto and Pechmann, the approach used in this study to examine the communication of health information focused on the dynamics/interactions of the pharmacist-client relationship. We will contrast and then discuss some of the implications of using this more dynamic, dyad-oriented approach to the communication of health information.

Symposia Summary
# Social Contagion Effects in Marketing
Suresh Ramanathan, University of Chicago, USA
Amy N. Dalton, Duke University, USA

## SESSION OVERVIEW

A key goal of consumer research is to better understand how consumers are impacted by interpersonal phenomena. For instance, how might enjoyment of a movie be affected by having a friend watch it with you? Does observing your friend's responses affect your own? How might a shopper be influenced by a salesperson's subtle nonverbal behaviors? These and other social contagion issues have been under-researched in our field. However, emerging research in social psychology demonstrates that social behaviors and emotions are contagious (e.g., Aarts, Gollwitzer and Hassin 2004; Hatfield, Cacioppo and Rapson 1994). We spontaneously yawn when we see others yawn, express sadness when watching sad movies, and adopt regional accents when on vacation. Moreover, social contagion has been linked to important interpersonal consequences. For instance, mimicking others cultivates rapport (Chartrand and Bargh, 1999), and people adopt the emotion associated with the facial expressions or mannerisms that they have mimicked (Neumann and Strack 2000). This session integrates and builds on this literature by elucidating how consumers can be influenced by our nonconscious and unintentional tendency to "catch" from our social surroundings the behaviors and emotions we observe.

This symposium's broad purposes are to illuminate how social contagion research can broaden our understanding of consumer issues, and to advance theory by delineating the affective, cognitive and behavioral processes at play in social contagion effects. In doing so, we identify several new dimensions to social contagion phenomena and add new insights about social influence to the domains of charitable giving, consumption experiences, and self control. Specifically, we will show how the emotions expressed in persuasive charity appeals cause emotion contagion that in turn influences charitable giving (Small and Verrochi). We will also demonstrate how behavioral and emotional contagion lead to a sense of long-run connectedness that predicts evaluations of shared consumption experiences (Ramanathan and McGill). Finally, we will show that disrupting behavioral contagion during an interaction makes the interaction more taxing, which impairs self-control on other tasks (Dalton, Chartrand and Finkel).

### Contribution

The papers in this session explore consumer issues through the lens of nonconscious behavioral and emotional contagion. To this end, they elucidate: *(a)* the psychological processes at play, whether cognitive, affective or behavioral, *(b)* the conditions that facilitate and impede these processes and the boundary conditions thereof; and *(c)* the prevalence of contagion effects in different domains and across multiple research paradigms.

The paper by Small and Verrochi shows that an important predictor of both the propensity to donate to a charitable cause and the size of the donation is the facial expressions of victims in the charity's persuasive appeals, as consumers nonconsciously catch the emotion conveyed by these facial expressions and different emotions differentially impact donating behavior. Sad expressions evoke sadness and sympathy, which translates into the greatest charitable response. In addition to this direct effect of emotion contagion on sympathetic responses, the authors demonstrate that supplementing a victim's picture with sad information evokes sadness sufficient to eliminate the social contagion advantage.

The paper by Ramanathan and McGill manipulates whether two people can or cannot observe each other during a consumption experience and explores the effect of behavioral and emotional contagion on evaluations of the experience. Using a continuous joystick measure of ratings of the experience and cross-spectral analyses of the resultant time series, they find that the evaluations of people who can observe each other synchronize over the long run. Moreover, the coherence of peoples' evaluations can be predicted from the amount of facial and behavioral mimicry during the consumption experience. Finally, the authors show that coherence predicts retrospective evaluations of experiences over and above the peak and end affect.

In the final paper by Dalton, Chartrand, and Finkel, behavioral contagion (here, mimicry of an interaction partners' nonverbal behavior) is manipulated rather than measured to explore how an interaction partner is affected by well- or poorly-coordinated nonverbal behavior. The authors find that whether or not interaction partners are coordinated behaviorally can impact success at self-control, an effect that is attributed to schema-violation. According to the authors, schema-consistent patterns of mimicry preserve regulatory resources, while schema-inconsistent patterns of mimicry deplete these resources. Consequently, in most social interactions, the absence of mimicry will make an otherwise-efficient interaction more taxing and thereby impair self-control.

This symposium sheds new light on social contagion processes, an emerging field of inquiry which has previously been neglected in consumer contexts. The papers implicate social contagion processes in consumers' judgments and behaviors, and examine contagion both in terms of emotion expression and nonverbal behaviors. They demonstrate that social contagion processes can influence individuals through affective and cognitive routes and that these effects can manifest in diverse domains of consumer behavior. Moreover, the papers each provide distinct conceptual and methodological contributions, triangulating on the effects of social contagion through innovative manipulations and procedures.

## EXTENDED ABSTRACTS

### "The Face of Need:  Reactions to Victims' Emotion Expressions"
*Deborah A. Small, University of Pennsylvania*
*Nicole M. Verrochi, University of Pennsylvania*

Victims are pictured on charity appeals to elicit the emotions thought to engender prosocial behavior. Research on this identifiable victim effect (Small and Loewenstein 2003) and the relative advantage of vivid over pallid information (Nisbett and Ross 1980) supports that notion. Pictures do evoke emotion; however, the emotional response might depend on the nature of the picture. Certain picture attributes might more effectively appeal to sympathy than others.

Facial expression of emotion is an important feature of person pictures. Faces on charity appeals display a variety of emotions. To examine what charities are actually doing, we coded all website homepages of human-need charities rated Exceptional (Four Stars) by a nonprofit charity evaluator, www.charitynavigator.org (N=363). From this set, 284 included a person picture and happiness was the

most common expression on their faces (37.5%). In contrast to expressions of happiness, 8.3% portrayed a person expressing sadness, 9.6% expressed neutral emotion, and the remaining images portrayed more than one victim whose expressions were not matching. This suggests that charity marketers either do not have a common theory about how emotion expressions matter, they simply have not thought about it, or they do not consider it an important determinant of prosocial behavior.

Although there is a large body of research on *experienced* emotion and prosocial behavior (see Carlson and Miller 1987 for a review), we know of no study isolating the impact of emotion *expression* on prosocial behavior. This gap is noteworthy because of the need to understand responsiveness to charity appeals, which often feature photos of victims. Thus this paper's primary contribution is to provide insight about how emotion expressions on a charity appeal influence charitable giving.

Psychological research highlights the critical role that emotion expression plays in interpersonal coordination. According to emotional contagion theory (Hatfield et al. 1993), people express and feel emotions that are similar to and influenced by those of others with whom they are in contact. Emotional contagion has been characterized as a primitive form of empathy. Indeed, research has shown that "catching" another person's feelings by responding to their facial expression happens automatically and outside of awareness.

Our theoretical framework builds upon emotion contagion theory by positing that people catch the feelings expressed in images of victims. Therefore, viewing a sad-faced victim should elicit feelings of sadness and viewing a happy-faced victim should elicit feelings of happiness. It also draws on findings about mood and helping (Carlson and Miller 1987; Clark et al. 1987) and on hot-cold empathy gaps (Van Boven and Loewenstein 2003) to put forward the notion that feeling sad allows for greater empathy with and sympathy for those who suffer. Consistent with this, sad faces should elicit higher levels of sympathy and greater donations than a neutral or happy face. Finally, we posit that because emotional contagion is a primitive and automatic process, it can be overridden by more conscious forms of thought, such as what might be deduced from other information on the same charity appeal. Thus, other information on the appeal could moderate the impact of facial expression. The studies we present test aspects of this framework and demonstrate the mediating role of emotional contagion and the moderating role of other information on prosocial behavior.

The three studies in this paper empirically tested the components of our proposed theory. Study 1 demonstrated that the emotional expression of a victim pictured on a charitable appeal systematically changes both propensity to give and the nominal donation amount, with sad expressions eliciting greater donations than happy or neutral expressions. After we established this phenomenon using actual donations, studies 2 and 3 employed psychological measures of sympathy to elucidate the possible mechanism. Study 2 replicated study 1's results with measured sympathy and demonstrated that participants' emotional states converge with that of the pictured victim, supporting the role of emotional contagion. Study 2 also established that in line with hypothesis 2, participants' reported emotional state mediates the effect of victim emotion expression on sympathy. Finally, study 3 built upon the findings of studies 1 and 2 by examining the moderating role of information through manipulation of an informational component in the appeals. Here we find that when sympathetic information accompanies the picture of a child, the effect of emotion expression disappears. Together, these studies illuminate the process by which photographs of victims can systematically influence sympathy and prosocial behavior.

This research draws attention to a sympathy-generating attribute of charity appeals that has been neglected both in theory and practice. To our knowledge, it is the first attempt in the literature to isolate the impact of emotion expression on prosocial feelings and behavior. In practice, charities usually do not portray victims expressing sadness. Our findings suggest that they should.

## "Consuming with Others: Social Influences on Moment-to-Moment and Retrospective Evaluations of an Experience"
*Suresh Ramanathan, University of Chicago*
*Ann McGill, University of Chicago*

Much of the work on affective experiences has focused on individual consumption and has centered on understanding the relationship between moment-to-moment affect felt by an individual over the course of an experience and the person's overall assessment of the experience (e.g., Fredrickson and Kahneman 1993; Redelmeier and Kahneman 1996). According to this stream of research, global evaluations of the experience can be predicted by two key moments in that experience, namely, the peak and the end affect felt by the consumer. These studies do not however consider what might happen to an individual's liking of the experience if there is someone else present and sharing the same experience.

In this paper, we examine how shared consumption of an experience may alter both the moment-to-moment affective reaction and consumers' overall retrospective evaluations of the experience. We suggest that global evaluations are influenced not just by the individual's own peak or end affective states but also by the degree to which the individual feels connected or entrained with another person sharing the same experience. In our first study, we examine one moderating variable–whether or not people can observe each other's expressions while going through the experience. Participants were either paired or alone while watching a popular comedy show on two adjacent computers. We manipulated observability for the pairs by using a tall or a short partition between the two computers. Online ratings were collected every second via a joystick. A cross-spectral analysis was run on the resultant time series (420 data points per individual), to determine how people move together in their ratings at various frequencies. This measure, called coherence, was found to be higher among people who could observe each other's expressions, suggesting that their ratings covaried with each other over the long run. This coherence, in turn, was found to independently predict the joint evaluations of the experience by both members of the pair, over and above the individuals' own peak and end affect.

In order to understand the processes underlying these effects, we surreptitiously videotaped pairs of participants in a second study while they were evaluating a short humorous video clip. Half the dyads could observe each other's facial expressions and head movements while the other half could not do so. Images from the videotaping were routed through a split screen generator to a digital video recorder that recorded a split screen image for both participants that was subsequently analyzed moment by moment by independent raters. The raters coded for glances initiated by either participant, and the emotional expressions on each face. We then modeled each participant's emotion at a given time t as a function of the following: a) the content of the program at the given moment, expressed as the average emotion across all individuals except the focal person at that instant, b) the focal person's own past emotions, suitably lagged several time periods, and c) the effect of the other person, captured via three social processes, namely emotional contagion (own unreciprocated look at other's emotion at time t-1), impression management/self-presentation (other's unreciprocated look at own emotion at time t-1), and empathy/disconnectedness

(reciprocated looks observing matched emotions and mismatched emotions, respectively). We found strong evidence that for pairs who could observe each other, each of these social processes predicted a person's emotions after controlling for own past emotions and program content. Further, these processes also predicted the coherence emerging in the joystick evaluations, which in turn predicted joint retrospective evaluations of the experience.

In sum, our results support and explain a familiar sensation: consuming with others feels different. Watching a movie with a friend produces different moment-to-moment judgments and changes the basis on which the quality of the movie will later be judged. Specifically, our results show that sharing the experience with another person may cause the consumer's moment-to-moment evaluation to become more like that of the other person, though processes of emotional contagion. Further, this shared pattern of judgment emerges in a subtle fashion over a fluid, broad time frame and not over short periods reflecting local agreement in moment-to-moment evaluations.

### "The Depleted Chameleon: Behavioral Contagion and Self-Regulation"

*Amy Dalton, Duke University*
*Tanya L. Chartrand, Duke University*
*Eli J. Finkel, Northwestern University*

Interaction partners tend to mimic each other's nonverbal behaviors without awareness or intention to do so. But what happens when behavioral mimicry is absent or unexpected in a social interaction? For instance, what if a vacationer fails to adapt to regional variations in socially normative nonverbal behaviors, and stands too close to his interaction partner or speaks to loudly? Or what if a salesperson, overly eager to affiliate, deliberately imitates every behavior of every consumer with whom he interacts? How do these instances of poorly coordinated mimicry impact interaction partners? We propose that whether or not interaction partners are coordinated behaviorally can impact the self-regulatory resources needed for social interaction, which has downstream consequences for an interactant's ability to exert self-regulatory effort on other tasks.

The basic paradigm employed in this research is as follows. A research participant interacts with a research confederate who spends the duration of their interaction engaging in either mimicry or anti-mimicry (i.e., adopting either the same or different physical postures, mannerisms, and gestures as the research participant). The participant then completes a self-control task. In Experiment 1, we show that mimicry and anti-mimicry differentially impact regulatory depletion, whereby participants who are anti-mimicked exhibit less persistence studying for an upcoming test compared to participants who are mimicked. We further show that our mimicry manipulation can account for unique variance even among participants who previously engaged in a depleting affect regulation task. Experiment 2 shifts to the domain of eating behavior and adds a control condition to address whether anti-mimicry is in fact a source of depletion, or whether mimicry might be a source of self-regulatory replenishment. The results of this experiment support the hypothesis that anti-mimicry leads to self-regulatory depletion.

We conjectured that anti-mimicry tends to tax self-regulatory resources more than mimicry because anti-mimicry tends violate our implicit expectations and social norms for social interactions. If this is true, then both anti-mimicry and mimicry should be capable of depleting individuals depending on the norms for a given interaction. To test this, we compared depletion following same-race interactions versus interracial interactions. We reasoned that schemas for mimicry might differ in same-race versus interracial interactions in the same way that other nonverbal behaviors (such

as standing distance, eye contact, and smiling) tend to differ, and therefore, mimicry could be depleting in interracial interactions. Supporting our hypothesis, anti-mimicry impaired inhibitory control (measured via Stroop Task performance) following same-race interactions and mimicry impaired inhibitory control following interracial interactions. Interestingly, we also found that depletion was dissociated from self-reported liking of the interaction. That is, whereas interracial interactants were more depleting when they were mimicked, they nevertheless enjoyed mimicry more than anti-mimicry.

In a final experiment, the self-regulatory burden of anti-mimicry (in same-race interactions) was examined using a divided attention paradigm. Participants engaged in a signal detection task while simultaneously interacting with a mimicking or anti-mimicking confederate. Consistent with our previous findings, anti-mimicry impaired self-regulatory performance more than mimicry. Moreover, the performance difference between mimicked and anti-mimicked participants emerged almost immediately after the interactions began, suggesting that the self-regulatory costs of schema-inconsistent patterns of mimicry are both significant and immediate.

Using several different measures of self-control and different experimental methods, this research finds that social contagion processes are intimately linked to self-regulatory functioning and can therefore impact successful self-control. We propose that poor self-control in these studies stems from the violation of behavioral schemas relevant to a particular social interaction, and is not related to anti-mimicry *per se*, or to feelings of negativity in anti-mimicry interactions. These findings reveal that nonverbal behaviors so subtle that they are not consciously perceptible can deplete the resources required for successful self-control.

SYMPOSIA SUMMARY
# Feeling Mixed?
## Emerging Perspectives on Mixed Emotions and Consumer Responses
A. Peter McGraw, University of Colorado, Boulder, USA
Loraine Lau-Gesk, University of California, Irvine, USA

## SESSION OVERVIEW

The experience of oppositely-valenced emotions, referred herein as mixed emotions, include the happiness and sadness felt when one's child leaves home for college, the excitement and fear aroused when one rides a rollercoaster, or the anger and hope experienced when one protests war. Indeed, many important milestones (e.g. planning one's wedding; Otnes, Lowrey, and Shrum 1997) as well as everyday consumptive episodes (e.g. watching commercials or movies; Edell and Burke 1987; Larsen, McGraw, & Cacioppo 2001; Andrade & Cohen 2007) are marked by mixed emotional reactions.

The nature, frequency, and consequences of mixed feelings make up a growing area of research on emotional experiences. While the existence of attitudinal ambivalence, which forms a basis for understanding mixed emotions, is not in question (e.g., Priester and Petty 1996), the existence of mixed emotions has been hotly debated (e.g., Russell & Carroll, 1999). Research on mixed emotions, until recently, has been largely overshadowed by single-valenced emotional approaches. The existing research on mixed emotions and consumer behavior has typically examined attitudinal or behavioral consequences of mixed emotions aroused by ads (e.g., Williams and Aaker 2002), consumption experiences (e.g., Lau-Gesk 2005), and decision making (e.g., Nowlis, Kahn, and Dhar 2001). The research in this proposed session reveals the complex nature of mixed emotions and demonstrates the value in understanding a bivalenced approach to affect. The three papers in the session help to deepen our understanding of how people interpret and manage complicated emotional experiences that arise from consumptive experiences and emotional advertising.

The first paper by McGraw and Larsen investigates simultaneous mixed emotions comprised of happiness and sadness. Their work provides more direct evidence for the debate over whether people actually experience mixed emotions simultaneously. Although previous research has documented that positive and negative emotions could coexist, the evidence relied on participants' self-report of their emotional experience (Larsen, et al. 2001) and it is not clear whether the reports reflect a summary of emotional experience over a short period of time or whether the reports reflect concurrent experience of positive and negative emotions at the same point in time. The results from four studies provide clear evidence that people can feel happy and sad at the same time, and rule out common alternative explanations that reports of mixed emotions are due to artifacts of measurement, demand characteristics, or people's lay theories. In short, the paper provides a foundation that mixed feelings do exist, even for seemingly diametrically opposite-valenced emotions. The subsequent studies show conflicting emotions at play in reactions to emotional advertisements or in the generation of persuasive advertising appeals.

Kramer, Lau-Gesk, and Chiu examine the interplay between mixed emotions and "mixed cultures." Specifically, three studies reveal how differences in feelings of conflict about people's own cultural duality relate to their responses to ad appeals arousing both happiness and sadness. They found that mixed emotional experiences are associated with greater discomfort for biculturals who feel more (vs. less) conflicted about their cultural duality. When provided with coping frames designed to help resolve the discomfort associated with dual experiences, biculturals who feel more conflicted about their duality respond more favorably to a message that elicits mixed emotions. The resolution of the discomfort occurs because coping frames help conflicted biculturals resolve the discomfort with mixed emotions, and induce discomfort for biculturals who are at ease with their duality.

Finally, Wadhwa and Aaker study sequentially arising mixed emotions that begin with a specific negative emotional experience (e.g., anger, anxiety) yet, due to mood regulation behavior, may end with a specific positive emotional experience (e.g., gratitude, humor). Results of two studies indicate that when people are made to feel anxious versus angry, they are more effective at generating gratitude-based advertisements and gratitude-based taglines for greeting cards. In contrast, when participants feel angry versus anxious, they are more effective at generating humorous taglines for greeting cards.

Joe Priester will synthesize the three papers as the discussion leader. Priester's expertise is in persuasion and attitudes; he has a particular expertise in the area of attitudinal ambivalence, which serves as the theoretical foundation for work on mixed emotions.

# EXTENDED ABSTRACTS

## "Midway Between the Two? The Case for Mixed Emotions"

*A. Peter McGraw, University of Colorado, Boulder*
*Jeff T. Larsen, Texas Tech University*

Philosophers and psychologists from Socrates to Hume to Wundt have debated the possibility of mixed emotions. The modern debate pits circumplex models of emotion, which posit that happiness and sadness are mutually exclusive (Russell 1980; Feldman Barrett & Russell 1999), against the evaluative space model, which allows for the co-activation of positive and negative affect (ESM; Cacioppo & Berntson 1994; Cacioppo, Gardner, & Berntson 1999).

We present four studies that address critiques of prior evidence of mixed emotions and support the hypothesis that people can feel happy and sad at the same time (see Larsen, McGraw, & Cacioppo 2001; Larsen et al. 2004). We rule out alternative explanations that our previous results are due to artifacts of measurement, participants' lay theories, or demand characteristics.

In previous research (Larsen et al. 2001), participants watched the tragicomedy *Life is Beautiful*, which depicts a father's often comic attempts to keep his son alive and unaware of their plight during their imprisonment in a World War II concentration camp. Participants were asked whether they felt 'happy' and whether they felt 'sad' either before or after the film. A significant proportion of respondents (44%) indicated mixed emotions after the film compared to before the film (10%). Similar results were obtained in field studies of first-year undergraduates moving out of their dormitory (54% vs. 16%) and seniors after their graduation ceremony (60% vs. 20%; Larsen et al. 2001).

Rather than judging their immediate experience, participants in previous studies may have summarized their emotions over time. To test this alternative explanation, Study 1 employed a button-press task that independently and continuously measures happiness and sadness during the film in a laboratory setting. Larsen et al. (2004) used the button-press procedure to show that people indicated mixed emotional reactions to wins that could have been better (i.e., disappointing wins) and losses that could have been worse (i.e., relieving losses). In this study, participants watched an emotionally complex film or a control film that were edited 20-minute versions *Life is Beautiful*. Sixty-seven percent of participants reported simultaneously mixed emotions during the emotionally complex film, which followed the original film's story line, whereas only eighteen percent indicated mixed emotions during the control film, which began as a comedy but abruptly switched to a tragedy.

Study 2 replicated the findings using an online affect grid (Larsen, Norris, McGraw, Hawkley & Cacioppo 2007; see also Andrade & Cohen 2007). Participants watched one of the edited versions of the film and moved a cursor throughout a two-dimensional grid to indicate whether they experienced happiness, sadness, neither happiness nor sadness, or both happiness and sadness. One axis was a scale of intensity for happiness that ranged from "not at all" to "extremely." The other axis was a scale of intensity for sadness that ranged from "not at all" to "extremely." Results of Studies 1 and 2 extend those of Larsen et al. (2001) by providing stronger evidence that people can experience simultaneously mixed emotions.

Another possibility is that participants report mixed emotions only because they are explicitly asked whether they feel happy and sad. In Study 3, we merely asked participants about their current emotions immediately after the control film or the emotionally complex film. Even with this open-ended style of questioning, participants spontaneously reported mixed emotions after the emotionally complex film. The pattern persisted even for respondents who had indicated several weeks prior to the experiment, as part of an unrelated survey, that they believed that people cannot feel happy and sad at the same time. The fact that these "skeptics" endorsed mixed emotions after the emotionally complex film rules out an alternative explanation that participants rely on their lay theories about mixed emotions when responding to the open-ended interview questions.

Study 4 used the same procedure as Study 3 to test possible demand effects by randomly telling some participants that the researchers did not expect to find support for mixed emotions, yet participants persisted in their endorsement even after receiving the bogus hypothesis information. To test if participants' responses were reactive to the experimenter's message, we included an additional condition where we told participants that the researchers expected to find support for mixed emotions, and mixed feelings were just as frequent after the emotionally complex film.

In sum, the present studies show that evidence for the simultaneous experience of happiness and sadness occurs A) when happiness and sadness are measured simultaneously, B) when participants believe a priori that people cannot experience mixed feelings, and C) without regard to the demand placed on participants by the experimental procedure.

## "Managing Mixed Emotions: The Role of Biculturalism"

*Thomas Kramer, Baruch College*
*Loraine Lau-Gesk, University of California, Irvine*
*Chi-yue Chiu, University of Illinois, Urbana-Champaign*

Though research has very recently started to explore the emotional reactivity levels of biculturals as a result of their own cultural duality (Chao, Chen, Roisman, & Hong, in press), little is known about bicultural individuals' responses to mixed emotions.

Emotional ambivalence may arise from psychological conflict when values and practices of heritage and mainstream cultural groups are perceived to be too distant or in opposition (Benet-Martínez, Leu, Lee, & Morris, 2002), from the fluctuating responses from others (e.g., approached with intimacy and familiarity in one context and responded to with fear and distance by the same individuals in another context) depending on which cultural identity is salient in the context (Zaharna, 1989), or from intragroup conflicts among newly arrived and established cultural groups who settle within the same geographical area (Niemann, Romero, Arrendono, & Rodriguez, 1999). Work in cultural anthropology and sociology has found that psychological problems often arise when biculturals confront the conflicting demands of two cultures with disparate value and belief systems (LaFrombroise, Coleman, & Gerton, 1993). For example, Jones (1986) showed that biculturals reported feeling psychologically disturbed when they could neither avoid nor resolve the inconsistency between two conflicting messages. In short, managing dual cultural identities is major life task for biculturals. Accordingly, the current investigation focuses on bicultural expertise as the capability to manage bicultural identities and navigate smoothly between the demands of seemingly conflicting cultures.

Bicultural individuals' responses to mixed emotional experiences, and, in particular as tested here, evaluation of a message that elicits mixed emotions, is likely to depend on their bicultural expertise, as reflected in how much experience they have in dealing with, and how conflicted they feel about, their cultural duality. A distinction has been made between biculturals who integrate their two cultural selves and those who compartmentalize and alternate between them (e.g., LaFrombroise et al., 1993). Given that bicultural integrators often access both cultural selves simultaneously, integrators tend to have more experience and thereby training than alternators in managing cultural duality and its attendant ambivalent emotions, which may in turn lead to the development of a generalized competence in managing mixed emotions. Therefore, we predict that mixed emotional experiences are less likely to arouse discomfort in these individuals, who consequently tend to respond favorably to mixed emotional appeals in persuasion settings. Conversely, bicultural alternators change their behavior and cultural perspective to fit a particular social context (Ogbu & Matute-Bianchi, 1986). They use different problem solving, coping, human relational, communication, and incentive motivation styles according to cues embedded in the environment (LaFrombroise & Rowe, 1984; Rameriz, 1984). Presumably, alternators temporally access only one cultural self as a way to cope with the contradiction that may exist with being affiliated with two cultures with disparate values and beliefs (Kazaleh, 1986). Because bicultural alternators avoid dealing with their cultural duality, they have fewer opportunities to develop expertise in managing it. We therefore expect that mixed emotional experiences create discomfort for these individuals, who subsequently will have relatively less favorable attitudes toward messages with mixed emotional appeals. However, biculturals who have relatively lower levels of expertise in managing their cultural identities and who need to cope with discomfort-evoking mixed emotions are likely to appreciate it when a coping frame that helps them reduce the discomfort is provided.

A coping frame is a verbal assurance of the availability of opportunities and resources to resolve ambiguity and experience positive outcomes. Prior research has demonstrated that framing may help individuals cope with messages that give rise to feelings of discomfort (Braun, 1999; Millar & Millar, 2000; see also Gleicher & Petty, 1992). Furhter, Klayman and Ha (1987) show that framing in advertising can activate confirmatory hypothesis testing,

which in turn may alter the interpretation of product information, especially when the information is ambiguous (Hoch & Ha, 1986). In sum, interpretive frames could help resolve conflict and ambiguity, and thus be an effective coping tool for bicultural individuals who have lower levels of expertise in dealing with their cultural duality.

We tested our hypotheses in three studies. Study 1 (N=75) investigated attitudes toward an advertising appeal that elicited mixed emotions as a function of bicultural types (integrators or alternators) and availability of coping frames. Results show that a relatively greater degree of cultural conflictedness led to less favorable responses to a mixed emotional appeal. Additionally, we found that the presence of coping frames alleviates negative evaluation of a message that evokes mixed emotions among biculturals with relatively high levels of conflictedness about their duality. Study 2 (N=90) sought to replicate Study 1 results using acculturation exposure as a proxy for expertise in managing dual cultural identities and further examined the mediating role of felt discomfort in the relationship between acculturation history and responses to mixed emotional experiences. Finally, Study 3 (N=35) provided a direct test of the hypothesized relationship of bicultural types and acculturation exposure (both as proxies for expertise in managing cultural duality) with responses to mixed emotional experiences. Our research is discussed in light of recent research that has examined separately the dynamic nature of culture and mixed emotions.

### "Anger Tickles Me: Emotional Energy Transfer from Anger to Humor"

*Monica Wadhwa, Stanford University*
*Jennifer Aaker, Stanford University*

*"War continues in Iraq. They're calling it Operation Iraqi Freedom. They were going to call it Operation Iraqi Liberation until they realized that spells 'OIL.'"* –Jay Leno

Anecdotal evidence suggests that people often use humor as an overt expression of anger. For example, political satirists such as Jon Stewart, Jay Leno, and David Letterman present the most frustrating of political embarrassments in the garb of humor. Similarly, in the recent years, feminist humor websites have seen a tremendous growth. A belief that is becoming increasingly popular among the feminists groups is that they can best express their opinions using humor. The aforementioned examples give rise to an interesting question—could anger be translated to humor? Research on affect regulation seems to point to this possibility. Specifically, research in this domain suggests that people in a negative affective state engage in behavior that is expected to put them in a positive affective state. One implication of this research stream, therefore, is that the negative emotional states are malleable; they can be translated into more positive emotional states by engaging in mood-lifting behavior (Keltner and Bonanno 1997; Zillmann 1988). Despite the research in the domain of affect regulation or the aforementioned anecdotal evidence, there is relatively little understood about whether and how a specific negative emotion such as anger can be better translated to a specific positive emotion such as humor.

One goal of this research, therefore, is to address this issue by examining whether anger motivation can make one more effective on a subsequent humor based creativity task (e.g., coming up with creative humor based versus gratitude based advertising ideas). A second goal of this research is to examine why anger can be better translated to humor as compared to any other positive emotion (such as, gratitude). Specifically, we propose the underlying rationale for these effects is drawn from the match between anger and humor on two important dimensions— approach motivation and high arousal.

Research has supported the idea that anger leads to a high arousal, high energy state that can last for hours or even longer. Similarly, incongruity-resolution theory (e.g., Katz, 1993) suggests how a humorous situation or joke is characterized by high arousal (Apter and Smith 1977; Berlyn 1972). Based on the excitation transfer theory (Zillmann 1971), arousal contained in anger is likely to facilitate performance on a humor based creativity task. However, we argue that arousal alone is not sufficient for anger to be translated to humor. Another important factor that helps anger to be effectively translated to humor is the approach motivation associated with anger. Extant research suggests that the dominant response associated with anger is that of approach as compared to avoidance. Similarly, humor has been associated with approach motivation and is linked to action tendencies. Thus, we argue approach motivation associated with anger is imperative for the energy contained in anger to be effectively translated to humor.

To test our hypotheses, we created an experimental context using the cover story of two purportedly unrelated experiments, the first on Emotions and Life Events and the second on Advertising and Consumer-Generated Content. First, participants participated in an emotional event writing exercise, which generated either anger or anxiety, which is associated with avoidance motivation. In a purportedly unrelated study, participants were told that a beer company, Ohio Flag, was creating a new advertising campaign around the notion of "Humor" (versus "Emotion" as the control condition), and wanted to gather consumer-generated ideas for the campaign. Next, participants created ads using either humor or any emotion appeal for the Ohio Flag Beer brand. Ads were coded by two independent coders on how humorous the ad was (as well as a set of other emotions on a seven point scale; *1=not at all; 7=very much*). We predicted that anger (as compared to anxiety) should lead to funnier ads. In support, angry (vs. anxious) participants created more humorous ads. No significant differences arose for other emotions (*F*s<1). Moreover, when asked to use any emotion to create the advertisement (control), those in the anger as compared to anxiety condition were more likely to spontaneously use humor in the appeal. Thus, the findings of study 1 demonstrate that anger as compared to a negative emotion (such as, anxiety) associated with avoidance motivation appears to be better translated to humor.

The goal of experiment 2 was to garner generalize ability of this effect and provide support to our arousal based hypothesis. Specifically, if our arousal based mechanism is valid, angered subjects should be more effective on a task requiring humor as compared to gratitude, which is associated with low arousal. Thus, after an emotion (anger/anxiety) induction exercise, participants generated either humor based or gratitude based greeting card taglines. Again, two coders rated the taglines for the use of humor, as well as a set of other emotions, on a seven point scale (*1=not at all; 7=very much*). Consistent with study 1 results, angered (vs. anxious) subjects generated funnier taglines. Further, as predicted, those in the anger condition were more effective in coming up with the humorous taglines than gratitude-based taglines.

Together, these results suggest that a negative emotion such as anger could also be effectively used for creative purposes. The implications of these findings discussed with regard to the dynamics of emotions as well as emotion regulation and coping.

# Health Communication and Consumer Action: Promise and Pitfalls

Christine Moorman, Duke University, USA
Mary Frances Luce, Duke University, USA

## SESSION OVERVIEW

From news reports on the radio, television, internet, and magazines to focused health campaigns targeting susceptible groups, consumers are bombarded with health messages produced by ongoing medical studies, government agencies, for-profit health and insurance firms, and community and public health non-profits. A Google search of "health" produced 939,000,000 hits, "nutrition" produced 148,000,000 hits, and the specific phrases "health news" (6,140,000) and "health communications (651,000) produced a sizable number of hits. These numbers suggest that health messages are a fundamental part of the mosaic of communications consumers encounter every day and constitute a key component of campaigns designed to reduce morbidity and mortality. These numbers and other indicators also point to trends involving increased consumer responsibility for their own care and shifts in medical culture from paternalism towards informed consent. Despite these positive forces, most health communications produce low compliance and rather dismal results.

Most health communications are undertaken to alter consumer action. Conventional wisdom is that if health communications are sufficiently informative and persuasive (increasing knowledge, efficacy, or motivation), then appropriate action will follow. This session's papers challenge this wisdom. The first two papers sharpen our understanding of how to use health communication to alter consumer action; the second two papers point to important downstream problems occurring after consumers are motivated to act.

Anand Keller and Lehmann report a meta-analysis of 85 health communications studies. They find that message factors, not individual differences or context, dominate explanations of effectiveness. They also show important differences in effects on attitudes toward health behaviors and intentions to change behaviors that may critically influence whether we judge a campaign to be successful or not. Their research underscores the importance of conceptualizing and measuring consumer action (rather than simply consumer attitudes) as a key health communication goal. The second paper, by Anand Keller, extends this theme of the focal nature of consumer action by using mental simulation of health-promoting actions as a focus of intervention. She challenges the current idea that hope and confidence produce more preventive health behaviors and suggests that increasing consumer anxiety is more effective by producing higher need for action taken to regain control.

The third and fourth papers illustrate complementary difficulties in using health communication to alter action. Moorman, Luce, and Bettman argue that consumers may not always benefit from the evolving nature of health guidelines. As medical science sheds more light on the effect of healthy choices or treatment options, communications that initially advocate positive actions (e.g., take a vitamin supplement) but later reverse these suggestions may ultimately degrade consumers' view of health guidelines and decrease their likelihood of performing related health behaviors. Tanner shows that teens may provide inaccurate reports of actions related to risky behaviors when participating in the evaluation of community-based health programs. Inaccuracy is particularly problematic when teens are made aware of desirable health behaviors, when they believe their anonymity may not be protected, or when minimizing, not exaggerating, certain behaviors.

Looking across papers, we see several emerging questions regarding the promise and pitfalls of using health communications to alter health behavior: (1) Do health communications work in the short and long-term? (2) What types of message factors are most predictive of health communication effectiveness? (3) How does the choice of evaluation approach influence the results obtained from health communication campaigns?

## EXTENDED ABSTRACTS

### "Designing Effective Health Communications: A Meta-Analysis of Experimental Results"
*Punam Anand Keller, Dartmouth College*
*Donald R. Lehmann, Columbia University*

**Introduction**

The massive costs of health care (1.7 trillion and counting) as well as the problems posed by various diseases (e.g., AIDS, obesity, diabetes, mental illness) are well documented (Connolly 2004). People worry more about their personal health care costs than losing their jobs or being a victim of a violent crime or terrorist attacks (Gurchiek 2005). To reduce health costs as well as health-related stress, the emphasis is shifting to the promotion of prevention and detection behaviors. As a consequence, massive efforts to improve knowledge about detection, prevention, and treatment continue to be undertaken.

Unsurprisingly, numerous studies have assessed the impact of different communication strategies (e.g. level of fear arousal or framing) on subjects' attitudes toward and intentions with respect to various health behaviors. However, the large number of studies and the variability of the findings suggest a quantitative synthesis of this area would be beneficial. The purpose of this paper, therefore, is to assess the current state of knowledge in the field via meta-analysis. In particular, we wanted to identify the context, message and individual factors that increased attitudes and intentions to comply with the recommended health behaviors. For that purpose, we conducted a meta-analysis on data reported in 85 published and unpublished articles in the consumer research, psychology, health, and communications literatures.

**Overview of the Study**

We examined studies that measured the effectiveness of health communications by assessing attitudes towards the recommended health behaviors and/or intentions to comply with advocated health behaviors. Twenty-two study characteristics reported in the 85 papers were identified as potential determinants of attitudes and intentions in response to health communications. These characteristics were divided into three categories: (i) Context (3 types), (ii) Message (14 types), and (iii) Individual differences (5 types). The results indicate a variety of message factors can be used to enhance attitudes, e.g., base (i.e., statistics) or case (a story about a real or fictitious individual) information, an emotional appeal, and strong arguments for why one should undertake the advocated health actions. Some of the most influential variables for increasing

intentions are case information, emphasizing social consequences (e.g., effect on loved ones), and advocating detection behavior. Intentions also depend on a number of context and individual differences including high perceived severity, response efficacy, and self-efficacy. Looked at more closely, the results have some interesting aspects which bear further discussion.

### Results: Attitudes versus Intentions

Results indicate that message factors explain more of the variance in attitudes than context characteristics or individual differences. By contrast, message factors explain about the same variance in intentions as individual differences and both explain more than context factors. Put differently, while message factors are more important than individual differences which in turn are more influential than the context factors we studied, the relative impact of message factors is greater for attitudes than intentions. In general, we seem to have more control over attitudes than intentions. Message communications are key to attitude formation, but individual and context differences compete with message factors in determining intentions to comply with the message recommendations.

Importantly, with one exception (the use of cases or stories), the five characteristics that best explain attitudes do not overlap with the five factors that most influence intentions. People seem comfortable forming positive attitudes towards healthy behaviors, but their intentions are lower when faced with these choices. Not surprisingly, lab studies are associated with more positive attitudes but lower intentions. While several message factors have a significant effect on attitudes or intentions, only three have similar effects (case information and multiple exposures have positive effects, using a male communicator has a negative effect).

Why might someone have positive attitudes toward the behavior yet not form intentions to comply with the behavior? According to the Theory of Reasoned Action (TRA), intentions are a function of attitude toward the behavior and subjective norms or social pressures regarding the performance of the behavior (Fishbein and Ajzen 1975). However, the TRA is based on the assumption that humans act rationally and that the behavior is under complete volitional control of the individual. In practice, however, individual differences (e.g., ability, motivation, knowledge, emotions) and context factors (e.g., social support, convenience) undermine volitional control (van Hooft et al. 2005).

Although attitudes and intentions have been disconnected in the past literature (Chandon, Morwitz, and Reinartz 2005; Chatzisarantis et al. 2004), our findings that attitudes and intentions have different antecedents is news. One explanation may be that health recommendations can result in conflict between health and non-health goals. For example, use of sunscreen may be viewed as an effective way to reduce the risk of skin cancer, but negatively related to looking attractive with a tan. Similarly, eating fish may be positively related to a health goal, but negatively related to the comfort goal met by meat loaf. Our findings also suggest that intentions may reflect tradeoffs across health and other behaviors, whereas attitudes may be formed in the context of a particular health behavior. In particular, the finding that self-efficacy influences intentions, but not attitudes, suggests that even if response efficacy is high, people are not willing to consider undertaking the behavior if they don't believe they can. They may, however, compensate by engaging in other behaviors related to health or even more abstract goals. For example, a poor diet may be compensated for by increased exercise and/or volunteer work to meet the goal of making one feel good about oneself.

### "The Role of Need for Control in Effective Health Communication"
*Punam Anand Keller, Dartmouth College*

### Introduction

Several goals may drive the design of health communications. However, more often the underlying purpose is to enhance prevention, detection and/or remedial behaviors. This paper examines the effectiveness of message frames for influencing preventative health behaviors among people who would like to, but cannot change their behavior. The framing literature indicates that a negatively-framed message is likely to lead to more favorable attitudes than a positively-framed message when it is uncertain that the recommended behavior will lead to the desired health outcome (Rothman and Salovey 1997). For example, a negatively-framed mammogram message (e.g., if you don't get a mammogram, you will not detect breast cancer early) will lead to more favorable attitudes towards mammograms than a positively-framed message (if you get a mammogram, you will detect breast cancer early) when it is uncertain mammograms are an effective means of detecting breast cancer (Block and Keller 1995; Meyerowitz and Chaiken 1987; Rothman et al. 1993). These findings suggest the differential advantage of negative over positive frames on behavior is rather limited since one is unlikely to get a mammogram if they are perceived as relatively ineffective. The literature also sends mixed messages for choosing message frames for prevention behavior if the audience is highly involved. On one hand, positive frames are recommended over negative frames for prevention behaviors (Rothman and Salovey 1997). On the other hand, negative frames are recommended over positive frames when people are already concerned about the issue (Maheswaran and Meyers-Levy 1990).

This study seeks to answer two questions: What is the effect of frame on behavior, especially for prevention behaviors among involved audiences? And other than uncertainty or low response efficacy, is there an alternative mediator to understand the message frame-behavior relationship in this context? The literature on emotion-based appraisal is used to predict that anxiety-producing negative frames result in more healthy preventative behaviors than hope-inducing positive frames because negative frames increase need for control (Raghunathan and Corfman 2004, 2006; Roseman Wiest, and Swartz 1994).

**Study and Results**

This hypothesis was tested in three experiments. Each of the experiments was divided into three phases. In phase 1, participants were exposed to a framed health message encouraging behavior change. In phase 2, participants were given an opportunity to engage in the behavior. Extent of planning and behavioral compliance was measured in phase 3. All three experiments used undergraduate participants who wished a-priori to reduce alcohol consumption, but stated they could not meet this goal.

Results support the premise that need for control mediates the relationship between message frames and prevention behavior among audiences with unfulfilled goals. The findings also demonstrate that messages that produce anxiety and enhance need for control are more effective than messages that evoke hope. Effectiveness is measured by self-reports on pre-behavior measures (extent of planning), behavior (alcohol use) and post-behavior measures (productivity and extent of control over future alcohol use).

The findings also address the role of behavioral recommendations and consequences in framed health communications. Most of the extant health communications focus on health consequences rather than detailed action steps. The present findings indicate that this message format will be effective as long as the health message enhances need for control. However, unaided planning is unlikely when the audience is not motivated. In these cases, it might be more effective to include detailed action steps (experiments 1 and 2). Together these findings suggest that the "if" aspect of message frames (action steps) may be more valuable than the "then" aspect (consequences).

Results highlight the mediating role of need for control. However, the need for control may be satisfied by the situation rather than personal control. Gollwitzer (1999) suggests that implementation planning often transfers control from the individual to the situation. For example, taking vitamins at noon transfers the control from the person to the situation (noon time). One inference from our results is that hope may prompt relinquishment of personal and situational control, thus explaining the absence of planning and behavior change. Future research is needed on the relationship between feelings and multiple dimensions of need for control.

The premise that feeling hopeful is not an effective means for goal attainment is not necessarily at odds with the view that self-efficacy or one's perceived ability to perform the advocated behavior successfully is the key predictor of behavior change (Ajzen 2000; Bandura 1982; Keller 2006; Maddux and Rogers 1983). The present study suggests that the influence of efficacy beliefs on attitudes versus behavior may depend on the specificity of the belief. One may be confident that one can quit smoking, but may have more doubts about specific action steps such as increasing food intake in response to increased hunger, wearing a patch, taking fewer breaks from work etc. According to this view, perceived ability to undertake specific action steps may be better predictors of behavior than general feelings of feeling confident.

*James R. Bettman, Duke University*

**Introduction**

Scientific advances in healthcare present important opportunities for disease prevention and treatment, but reaping the full benefit of these advances is often complicated by consumer reactions. The press is replete with reports of medical researchers gaining new insights into the effects of preventive health behaviors such as exercise, vitamins, cancer screening, and food consumption and the effects of alternative medical treatments (e.g., prescriptions, surgical procedures, mental health regimens). As science advances, preventive guidelines must evolve— sometimes even contradicting prior guidelines. Such advancements are vital to health care improvements. However, consumers adopting health guidelines may be resistant to change; the evolving nature of guidelines may influence adopters' confidence in recommendations and their willingness to adopt them. From the individual consumer's perspective, evolving guidelines on mammography, HRT, or nutrition, for example, may have unintended and unfortunate outcomes, including losing faith in guidelines, avoiding any proactive approach to healthcare, and feeling hopeless. In short, consumers may feel that evolving guidelines give them a reason to ignore even well-validated preventive health behaviors.

We examine the effect of evolving health guidelines on consumers' reactions to the information in the guideline and on two critical "spillover" outcomes—consumers' faith in health guidelines in general and consumers' intention to perform related health behaviors not specified as part of the guideline. We predict that consumers will have a positive reaction to initial new guidelines in

an area and that such initial guidelines will appropriately affect intention to monitor the behavior noted in the guidelines. However, in the presence of updated scientific information that changes the guideline, we predict that consumers may be less positive. Specifically, we predict consumers will react differently to two types of changing guidelines. The first type, positive-negative, first recommends a behavior for its positive impact but then, in the update, suggests that new research has identified a negative impact for the same behavior. The second type, negative-positive, suggests the opposite and is likely to be less upsetting for consumers. Consistent with work on omission bias (actions are judged more harshly than normatively equivalent omissions, Spranca, Mintz, and Baron 1991) and betrayal aversion (particularly strong emotional reactions when a protective action turns harmful, such as when airbags mandated for automobiles actually hurt occupants, Koehler and Gershoff 2003) we expect consumers to react particularly negatively to being told they should adopt an ostensibly positive behavior, only to be later told that the behavior is in fact negative or harmful. As science marches on with positive-negative updates, we predict that consumers will form negative impressions of the information-value of health guidelines overall and that they will also be less likely to perform unrelated spillover health behaviors.

**Study and Results**

We test our ideas with health information presented through mock newspaper articles. In our study, we formulated guidelines regarding use of pyridoxine (vitamin B6) as a nutritional supplement. An adult community sample initially read either "positive" information supporting use of the supplement or "negative" information warning of dangers of overuse. In both cases, pyridoxine was described as having an effect on the heart (e.g., negative-dangerously irregular heart beat, which can increase the likelihood of fatal heart disease). Half the participants responded to dependent measures after this initial information. The other half was presented with information reversing their initial guideline (e.g., half of the sample who initially read positive information was subsequently told that this information had been revised to be negative, suggesting dangers from overuse. Thus, our design manipulated (between-subjects) the valence of the initial guideline (positive action towards pyridoxine versus negative information suggesting avoidance) and the presence or absence of a reversal. Finally, a control group indicated intentions in the absence of a specific guideline regarding pyridoxine; they were told only that it had recently been covered in the press.

Relative to control, groups receiving a pyridoxine guideline at time 1 reported a positive emotional reaction to the presence of the guideline and an increased likelihood of monitoring pyridoxine levels. However, upon receiving updated guidelines, either negative-positive or positive-negative, consumers reduced intention to monitor pyridoxine, even though the guideline would suggest, from either a positive or negative perspective, that it would be helpful. Most importantly, we found a backlash spillover effect concentrated in those participants who were initially instructed to increase pyridoxine usage (positive) and later were told that they should decrease usage (negative). These participants reported reduced faith in health guidelines in general and also reduced intentions to engage in unrelated heart-healthy behaviors (e.g., cholesterol monitoring, blood pressure monitoring). Specifically, these participants show lowered evaluation and intention behaviors as compared to the negative-positive change group and to the no-change and holdout control groups. Thus, we have isolated one particular type of backlash to guideline change.

*John F. Tanner Jr., Baylor University*

**Introduction**

Although federally-sponsored health campaigns are increasingly required to demonstrate impact (e.g., Community-Based Abstinence Education (CBAE) grants require 15% of the budget to be spent on evaluation), evaluations of such campaigns may be fraught with biased responding. Participants' accuracy in reporting health-risk behaviors is particularly problematic. One study found that 25% of male middle school students, compared to 15% of girls, overstated their sexual experience (Seigel, Alen, and Roghmann 1998). Rosenbaum (2006) also noted systematic patterns of inaccurate responding in the National Longitudinal Study of Adolescent Health. Teens who pledged abstinence were more likely to recant their sexual history, claiming to be virgins in the post-pledge survey in spite of reporting being non-virgins in the pre-pledge survey.

We use self-evaluation maintenance (Tesser and Paulhus 1983) and impression management (Paulhus 1984) theories to explain when, to what degree, and in what direction teen subjects may lie when reporting the health-risk behavior of teenage intercourse. In this case, self-identity may be tied up with the risky behavior. Health campaigns require comparing self to a recommended behavior, which can lead to lying if comparisons are negative (Tesser and Paulhus 1983; Argo, White, and Dahl 2006). Impression management, however, suggests that subjects may sometimes cope by hiding their identity on post-campaign evaluations.

**Experiments**

Three experiments were conducted using data from two saturation health campaigns promoting abstinence via in-school programming and multi-media advertising. In all experiments, subjects were exposed to campaigns promoting sexual abstinence in class and via multi-media advertising.

The goal of study 1 was to determine the degree to which identity protection occurs when presented with an ideal behavior. Using data from an evaluation survey of a CBAE grant, a dummy variable was created reflecting whether the birthday provided by the subject did or did not appear accurate. An (in)accurate birthday was comprised of a (in)valid month, date, and year for the age that was reported. This method assumes that an incorrect birthday is due to "hiding" and not inability to follow directions communicated in writing and verbally with examples by administrators. There were 1734 pre-campaign and 1960 post-campaign surveys from 7th-9th graders. Pre-to-post comparisons indicate no differences in the percentage of students "hiding" or providing inaccurate birthdates. 7th grade girls are more likely to hide than 7th grade boys; there were no other gender differences. Hiders are more likely to report intentions to engage in sex and consume drugs for 7th and 8th graders, with no significant differences among 9th graders. Hiding

was not a function of the campaign, but may have still been due to comparison to an ideal based on the activity reported by hiders.

Experiment 2 examined the degree to which reports of activity or identity were altered when presented with the ideal. The experiment was a 2 (tracking information order, first or last) x 2 (test timing, pre-campaign vs. post-campaign) between-subjects design utilizing a CBAE campaign promoting sexual abstinence. Based on impression management theory, an interaction of these two factors on accuracy was predicted. Specifically, inaccuracies of either type (hiding or lying) should be highest when subjects are aware they are being tracked and when they have been exposed to the "ideal" (i.e. following the campaign). Subjects were 521 ninth graders randomly assigned to the four conditions. Results indicate no difference in hiding, sobriety intentions, or sex intentions for either of the main effect conditions. There was, as predicted, a tracking information order X test timing interaction, but only for lying and not hiding. Post-test, tracking-first subjects were more likely to report being virgins and less likely to report intentions to remain sober. Being exposed to the campaign increases lying about one's virginity status when one knows that identity is being tracked, even though the survey was anonymous. Hiding was not influenced by exposure to the campaign or the position of tracking information.

Experiment 3 sought to determine the direction of impression management. Subjects were randomly assigned to this study from a larger CBAE project and exposed to the campaign. 230 9th graders responded in the pre-test and 220 in the post-test. Teens were asked to agree/disagree with "I exaggerated how much sex I've had on this survey" (exaggerating) and "It is important that my school look good (show less sex) on this survey" (minimizing). Exaggerating appears to remain constant, pre-to-post, suggesting that lying may occur in comparison to ideals held by other potential impression targets such as peers. However, minimizing increases when exposed to the health campaign, consistent with self-evaluation maintenance. In addition, those who said they exaggerated did report greater sexual activity and intentions to engage in such activity while those who said it was important for the school to look good reported less activity and lower intentions.

# Attraction and Compromise Effects Revisited: The Role of Attribute Characteristics and Representation in Context Effects

Selin A. Malkoc, University of Minnesota, USA

## SESSION OVERVIEW

Context effects have been of interest to consumer behavior researchers for the past several decades. This line of research has established that consumers' preferences are significantly and systematically influenced by otherwise irrelevant changes in the decision context. Two of the most important and robust context effects are the attraction effect (a.k.a. asymmetric dominance) and the compromise effect. The attraction effect refers to the phenomenon whereby an asymmetrically dominated alternative, when added to a set, increases the attractiveness and choice probability of the dominating alternative (Huber, Payne and Puto 1982). On the other hand, the compromise effect occurs when the choice probability of an alternative increases when it is the middle option, compared to being an extreme option (Simonson 1989).

The three papers in this symposia further our theoretical knowledge of these two important context effects by identifying factors that amplify, nullify or reverse attraction and compromise effects. These papers focus on the consumers' goals (e.g., promotion or prevention), attribute characteristics (e.g., positive or negative) and attribute representations (e.g., numerical or visual), and demonstrate that these robust context effects can be significantly and systematically moderated.

The first paper, by Frederick and Lee, investigates the role of attribute representation in the extent and direction of the attraction effect. The authors suggest that numerical ratings that have been used to date in this line of research increases the saliency of the dominance relationship–leading to strong attraction effects. Their results indicate that if the same information is presented in a perceptual manner (i.e., visual pictures), the attraction effect disappears or even reverses, a phenomena they name the repulsion effect.

The second paper, by Malkoc, Hoeffler and Hedgcock, critically examines the role of attribute valence in attraction effects. Their results show that the attraction effect is only robust when the options considered are predominantly favorable (positive). In negative domains adding a decoy leads to both an attraction and a repulsion effect. Specifically, the authors show that in negative domains adding a decoy leads to a share increase for the option that is superior on the focal attribute (i.e., an attribute that consumers resist trading off when negative but are willing to do so when positive). They suggest that one of the mechanisms behind this effect is the shift of attribute representations from promotion to prevention as the valence changes.

The third paper, by Levav, Kivetz and Cho, studies the fit between consumers' goals and the attribute characteristics in determining the extent of attraction and compromise effects. They find that both compromise and attraction effects are amplified when the there is a fit between regulatory states and the nature of the attributes. Specifically, when consumers are in a promotion (prevention) focus and are evaluating options that have promotion-(prevention) based attribute tradeoff, they show higher context dependence, compared to when there is a mismatch of goals and attribute characteristics.

Collectively, the three papers in this symposium provide new insights about context effects in general and attraction/compromise effects in particular. These papers show that the attraction and compromise effects are systematically affected by the nature of the attributes, and that they can be attenuated and even reversed. The fist paper illustrates the role of attribute representation and demonstrates that the attraction effect is reversed when attributes are presented in a visual manner (as opposed to numerical representation). Exploring valence effects, the results of the second paper point out that when the attributes considered are predominantly unfavorable; consumers' preferences show both an attraction and a repulsion effect. Lastly, the third paper demonstrates the importance of the fit between attribute characteristics and goals, showing that when there is a high fit, both the attraction and compromise effects are amplified. Following the three papers, the discussant, Joel Huber, will comment on how the three papers inform and qualify the findings of previous research. He will also comment on some of the ways in which the three papers offer diverging perspectives on the common theme of the session. Joel will then engage the audience by inviting questions, comments, and future research ideas.

## EXTENDED ABSTRACTS

### "Attraction, Repulsion, and Attribute Representation"
*Shane Frederick, Massachusetts Institute of Technology*
*Leonard Lee, Columbia University*

The "attraction effect" (Huber, Payne, & Puto 1982) is among the most studied of all contextual effects on choice. Many studies have shown that the presence of an inferior "decoy" option enhances the attractiveness of the option with which it is most similar, and a casual reading of the literature suggests that this phenomenon is extremely robust, and widely replicated across diverse domains.

However, we propose that the way in which attributes are represented plays a critical role in the effect–that it may determine not only the effect's magnitude, but even its *direction*. First, representing naturally experiential or perceptual attributes (such as taste or visual clarity) through contrived numerical ratings (e.g. picture quality rating of a TV) both permits and encourages the computation of tradeoff rates (e.g. quality points per dollar) as a basis for comparison. Second, it enhances the salience of the dominance relationship between the decoy and the target–the difference between the number 9 and the number 8 is simply more apparent and unambiguous than even highly reliable perceptual differences. Third, describing choice stimuli by a vector of numbers strips them of affective content, influencing the types of comparative processes that are invoked. Specifically, we propose that perceptually represented attributes favor assimilation effects whereas numerically represented attributes favor contrast effects. In two experiments, we found that the attraction effect was either eliminated (Experiment 1) or reversed (Experiment 2) merely by shifting attribute representation from a numeric format to a graphical format.

In *Experiment 1*, 560 respondents chose between gambles that varied in probability of winning and reward. For all respondents, two options included an 83% chance to win $12 (the "P-gamble") and a 30% chance to win $33 (the "$-gamble"). For half of the respondents, the choice set also included a third, dominated decoy option–a 30% chance to win $30. Although winning amounts were always represented as a number, the probability of winning was represented either as a numeric percentage or as the shaded region of a probability wheel. When probabilities were represented nu-

merically, we observed a significant attraction effect–the decoy increased the choice share of the target $-gamble from 21% to 34%. However, when probability was presented graphically, the decoy had no effect.

In *Experiment 2*, 240 respondents chose between television sets of different price and image quality. Price was always represented by a number. However, image quality was represented either as photos of the TV screens (the clarity of which was manipulated by adjusting the resolution of a picture file), or by the numeric ratings of those images as judged by a separate group of respondents (8.0, 5.5, and 3.5). When image quality was represented numerically, the choice share of the target TV (low price, *medium* quality) was dramatically increased by the presence of the decoy TV (low price, *low* quality) but when image quality was represented naturally, by a picture of the TV's, the decoy TV substantially underlined decreased the choice share of the target (what we term a "repulsion effect").

Until now, the repulsion effect has been studied only indirectly in research on brand extensions, where imprudent brand extensions not only met early deaths, but also tainted the image and market share of the brand's core products, thereby repelling toward the competitors. Despite the managerial relevance of this phenomenon, there has been next to no experimental research on the repulsion effect, let alone investigations of psychological mechanisms underlying it. The experiments we describe here are among only a handful that have examined the role of attribute representation on context effects, and are the first to focus specifically on the repulsion effect.

### "Valence Asymmetries in Preference: The Case of Attraction Effect"

*Selin A. Malkoc, University of Minnesota*
*Steve Hoeffler, Vanderbilt University*
*William Hedgcock, University of Minnesota*

Extant research in decision making has dealt with context effects, examining how individuals are susceptible to seemingly small (and often rationally irrelevant) factors in the decision environment. One of the most important context effects is the attraction effect (a.k.a. asymmetric dominance). The attraction effect refers to the phenomenon whereby an asymmetrically dominated alternative, when added to a set, increases the attractiveness and choice probability of the dominating alternative (Huber, Payne and Puto 1982).

Several explanations and possible mechanisms have been offered to account for the attraction effect, such as attribute importance signals (Ariely and Wallsten 1995), changes in the range of attribute values considered (Simonson and Tversky 1992) or ease of justification (Simonson 1989). Although this phenomenon have researched extensively and found to be very robust in variant domains (consumer products, politicians, romantic dates, job candidates and medical treatments), most of this research employed options that were predominantly favorable. Past research has shown, however, that people's motivation, perceptions, learning and evaluations are systematically affected by the valence and framing of the options considered (Baumeister et al. 2001; Higgins 1997; Kahneman and Tversky 1979).

Accordingly, in this work, we explore how consumers react to context effects, like asymmetric dominance, when they are choosing among predominantly unfavorable options. We suggest that attribute representation and evaluation are significantly altered in negative domains, which reverse attraction effects in predictable ways. We argue that when attributes values are negative or unfavorable, consumers shift their representations. An attribute (e.g., battery life) that is reasonably good is viewed more as a promotion attribute, (which consumers would like to have more of). However, when the same attribute has values that are predominantly unfavor-

able, then consumers are more likely to view it as a prevention attribute, whereby their focus shifts to attempting to avoid the lower levels. This focus on the prevention of highly negative values, in return leads to increased choice of the option that is superior on the prevention attribute–irregardless of the decoy introduced to the set. More importantly we suggest that this representational shift is more pronounced for the attributes that are more focal (critical). Based on the aforementioned theorization, we predicted to observe asymmetric dominance in the positive domain when a decoy is introduced. However, in the negative domains, we expected both a repulsion and an attraction effect, where the choices systematically favor the critical attribute and ignore the decoy option. We report results from two studies that systematically manipulate the favorability of the attributes and find support for our predictions.

In Study 1, participants were asked to imagine purchasing a digital camera, represented on ergonomics and battery life (focal attribute) that could have a value between –10 and +10. Option A was superior on ergonomics and option B was superior on battery life. The third option was either an A decoy (A') or a B decoy (B'). We also manipulated the attribute valence by keeping the absolute values of the attributes same, but adding a negative sign. The results replicated the attraction effect in the positive domain. When no decoy was present, 35% of the participants choose option A. However, when A' was introduced to the set, choice for A went up to 63%. Conversely, when B' was added, only 22% of the participants chose option A. In the negative domain however, the 60% preference for A when no decoy was present, was decreased when A' (37%) or B' (43%) was introduced to the set. In another words, no matter whether A or B was the asymmetrically dominating alternative, participants indicated a preference for option B, which was superior on battery life (the focal attribute).

After demonstrating the proposed effect in a controlled setting with absolute negative numbers, Study 2 attempted to replicate the findings in a more externally valid context (i.e., where the stimuli had *relative* valence difference). We used a vacation scenario, asking participants to choose a hotel that was presented on two attributes: beach safety (focal attribute) and years since remodel. In the positive (negative) domain, the safety of hotels ranged from 6 to 19 deaths in a million (180 -235/1,000,000) and the years to remodel were 2 to 7 years in positive and 9 to 15 years in the negative domain. The results replicated study 1. Specifically in the positive domain, the choice share increased for option A (superior on safety) when A' was introduced to the set (29% to 52%) and decreased when B' was present (29% to 23%). In the negative domain though, adding both A' (23% to 38%) and B' (23% to 49%) increased the share of option A, which dominated on the focal attribute (beach safety).

In conclusion, we introduce attribute valence as a moderator of the attraction effect and show that one of the most robust context effects is eliminated (and even reversed) when identical attributes are presented in an unfavorable format. We further show this change takes place in a systematic manner and in negative domains introduction of any decoy leads to a higher choice of the option that is superior on the focal attribute.

### "Too Much Fit? How Regulatory Fit Can Turn Us Into Buridan's Asses"

*Jonathan Levav, Columbia University*
*Ran Kivetz, Columbia University*
*Cecile Cho, Columbia University*

This research is motivated by the idea that the robust phenomena of context effects in consumer choice are a function of not only lack of well-defined preferences, but also of goal states and the multiple goals that drive one's judgment and choice. The idea that

there is a relationship between task type and the attribute type being considered for the choice options has been supported in decision research (Nowlis and Simonson 1997). Similarly, research on goal-attribute compatibility suggests that an attribute's relevance to a goal influences the weight of the attributes being considered, whereby the attribute that is more compatible with the goal is given greater weight over another less goal-relevant attribute (Chernev 2004).

Our work builds on this research on goal-attribute compatibility, but from the perspective of context-dependent choice. Drawing on the literature on regulatory orientation and fit, we propose that when there is fit between the one's regulatory goal and the nature of the attributes being considered, context dependence increases. In other words, instead of fit being "good," as implied by the regulatory fit literature, fit actually leads to more non-normative choice. We test this prediction using the compromise and asymmetric dominance effect framework in four studies (Huber, Payne, Puto 1982; Simonson 1989).

Study 1 tested the main hypothesis using the compromise effect paradigm, creating a tradeoff conflict involving attributes that are both high in promotion strength (versus both high in prevention strength). We predicted that preference for the compromise option would be higher when the participant's goal state was promotion-oriented (fit) than when the participant's goal state was prevention-oriented (nonfat). (We also conducted the same test for a prevention-oriented goal state.) Participants were given a series of trinary-choice tasks involving various purchase scenarios. Regulatory orientation was manipulated by having respondents report their hopes and aspirations (or duties and obligations; Higgins, Roney, Crowe and Hymes 1994). Two sets of attributes were used to create a tradeoff conflict for each of the choice scenarios. For example, a laptop category had two attributes that both mapped onto either promotion (processor speed and RAM memory) or prevention concerns (warranty and weight). Results showed robust support for the hypothesized fit effect; for seven out of the eight categories we used, the relative choice share of the compromise option was higher when there was a fit between the primed goal orientation and the attribute type.

In Study 2 we tested for the hypothesized too much fit effect using the asymmetric dominance test. Again, conflict was created using two promotion- or two prevention-type attributes. As with Study 1, respondents first completed the same priming tasks before making their choices in eight purchase categories. The effect differentials for the fit vs. no fit conditions were consistent with our hypothesis for six of the eight categories. For the vacation package item, for example, the asymmetric dominance effect was 17% under fit versus 5% under no fit for choices involving prevention-consistent attributes of "number of flight stopovers" and type of travel insurance included in the package.

We propose that the explanation behind this pronounced tendency to make context dependent choices under fit is that of decision conflict. Our underlying premise is that the greatest degree of context-dependent choice occurs when one is faced with the conflict of choosing between options that differ on two similarly weighted attributes. We tested this explanation in Study 3 by directly measuring perceived conflict and decision difficulty. To operationalize this we used choice deferral (i.e., an explicit no choice or "decide later" option) as one of the options, in addition to the two choice options. Next, respondents rated their preference for delaying their purchase, and the difficulty of choosing either of the two product options should they be forced to choose. We predicted that respondents in the fit condition (e.g. promotion prime-promotion attribute type) would have higher preference to delay their decision and rate the decision as more difficult. Results were consistent with our prediction: The ratings of "prefer to delay" and "difficulty of choice" were significantly higher under fit than under non-fit for seven of the nine categories tested.

Study 4 addressed the role of attribute weighting in the too much fit effect observed in the previous studies. In this study, attribute types used to create conflict were "mixed," such that each choice would involve having to tradeoff between a promotion and a prevention-consistent attribute. We predicted that the attribute that fit the participant's primed regulatory orientation would receive greater weight, and hence lead to a reduction in the share of the compromise option in favor of the attribute that is consistent with the primed goal state. We used the compromise effect task from study 1, except here attribute types were mixed, such that each choice option included one promotion and one prevention attribute. Choice shares were greater for the option that was superior on the goal-consistent attribute than on goal-inconsistent attribute. Ratings of importance were also higher for goal-consistent attributes than for goal-inconsistent attribute for thirteen out of sixteen attributes tested, lending further support to the notion that the observed fit effect occurs due to conflict and that this conflict occurs due to augmented weighting of the goal-consistent attribute.

In contrast to an abundance of consumer behavior and social psychological research that suggest that fit is "good," our findings indicate that in certain decision contexts fit can actually increase non-normative choice.

# Breaking Behavior Repetition: New Insights on the Role of Habits and Intentions

Pierre Chandon, INSEAD, France
Vicki G. Morwitz, New York University, USA

## SESSION OVERVIEW

First year psychology students learn that most behaviors are repeated, that past behavior is the best predictor of future behavior, and that habits are hard to break. For example, diary studies show that 45% of all the daily activities of students occur almost every day and in the same location (Wood and Quinn 2005). Many studies have also shown that past behavior has a significant effect on future behavior and that these effects are not fully mediated by beliefs and intentions (Ajzen 2002). Interventions that attempt to break habits by changing people's beliefs and intentions are often unsuccessful, even when they significantly influence intentions (Ouellette and Wood 1998; Verplanken and Wood 2006). In fact, repeated behaviors (e.g., inadequate exercise, overeating, smoking) are among the leading causes of preventable deaths.

However, there are significant disagreements regarding the conceptual significance of behavior repetition ("Is it proof of real habituation?"), its empirical reality ("Does the residual effect of past behavior disappear once intentions are measured?"), about methods ("Is behavior frequency a valid measure of habit strength?" and "Is behavior repetition subject to mere-measurement effects?"), and about their implications for behavior change ("When are intentions stronger than habits at guiding behavior?" and "Which interventions work for breaking habits?").

Yet, these important issues are largely absent from current consumer research, which tends to undervalue habit as a concept. The goal of this symposium is to provide an opportunity for consumer researchers to take a new look at habits and to learn about the exciting new research that is being done by colleagues in social psychology. To this end, we bring together prominent habits researchers from social psychology and marketing to summarize the state of the art in habits research and to chart new avenues for research in this important domain.

To achieve these goals, Bas Verplanken will start with an overview of how habits have traditionally been conceptualized (i.e., as behavior repetition) and measured (i.e., as behavioral frequency). He will then provide a new scale to measure habit strength that is consistent with current views of habit as automatic, stimulus-based disposition to repeat well-practiced responses. Finally, he will show how this new conceptualization of habits provides new insights on what can be done to break bad habits.

In the second presentation, David Neal will show the results of a series of studies conducted with Wendy Wood and Anthony Pascoe showing that many everyday repetitive behaviors are automatically triggered by recurring environmental cues and not by deliberative, intended, and goal-mediated psychological processes. He will then show that changing environmental features (e.g., moving to a new house) and ensuring high levels of self-control capacity brings behavior under intentional control and helps people change their purchase and consumption habits.

In the third presentation, Pierre Chandon (in joint work with Vicki Morwitz, Ronn Smith, Eric Spangenberg, and David Sprott) will show how question-behavior research on the unintended effects of measuring intentions can contribute to the current debate about the relative importance of habits and intentions in guiding behavior. He will present the results of four longitudinal experiments (two in the field and two in a laboratory context) that demonstrate that measuring intentions strengthens behavior repetition when personal norms are weak but disrupts behavior repetition when personal norms are strong.

The discussion leader will be Gavan Fitzsimons. Gavan Fitzsimons will draw on his research on automatic behavior and on the effects of measuring intentions to discuss the contribution of the three papers of the session and to lead a discussion about an appropriate research agenda for continued work in this area.

## EXTENDED ABSTRACTS

### "Habit and Consumer Behavior: Implications for Interventions and Behavior Change"

*Bas Verplanken, University of Bath*

We seldom do things for the first time. A large portion of everyday behavior, including many consumer behaviors, is repeated in one form or another. While a single act may have important personal consequences, when behaviors are repeated, they exert significant, cumulative impact on medical, social, and economic outcomes experienced by both individual consumers and society as a whole. An important aspect of repetition is that repeating behaviors may turn these into habits. A habit can be conceptualized as a recurrent, often unconscious pattern of behaviour that is acquired through frequent repetition in a stable context. In this presentation, I will (1) argue that habit is an undervalued concept in consumer research, and show why habits are important to study; (2) claim that habits have been incorrectly conceptualized as 'frequency of past behavior,' and propose a more adequate conceptualization; and (3) discuss implications of considering the habit concept for interventions and behavior change.

Although many consumer behaviors are highly repetitive, this aspect is not or is only indirectly incorporated in most models of consumer behavior. For instance, according to the theory of planned behavior, past behavior influences future behavior through the mediating effects of model variables such as attitudes and behavioral intentions. Nevertheless, research on the residual variance effect shows that past behavior has a distinct and independent effect on future behavior over and above the model variables. Although this effect may have many causes, some of our research demonstrates that habituation may be one of those. In addition, habit has been found to attenuate the influence of attitudes and intentions on behavior, which suggests that habits may function as boundary conditions for the validity of social cognitive models. Habituation has also been found to affect information processing, such as information acquisition. In all, there is good reason to pay more attention to habit as a concept of interest to consumer behavior researchers.

Habit has always been conceptualized as frequency of past behavior. Consequently, most instruments to assess habit strength comprise of some measure of past behavioral frequency. However, it can be argued that repetition of behavior is a necessary, but not a sufficient condition to define behavior as habit. In addition to repetition, habits are defined by the automatic nature of acting. That is, habits may be executed without much awareness, deliberation or conscious intent, may efficiently co-occur with other activities, and are sometimes difficult to control. These features of automaticity, in addition to the aspect of repetition, provide a more appropriate and psychologically meaningful account of habit than confining

habit to past behavioral frequency. Following this reconceptualization of the habit construct, we developed a generic 12-item meta-cognitive instrument to measure habit strength. This instrument is not only a more valid measure of habit, it also provides the opportunity to test hypotheses that could not be tested with past behavioral frequency measures.

The features of automaticity that define habits, are the very features that make existing habits difficult to change. That is, the lack of awareness, deliberation and conscious intent that characterizes habits, the efficiency of habitual behavior, and the difficulty to control habits, may all contribute to the perseverance of habitual behavior. Unhealthy snacking habits, for instance, are difficult to change because habitual snackers typically do not make deliberate tradeoffs, take their snacks while doing other things simultaneously, and simply find it hard to leave. Together with the findings that habits are associated with a "tunnel vision," as well as the weak relations between attitudes, intentions and habitual behavior, the defining features of habits spell bad news particularly for the effectiveness of informational campaigns. However, I will also argue that there may be windows of opportunities for such interventions when habits are broken in a more or less natural fashion. This may occur, for instance, when people move, when companies merge, or when people's everyday routines are jeopardized or temporarily changed.

Finally, it can be argued that the features that define habits are the very features that are attractive for desirable behaviors to obtain. That is, we would like desirable behaviors to be executed frequently and automatically, and not be easily challenged by external information. In other words, the creation of desirable habits may be explicitly adopted as an intervention goal. This often will require much more than providing information. New habits should first and foremost be satisfactory solutions. Creating habits also implies creating stable contexts in which the new habits are sustained. For instance, the purchase of healthy food may only be expected to become habitual when such food is easily available at the right times and places.

Habit has long been ignored as a distinct and interesting construct. The conceptualization of habit as frequency of past behavior seems at least partly responsible for this. By defining habit as repeated behavior that has gained a degree of automaticity, we may now work with a more valid and psychologically more interesting concept. Taking habit into account may lead to new approaches to changing existing as well as creating new consumer behavior.

### "Triggers of Real-World Habits: Implications for Consumer Behavior"

*David Neal, Duke University*
*Wendy Wood, Duke University*
*Anthony M. Pascoe, Duke University*

Classic approaches to consumer behavior have tended to focus on the role of relatively conscious, deliberative decisions in driving action (e.g., information processing models; elaboration-likelihood model; see Bargh, 2002). Within this perspective, consumers are depicted as engaged in fairly dynamic processes of updating and adjusting their behavior to maximize subjective utility. How well does this model apply to well-established consumer habits? In this talk, we use a combination of naturalistic and experimental data to argue that habits are relatively isolated from people's deliberative, intended, and goal-mediated psychological processes (Wood & Neal, in press). We argue that habits depend instead on cues in the performance environment that have historically co-varied with the response. Specifically, environmental cues come to be represented with habitual responses in memory so that the simple perception of the cues can trigger performance of the response.

In support of this habit model, we present data from a series of studies some of which directly measure consumer behavior and some of which assess habits more broadly. Our first three studies indicate that habits are relatively independent of people's current goals and intentions. Study one used a diary paradigm in which participants' fast food purchases were tracked over a one-week period and then predicted from (a) the strength of their past purchasing habits and (b) the favorability of their stated intentions (i.e., whether they held favorable or unfavorable purchase intentions). Regression analyses showed that intentions were powerful predictors of actual purchasing behavior when habits were not in place, but did not predict behavior for those with strong habits (Ji Song & Wood, in press).

We then will present convergent evidence from a second, more controlled experimental paradigm. These studies simulated habit formation in the laboratory using a probabilistic learning task borrowed from cognitive neuroscience (Poldrack et al., 2001). Specifically, participants played a computer game in which they learned to predict weather outcomes (rain vs. shine) based on probabilistically associated visual cues. For some participants, the learning trials involved procedures known to encourage use of habit-based, procedural associations in memory. For others, the learning trials involved more explicit, declarative learning of specific outcomes. After learning, we primed a task-relevant goal (i.e., achievement) in some participants but not others using a scrambled sentence task. Participants were then tested on their weather prediction ability. Implicit achievement goal priming improved the performance of those relying on declarative memory, but impaired performance of those using habit-based procedural memory. This effect was replicated in a second study using an explicit goal-priming technique (performance-contingent payment). Thus, activating response-relevant goals not only failed to facilitate, but actually impaired, habitual responding.

These first two studies, although employing radically different paradigms, support a similar conclusion. They suggest that people's habits are relatively independent from current goals and intentions. Extrapolating to the consumer domain, we theorize that marketing campaigns should tailor content to the strength of consumers' habits in the target domain. Change in consumer habits will not be easily accomplished by a focus on changing intentions and goals.

In the second part of the talk, we address the mechanisms by which it is possible to change purchase and consumption habits. The results of a real-world diary study will be presented showing that people's newspaper reading and TV watching habits tend to be disrupted when the context in which they perform those behaviors changes in some way (e.g., when cohabitants' behavior changes). These data provide a real-world analogue for experimental work conducted by others showing that habits are linked to, and triggered by, the contextual cues that have consistently co-varied with past performance. Importantly, the diary data also reveal that context change tends to bring behavior under the control of people's intentions. Specifically, even those with strong habits to read the newspaper or watch TV acted in line with their (favorable or unfavorable) intentions when the context had been disrupted. Based on this, we argue that context change (e.g., when people move to a new house) offers opportunities to target the formation of new consumer habits by influencing people's intentions and goals when their old habits have been disrupted. In particular, new resident marketing programs hold great promise to alter habitual consumer behaviors (see Verplanken & Wood, 2006).

Also relevant to understanding the mechanisms for changing consumer habits is recognition of the extensive self-control resources required for consumers to control existing habits. In line with recent work showing that self-control is a readily depleted, finite resource (Muraven & Baumeister, 1998), we present diary data suggesting that people's real-world habits are especially difficult to inhibit when their self-control resources are low. Over four days, we tracked people's performance of personally important desirable (e.g., attending gym) and undesirable behaviors (e.g., purchasing candy bars). For two of the four days, we imposed a chronic self-control drain on participants by having them use their non-dominant hand for a variety of tasks (e.g., opening doors, answering cell phones). When self-control capacity was taxed in this way, participants were significantly more likely to fail at inhibiting unwanted habits. These data suggest that consumer habits will be especially unlikely to be amenable to change through marketing techniques that address intentions and goals when people's self-control resources are low (e.g., at the end of the day).

### "When Does the Past Repeat Itself? The Role of Behavior Prediction and Personal Norms"

*Pierre Chandon, INSEAD*
*Vicki Morwitz, New York University*
*Ronn Smith, University of Arkansas*
*Eric R. Spangenberg, Washington State University*
*David E. Sprott, Washington State University*

Whether done intentionally or out of habit, many behaviors are repeated. Although no one denies the empirical evidence regarding the prevalence of repeat behavior and the predictive power of past behavior, two issues remain intensely debated. The first issue is whether behavior repetition provides evidence of habituation or whether it is simply a proxy measure of other unobserved or poorly measured factors, such as intentions, that actually drive behavior (Bargh and Chartrand 1999; Ouellette and Wood 1998; Webb and Sheeran 2006). Unfortunately, all the studies attempting to answer this question share a common methodological problem: In order to assess the unique contribution of each factor, they measure both intentions and behaviors in the same groups of people. If the simple act of measuring intentions changes behavior repetition, the results of these studies a) may not generalize to the general population of people whose intentions were not measured and b) may be systematically biased by factors such as subjective norms, which, as we argue, determine whether measuring intentions strengthens or weakens behavior repetition.

The second debated issue is to determine, from a practical standpoint, which interventions can be used to reinforce the repetition of behaviors generally considered virtuous and to disrupt the repetition of harmful behaviors. We hope to provide new insights into this question by examining the role of behavior prediction. Asking people about their future behavior is known to influence both socially normative and non-normative behaviors ( Chandon, Morwitz, and Reinartz 2004; Chandon, Morwitz, and Reinartz 2005; Sherman 1980; Spangenberg and Greenwald 1999; Spangenberg et al. 2003). It is also an important question from a public health perspective because many research and prevention programs routinely include behavior prediction requests (Williams, Block, and Fitzsimons 2006), and may therefore unknowingly disrupt socially beneficial habits or reinforce socially harmful ones.

The objective of this research is to examine how behavior predictions and personal norms interact to reinforce or disrupt behavior repetition. Drawing on mere-measurement and self-prophecy studies (known collectively as question-behavior research,

Sprott et al. 2006), we hypothesize that asking people to predict their future behavior disrupts behavior repetition when personal norms are strong but increases repetition when they are weak. Stated differently, we hypothesize that prediction leads people to act according to their personal norm—and hence reduces the likelihood of repeating past behavior—when personal norms about the appropriate frequency of behavior are strong, but leads to behavior polarization—and hence to a higher likelihood of repeating the past—when personal norms are weak.

Two field experiments, one in a low-norm context (grocery purchasing) and one in a high-norm context (exercising), provide empirical support for our hypotheses. Study 1 shows that asking people about their future online grocery shopping intentions increased the number of transactions and total expenditures among frequent shoppers, but decreased these behaviors for those with medium and low pre-study usage. Hence, Study 1 shows that self-prediction increases online grocery purchasing habits. In Study 2, we obtain the exact opposite results when looking at exercising, a high-normative behavior. We find that asking people about their future exercising behavior reduced attendance at a health and fitness club among the top tier of its most assiduous members and increased it among the more intermittent users. Both Studies 1 and 2 used unobtrusive measures of behavior (e.g., shopping transaction data and daily attendance data) obtained in collaboration with the online grocer and with the health club.

The results of the field studies were supported by two laboratory experiments in which we manipulate and measure normative beliefs in a more controlled environment. In Study 3, we asked students to keep diaries measuring how much time they spend each day on a behavior with high normative beliefs (exercising) and on two behaviors with low normative beliefs (news watching and book reading). We also collected data on norm importance beliefs for each behavior by each participant. Participants were then asked to predict whether or not they would engage in one of the three behaviors in the following weeks. One week later, participants filled out unanticipated surveys of their post-prediction behavior duration. As expected, Study 3 shows that for behaviors with low normative beliefs (i.e., news and books) asking questions about future behavior increased the time spent amont the most frequent users but reduced it for the least frequent users. For example asking questions about future behavior increased the time spent watching news by 47 minutes (+31%) among top-tier news watchers, but led to a 25-minute reduction (-74%) among the bottom tier. In contrast, self-prediction increased the time spent for the high social norm behavior (i.e,. exercise) by 41 minutes in seven days (+69%) among the bottom tier of exercisers, but decreased exercise duration by 141 minutes (-49%) among the top tier. Finally, Study 4 provides initial evidence that personal norms strength interacts with behavior prediction because of the different accessibility of strong and weak personal norms and because of the resulting conflict with past behavior. Specifically, it shows that personal norms are more available for exercising than for either book reading or news watching and are more likely to conflict with past behavior when people are asked to predict their future behavior for exercising than for either book reading or news watching. It also shows that the strength and availability of personal norms are correlated at the individual level.

Although the focus of this research is on the effects of behavior prediction (i.e., the effects of *measuring* intentions, not the effects of intentions per se), our framework and results provide new insights on the two related debates of the relative importance of past behavior in guiding future behavior and on the factors that influence behavior repetition. We also contribute to the question-behavior

literature by demonstrating a new consequence of prediction, namely that it affects behavior consistency over time, and by providing new insights on the processes underlying question-behavior effects. Finally, our findings help unify this literature by showing that some of its seemingly contradictory results can be explained by the fact that some looked at behaviors, such as exercising, for which personal norms tend to be strong whereas others looked at behaviors, such as grocery shopping, for which personal norms tend to be weaker.

# Deal or no Deal? The Neural Basis of Decision Utility and Loss Aversion During Consumer Decision-Making

Hilke Plassmann, California Institute of Technology, USA

## EXTENDED ABSTRACTS

### "Neural Encoding of WTP Computation During Simple Purchasing Decisions"

*Hilke Plassmann, California Institute of Technology*
*John O'Doherty, California Institute of Technology*
*Antonio Rangel, California Institute of Technology*

Over 43 trillion dollars in goods and services are exchanged every year in the world economy. An essential component of every marketplace transaction is a willingness-to-pay (WTP) computation in which consumers calculate the maximum amount of resources that they are willing to give up in exchange for the object being sold. This WTP is then used to evaluate whether a proposed purchasing offer is beneficial (e.g., when the WTP exceeds the price at which the product is being offered). Clearly, in order to make good purchasing decisions, individuals must be able to assign a WTP to an item that is commensurate to the utility that it will generate. Otherwise consumers would end up purchasing items for a price that exceeds their worth to them. Despite its pervasiveness and importance for consumer welfare, little is known about how the brain carries out the WTP computation in everyday transactions, or about how its ability to do so is affected by diseases such as addiction or obsessive compulsive disorders. This makes understanding how and where the brain makes these computations one of the most important open questions in the nascent field of Neuroeconomics (Camerer, Loewenstein, and Prelec, 2005).

Based on the results of several previous studies, we hypothesized that activity in the medial orbitofrontal cortex (mOFC) encodes WTP. Monkey electrophysiology studies of binary choice have found that activity in the OFC encodes the expected value of the chosen action (e.g. Padoa-Schioppa and Assad, 2006). Several fMRI studies have found analogous results in humans (e.g. Daw et al. 2006, Knutson et al. 2007, Tom et al., 2007). Although all of these studies suggest that the medial OFC plays a critical role in the evaluation of choices and the computation of reward values, none of them have established that the medial OFC correlates with the subjective economic computation of WTP.

We investigated the neural basis of the WTP computation by scanning hungry subjects' brains using fMRI while they placed bids for the right to eat different junk foods in a Becker-DeGroot-Marshak auction (Becker, DeGroot, and Marschak, 1964). Because of the characteristics of this auction, individuals always bid their exact WTP for the object (Wertenbroch and Skiera, 2002) and thus we get a measure of the WTP computed by the brain for every bidder and item at the time of decision-making, which we can then compare with the BOLD measure of neural activity.

Subjects were asked to place bids in two different conditions: free bidding trials and forced bidding trials. In free bidding trials they chose how much to bid. In forced bidding trials they were told how much to bid. Both types of trials were otherwise identical. Each item received one bid of each kind. The only difference between both types of trials is that the subject needs to perform a WTP computation in the free trials, since she needs to decide how much to bid, but not in the forced trials, since she is told what her bid should be. Every other computation, such as the anticipated taste of the food, should be carried out equally in both types of trials. As a result, we can conclude that a brain area encodes the WTP compu-

tation whenever its activity increases with the WTP in the free trials, but not in the forced trials.

As predicted, we found that activity changes within the medial OFC were modulated by the subject's WTP in free as compared to forced bid trials. Unexpectedly, we also found that right dorsolateral prefrontal cortex (DLPFC) involved in this computation. We thus concluded that activity in the medial OFC and DLPFC encode for WTP in everyday purchasing decisions.

Part of the research agenda in neuroscience related to behavioral decision research is to understand how the brain evaluates potential goals and outcomes at the time of decision-making, and how do other cognitive, emotional, and visceral processes affect the computation of economic utility. A first step in this research agenda is to understand what are the brain structures involved in the computation of (decision) utility in simple everyday purchasing decisions. Our results suggest that the medial OFC and DLPFC are places where a variety of variables computed in other brain regions are integrated into a single representation of utility. If this hypothesis is correct, other brain processes may be able to influence decision-making by modulating activity in the medial OFC and DLPFC.

Additionally, our results have also implications for decision-making disorders and transformative consumer research. From a neuroeconomic point of view, addiction and compulsive gambling, eating, or purchasing behavior can be characterized as diseases in which the brain miscomputes the WTP of drugs, gambles, food and goods. Given our findings, these diseases might act through brain mechanisms modulating activity within mOFC and DLPFC (further preliminary evidence for this hypothesis comes from Volkow et al., 2005).

### "The Neural Basis of Loss Aversion in Decision-Making Under Risk"

*Craig Fox, University of California, Los Angeles*
*Sabrina Tom, University of California, Los Angeles*
*Christopher Trepel, University of California, Los Angeles*
*Russel Poldrack, University of California, Los Angeles*

Many decisions, such as whether to invest in the stock market or to accept a new job, involve the possibility of gaining or losing relative to the status quo. When faced with such decisions, most people are strikingly risk averse. For instance, people typically reject gambles that offer a 50/50 chance of gaining or losing money, unless the amount that could be gained is at least twice the amount that could be lost (e.g., a 50/50 chance to either gain $100 or lose $50) (Tversky, 1992). Prospect theory explains risk aversion for "mixed" (gain/loss) gambles using the concept of loss aversion: People are more sensitive to the possibility of losing objects or money than they are to the possibility of gaining the same objects or amounts of money. Thus, people typically require a potential gain of at least $100 to make up for exposure to a potential loss of $50 because the subjective impact of losses is roughly twice that of gains. Similarly, people demand substantially more money to part with objects they have been given than they would have been willing to pay to acquire them in the first place (Kahneman, 1990). Loss aversion has been used to explain a wide range of economic behaviors outside the laboratory (e.g. Benartzi, 1995) and is seen in trading behavior of young children (Harbaugh, 2001) and capuchin

monkeys (Chen, 2006), suggesting that it may reflect a fundamental feature of the primate brain.

In the current study we aimed to isolate activity associated with the evaluation of a gamble when choosing whether or not to accept it (i.e., decision utility) without the expectation that the gamble would be immediately resolved. This allowed us to test whether neural responses during the evaluation of potential outcomes are similar to patterns previously reported in studies of anticipated and experienced outcomes. Moreover, we explore whether enhanced sensitivity to losses is driven by negative emotions, such as fear or anxiety (e.g., Camerer, 2005) that might be mediated by enhanced activity in brain areas such as the amygdala or anterior insula, cf., (Kahn, 2002; Kuhnen, 2005) or whether loss aversion reflects an asymmetric response to losses versus gains within a single system that codes for the subjective value of the potential gamble, such as ventral striatum (e.g. Breiter, 2001).

We collected functional magnetic resonance imaging (fMRI) data while participants decided whether to accept or reject mixed gambles that offered a 50/50 chance of either gaining one amount of money or losing another amount. The sizes of the potential gain and loss were manipulated independently, with gains ranging from $10 to $40 (in increments of $2) and losses ranging from $5 to $20 (in increments of $1). To introduce incentive-compatible payoffs, we endowed participants with $30 one week prior to scanning and told participants that one decision from each of three scanning runs would be honored for real money.

We assessed behavioral sensitivity to gains and losses by fitting a logistic regression to each participant's acceptability judgments collected during scanning, using the size of the gain and loss as independent variables. We computed a measure of behavioral loss aversion ($\lambda$) as the ratio of the (absolute) loss response to the gain response, yielding a median $\lambda=1.93$ (range: 0.99-6.75). This finding is consistent with the observation that participants were on average indifferent to gambles in which the potential gain was twice the potential loss and also accords well with previous findings (Tversky, 1992).

We next analyzed the imaging data to identify regions whose activation correlated with the size of the potential gain or loss, using parametric regressors. This analysis isolated a set of regions responsive to the size of potential gains when evaluating gambles (averaging over levels of loss). The gain-responsive network included regions previously shown to be associated with the anticipation and receipt of monetary rewards, including dorsal and ventral striatum, ventromedial prefrontal cortex (vmPFC), ventrolateral PFC (vlPFC), anterior cingulate (ACC), orbitofrontal cortex (OFC), and dopaminergic midbrain regions. There were no regions that showed decreasing activation as gains increased.

Surprisingly, no brain regions showed significantly increasing activation during evaluation of gambles as the size of the potential loss increased (averaging over all levels of gain). Instead, a group of brain regions including the striatum, vmPFC, ventral ACC, and medial OFC, most of which also coded for gains, showed decreasing activity as the size of the potential loss increased. A conjunction analysis between increasing activity for gains and decreasing activity for losses demonstrated joint sensitivity to both gains and losses in a set of regions, including the dorsal and ventral striatum and vmPFC.

Examination of regions of interest in the striatum and vmPFC from the gain/loss conjunction analysis revealed that these regions exhibited a pattern of "neural loss aversion"; that is, the (negative) slope of the decrease in activity for increasing losses was greater than the slope of the increase in activity for increasing gains in a majority of participants (striatum: loss>gain for 14/16 participants,

p=.004; vmPFC: loss>gain for 13/16 participants, p=.021). In order to more directly assess the relationship between neural loss aversion and behavioral loss aversion, we performed a whole-brain robust regression analysis with these measures. This analysis revealed significant correlations between behavioral and neural loss aversion in several regions, including bilateral ventral striatum (r=.85) as well as bilateral lateral and superior PFC (pre-SMA), and right inferior parietal cortex. These results demonstrate that differences in behavior were strongly predicted by differences in neural responses.

The present study replicates the common behavioral pattern of risk aversion for mixed gambles that offer a 50/50 chance of gaining or losing money, and shows that this pattern of behavior is directly tied to the brain's greater sensitivity to potential losses than gains, consistent with prospect theory. The study also shows that potential losses are represented by decreasing activity in regions that seem to code for subjective value rather than by increasing activity in regions associated with negative emotions.

### "Neural Predictors of Purchases"

*Scott Rick, University of Pennsylvania*
*Brian Knutson, Stanford University*
*Elliott Wimmer, Stanford University*
*Drazen Prelec, Massachusetts Institute of Technology*
*George Loewenstein, Carnegie Mellon University*

The decision whether to purchase a product is the fundamental unit of economic analysis. The success of economic theory rests on its ability to characterize this repeated and elementary decision process. While some neuroeconomic research (e.g., McClure et al., 2004) has examined how people choose between well-defined immediate and delayed rewards, note that consumers rarely face such explicit choices. Although the standard economic perspective assumes that the price of a good represents how much future pleasure must be foregone to finance immediate consumption, it is not at all clear that people spontaneously consider such "opportunity costs" in their purchasing decisions. Consider, for instance, a study by Frederick et al. (2006) in which participants were asked if they would (hypothetically) be willing to purchase a desirable video for $14.99. The researchers simply varied whether the decision not to buy it was framed as "not buy this entertaining video" or "keep the $14.99 for other purchases." Although the two phrases represent equivalent actions, the latter highlights the pleasure that is foregone by purchasing the video. Frederick et al. (2006) found that drawing attention to opportunity costs significantly reduced the proportion of participants willing to purchase the video, suggesting that some participants are not spontaneously considering opportunity costs.

If prices do not deter spending through a deliberative consideration of opportunity costs, then what role do prices play in spending decisions? Prelec and Loewenstein (1998) propose that prices deter spending through an immediate "pain of paying." According to their model, people consume immediately if the anticipated benefits of doing so exceed the pain of paying for the good. We examined these competing perspectives in an experiment in which participants chose whether or not to purchase a series of discounted consumer goods while having their brains scanned with fMRI. Before each of two sessions participants were given $20 to spend and were told that one of their decisions would be randomly selected to count for real. In order to isolate participants' reactions to the different components of purchasing decisions, participants first saw the available good for four seconds, then saw its price for four seconds, and then had four seconds to decide whether or not to purchase it. Goods ranged from hedonic (e.g., The Simpsons DVDs) to utilitarian (e.g., Crest Whitestrips), retailed from $10-

$80, and were offered at a 75% discount in order to encourage spending. At the conclusion of the experiment, participants indicated how much they liked each product and how much they would be willing to pay for it.

Consistent with both the standard economic perspective and Prelec and Loewenstein's (1998) Red and Black model, we found that the extent to which participants reported liking the products correlated positively with activation in nucleus accumbens, a region previously associated with anticipation of gains and positive arousal (Knutson et al. 2001). Nucleus accumbens activation was also positively correlated with purchasing decisions. However, inconsistent with the standard economic account, we also found that activation in insula, a region previously associated with experiencing a variety of painful stimuli such as disgusting odors (Wicker et al., 2003), unfairness (Sanfey et al., 2003), and social exclusion (Eisenberger et al., 2003), correlated negatively with purchasing decisions. The difference in insula activation between purchased and non-purchased products occurred as soon as participants saw the good's price, four seconds before the actual purchase decision was made. The difference remains significant controlling for price, willingness to pay, and activation in related brain regions. The results suggest that an anticipatory pain of paying plays a critical role in consumer choice.

The pain of paying may explain a variety of market phenomena. For example, people may spend more with credit than they would with cash (on hedonic goods, at least; Prelec and Simester, 2001; Soman, 2003) partly because swiping a credit card is simply less painful than forking over money. The pain of paying may also differ across individuals; indeed, such individual differences may explain why "tightwads" find it so difficult to indulge themselves (excessive pain of paying) and why "spendthrifts" find it so difficult to control their spending (insufficient pain of paying). Motivated by the findings of this study, Rick, Cryder, and Loewenstein (in press) developed a "Tightwad-Spendthrift" scale to assess individual differences in the pain of paying. Contrary to the media's persistent attention toward over-spending and credit card debt, Rick, Cryder, and Loewenstein (in press) found that tightwads outnumber spendthrifts by a 3:2 ratio in a sample of over 13,000 people. If prices deter spending through a pain of paying, understanding how and why that pain varies across situations and individuals is a crucial task for future research.

SYMPOSIA SUMMARY
# On the Metacognition of Emotions: What I Think about How I Feel
Aparna A. Labroo, University of Chicago, USA
Anirban Mukhopadhyay, University of Michigan, USA

## SESSION OVERVIEW

*Session Objective*: It is a central tenet in social psychology and consumer research that emotions are used as inputs in judgments and decisions. However, twenty years after the How Do I Feel (HDIF) heuristic was introduced, there is a growing realization that a variety of metacognitive factors might determine the exact manner in which such affective influences operate. The purpose of this special session is to present current research that investigates such factors, and to provide an integrative platform for a discussion of fruitful research directions.

*Overview*: Much research has demonstrated that people use feelings as inputs into their judgments and decisions. Indeed, the great interest in this field has served to establish several robust findings (cf. Schwarz and Clore 1988; 2007). However, one question that remains only partially addressed pertains to the universality of the HDIF heuristic—do individuals always use their feelings as inputs to their judgments, and in the same manner each time? The four papers in this session attempt to answer this question by demonstrating that metacognitive considerations such as perceptions of trust, confidence, and implicit theories may moderate both when and how feelings are used as inputs to judgment and decision-making.

*Papers*: As mentioned, the four papers in this session all propose that the manner in which feelings are used as inputs depends on a set of higher-order, metacognitive considerations. Essentially, factors determining the applicability and nature of felt emotions should guide the manner in which these emotions influence judgments. In the first paper, Avnet and Pham suggest that trust in ones feelings impacts the degree to which people rely upon their feelings in judgments. Their results indicate that the influence of affect on judgment depends on the momentary trust that people have in their feelings, and this trust moderates the influence of affect only when cognitive resources are available. In the second paper, Briñol, Rucker, and Petty examine how metacognitive confidence can both affect emotions and be influenced by emotions. Across two sets of findings they show first that emotions are affected by the confidence present at the time of an emotion inducing event, and then that emotions can influence persuasion by affecting confidence in one's thoughts. In the third paper, Labroo and Mukhopadhyay demonstrate that people have implicit theories about the transience of emotions which determine whether they make choices that reflect mood-improvement or self-regulation. People who believe emotions are transient engage in self-regulation when unhappy but in mood-improvement by opting for hedonic options when happy. In contrast, people who believe emotions are stable choose self-regulation when happy but mood-improvement when unhappy. Finally, Schwarz, Xu, Song, and Cho present an integrative overview of two decades of feelings-as-information research, specifically, the roles of metacognitive experiences and naïve theories as sources of information.

*Contribution*: These papers have several important findings that shed light on the question of how and when effect is incorporated into judgments and decisions. Avnet and Pham demonstrate that emotions are used in judgments if people feel they are appropriate, and can be trusted. In related work, Briñol et al. demonstrate that similar metacognitive assessments can shape confidence in the feelings themselves. Labroo and Mukhopadhyay then show that the

manner in which emotions are applied depends on the lay theories that people have about their transience. Finally, Schwarz et al. present an integrative overview not just of these three papers, but the area as a whole. Taken together, these papers constitute a significant step in the study of the metacognitions of emotion. All papers include multiple completed studies that have not been presented at ACR before. The session is structured such that Norbert Schwarz, a pioneer in this field, will present an integrative overview model that incorporates aspects of the other three papers, thereby going well beyond the traditional role of discussant.

## EXTENDED ABSTRACTS

### "Metacognitive and Nonmetacognitive Influence of Affect In Judgment"
*Tamar Avnet, Yeshiva University*
*Michel Tuan Pham, Columbia University*

A growing body of evidence suggests that the effects of beliefs and thoughts on judgment depend not only on the evaluative content of these beliefs and thoughts, but also on various metacognitive considerations about these beliefs and thoughts (e.g., Petty, Brinol, and Tormala 2002). We hypothesize that people invoke similar metacognitive considerations with respect to their feelings. In particular, the reliance on feelings may be regulated by a metacognitive assessment of whether one's feelings *should* be used in a given judgment rather than by a sole concern for judgmental efficiency. Our main hypothesis is that the reliance on feelings in judgment depends on the momentary trust that people have in their feelings at the time of judgment—a trust that arises from a metacognitive assessment based on multiple considerations. We suggest that the first stage of metacognitive processing requires a cognitive awareness of feelings. Without this awareness the assessment of trust cannot be performed. Therefore, the metacognitive assessment of feelings should depend on the availability of processing resources. If sufficient resources are available, feelings will tend to influence the decision in a reflective manner. If resources are unavailable, feelings will tend to influence the decision more mindlessly, without much appreciation for the trustworthiness of the feelings.

The purpose of this research is to provide a better understanding of when and why people rely on their feelings in judgment. Results from four studies suggest that an increased reliance on feelings seems to reflect a fairly strategic process whereby people perform a metacognitive assessment asking if they *should* use their feelings and draw conclusions from the level of trust they experience in their feelings. Results also confirm that processing resources are required to perform this metacognitive assessment.

In all four studies trust was manipulated using a procedure adapted from Schwarz and colleagues (1991). The rationale behind this procedure is that when people are asked to generate information, they monitor not only the content of the information they generate but also the ease with which this information is generated. People draw inferences that are consistent with the implications of accessible content when generation of content is experienced as easy. However people draw inferences that are contrary to the implications of accessible content when generation of content is experienced as difficult. In our studies respondents were asked to

describe either 2 (high trust condition) or 10 (low trust condition) situations in which they trusted their feelings to make a judgment. It was expected that the ease respondents felt when identifying 2 versus 10 such situations would affect their momentary trust in their feelings. This manipulation was validated in a pretest.

The purpose of study 1 was to show that people reflect on the use of their feelings in judgment and that the level of trust in feelings would affect the reliance on feelings in the evaluation process. After being primed for either high or low trust in feelings, respondents were asked to express their attitude toward the issue of reading based on a British TV commercial praising the virtues of books. To manipulate respondents' subjective affect toward the issue (holding the TV commercial constant), we varied the pleasantness of the musical soundtrack of the commercial. Consistent with our theory, we found that the pleasantness of the commercial's soundtrack had more influence on attitudes when respondents experienced high trust in their feelings than when they experienced low trust in their feelings.

The purpose of study 2 was to test the reliability and generality of study 1's findings, using an incidental mood manipulation of feelings toward the target. After manipulating trust as in study 1, respondents' mood state was manipulated. Respondents were then asked to evaluate a book based on a synopsis. Results showed that respondents who were primed to trust their feelings were more influenced by their mood states in their evaluations than respondents who were primed not to trust their feelings. This result suggests that the metacognitive assessment of feelings applies to feelings in general, including to incidental feelings arising from a mood state.

The purpose of study 3 was to test the proposition that (a) assessing the diagnosticity of feelings from a metacognitive standpoint requires a significant amount of processing resources, and (b) if sufficient resources are unavailable, people rely on their feelings without much consideration to the diagnosticity of the feelings. Using study 1's manipulation of integral feelings, the influence of these feelings was compared across 3 conditions representing different combinations of respondents' momentary trust in their feelings and the availability of processing resources (controlled through a cognitive load manipulation). Results confirmed that under high resource availability, respondents replicated the results of study 1. However, under low trust with limited resource availability, respondents behaved differently. These respondents relied on their feelings without much consideration to these feelings' diagnosticity, and therefore were influenced by the commercial's soundtrack despite being primed not to trust their feelings.

The purpose of study 4 was to test the robustness and generality of the results of study 3 using an incidental mood manipulation of respondents' feelings toward the target. As in study 3, the effects of the manipulation of affect were compared across three conditions. Replicating the results of study 2, respondents' evaluations were more influenced by their mood when they were primed to trust their feelings than when they were primed not to trust their feelings. In contrast, under conditions of limited resource availability, evaluations were influenced by mood even though they were primed not to trust their feelings, replicating the results of Study 3.

Based on our results, it is proposed that the reliance on feelings in judgment often involves a metacognitive assessment of whether one's feelings should be used in judgment. It is conjectured that the reliance on feelings in judgment operates in two different ways: a reflective way that involves a metacognitive assessment of the diagnosticity of the feelings when resources are available, and a non-reflective way that is insensitive to the diagnosticity of the feelings when resources are unavailable.

## "Metacognition and Emotion: The Dynamics of Emotions and Confidence"

*Pablo Brinol, Universidad Autonoma de Madrid*
*Derek Rucker, Northwestern University*
*Richard Petty, Ohio State University*

A significant amount of research confirms emotions play a critical role in consumers' response to persuasive efforts (Petty et al. 2001) and behavior more generally (Pham 2007). In this talk, we examine the role of emotions in consumer behavior from a metacognitive perspective. The idea of meta-cognition relies on the distinction between two types of cognitions: primary and secondary. Primary thoughts are those that occur at a direct level of cognition such as "I feel very happy today." Following a primary thought, people can also generate "secondary cognitions" or thoughts which involve reflections on the first level thoughts (e.g., "I am not very certain about how well I am feeling today"). Thus, *metacognition* can be thought of as second order thoughts, or thoughts about one's primary thoughts.

Perhaps one of the most important meta-cognitive judgment consumers' can make is with respect to the confidence one has in one's beliefs (Alba and Hutchinson 1989; Gross, Holtz, and Miller 1995). We present two research findings converging on the importance of meta-cognition in relation to confidence. Specifically, we focus on how emotions can be affected by confidence at the meta-cognitive level and how emotions can affect confidence at the meta-cognitive level. Taken together, we offer a novel theoretical framework based on meta-cognition to understand the role of emotions in consumer behavior.

*Confidence Can Shape Emotions*. Extensive research has shown that when people think about personal experiences of emotion they report feeling in line with those past episodes. That is, our emotions are affected by the thoughts we generate. In our first set of findings, we examined whether confidence can moderate the influence of those thoughts in affect. We predicted that the confidence associated with one's emotional thoughts would influence the experience of emotion. To examine this, participants were asked to write about recent situations in which they felt happy or sad. After describing their emotional episodes, and as part of an apparently unrelated study, we manipulated confidence by asking participants to think about situations in which they had felt confidence or doubt in their thinking (see Briñol, Petty, and Tormala 2004).

Those who generated instances of confidence became more confidence of the validity of their previously induced emotional thoughts than those who generated instances of doubt. Thus, participants who wrote about past events of happiness reported feeling happier when they were induced to have confidence in those emotional thoughts (confidence condition) than when they were induced to doubt those emotional thoughts (doubt condition). Conversely, participants who wrote about past events of sadness reported feeling sadder when they were induced to have confidence versus doubt in their emotional thoughts. Viewed differently, this interaction between the mood and confidence inductions revealed that the direction of the primary emotional thoughts only influenced the affective state reported by confident participants. In a second experiment, we replicated these findings using a different manipulation of confidence based on an ease of retrieval paradigm (e.g., Tormala, Petty, and Briñol 2002). In this experiment we expected and found that the confidence induced by ease (vs. difficulty) affects not only the reported experience of emotion but the reliance on one's emotion in actual judgments.

*Emotions Can Affect Thought Confidence*. In the second set of findings, we examined whether the relationship between emotion and confidence could be reversed, such that emotions could influ-

ence confidence in one's cognitions. This signifies a situation where primary cognitions are influenced by emotional secondary thoughts. Indeed, according to appraisal theories, one of the critical dimensions along which emotional experience varies is the certainty-uncertainty dimension (Smith and Ellsworth 1985). For example, happiness is often accompanied with greater confidence than sadness (Clore, Gasper, and Garvin 2001; Tiedens and Linton 2001). If mood can influence confidence, people in a happy mood should be more reliant on their thoughts than people in a sad mood. As a consequence, mood might increase or decrease persuasion depending on the direction of the thoughts generated in response to the advertisement. That is, attitudes should reflect the valence of thoughts to a greater extent when participants are placed in a happy mood following the ad as opposed to a sad mood because happy mood would increase reliance on the generated thoughts.

We tested this logic in a series of experiments. In the first experiment, participants received an ad composed of strong or weak arguments. This manipulation was intended to influence the direction of the thoughts generated with more favorable thoughts toward the message after the strong rather than the weak message (Petty and Cacioppo 1986). Then, as part of an ostensibly unrelated study, participants' mood was manipulated by asking them to write down personal experiences in which they felt happy or sad. Following the mood induction, participants reported their attitudes toward the proposal of the ad. Consistent with predictions, we predicted and found that mood interacted with argument quality to influence persuasion. Participants exposed to a strong ad (thus generating predominately favorable thoughts) showed greater attitude change with positive mood than negative mood. However, participants who were exposed to the weak version of the ad (thus generating mostly unfavorable thoughts) showed greater persuasion with negative than positive mood. Viewed differently, this also indicates that the effect of argument quality on attitudes was greater with positive than negative mood. Of importance, a second experiment in which participants reported the confidence they had in their thoughts revealed that differences in confidence mediated our observed effects. Furthermore, thought confidence induced by mood influenced attitudes only under high elaboration conditions.

*Contributions and Conclusions.* Taken together, the present findings significantly advance our understanding of the role of emotions in consumer behavior. In particular, while past research has examined emotion at the primary level of cognition, the present research demonstrates important advantages from taking a meta-cognitive perspective in examining emotions. Specifically, not only are consumers' emotions affected by metacognitive confidence, but emotions can also affect metacognitive confidence. This provides a number of interesting insights for future research.

### "The Effect of Mood and Lay Theories of Emotion on Self Regulation"

*Aparna Labroo, University of Chicago*
*Anirban Mukhopadhyay, University of Michigan*

Over their lifetimes, most people want to improve their lives, be healthy, succeed professionally in the future, and grow to become better, kinder, and nobler individuals, for example by being more charitable. In the moment, most people also want to improve their mood, eat foods that are tasty and not necessarily healthy, relax rather than agonize about their everyday professional endeavors, and avoid exposing themselves to negative information about the unfortunate circumstances of others who need help. This choice, of whether to pursue self regulation or to pursue mood regulation, poses a dilemma for most individuals: should one accept short-term pain and exert self-control to accomplish self improvement or should one pursue mood improvement? What determines the choice

that people finally make, and what role does a person's current mood play in this decision?

Previous research on mood poses an apparent contradiction in addressing the effects of mood on self-control. On the one hand, some researchers have suggested that mood is a signal of the extent of goal progress (Carver and Scheier 1998; Hsee and Abelson 1991). Thus, a positive mood signals that adequate goal progress has been made and efforts can now be conserved, a negative mood signals that more effort is required. In self-improvement tasks, unhappy participants therefore outperform happy participants. In contrast, other researchers have attested that positive (vs. a negative) mood is a resource that facilitates self regulation (Raghunathan and Trope 2002). More recently, Fishbach and Labroo (2007) demonstrated that a positive mood lowers the threshold for adopting any goal that is accessible, and that happy participants do more of self regulation or mood regulation based on whatever goal is accessible, but question remains regarding what determines goal importance and which goal will be seen as more important? In the current research, we propose that people have lay theories about emotion transience and whether they choose a goal of self improvement or of mood improvement depends on the lay theory of emotion transience and the current mood.

We draw on research on implicit theories which suggests that people have naïve beliefs about the nature of intelligence and self-control—that they are malleable (changeable) or fixed (unchangeable; cf. Dweck 1999; Mukhopadhyay and Johar 2005). These lay theories have been shown to differentially influence goal-directed behavior. We propose that people similarly have beliefs about emotion, that emotion is relatively malleable (changing) or fixed (unchanging), which influence their self-control efforts and the kinds of goals (self improvement or mood improvement) they choose to follow. In particular, we propose that people who implicitly believe that emotion is malleable (transient) choose mood management (over self improvement) when they are feeling a positive (vs. a negative) mood. That is, because malleable theorists believe that emotions will pass, they believe that effort is required to improve ones mood feeling positive (otherwise it will pass) and effort is not required to improve ones mood feeling negative (it will pass). In contrast, people who implicitly believe that emotion is fixed choose mood management (over self improvement) when they are in a negative (vs. positive) mood. This is because if emotion is fixed (stable), effort must be invested into mood improvement when one is in a negative mood (it will not pass on its own), and effort need not be invested into mood management when one is feeling good (it will not pass on its own). For example, consumers who are malleable theorists should choose healthy foods when feeling unhappy but tasty foods when feeling happy, because the currently experienced emotion will pass by on its own. In contrast, consumers who are fixed theorists should choose healthy foods when feeling happy but tasty foods when feeling unhappy, because the current emotion will not pass by itself.

Five experiments provide support to these arguments. In experiment 1, we primed lay theories of emotion by appropriately adapting passages used by Dweck and her colleagues to prime lay theories of intelligence, and induced mood by having participants write about a happy or unhappy life event. In a second, unrelated task, participants read an ad appeal for Save the Children and stated an amount of donation to the charity. As predicted participants primed with malleable emotion theory self-regulated and donated more when they were feeling unhappy (vs. happy). In contrast, participants primed with fixed emotion theory self-regulated and donated more when they were feeling happy (vs. unhappy). Experiment 2 conceptually replicated this effect. We induced mood by exposing respondents (all dieters) to line drawings of smiling

versus frowning faces and then primed emotion theory by asking respondents to color the face with a thick tip sharpie or a thin micro-tip pen. We expected that participants coloring the drawing with a thick (vs. thin) tip pen would misattribute the transience of the task to transience of the emotion. That is, participants coloring a smiling (frowning) face with a thick-tip pen would feel that happiness (unhappiness) is transient. Participants coloring a smiling (frowning) face with a thin-tip pen would feel that happiness (unhappiness) is lasting. All respondents subsequently chose between a healthy apple and a high calorie chocolate bar. As expected, participants who used the thick-tip pen chose chocolate more often when they colored a smiley vs. frowney face. In contrast, participants who used the thin-tip pen chose chocolate more often when they colored a frowney vs. smiley face.

Experiment 3 replicated the effect observed in experiments 1 and 2, but with measured lay theories. Respondents who tended to agree with items stating that emotions are transient exerted more self-control (choosing an apple over chocolate, donating more to charity) when feeling unhappy (vs. happy). Fixed theorists exerted more self-control (choosing an apple over chocolate, donating more to charity) when feeling happy (vs. unhappy). Interestingly, when their beliefs were made salient through a misattribution manipulation, respondents corrected for their choices and the differences were no longer observed. Experiment 4 further tested whether the lay theories are about emotions in particular or about transience/stability in the world in general and found evidence in support of the former. Experiment 5 demonstrated that lay theories are about emotion transience in an alternative way. Taken together, these thus studies provide clear evidence that people have lay theories about emotion transience, and the accessibility of those theories along with the current emotion that consumers are feeling interactively determine their choices of whether they choose to manage their mood or to exert self-control efforts.

### "From Feelings to Judgments: Constructing Heuristics on the Spot"

*Norbert Schwarz, University of Michigan*
*Jing Xu, Peking University*
*Hyunjin Song, University of Michigan*
*Hyejeung Cho, University of Texas, San Antonio*

Two decades of feelings-as-information research have shown that people draw on their feelings (moods, emotions, bodily sensations, and metacognitive experiences like fluency of perception and ease of recall) as sources of information (for a recent review see Schwarz and Clore 2007). This is not the case when the feeling is attributed to an unrelated source (e.g., Schwarz and Clore, 1983; Schwarz et al., 1991), thus undermining its informational value. Moreover, the weight given to feelings depends on their perceived relevance to the task at hand; for example, feelings receive more weight in hedonic than utilitarian judgments or when choosing for the self rather than another (see Pham 2004). In addition, people don't rely on their feelings when they think they can't trust them (e.g., Avnet and Pham, this session). All of these assessments of the informational value of feelings involve the application of naïve theories of affective processes, which bear on the relevance of the feeling to the task at hand. However, the importance of naïve theories goes beyond these assessments and naïve theories are central to a very basic but largely ignored question: Which information does a given feeling convey?

A growing body of findings indicates that the same feeling can result in different, and sometimes opposite, conclusions. We trace this malleability to the role of naïve theories that link the feeling to the target of judgment. Specifically, we assume that people hold multiple naïve theories about feelings (as illustrated below). Which of these theories is recruited depends on the judgment task and other contextual influences. Application of a given theory entails an explanation of the feeling in terms of a specific cause; this renders the feeling nondiagnostic for inferences that require a different theory, entailing a different cause.

As an example, consider naïve theories about the metacognitive experience of ease of recall. People assume, for example, that it is easier to recall examples when (i) there are many in the world or (ii) when they have high expertise in a domain. To manipulate experienced ease of recall, participants in one of our studies listed few (easy) vs. many (difficult) fine restaurants. When first asked how many fine restaurants there are, they inferred a higher frequency from ease, replicating the usual finding predicted by Tversky and Kahneman's availability heuristic; but when first asked about their expertise, they inferred high expertise from ease of recall. Note, however, that this initial inference of expertise entails an attribution of ease to expertise, which renders the experience uninformative for a subsequent frequency judgment–after all, experts should be able to recall examples even if there aren't that many in the world. Participants now turned to the content of recall and inferred a higher frequency after listing many rather than few examples, resulting in higher frequency estimates under conditions of difficult recall. This observation reverses the classic availability pattern. Conversely, an initial inference of high frequency entails an attribution that renders the experience uninformative for later judgments of expertise–after all, if there are many restaurants, even non-experts can recall a few. As a result, participants now inferred higher expertise after listing many rather than few examples, again reversing the pattern.

Other experiments extend this conceptual logic from metacognitive experiences to the inferences drawn from moods and bodily sensations. Throughout, the findings highlight (i) that inferences from feelings are guided by naïve theories about the processes that give rise to feelings; (ii) that applicable theories are recruited by the judgment task; and (iii) that application of a given theory entails an attribution of the feeling that changes its informational value for tasks that require the application of alternative naïve theories.

# Indulgence and Guilt: Evaluating the Boundaries of Consumers' Guilt-Management Strategies

Patti Williams, University of Pennsylvania, USA

## SESSION OVERVIEW

A large body of research has examined the conflicts consumers face in making choices between hedonic and utilitarian options. "Hedonic" and "utilitarian" refer to two dimensions of the consumption experience distinguished by the level of affect and emotion evoked by, and the motivation to engage in, the consumption. Hedonic consumption, which is experiential in nature refers to "multi-sensory, fantasy and emotive aspects of one's experience with products" (Hirschman and Holbrook 1982) while utilitarian consumption is instrumental and functional in nature (Dhar and Wertenbroch 2000; Strahilevitz and Myers 1998). A number of choice conflicts have been examined under the broad "hedonic-utilitarian" choice umbrella (Khan, Dhar, and Wertenbroch 2005), such as choices between hedonic and utilitarian options (Dhar and Wertenbroch 2000), luxuries and necessities (Kivetz and Simonson 2002a,b), frivolous and practical consumption (Strahilevitz 1999; Strahilevitz and Myers 1998), vices and virtues (Read, Loewenstein, and Kalyanaraman 1999; Wertenbroch 1998) "shoulds" and 'wants" (Bazerman, Tenbrunsel, and Wade-Benzoni 1998), affective and cognitive preferences (Shiv and Fedorikhin 1999) and "affect-rich" and "affect-poor" (Hsee and Rottenstreich 2004) consumption.

Most of this stream of research implicitly assumes that "hedonic" and "utilitarian" are end-points on a bipolar continuum. Further, much of the research has focused on the inhibitory role of guilt in restricting indulgence. Hedonic options are pleasurable and guilt-laden, utilitarian options are less pleasurable and result in no guilt. Justifications, such as higher effort (Kivetz and Simonson 2002a), type of resources (O'Curry and Strahilevitz 2001) or virtuous behavior in another domain (Khan and Dhar 2007) free consumers to choose the hedonic option; in the absence of such justifications, consumers are more likely to choose the less pleasurable but also less guilt-laden utilitarian option.

Despite considerable progress in this area, it remains a fertile area for research. This session seeks to address a number of questions. Is the typical depiction of options as either hedonic or utilitarian representative of the complex choices that consumers make? We believe not, given the recent introduction of mixed products (heart-healthy chocolate, vitamin-enriched sodas) that attempt to combine pleasure with lack of guilt. Second, do consumers respond to all kinds of justification or only selectively? Finally, do consumers always seek guilt-management strategies? Is guilt always avoided? In this session, we attempt to discuss these questions about indulgence and guilt-management by considering complex products and situations.

This session comprises three papers. The first two papers examine how consumers perceive complex hedonic-utilitarian mixtures either in product form (mixed indulgence) or as a product bundle. The two papers together highlight the boundary conditions of guilt-management strategies. The third paper complements the first two papers by discussing the motivating role of guilt which may lead some farsighted consumers to seek, rather than avoid, guilt. Together these three papers shed light on consumers perceptions of complex products while highlighting conditions under which traditional guilt-management strategies may not work.

Saldanha and Williams examine consumers' perceptions of "mixed indulgences"–hedonic products with added utilitarian attributes. Across several experiments the authors find that the hedonic dimension comprises not just one factor (as previous research has shown) but two factors–a "pleasure" factor and a 'sin' factor. In this three-dimensional space, mixed indulgences are perceived to be less sinful and more utilitarian, but not less pleasurable, than the corresponding pure indulgence. Despite these positive perceptions, mixed indulgences are less likely to be chosen than the corresponding pure indulgence. The results of their studies suggest that mixed indulgences as guilt-management studies may not always resonate with consumers.

Khan and Dhar discuss consumers' perceptions of product bundles containing a hedonic and an utilitarian product. The authors show that consumers are more likely to purchase the bundle if a price discount is offered on the hedonic item than if the same price discount is offered on the utilitarian item in the bundle or on the entire bundle. This finding suggests that consumers do not aggregate the pleasure and guilt in a hedonic-utilitarian bundle but treat each part of the bundle separately.

Finally, Dai, Wertenbroch, and Brendl demonstrate that far-sighted consumers may actually seek guilt as a motivating device to solve self-control problems that are essential for the success of future task completion. This guilt seeking for the purpose of building up motivation thus systematically affects consumer preference and choices.

This session should benefit the growing body of researchers working in the area of hedonic consumption and self-control. We also expect it to benefit research on consumption emotions as guilt has not been extensively examined in the domain of consumption emotions. Finally, we expect that the mixed nature of the products discussed will benefit those who work in the area of mixed affective and emotional experiences. The discussion leader, Baba Shiv, will synthesize the three papers and address their distinct contributions in the light of additional work in psychology, consumer behavior and now neuroeconomics that addresses affective-cognitive distinctions.

## EXTENDED ABSTRACTS

### "Mixed Indulgences: When Removing Sin May Backfire"

*Neela Saldanha, University of Pennsylvania*
*Patti Williams, University of Pennsylvania*

Research on the hedonic-utilitarian choice conflict has typically presented consumers with choices between "hedonic" or "utilitarian" options, a binary choice which implicitly assumes that hedonic-utilitarian perceptions lie along a single bipolar continuum. Although researchers have theoretically demonstrated that the hedonic-utilitarian space is bivariate (LeClerc, Schmitt, and Dubé 1994; Voss, Spangenberg, and Grohmann 2003), little prior research has examined consumer reactions to choices that might be both hedonic and utilitarian. At the same time, a number of new products are being launched in exactly this mixed space –baked crisps, heart-healthy chocolates by Mars Inc. (Barrionuevo 2005) and recently, the announcement of vitamin-enriched sodas by Pepsi & Coke (Martin 2007). In this research, we examine consumers' hedonic and utilitarian perceptions and their evaluation and choice of such mixed products. We examine a specific kind of mixed product: a hedonic option with added utilitarian attributes, which we term a "hedonic-plus" mixed indulgence. Examples of this kind of mixed indulgence in our studies are heart-healthy chocolate cake with flavonols, protein enriched potato chips, calcium-enriched cheese curls.

Across several studies, we find that, contrary to previous research, the hedonic-utilitarian space is not a continuum or even a bivariate space, but rather, a three-dimensional space. Specifically, while the "utilitarian" construct is consistent with past research, the hedonic construct is not, as previous research suggests, a uni-dimensional construct. Instead it comprises two factors: a "pleasure" factor and a "sin" factor, thus suggesting that consumers perceive simultaneous and separate "good" and "bad" sides of indulgence. Further, our research suggests that adding utilitarian attributes to an indulgence may change perceptions along one dimension (sin) without affecting perceptions along the other dimension (pleasure) and this may have implications for evaluation and choice of such mixed products.

In Study 1, we presented subjects with a variety of pure (mixed) indulgences and asked them to rate the products on hedonic/utilitarian perceptions and evaluate the products. A factor analysis on hedonic-utilitarian perceptions suggests a three-factor structure that explains 89% of the variance. On the utilitarian dimension a single consistent factor emerges. On the hedonic dimension, however, we find evidence for two factors, reflecting the conflicting nature of indulgence. The first factor we term as "pleasure" comprises high factor loadings on items such as "pleasurable", "enjoyable", "delightful," "fun." The second hedonic factor comprises high loadings on the terms "sinful", "a vice", "harmful", "frivolous". We term this second factor the "sin' factor.

This three-dimensional model allows for specific changes along the dimensions: mixed indulgences are perceived as more utilitarian than pure indulgences. They are also perceived to be less sinful although they are not perceived to be significantly less pleasurable than pure indulgences. At the same time, mixed indulgences are not evaluated more positively than pure indulgences.

In Study 2, we examined choice for the mixed versus pure indulgence. In this study subjects were exposed to one of two choice sets from which they had to choose one item as a dessert. In the control (experimental) condition subjects were exposed to a choice set containing three items: a pure indulgence i.e. ice-cream, a pure utilitarian product i.e. fruit salad and the indulgence under study i.e. chocolate cake (heart-healthy chocolate cake). We find that despite evaluations suggesting that mixed indulgences might be a superior option (equally pleasurable, more utilitarian and less sinful than pure indulgences) mixed indulgences actually fare worse than pure indulgences on choice: the choice share of the mixed indulgence falls significantly from the pure indulgence condition to the mixed indulgence condition (65% vs. 43%), ($p<.05$).

In Study 3, we show that intentions to choose a mixed indulgence are moderated by temporal construal (Fujita et al. 2006) that changes the relative salience of pleasure and sin factor. A distant time horizon increases preference for the mixed indulgence, a prediction consistent with construal-level theory. Abstract construals of mixed indulgence which incorporate the lower sin and higher utility relative to the pure indulgence are more attractive than concrete construals which focus on the pleasure obtained in indulgence. However, near time horizons highlight the pleasure factor in indulgences and lead to preferences for pure indulgences over mixed ones.

In addition to these studies, we will also discuss the difference that process makes to final evaluations of mixed indulgences. Drawing on the negativity dominance and contagion literature (Baumeister et al. 2001; Rozin and Royzman 2001), we propose that adding utilitarian attributes to hedonic products results in a mixed indulgence that is negatively evaluated, while adding hedonic attributes to utilitarian products leads to a mixed indulgence that is positively evaluated relative to the base product.

Our research makes contributions to both theory and practice by exploring a new space in the hedonic-utilitarian domain to uncover two dimensions of indulgence. Further, the separability of

the "good" and "bad" face of indulgence has implications for when mixed indulgences, with their promise to remove sin, might succeed with consumers and when they might backfire.

## "Differential Effectiveness of Discounts in Product Bundles"

*Uzma Khan, Carnegie Mellon University*
*Ravi Dhar, Yale University*

Marketers often encourage purchase aggregation through contingent discounts to stimulate demand (Guiltinan 1987). The current research examines whether a contingent discount on certain items in the bundle is more effective than an equivalent discount on the bundle as a whole when the shopping basket contains both hedonic and utilitarian components. Several studies suggest that the purchase of hedonic goods is often associated with disutility beyond its monetary costs, e.g., higher pain of paying (Prelec and Loewenstein 1998), guilt from indulgence, and difficulty of justification (Okada 2005; Dhar and Wertenbroch 2000). Because of these differences in hedonic and utilitarian products, we propose that a bundle purchase is more likely when a discount is offered on the hedonic item rather than on the utilitarian item or the bundle. We explain that a discount provides a justification that can increase the likelihood of hedonic purchases while such justifications have little impact on utilitarian consumption as it faces lower disutility. Our proposition is hard to reconcile with the economic notion of fungibility, which would argue that $10 saved should feel like $10 regardless of the item on which this saving is incurred. However, the reasoning is intuitive if saving money on a hedonic item is psychologically more rewarding than saving the same amount on a utilitarian item. Five studies demonstrate our proposed effect.

Study 1 used a reading lamp as a utilitarian and a soundcard as a hedonic item in a bundle offer. Participants saw a hypothetical scenario in three conditions that offered a discount on different components of the bundle. Participants imagined that they were shopping for a lamp when they come across this special offer -Buy a $50 soundcard (for intense gaming) with any $50 lamp and get $10 off the soundcard (lamp, total purchase). Thus, the total cost of the items was kept constant across the three conditions while the discount was placed on the lamp, the soundcard or the bundle. Participant then indicated the likelihood of buying the bundle on a 9-point scale. The data show that purchase likelihood of the bundle was significantly higher (M=6.3) when the discount was on the soundcard than on the lamp (M=4.1, t(45)=4.33, p<0.05) or on the bundle (M=4.96, t(46)=2.55, p<0.05). Moreover, when the discount was on the bundle the purchase likelihood of the bundle was higher than when the discount was on the lamp (t(45)=1.85, p=0.07). The results are consistent with the idea that a discount is more effective on a hedonic item as it provides an added justification for the purchase. Although, people can reallocate savings as they want, the results suggest that the discount earned remains associated with the item on which it is offered.

An alternative account for these results could be that a discount is most effective when placed on the item which is not part of the shopping plan in the instructions. Study 2 ruled out this possibility by focusing on bundle purchase in two conditions that used a blender as an unintended purchase option. Specifically, participants imagined that they were at a mall to purchase the lamp when they find the deal bundling the lamp with a blender. The blender was either framed as hedonic (for making cocktails) or utilitarian (for making healthy shakes). Other instructions and measures were same as in Study 1. If placing a discount on the unintended item is driving the results then framing the blender as hedonic or utilitarian should not affect the purchase likelihood of the bundle. However, if hedonic or utilitarian nature of the purchase is responsible for our results then the effect observed in Study 1 should attenuate when the blender is framed as utilitarian. The main result was replicated. In the hedonic framing, the purchase likelihood of the bundle was significantly higher when the discount was on the blender (M=6.6) than when the discount was on the lamp (M=5.25; t(68)=3.02, p<0.05). Moreover, there was no significant difference in the purchase likelihood of the bundle in different conditions (t(68)=1.01, p=*ns*) when the blender was framed as utilitarian.

Study 3 tests whether the difficulty of justification moderates the effect. Past research shows that buying something as a gift does not have the usual guilt and difficulty of justification that is associated with hedonic purchases (Thaler 1985). We predict that the effect observed in Study 1 would diminish when the blender is purchased for a gift. Participants imagined that they were buying a lamp for themselves when they come across a deal bundling the lamp and a blender for making exotic cocktails. In one condition participants were told that the blender will make a great gift for their roommate while in the other they were suggested that the blender would be an exciting addition to their kitchen. Results show that placing the discount on the blender significantly increased the purchase likelihood of the bundle when the blender was for personal use (t(65)=2.36, p<0.05) but not when it was for a gift (t(68)=0.44, p=*ns*). In other words, a discount on the blender increased the purchase likelihood of the bundle when it provided an added justification and not when the justification was inherent in the purchase.

Finally, Study 4 shows that the guilt anticipated in a hedonic purchase mediates the proposed effect of discount framing, and Study 5 demonstrates the effect with real choices. An interesting implication of these studies is that people process the discounts as they are offered and do not aggregate across different items. This is consistent with mental accounting research showing that money is not treated interchangeably. Furthermore, our findings suggest that people may not be motivated to interpret a discount in a manner that makes it easier to purchase the hedonic item.

### "Strategic Motivation Maintenance: The Case of Guilt-Seeking"

*Xianchi Dai, INSEAD, France*
*Klaus Wertenbroch, INSEAD, France*
*Miguel Brendl, INSEAD and Northwestern University*

Imagine that a consumer, who is very interested in history, is planning to visit three historical sites accessible by foot only. He decides to buy a pair of hiking boots for that purpose. Consider the following two situations: in one he has to visit all three sites (due to external constraints) to be able to return to the hotel in which he stays. In the other situation he can quit at any point of the hiking trip and return to the hotel easily. In which situation would he be more likely to buy expensive hiking boots (rather than cheap ones) if he wants to visit all three sites? We predict and show that consumers are more likely to buy expensive boots in the latter situation, in which they are faced with a variable-effort self-control task (rather than a fixed-effort task as described in the former situation). We propose that consumers are more likely to choose expensive boots in the latter situation because they want to motivate themselves to finish the task. Buying more expensive boots can make themselves feel guilty, which, in turn, leads to higher motivation to finish the future task (hiking to all three sites). That is to say, consumers strategically choose a guilt-laden option (vice rather than virtue option) to build up their motivation for the future task.

More generally, we propose that people have a lay theory of the positive relation between experienced guilt and motivational intensity. Based on such a lay theory, far sighted consumers strategically choose guilt-inducing vice options to enhance their motivation to engage in a subsequent self-control task when they feel they need strong motivation, and/or when they feel they don't have enough motivation for the tasks. This form of self-induced motivational commitment, or motivation maintenance, is related to self-control by precommitment (e.g., Hoch and Loewenstein, 1991; Scitovsky 1992; Wertenbroch and Carmon 1997, Wertenbroch, 1998), according to which consumers self-impose constraints on their future ability to give in to temptation.

Our empirical tests of this proposition include two parts. In the first part, we test consumers' lay theory about the relation between experienced guilt and motivational intensity. In the second part, we examine whether the motivational concern about a future self-control task predicts consumers' preferences for vice and virtue options.

In study 1, students primed with guilt predicted that they would be more motivated, study longer hours, and devote a higher percentage of time to studying in the upcoming semester. In study 2, we manipulated the importance of the future task and asked participants to predict their motivational level after engaging in two different activities: resting at home or going to a party. The results showed that for an unimportant future self-control task (studying for an unimportant exam), resting led to greater predicted motivation and effort input, whereas for an important future task (studying for an important exam), going to the party led to greater predicted motivation and effort input. These studies imply that consumers have a lay theory about the relation between guilt and motivation. Furthermore, consumers put more weight on their mental energy (motivation) versus psychical energy when the future task is important than when it is unimportant.

In the second part, we tested whether consumers would make choices based on strategic motivation maintenance and thus prefer guilt-laden options. Consistent with our prediction, we found the following: (1) Participants who had failed in a preceding self-control task were more likely than those who had succeeded to go to a bar rather than stay at home the evening before they wanted to quit smoking, presumably to build up their motivation for the upcoming self-control task (study 3). (2) Participants who faced a future self-control task, in which they could freely choose their effort level (from one to three days of volunteer work), were more likely than participants who faced a task with fixed effort levels (three days of volunteer work) to attend a party than to stay at home, again, for the purpose of motivating themselves to work longer (study 4). (3) Furthermore, consumers with a variable-effort future self-control task (5-15 miles of hiking) were more likely to buy luxury hiking boots than those facing a fixed task (15 miles of hiking) (study 5). (4) Finally, when the future task was important, those who were less confident in their ability to finish the task were more likely to reward themselves before the task (rather than after the task) than those who were more confident. In contrast, when the future self-control task was not important, the rewarding timing choice is not different between those who are more and less confident in their ability to finish the task, again consistent with our proposition that consumers self-induce guilt to build up their motivation for future task. These results provide converging evidence for our hypothesis of strategic motivation maintenance and cannot be explained by other theories of sequential decision making such as licensing (Khan & Dhar, 2006).

Our results have important implications in a number of fields. First, contrary to all the previous literature on emotions, which suggests that people avoid negative emotions, we demonstrate that people sometimes strategically self-induce guilt, a specific type of negative emotion. Second, empirical research on the role of specific emotions in self-control is lacking (Loewenstein & O'Donoghue, 2006). We try to identify conditions, under which people use self-induced emotional states as a means of self-control, demonstrating the mediating role of emotions underlying many self-control strategies.

SYMPOSIA SUMMARY
# Consumer Response to Aesthetic Aspects of Product Design: 1-, 2-, and 3-Dimensional Perspectives
Wes Hutchinson, University of Pennsylvania, USA

## SESSION OVERVIEW

The aesthetic responses of consumers to product designs (and their effects on purchase, usage, and satisfaction) are issues of considerable interest to both consumer researchers and managers of new product development. The objective of this session was to present a collection of research projects that have drawn from both areas for theory, method, and data. Thus, it should be of interest to both academics and practitioners

Most of the existing work on product design has been concerned with visual aesthetics or how consumers respond to a product's aesthetic aspects (Veryzer and Hutchinson 1998, Block, Brunel, and Arnold 2003; Chitturi, Raghunahan, and Mahajan 2007; Hoegg and Alba 2005). Building on previous research, our session revisits product aesthetics from several new angles. More importantly, our session aims at examining product design from more comprehensive perspectives including, but not limited to, aesthetic inquiry. Product design is defined as "the professional service of creating and developing concepts and specifications that optimize the *function*, *value* and *appearance* of products and systems for the mutual benefit of both user and manufacturer" (the Industrial Designers Society of America). The three papers in this session investigate how consumers respond to a product's *appearance* (or *form*) differently (Brunel and Swain), how they respond to a *form-function* entity as a semantic unity (Luchs et al.), and how they respond to a synergy or gestalt of *form*, *function*, and *value* as these elements being reintegrated by a visual metaphor (Deng and Hutchinson), respectively. Our 1-, 2-, and 3-dimensional inquiries generate contributions to the consumer literature and insights for design management.

Prior research on product aesthetics emphasized variations on the part of products. Variations on the part of consumers have been largely ignored. Although Block, Brunel, and Arnold (2003) explored individual differences in the centrality of visual product aesthetics (CVPA), they treated this variation as a stable, trait-like concept. Extending this line of research, our first paper, by *Brunel* and *Swain*, investigates how consumers' aesthetic evaluations of products are influenced by a dynamic interaction between their individual characteristics and their aesthetic perceptions of the product's categorical stereotype and ideal. In one laboratory and two national field studies, they found that aesthetic evaluations arise from (1) the perceptual distance between the product and the stereotype (novelty) and (2) the perceptual distance between the product and the ideal (concinnity). Moreover, the relative weight that consumers place on each distance is moderated by their aesthetic "expertise," as measured by the CVPA. While focusing on one dimension (aesthetics) their paper discovers the hidden "meaningful heterogeneity" ignored by previous research on this dimension.

Our second paper, by *Luchs*, *Raghunathan*, and *Mahajan*, examines the *semantic unity of form and function* of a product, extending previous research (e.g., Veryzer and Hutchinson 1998) in an important way. Moreover, they generalize "form" to visual representations such as abstract shapes, concrete product forms, and brand logos; and "function" to verbal representations including words, product functionality, and brand positioning. Their experiment shows that shape-word pairings that are semantically more

unified are preferred to pairings that lack such a semantic match. They plan to replicate this finding in product design and corporate identity design contexts. They expect that a semantic match between a product's visual design and its functional description would lead to higher product evaluations. By the same vain, semantically unified logo design and brand tagline would contribute to more favorable brand attitudes. Their research extends the concept of unity from 1-dimentional to 2-dimentional domain of product design.

Norman (2004) developed a three-level model of how consumers respond to product design basing on empirical evidences that human brain enables three levels of processing, namely the visceral, behavioral, and reflective level. He proposed that the design of human artifacts should be concerned with these levels. Drawing upon Norman's theory, our third paper, by *Deng* and *Hutchinson*, focus on a product's *visceral design* (which is about the initial impact of a product; about its appearance, touch, and feel), *behavioral design* (about the pleasure and effectiveness of use; about its function, understanding of function, and usability), and *reflective design* (about how a product evokes meanings and remembrances in users and how it defines the user's self-image). In light of McQuarrie and Mick's (1999) work on visual rhetoric, and seeing product design as a unique form of persuasive communication, they posit that a *visual metaphor* increases the product's persuasiveness via its effects on the three levels. Two experiments (the second one was conducted in two countries) support their claims. This is also the first consumer research to empirically tests Norman's theory and, as such, complete the progression across the papers with a 3-dimentioanl inquiry into consumer responses to product design.

## EXTENDED ABSTRACTS

### "A Moderated Perceptual Model of Product Aesthetic Evaluations"
*Frédéric F. Brunel, Boston University*
*Scott D. Swain, Boston University*

Researchers in marketing and consumer behavior have begun to develop a theoretical base and a body of evidence pertaining to consumers' evaluations of product aesthetics. However, statistical effects that are generalizable across products or settings have proven elusive. Although it could be argued that this reflects a pervasive idiosyncrasy in aesthetic evaluations, it may also be the case that existing models have not yet identified or accounted for "meaningful heterogeneity" in design evaluations (Holbrook 1986). We examine the potential for interactions between product and consumer characteristics to capture such meaningful heterogeneity.

In this research, we take a contingency perspective, where aesthetic preferences are seen as the result of systematic interactions between consumers' and product designs' characteristics. We propose that consumers hold mental models for each product category they consider and that products share aesthetic features that individuals can interpret in fairly consistent ways. For example, most consumers would tend to agree that an Apple iPod has a "unified, balanced and simple look," yet they may disagree on how

desirable each of these aesthetic properties is, and how much variation around each one they may enjoy or tolerate. We develop and test an integrative model that provides a more comprehensive account of how aesthetic evaluations are formed.

The model is built on four vectors of data: (1) consumers' perceptions of a target product's aesthetic characteristics, (2) consumers' perceptions of the aesthetic characteristics of the self-identified "stereotypical" product in the category, (3) consumer's perception of the aesthetic characteristics of their "ideal" product in the category, and (4) consumers' own characteristics (in particular as measured by the Centrality of Visual Product Aesthetics, CVPA, Bloch, Brunel and Arnold 2003). Extending the existing conceptualization of the first three elements (Coates 2003), we undertake algebraic formalization of the relationships therein. Through the model, we build an aesthetics perceptual space for the product and category at hand. For a given product in a specific category, we can measure perceptual evaluations (using semantic differential scales) for a relevant series of aesthetic dimensions for the product, the category stereotype, and the category ideal. We can use these vectors of data to compute several perceptual distances and then locate each object in a perceptual space. The first distance of interest is the perceptual distance between the object and the stereotype (DS$_i$), and it can be conceptualized as a measure of novelty. The second measure of interest is the perceptual distance between the object and the ideal (DI$_i$), and can be conceptualized as a measure of design concinnity (i.e., harmony, beauty). Further, we can conceptualize the distance between the stereotype and the ideal as a measure of design potential.

Although previous conceptualizations have struggled to explain why different consumers place different weights on design characteristics that evoke stereotypicality versus novelty, we suggest that much of the variation arises from differences in CVPA. Briefly, the Centrality of Visual Product Aesthetics scale (CVPA; Bloch, Brunel, and Arnold 2003) measures the salience of visual design in a consumer's relationships with products, specifically, it captures the extent to which a consumer (1) values design, (2) responds to design, and (3) evaluates design with skill (acumen). CVPA has been shown to moderate the effect of product design on aesthetic evaluations, product attitudes, purchase intentions, and willingness to pay (Bloch et al. 2003), yet no research has yet examined skill-related outcomes of CVPA.

To assess our conceptualization, we analyzed two national field experiments as well as a controlled laboratory experiment. The field experiments were carried out in conjunction with a major automobile manufacturer and involved nationally representative samples of sport utility drivers. The lab experiment involved university students who participated in return for course credit. Across these three studies, we find consistent empirical support for the notion that product aesthetic evaluation systematically varies with DS$_i$ and DI$_i$., and interacts with CVPA. This suggests that consumers' aesthetic evaluations are not purely idiosyncratic but rather are a function of previous exposure to the category (as represented by the perceived category stereotype) as well as idealized notions of the category (as represented by the perceived category ideal).

Additionally, we find that the visual information conveyed in product a design is differentially available to consumers and that CVPA scores are predictive of this heterogeneity. Of course, it is important to keep in mind that consumers' ability to recognize and categorize designs can be (but are not necessarily) independent of their design attitudes and preferences. Still, variation in skill leads to variation in the informational inputs to attitudes and preference, and we can expect consumers with greater skill to have greater

attitude certainty, lower attitude ambivalence, more precisely defined preferences. An important area for future research is to determine the reasons for differences in design evaluation skill. Candidate factors include differences in the way product shapes are stored in memory (e.g., verbal, visual), in knowledge structure (e.g., quantity, density, accessibility), and in visual acuity (e.g., bandwidth, resolution, resources).

### "Form-Function Unity: Understanding the Interactive Relationship between Product Form and Function"

*Michael Luchs, University of Texas at Austin*
*Raj Raghunathan, University of Texas at Austin*
*Vijay Mahajan, University of Texas at Austin*

While past research has demonstrated the importance of product form and product function as independent antecedents of consumers' evaluations of products, the focus of the current research is on examining the interdependent relationship between form and function on consumers' product evaluations. Specifically, we examine product evaluations based on the degree to which a given product's form and function are perceived to be "unified," which we define and operationalize as the degree to which they share common associations or meanings. Our research addresses the following questions.

1. Do consumers prefer products when form and function elements are unified?
2. What factors moderate consumers' preferences for form-function unity?
3. What factors mediate consumers' preferences for form-function unity?
4. Is the preference for form-function unity conscious?

There are several reasons that could lead one to conclude that consumers will, in general, prefer products whose form and function are unified. According to Gestalt theory, people delight in order. As such, product preferences may be guided by holistic features such as unity. For example, Veryzer and Hutchinson (1998) demonstrated that consumers prefer products whose visual elements are perceived to be unified. Also, to the degree that unified products are processed more easily (Banks, Clark and Lucy, 1975), we would expect them to be preferred over disunified products given that objects that are processed more easily tend to be preferred in general (Reber, Schwarz and Winkielman, 2004). Another reason to expect that consumers will prefer unified products is based on the notion of psychological essentialism (Medin and Ortony, 1989). According to psychological essentialism, people assume that objects have an underlying essence or nature. This underlying nature manifests itself in both how the object appears as well as what the object does (i.e., its function). We would expect, then, that unified products will be perceived to make more sense given that form and function share an underlying essence and that, therefore, they will be preferred over disunified products.

While there are several reasons to expect that consumers will prefer products whose form and function are unified, there are also reasons to expect just the opposite, i.e. that consumers might prefer products whose form and function are disunified. Berlyne (1971, 1974) argued that there is an ideal balance between Gestalt preferences for unity, for example, and a need for some optimum level of arousal due to factors such as complexity. As such, consumers might prefer products whose form and function are disunified as long as they are not so extreme as to be incredible or overly complex. In addition, it is possible that under certain conditions, some consumers will base their evaluations on atomistic properties

(e.g., individual features) vs. holistic properties such as unity (Hoegg and Alba, 2005). As such, it is plausible that a disunified product will be perceived as offering greater value given its potential for providing value along more than one dimension (e.g. a "disunified" car that looks powerful and that is described as fuel efficient may be seen as providing both benefits). Evaluations based on atomistic properties require greater elaboration than do evaluations based on holistic properties, and prior research suggests that greater elaboration is likely among consumers with higher product knowledge (Sujan, 1985) and felt involvement (Celsi and Olson, 1988). Thus, we would expect the relative preference for unity (vs. disunity) to be moderated by product knowledge and felt involvement.

In study 1 we demonstrated, using abstract stimuli (shape-word pairs), that people prefer objects whose elements are unified (M=3.57) relative to objects that are disunified (M=3.17), (F(1, 241)=16, p<.0001). Specifically, participants preferred objects whose shapes connoted "strength" when paired with synonyms of "strength," and preferred shapes that connoted "flexibility" when paired with synonyms of "flexibility." This result was statistically significant even when a comprehensive set of potential covariates was included in the analysis.

In study 2, we replicated the main effect of unity in a consumption context, across two product categories. Specifically, participants liked non-alcoholic beverages more when form and function were unified (M=3.98) vs. disunified (M=3.15), (F(1, 55)=26.34, p<.0001); they also liked air purifiers more when form and function were unified (M=6.46) vs. disunified (M=6.12), (F(1, 55)=6.62, p=.01).

The objective of Study 3 was to examine whether product knowledge and felt involvement moderate the effect of unity on product liking. While neither product knowledge nor felt involvement had a significant effect on their own, (F(1, 127)=0.30, p=.58) and (F(1, 127)=1.02, p=.32) respectively, results revealed a significant interaction between product knowledge and felt involvement, (F(1, 127)=6.63, p=.01). As predicted, participants with relatively higher product knowledge who were also relatively higher in felt involvement preferred the disunified pairs to the unified pairs.

Collectively, our studies demonstrate that consumers do, in general, prefer products whose form and function are unified. We argue that this result is primarily due to consumers' desire for order in the world around them. Importantly, the unity effect is qualified by product knowledge and felt involvement such that, when both are high, a relative preference for disunity emerges. Because consumers' qualified preference for form-function disunity (when knowledge and felt involvement are sufficiently high) could be mediated by perceptions of greater complexity and/or by perceptions of higher value, a proposed experiment will be examine whether these processes underlie the preference for disunity. In another experiment, we intend to examine whether consumers are aware of their preference for unity and disunity, i.e. whether they realize that the form-function interaction is influencing their preferences.

### "What You See Is What You Get: The Effects of Visual Metaphor on Consumer Response to Product Design"

*Xiaoyan Deng, University of Pennsylvania*
*Wes Hutchinson, University of Pennsylvania*

Product design is increasingly being recognized as an important strategy that firms use to create a substantial competitive advantage. A well-designed product sells more, enlarges market share, gains wider distribution, increases margins and carves out new opportunities. For example, by launching a series of groundbreaking products such as iMac, iBook, iPod and the forthcoming iPhone, Apple has revolutionized revitalized itself and reinforced its status as a legend in the history of business. By harnessing the power of design, Apple has cemented a unique position as a force in computing, consumer electronics (via iPod, iPhone), music (iPod again) and movie industry (Pixar).

However, compared to other areas, surprisingly little experimental work has been done to study product design, either by scholars in design field or by researchers of adjacent disciplines such as marketing that share a stake in design. An empirically based, "design science" has yet to emerge—particularly from the perspective of consumer responses to design variables. The goal of the present research is to contribute to the foundation of such a design science.

Product design is defined as "the professional service of creating and developing concepts and specifications that optimize the *function*, *value* and *appearance* of products and systems for the mutual benefit of both user and manufacturer" (the Industrial Designers Society of America). Norman (2004) proposes a three-level (namely *visceral*, *behavioral*, and *reflective*) model of how consumers respond to product design. Building on practitioners' wisdom and Norman's framework in the present research, we divide product design into three relatively independent design levels: visceral, behavioral, and reflective design. We further postulate that *visual metaphor* as a design component can integrate the three levels in a fashion that increases the persuasiveness of a design. Drawing upon McQuarrie and Mick's (1999) work on visual rhetoric in advertising, and seeing product design as a form of persuasive communication, we posit that a visual metaphor increases the product's persuasiveness via its effects on the three levels. Two experiments reported here lend supports to these claims. To our knowledge, this is the first research that empirically tests Norman's theory of design. Moreover, this work extends McQuarrie and Mick's visual rhetoric research from two-dimensional advertising design to three-dimensional product design.

The essence of metaphor is to understand and experience one thing in terms of another (Lakoff and Johnson 1980). At visceral level, because of this "seeing as" or "aspect seeing" nature (Hester 1966), metaphoric experience is akin to mental imagery and aesthetic perception (Aldrich 1958). At behavioral level, because metaphor is meant to communicate an unfamiliar target concept (e.g., a product's function) in terms of a familiar base concept (e.g., the product's "metaphoric" form) via structural mappings between the two (Gentner 1997), it facilitates the understanding of product function. Such understanding further enhances the product's functionality and usability. Finally, at reflective level, because metaphor (and rhetorical figures in general) is an "artful deviation" in the form taken by a statement (McQuarrie and Mick 1999), it "deviates" from the expectations held by a communication encounter, therefore it elicits elaboration. Because such a deviation is "artful," metaphor (and rhetorical figures in general) produces pleasure. Considering its effects on all three levels, but especially its "elaboration" and "pleasure" effects on the reflective level, we expect visual metaphor to render a product more persuasive in the sense that it induces a more favorable attitude and a higher purchase intention in consumers.

In study 1 (N=185), we selected "metaphoric" designs from existing products in the market. We then removed the visual metaphor from the design to create a non-metaphoric, baseline design while keeping other design elements (shape, color, texture, etc.) unchanged (cf. Veryzer and Hutchinson 1998). Our data show that, comparing to the baseline, metaphoric designs were systematically rated higher across nine measures of the three levels as well as

the two dependent measures (product attitude and purchase intention). However, although visual metaphor has a significant effect on the reflective level, its effects on the other two levels were not significant. Nor was its effect on product attitude and purchase intention. In retrospect, we realize that our experimental procedure informed subjects about product function and might have compromised the communication function of metaphor and its effects. Another limitation of study 1 was how we prepared product stimuli. That is, because we constructed baseline design by removing visual metaphor from an existing product, any observed effect of visual metaphor might due to the fact that the "baseline" might have been made "worse" in ways that professional designers would never do.

In study 2, in contrast to study 1, we chose non-metaphoric, baseline designs from actual products available in the market. We then added a visual metaphor to the original design to create a metaphoric version of product while holding other design elements constant. We improved our study procedure so subjects were blind to the function of each product stimulus throughout the study. Based on what we found in study 1, that is, visual metaphor's effects disappear when a product's function is known, we hypothesize that visual metaphor is advantageous only for poorly designed products. When a (non-metaphoric) product is well-designed in the sense that it is functionally unambiguous and aesthetically attractive, adding a visual metaphor cannot offer too much help. In order to test this hypothesis, a pretest (N=163) was conducted from which eight product stimuli, spanning the range of "functional ambiguity" and "visual attractiveness," were selected to be used in study 2. In study 2 (N=441, conducted in the U.S. and Australia), we confirmed that, when a non-metaphoric, baseline product is functionally ambiguous and visually unattractive, adding a visual metaphor to it significantly increases its ratings on product aesthetics (visceral level); understandability, functionality, and usability (behavioral level); reflectivity, imagistic and discursive elaboration (reflective level); as well as product attitude and purchase intention (persuasiveness). Regression analyses also show that responses to visceral, behavioral, and reflective design significantly predict a product's persuasiveness, providing empirical support for Norman's model.

# Entertainment-Education: Dramatic Vehicles and Health Education

Barbara Stern, Rutgers University, USA

## SESSION OVERVIEW

### Introduction

The term "symposium" derives from the Greek word for "fellow-drinker" and was popularized by Plato's *Symposium* (c. 5th C. B.C.E.), where it refers to a discussion among banquet guests about "love, idealism, creativity, sex, and the effects of alcohol" (Sparshott, p. 576). By 1784, (Symposia or Table Talk in the month of September 1784), it was defined more soberly as a meeting for discussion of some subject, "a collection of opinions delivered…by a number of persons on some special topic" (*Oxford English Dictionary* 2005). Nonetheless, the definition was somewhat less solemn in that the Symposia was labeled "a rhapsodical hodge-podge," which the authors of the following proposal wish to avoid. Rather, in the spirit of conviviality, we aim at intellectual nourishment conducive to ongoing conversation accompanied by food and drink.

### Objective

The session focuses on a specific form of modern "intellectual entertainment"—the creation and use of entertainment-education (EE) media vehicles both to promote good health practices (regular medical checkups) and to deter bad ones (dangers of alcohol or tobacco). Our objective is to gather presenters from different theoretical and methodological perspectives who examine dramatic EE vehicles such as sitcoms and soap operas, and who use theories borrowed from the humanities (rhetoric, drama criticism) and the social sciences (social psychology, cognitive psychologies) to educate consumers about the importance of healthy living and disease prevention.. The discussion will be led by the author of a fotonovela—here, a comic book called "*No Vale La Pena* (*It's Not Worth It*)–aimed at warning Hispanic immigrants about the dangers of entering the methamphetamine trade. To stimulate discussion, he will distribute copies so that the attendees can exchange opinions about a real-world EE exemplar.

In this way, the session functions as a symposium insofar as it is a meeting ground for different perspectives on EE vehicles that leads to a group discussion of EE creation, message format, target audience appeal and consumer responses. The topic of using dramas to deter unhealthy behaviors should be of special interest in consumer research, which for the most part has not fully considered the issue of reaching vulnerable audiences more likely to watch dramatized messages than to read informational brochures. Our format aims at encouraging interaction among the presenters, the discussant, and the audience that may inspire research collaborations able to advance knowledge of the way that health education messages can affect consumers' lives for the better (Singhal et al. 2004).

The importance of delivering health messages in an entertainment format lies in their capacity to persuade difficult to reach populations such as minorities or teens to whom health education messages in written materials or advertisements have little appeal. The power of EE vehicles is recognized globally, for soap operas are not only produced in or exported to most countries, but also are the most viewed media vehicles by the majority of viewing audiences in any country ( in the world. Similarly, sitcoms are globally popular, and short dramatic comic books have higher penetration among less literate and economically empowered consumers, to whom information in the guise of fiction may be more accessible. EE characters who display good, but more often bad, health practices, vivify the essential dramatic conflict between characters who are good or evil, at the heart of health messages.

### General Orientation

The symposium will begin with Hope Schau's presentation of Cristel and Dale Russell's study of the effects of mixed alcohol messages in a prime time television soap opera, *O.C.*, on young viewers' beliefs about drinking. The paper first documents the intertwining of anti-alcohol EE efforts and pro-alcohol placements and then investigates audience responses. Pechmann will present a study of the efficacy of televised EE in which a sitcom incorporates anti-smoking messages to deter high/low-risk adolescents from smoking. Finally, the symposium leader, Virginia Maduena, will lead a discussion aimed at integrating the presentations by means of a Spanish comic book "*No Vale La Pena*," that she wrote to warn migrant agricultural workers about the dangers of entering the methamphetamine trade. She will give attendees the short comic book to generate informed conversation about the effectiveness of EE as a means of conveying positive health messages to low-literate or illiterate Hispanic immigrants. Thus, the presentations focus on the form and content of positive/negative EE dramas, with the discussion providing a real-world exemplar to stimulate discussion.

### Likely Audience

The audience is likely to include researchers interested in the consumer behavior implications of EE, public policy and health education officials, consumer advocacy groups, and international scholars, who have the language skills needed to investigate EE across the globe. Among the research topics requiring at least one partner who is fluent in another language are the macro effects of public vs. private EE funding, government regulations and the inclusion of health education messages, and product placements that influence consumption. We anticipate broad appeal stemming from both the newness of the topic and the experiential discussion focusing on "show" rather than "tell."

### Issues to be Considered

The central issue is the way that EE dramas function to educate and inform consumers. The underlying theory of EE as persuasive drama is applied to different messages, program types, and audiences, in order to uncover the construction of an EE stimulus, its effectiveness in promoting good, bad, and ugly health messages to consumers. The symposium will integrate different research approaches and methods that focus on encouraging positive health behaviors and discouraging poor ones.

### Contribution to Consumer Behavior Research

Our goal is to raise awareness of dramatic popular culture vehicles that reflect consumption problems/solutions more persuasively than advertisements or written materials. Attention to the persuasion process in not fully researched EE vehicles points to similarities/differences in form, content, and audiences. Greater understanding of the way that messages work can contribute to a more sophisticated assessment of the persuasive elements built into EE dramas, the viewer responses flowing from audience consumption habits, and the cultural context in which responses occur.

# EXTENDED ABSTRACTS

## "Mixed Alcohol Messages In Television Series: Product Placement Meets Edutainment"

*Cristel Dale Russell, Auckland University of Technology*
*Hope Schau, University of Arizona*

This research, funded by the National Institute on Alcohol Abuse and Alcoholism, addresses the impact of alcohol messages in television programming on young viewers' attitudes about drinking, and ultimately their alcohol consumption behaviors. In this presentation, we document the nature of alcohol messages in prime time television programs and present the results of a study assessing the impact of mixed alcohol messages on consumers. Television programs often incorporate both positive and negative alcohol messages (Blair et al, 2005). Positive alcohol messages, particularly in the form of product placements, are a common occurrence within the content of television programming. Concurrently, as entertainment-education techniques become more common to tackle especially difficult issues, targeting especially vulnerable audiences, messages that communicate the negative consequences of drinking are increasingly included in the storylines of television series (Singhal and Rogers, 2002). What impact do these mixed messages have on consumers' drinking attitudes, beliefs and behaviors? We report research findings based on *The O.C.*, a teen television series where mixed alcohol messages abound.

In the first phase of this research, alcohol messages in *The O.C.* were content analyzed on the basis of the three dimensions of the tripartite typology of product placement (Russell, 2002). The analysis revealed that negative messages about alcohol (i.e., drunk driving, addiction, death, etc.) are usually discussed in the script and tend to be highly tied to the plot of the episode. However, *The O.C.* also contains positive messages about alcohol (i.e., having fun, relaxing, escaping problems) but those messages are conveyed visually, and mainly through the use of low plot / background type visual depictions. Hence the messages are often mixed with education-entertainment messages stemming mainly from auditory discussions that are connected to the plot and positive messages communicated visually and more subtly.

The second phase was designed to test a model of how alcohol messages are related to viewers' attitudes, beliefs, and behaviors related to alcohol. The model incorporates the dual route models of persuasion (Petty and Cacioppo, 1984) and the concept of television connectedness, which previous research found to be a key driver of television programs' influence (Russell, Norman, and Heckler, 2004). Previous research has shown that subtle visual messages are effective agents of persuasion due to their subtleness, whereas audio high plot messages are processed centrally and thus more likely to be countered. Data from a cross-sectional survey of 198 viewers of *The O.C.* provide evidence that negative alcohol messages are processed centrally. However, because these centrally processed messages are more salient, they are also easier to discount and we find no evidence of impact on viewers' negative beliefs about drinking. Evidence is also found that the subtle pro-alcohol messages impact highly connected viewers: the more connected the viewers, the more they believe that alcohol is linked to positive consequences not only within the television series *The O.C.* but in real life as well.

In conclusion, we address the public policy implications of the research. The societal impact of alcohol on youth is worrying and policymakers are working to develop new strategies to address the problem of underage drinking. These efforts include working with the alcohol and media industries to limit alcohol messaging to youths (Leavitt, 2006) as well as entertainment-education campaigns to communicate the risks associated with alcohol consump-

tion. However, this research provides initial evidence that EE efforts are often drowned by the abundance of pro-alcohol messages that operate under the radar.

## "The Use of Entertainment Education to Deter Youth Smoking: Does Balance, Transformation, and a Public Service Announcement Epilogue Help or Hurt?"

*Cornelia (Connie) Pechmann, University of California, Irvine*
*Liangyan Wang, University of California, Irvine*

Entertainment Education on television is seriously underutilized in tobacco control as compared to other health domains such as AIDs, and experts opine that it is the most critical addition to tobacco control that can be made (Singhal and Rogers 2004). Entertainment Education costs very little because most costs are underwritten by television networks. Networks voluntarily embed educational content in plots or subplots and generally only seek assistance to ensure accuracy. In the United States, the Centers for Disease Control and Prevention, National Institute on Drug Abuse, National Institute of Mental Health, and Office of National Drug Control Policy promote Entertainment Education.

The aim of this research is to assess the efficacy a various approaches to using Entertainment Education for youth smoking prevention. Many experts recommend three specific approaches to conveying an educational but entertaining message: use a balanced or two-sided (vs. one-sided) message, show character transformation, and include a public service announcement epilogue (Greenberg et al. 2004). However, other experts have expressed concern that balance may be confusing, and that an epilogue may be counterproductive (Slater 2002). No controlled study of these issues have been conducted.

We studied a real episode of the youth-targeted situation comedy Clueless called "Model Smoker." Clueless is a popular show in reruns but the "Model Smoker" episode does not appear in the rerun schedule so there is no prior exposure and clean tests can be conducted. We created and experimentally tested eight different versions of the episode to identify the best and worst approaches to conveying the antismoking educational content. A prime objective was to study any possible adverse effects, particularly among smokers or those who coorient with the smoker.

In this episode of Clueless, the lead character Cher dates a new male student at her school, Brad, who is a smoker and had worked as a professional model in France; hence the title "Model Smoker." Cher finds out that Brad smokes, expresses strong disapproval of his smoking, and ultimately decides she can no longer date him. However, the writers included substantial balanced content. Cher's friends express approval of Brad's smoking, and say his smoking is sexy and alluring. Brad quits smoking for Cher but immediately starts again. An antismoking public service announcement epilogue was included as well, in which Cher restates her disapproval of smoking.

We examined the effects of the episode on adolescents after it had been edited in different ways, by conducting a 2 x 2 x 2 randomized factorial experiment. A professional editor created eight versions. The content was edited to be wholly antismoking or balanced. Also the content was edited so that Brad did or did not succeed in quitting smoking and transforming into a nonsmoker. Finally, the original antismoking public service announcement epilogue was included or edited out. All versions were the same length (11 minutes); control or nonsmoking scenes were used as fillers. There was also a control version with no smoking whatsoever.

We tested the versions among ninth graders. Students were released from class and sent to different rooms, where each group of students was shown a randomly selected edited version. After

showing it, we measured their thoughts and feelings about the characters and smoking in general, their coorientation with or attitudinal similarity to the smoker Brad, and their intent to smoke. Two weeks previously, we had measured students' smoking behavior and other factors that might moderate their reactions to the episode, including personality traits such as reactance.

To understand the episode's effects we used Reference Group Theory which posits that there are three types of reference group influence: utilitarian, value-expressive and informational (Park and Lessig 1977). Utilitarian influence dictates how people should behave to comply with society's moral and ethical rules. Value-expressive influence dictates people should behave to achieve status and standing in society. Informational influence conveys how people often do behave to function adaptively in society and provides heuristics or rules of thumb (Cialdini et al. 1990). Reference Group Theory predicts that referent effects may be moderated by coorientation or attitudinal similarity (Price et al. 1989) .

We conducted our experiment among 1424 ninth graders in several public high schools in middle to lower middle class, ethnically diverse neighborhoods. We analyzed the data using ANOVA and ANCOVA. Including either past smoking behavior or coorientation with the smoker referent as a moderator, we found three two-way interactions and a three-way interaction on intent to smoke. The interactions indicate that balance is counterproductive among smokers or those cooriented with the smoker referent because these viewers misinterpret the two-sided message as prosmoking. A public service announcement epilogue is also counterproductive for these viewers, who find it preachy. The combination of balance and an epilogue actually increases such viewers' intent to smoke. Transformation is immaterial, perhaps because youths realize that quitting smoking may be temporary.

### "The Creation and Use of *"No Vale La Pena"* (*"It isn't Worth It"*): **A Spanish Comic Book aimed at Hispanic Migrant Workers about the Dangers of the Mephamphetamine Trade"**

*Virginia Maduena, Imagen Public Relations Agency*
*Barbara Stern, Rutgers University*

This presentation describes the development of a Spanish-language comic book (a *graphic novella)* to distribute to Hispanic farm workers in central California in order to warn them against entering the lucrative but dangerous methamphetamine trade. The audience is low-literate in English, and often in Spanish as well, isolated in the central valley, and often illegally in the U.S. The valley is the center of meth production in the area, and according to Mark Pazin, the county Sheriff, is also a central distribution point for the drug. Migrant workers are likely to be lured into meth production by promises of big money, lack of danger, and low likelihood of being caught. Nonetheless, production is highly dangerous insofar as the cooking process takes place near houses and trailers, releasing toxic fumes near where the workers' families live.

The promises attract migrant workers, who cannot be warned by means of informative booklets that tend to require higher literacy levels to be comprehended. The author, also a city Councilwoman, developed a more effective means of reaching the audience by creating a free print comic book to be distributed in Hispanic supermarkets across California, and the books were so successful that the first 15,000 were quickly snapped up. Somewhat later, Ben Duran, the President of Mercer Community College, worked with the author to create a videonovela that dramatized the story of the family tragedy and was shown in various locales such as churches, schools, and so forth.

The reason for the positive reception of both the comics and the video lies in their familiarity to the primarily Mexican audience: both *fotonovelas* (Spanish-language print comic books with pictures and simple text) and *telenovelas* (Spanish-language electronic soap operas) originated in Mexico, where they have remained popular for over a century. Men and women carry the pocket-sized books with them, and are avid fans of the soaps. Both forms are dramas, presenting outsize and recognizable good versus evil characters in family situations that notwithstanding their exaggerations typify universal emotions such as love, hate, envy, deceitfulness, indifference, rage, and so forth. Clear-cut villains and heroes act out scenarios of romance or vengeance, and consumption of goods and services plays a central role in the plot.

"*No Vale La Pena*" pits the central character, Jose, a farmworker who agrees to meth production against his pregnant wife, who does not want him to. She becomes sicker and sicker, finally losing the baby, and Jose's daughter dies as a result of inhaling the fumes. These popular culture forms do not contain explicit anti-drug messages, which would disrupt the dramatic progress by introducing a narrative voice, but, rather, follow the drama conventions of characters who interact with others–that is, they show rather than tell what happens. In this way, they draw the audience directly into the plot without any interpolating voice telling audiences what to think (Stern 2007), and hence avoid the preachiness of an appended epilogue that Pechmann and Wang's study found counterproductive.

# To Breakup or Make Up? The Psychology of Consumer Forgiveness

Cassie Mogilner, Stanford University, USA

## SESSION OVERVIEW

As brands are highly motivated to foster their relationships with consumers, they actively nurture the number and frequency of positive interactions with those consumers (Fornell and Wernerfelt 1987). However, brands, like all relationship partners, inevitably make mistakes (Grayson and Ambler 1999; Rusbult et al. 1991). Traditionally marketers have documented the negative consequences that result when brand transgressions occur (Boon and Holmes 1999; Davidow 2003), yet a small but growing literature is starting to acknowledge the more complex qualities of relationships (Gottman 1993) and the possible positive consequences that might result when brands do bad (Aaker, Fournier, and Brasel 2004). The three papers in this session and the discussant's comments all focus on the subjective qualities of brand transgressions, which remain poorly understood. Broadly construed, this symposium aims to identify the psychological processes driving consumers' reactions to brand transgressions in order to gain deeper insight into when and why consumers will forgive brands for their mistakes . Drawing on principles of accessibility, these papers identify how consumers perceive (Mogilner and Aaker 2007), remember (Kyung, Menon and Trope 2007), and, therefore, react (Moore and Fitzsimons 2007) to brand transgressions.

To offer a fuller understanding of the psychology underlying consumers' forgiveness, each paper takes a distinct approach and perspective. First, Mogilner and Aaker (2007) examine the extent to which particular forms of compensations make consumers' prior brand relationships accessible, which in turn influence consumers' subsequent brand attitudes. Second, Kyung et al. (2007) explore how the temporal distance from a transgression influences what type of information is accessible and, therefore, whether consumers assign blame to the brand. Finally, Moore and Fitzsimons (2007) focus on stockouts, examining how the relative accessibility of the product versus the source of the stockout influence consumers' tendency to forgive once the availability of the desired product has been restored. Together these papers suggest that where consumers direct their attention when considering a negative brand experience determines their likelihood of forgiving the brand.

This symposium aims to contribute to consumer research by bridging the gap between the growing research on mixed emotions (Williams and Aaker 2002) in consumer psychology and consumers' growing negative impressions of marketers and marketing (Friestad and Wright 1994). That is, even though mounting evidence suggests that most relationships are defined by a mix of positive and negative experiences (Gottman 1993), much of consumer research implicitly or explicitly assumes that brands' actions will always be positive—garnering good will and ultimately leading to favorable brand attitudes. These assumptions starkly contrast with consumers' increasing distaste towards and distrust of marketers and their tactics. Thus, this session bridges this apparent disconnect by focusing on specific instances wherein brands behave badly, determining when and why consumer goodwill decreases, attitudes plummet, and relationships dissolve.

## EXTENDED ABSTRACTS

### "Forgiving by Not Forgetting: The Effect of Compensations following Brand Transgressions"

*Cassie Mogilner, Stanford University*
*Jennifer Aaker, UC Berkeley*

Imagine that you are checking-in for your flight on United Airlines. At the ticket counter, the airline attendant informs you that your flight is overbooked and that you have been bumped off and rescheduled to leave on a flight the following day. The attendant apologizes on behalf of United Airlines by offering you a voucher for a future free flight on United. Consider your reaction. Despite United's recovery efforts, might the United voucher aggravate you even more—particularly given they just bumped you off your flight? What if they instead offered you a voucher for a free meal at an upscale restaurant? More generally, if United wants to keep you "onboard" as a loyal consumer, which of the two forms of compensation should they offer you, and why?

Although a considerable amount of consumer psychology research has focused on the occurrence and impact of transgressions on consumer-brand relationships (e.g., Aggarwal 2004; Bolton and Lemon 1999; Folkes 1984; Grayson and Ambler 1999), much less work has examined when recovery efforts serve to further hurt a brand versus repair consumer attitudes, and why such effects may occur. This sparseness of research is even more surprising in light of research noting that nearly all partners in close relationships eventually behave badly (Finkel et al. 2002; Rusbult et al. 1991) and that recovery efforts vary considerably in their effectiveness (Davidow 2003; Maxham and Netemeyer 2002a).

The goal of this research is to address the aforementioned questions by examining brands' compensation efforts following a transgression and the differential ability of those efforts to promote consumers' forgiveness. To do so, we build on a recent literature stream which argues that transgressions may serve as defining moments in consumer-brand relationship development that, if managed properly, can in fact strengthen (rather than threaten) the relationship (Aaker, Brasel and Fournier 2003; Smith and Bolton 1998). However, rather than focusing on the severity of the transgression or on the fit between the transgression and the compensation as prior work has (e.g., Gilly and Gelb 1982; Maxham and Netemeyer 2002b; Smith, Bolton, and Wagner 1999), we focus specifically on the type of compensation—whether it relates to the brand (e.g., United voucher) or is unrelated to the brand (e.g., voucher for an upscale restaurant).

Drawing on principles of accessibility and the literature on the psychology of relationships, we posit and show that the effectiveness of these two compensation types depends on (a) whether a prior relationship with the brand exists and (b) the nature of that relationship. The results from three experiments demonstrate that when consumers have a positive prior relationship with the brand, the attention culled by the brand-related compensation can prime that positive prior relationship, diverting attention from the transgression. In such cases, brand-related (vs. brand-unrelated) compensations are indeed effective. However, brand-related compensations become ineffective when there is no such prior relationship to prime, and can even backfire when the prior relationship was negatively-valenced. Insight into the underlying process was documented through tests of moderation where transgressions were

manipulated (Café Study), were imagined (Airline Study), and naturally occurred (Baseball Study).

First, the Café Study was conducted at a café among customers with prior brand relationships to test whether a brand transgression followed by a brand-related compensation (a brand name inscribed coffee mug) or a brand-unrelated compensation (a "Coffee" inscribed coffee mug) would induce more positive attitudes. After the café employee had "messed up" their order, customers reported more positive attitudes from receiving the brand-related compensation than from receiving the brand-unrelated compensation.

Next, the Airline Study was a scenario-based study conducted among travelers as they were waiting to board their flights. These travelers reported to either have positive or negative prior relationships with the airline. Results revealed that following a brand transgression, although travelers with positive prior brand relationships reported more positive attitudes from receiving a brand-related compensation (an airline voucher), travelers with negative prior brand relationships reported more positive attitudes from receiving a brand-unrelated compensation (a restaurant voucher).

Finally, the Baseball Study was conducted among attendees of college baseball games wherein the team either won or lost. Results revealed that after having been let down by a team loss, attendees who had a positive prior relationship with the team reported more positive attitudes from receiving a brand-related compensation (a team t-shirt) than a brand-unrelated compensation (an ice cream gift certificate). However, the attitudes of attendees who did not have a prior relationship with the team were not differentially affected by the type of compensation received.

Together, these findings (a) suggest how brand managers should focus their recovery efforts following a transgression, and (b) provide insight into the psychological mechanism by which prior relationships influence pursuit of future relationships, despite negative interactions.

### "Reconstructing History: How Construal of Past Events Influences Judgments of Recency and Culpability"

*Ellie Kyung, New York University*
*Geeta Menon, New York University*
*Yaacov Trope, New York University*

Human memory is ill equipped to handle temporal information due to the fact that it is stored associatively (Davachi, Mitchell, and Wagner 2003), must be contextually reconstructed (Hayes, Ryan, Schnyer, and Nadel 2004), and was an evolutionarily unnecessary skill for survival (Friedman 2004). Given the malleability of these judgments, we examine how construal level at memory recall influences these temporal judgments given the constraints of information availability and accessibility. Further, we demonstrate that influencing these temporal judgments can in turn influence judgments of culpability of responsible parties in negative events.

Construal Level Theory illustrates that those things that are in the near future are construed in more concrete terms while those in the distant future are construed in more abstract terms (Trope and Liberman 2003). In this research, we focus on whether inducing abstract versus concrete mindsets (Freitas, Gollwitzer, and Trope 2004; Fujita, Trope, Liberman, and Levin-Sagi 2006) can actually influence people's perception of when an event happened in time such that concrete mindsets will lead people to believe an event happened in the more recent past while abstract mindsets will lead people to believe an event happened in the more distant past.

However, given that memory-based judgments (particularly temporal judgments) are subject to contextual influence, we propose that construal level will have a differential impact on temporal judgments depending on information availability and accessibility. Judgments of recency (e.g. subjective temporal judgments) can be driven by 1) the content of what is recalled, such that events remembered with a greater level of detail are judged to be more recent (Brown, Rips, and Sheval 1985); or by 2) the metacognitive experience of recall, such that things that are more easily remembered are judged to be more recent (Tversky and Kahneman 1973; Schwarz et al 1991). Reliance on recall content versus the metacognitive experience of recall has been found, in certain contexts, to depend upon the discrepancies between expected and experienced ease of retrieval, such that judgments tend to depend

more upon content when expected and experienced ease of retrieval are consistent, and to depend more upon ease of retrieval when there is a discrepancy between expected and experienced ease (Raghubir and Menon 2002).

We draw on this research and make several propositions. First, those people that have low information availability for an event will make temporal judgments based on the content of what they remember, such that a concrete mindset cuing event details will lead people to believe an event happened more recently, relative to an abstract mindset. Second, those people with high information availability for an event will make temporal judgments based on the metacognitive experience of recall, such that abstract mindsets cuing high-level features of an event will lead people to believe an event happened more recently relative to a concrete mindset because these higher-level features are easier to remember. Third, this differential effect is due to when and how the discrepancy (or lack thereof) between expected and experienced ease of retrieval influences judgments. Finally, because greater temporal distance in both the future and the past is associated with greater dispositional (versus situational) attributions (Nussbaum, Trope, and Liberman 2003; Frank and Gilovich 1989, Ross and Wilson 2002), we suggest that decreasing perceived temporal distance from an event decreases judgments of culpability.

These propositions are supported by five experiments involving negative events with potentially culpable parties. In all the studies we demonstrate that with low information availability, temporal judgments follow those expected from construal level theory, where concrete mindsets lead to more recent temporal judgments relative to abstract mindsets while with high information availability, the opposite effect holds true if there is an effect of construal at all. This holds true for both temporal judgments involving objective dates (experiments 1 and 4, Hurricane Katrina) and subjective passage of time (experiment 2, Dell laptop battery recall, and experiment 3, Dole spinach recall). In experiments 3 through 5, using information availability defined by self-report (experiment 3) and objective knowledge (experiment 4 and experiment 5), we find that dispositional and situational attributions follow judgments of temporal distance, such that dispositional attributions (defined as blame assigned to specific parties) decreased and acknowledgement of situational constraints (defined as recognition of circumstances beyond anyone's control) increased when events were judged to have occurred more recently in time.

We demonstrate that the mechanism for the differential effect of construal on temporal judgments depends upon the discrepancy between expected and experienced recall. Those people with low information availability make judgments based upon the content of what they recall because they both expect and find that experience of recall is difficult (e.g. use content for the basis of judgments). Those people with more information availability expect ease of recall to be easy. Thus when in a concrete mindset, which cues more difficult to recall episodic qualities of an event rather than higher-level semantic ones (Tulving 1972), people with more information availability actually judge an event to have happened less recently in time based on their subjective experience of recall. Thus, we show that given constraints of information availability, construal level can drive judgments of greater temporal recency in a concrete mindset for people with low information availability and in an abstract mindset for people with high information availability. In addition, when the temporal judgment results in perceptions of greater recency, culpable parties were blamed less for the negative event: that is, the federal government was blamed less for the disastrous evacuation of New Orleans, Dole was blamed less for the *e coli* outbreak from its tainted spinach, and JetBlue was blamed less for its extensive flight cancellations after the Valentine's Day ice storm.

In conclusion, from a theoretical perspective, we demonstrate that 1) construal level can influence both objective and subjective perceptions of time in memory and that its influence depends upon information availability; and 2) these temporal judgments can influence those of culpability.

### "Just Say No: Can Firms Enhance Customer Happiness by Denying Their Requests?"

*Sarah Moore, Duke University*
*Gavan Fitzsimons, Duke University*

Denying customer requests is seldom touted as a key success factor for marketers. Indeed, stockouts are a frequent marketing problem to which consumers generally react negatively (Fitzsimons

2000). However, stockouts may be used as a strategic tool. For example, Nintendo's resurrection of the video game market in the 1980's has been partially credited to "a controlled dearth of game cartridges… [which] kept consumer interest … high" (Wolpin 1989). Thus, imagine that you are at the store to purchase a certain game cartridge, which the salesperson informs you is out of stock. You request a second choice, and as the salesperson retrieves it, he finds a copy of the original game you requested. How would you respond to the restored availability of your preferred option? Would you be satisfied with the store? Could the restoration of the option make you happier than if the product had been immediately available?

This research examines how individuals respond when formerly "forbidden fruits" or unavailable products become available. We investigate how consumers react when they experience a service transgression followed by a recovery, that is, how consumers respond when their freedom is restricted and then restored. We identify conditions under which individuals respond positively and negatively to restoration of previously unavailable products. To examine these issues we rely on reactance theory, which posits that individuals have specific psychological and behavioral responses when their freedom to make a decision is restricted or removed, as in a stockout situation. Although a great deal of research has examined responses to restriction of freedom (Brehm 1966; Fitzsimons and Lehmann 2004), less research has investigated responses to restoration of freedom (Worchel and Brehm 1971).

We argue that reactance motivation and its psychological consequences will not dissipate "no matter how restoration comes about" (Worchel and Brehm 1971), but rather that responses to restoration of freedom can be positive or negative, depending on how individuals react to the initial transgression and subsequent restoration of freedom. Restriction of freedom leads to 1) increased desirability of the restricted object (product desirability), and 2) a negative evaluation of the source of the restriction (source negativity). We hypothesize that responses to restoration of freedom arise from different strengths of these two forces, and that individuals focus on the stronger of the two reactions in responding to restoration of freedom (Taylor and Thompson 1982). If product desirability outweighs source negativity, then responses to restoration should be positive (relative to an "unrestricted" situation), as the valued product is attained. If source negativity is the stronger response, responses to restoration should be negative, because the focus is on the transgression and not on the attainment of the product. If the two forces are balanced, individuals should display neutrality in terms of their response to the restoration—as Worchel and Brehm argue (1971), it will be as if reactance motivation was never experienced.

The strengths of these two forces in response to restriction and restoration of freedom depend on various moderators which influence product desirability and source negativity. The studies presented in this paper examine three variables that moderate responses to restriction (and thus restoration) of freedom: individual levels of reactance, attributions, and product attractiveness. Studies 1 and 2 examined consumer responses to restoration based on chronic levels of reactance. Study 3 used a high-involvement context, and incorporated product attractiveness and attributions about the restriction of freedom as additional moderators.

In our first two studies, individuals went on multiple shopping trips to choose jelly bean flavors from different stores. On one shopping trip, individuals were told that the store was out of their favorite flavor and they would have to make a second choice, but at the last minute, the shopkeeper discovered some additional stock of their preferred flavor. We compared individuals' satisfaction after this unintentional restriction and restoration of freedom to a control condition where they received their favorite jelly beans with no incidents. We also measured individual levels of reactance motivation. We hypothesized that in an unintentional restriction situation, high reactance individuals would feel minimal source negativity and strong product desirability, leading to positive responses to restoration of freedom. Low reactance individuals, on the other hand, would not experience strong product desirability and would instead focus on the service failure aspect of the experience, leading to a negative reaction to restoration of freedom. As predicted, high reactance individuals were more satisfied with the store after having their freedom unintentionally restricted and restored than they were in a control condition. Low reactance individuals showed the opposite results.

Study 3 investigated two additional moderators of responses to restoration: attributions of intentionality and product attractiveness. In Study 3, we manipulated whether individuals perceived the restriction as intentional or unintentional on the part of the store, and we measured product attractiveness. Further, Study 3 used a high-involvement situation (choosing Spring Break vacations) where both high and low reactance individuals should experience reactance. We found that in such a high-involvement scenario, high and low reactance individuals were willing to forgive service transgressions after restoration of freedom, but were particularly forgiving for highly attractive, formerly unavailable products. The exception to this finding was high reactance individuals who perceived the initial restriction of freedom as intentional on the part of the firm—in this case, even if the product was highly attractive, they were much less forgiving.

This work extends reactance theory by proposing a model of how individuals respond to restoration of freedom, and provides a useful framework for understanding when consumers will respond positively or negatively to trangressions and recoveries. We identify conditions under which some individuals are happier to experience a temporary stockout than to have an uneventful service encounter. Further, for most consumers, restoring freedoms by remedying the stockout is an acceptable means of repairing relationships—most individuals' change in satisfaction was positive after restoring freedom. However, the degree of forgiveness depends on individual levels of reactance, product attractiveness, and attributions regarding intentions.

# Ownership: How Thought, Effort, Emotion, and Memory Influence the Desirability of Possessions

Carey Morewedge, Carnegie Mellon University, USA

## ABSTRACTS

### "Effects of Merely Thinking about What One Might Acquire"

*Carey Morewedge, Carnegie Mellon University*
*Daniel Wegner, Harvard University*

Thinking about the possible consequences of behavior before acting-—premeditation—-is often encouraged as a way to make sound decisions. But merely going through the motions of premeditation by considering possible options may be enough to convince people that they received the option they desired—even when such premeditation is irrelevant to its selection. The results of five experiments suggest that people judge the desirability of options selected on the basis of their ability to consider those options in advance, even when this premeditation ritual has no influence the selection process.

### "The "IKEA Effect": Why Labor Leads to Love"

*Michael I. Norton, Harvard University*
*Dan Ariely, Massachusetts Institute of Technology*

We show that people value goods more highly when they invest their own labor in creating them–the IKEA effect. Novices who made origami valued their creations as highly as those made by experts, though outside bidders recognized the difference in quality. While individuals valued sets of Legos they built more highly than sets built by others, however, the effect dissipated when the sets were deconstructed, suggesting that only fruitful labor leads to love. The increased valuation of self-created goods seems to be caused by two dissociable–and seemingly contradictory–components: the pain and pleasure caused by labor.

### "When the Status Quo Turns Sour: Robust Effects of Incidental Disgust in Economic Transactions"

*Seunghee Han, Carnegie Mellon University*
*Jennifer Lerner, HarvardUniversity*

Decision-makers are powerfully motivated to maintain the status quo, even when doing so comes at a cost. But research suggests that disgust triggers a goal to rid oneself of present circumstances and hence may counteract the status-quo bias. Three experiments found that incidental disgust carried over to decisions and eliminated the status-quo bias. Decision-makers were unaware of and could not correct for the carryover, even when explicitly warned to do so. Because all three studies involved real commodities and real behavior, they provide not only theoretical insights into emotion and decision making but also practical implications for economic transactions.

### "Aspects of Endowment: A Query Theory of Value Construction"

*Eric Johnson, Columbia University*
*Gerald Haubl, University of Alberta, Canada*
*Anat Keinan, Columbia University*

We introduce a memory-based account of the endowment effect–the observation that mere ownership of an object increases people's valuation of that object. According to this account, individuals construct their valuations of objects by posing a series of queries whose order differs between owners and non-owners. We show that ownership state influences the nature of the thoughts that come to mind when contemplating a possible trade involving the object, and that these thoughts predict valuations. We also demonstrate that merely altering query order can eliminate the endowment effect, as well as produce endowment-like effects without actual differences in ownership state.

# Subjective Time and Decisions: The Role of Perception and Experience of Time in Consumer Decision Making

Selin A. Malkoc, University of Minnesota, USA

## SESSION OVERVIEW

Almost every decision that a consumer engages in has a temporal dimension. For instance, consumer decisions on which shipping option to choose and how long to wait for service, whether and when to save for future, decisions to keep on waiting on hold when calling customer service or renege from queue, all involve time decisions. While oftentimes the end behavioral variable studied varies, e.g. line chosen, time delivery option, renege or stay; most of them deal with first making a time estimate that is often biased that then leads them to display a downstream behavior. Prior research in different domains have often looked at this problem as either a pure time perception problem or alternatively as an intertemporal decision with the implicit or explicit assumption that time perceptions are unbiased and it is the outcomes valuation that changes at different points in time. Unlike previous research, the three papers in this symposia systematically study how consumers perceive and experience time, and point out the important consumer behavior implications in intertempooral as well as non-temporal settings. Specifically, these three papers explore

- Whether and to what extent consumers' subjective time estimates map onto objective time (papers 1 and 3).
- Whether consumers pay adequate attention to time in their consumption decisions (papers 2 and 3).
- The implications of time insensitivity to intertemporal presences (papers 1 and 2) and to consumer decision making (paper 3).

The first paper by Zauberman, Kim, Malkoc and Bettman critically examines subjective perceptions of different time horizons and consistent with the psychophysical Weber-Fechner Law demonstrate that subjective time is more compressed than objective time. More importantly though, their results show that the commonly reported present bias (i.e., hyperbolic discounting) disappears if discount rates are calculated with subjective time. Their findings suggest that the psychology of time perception, and not simply outcome value, plays an important role in choice over time.

The second paper, by Ebert and Prelec, provides converging evidence by demonstrating that consumers are insensitive to the time dimension of their decisions. They develop a discounting function that separates time sensitivity from impulsivity. More notably, their empirical analyses show that time is especially malleable to insensitivity (compared to other dimensions such as money) and that simple manipulations like time pressure and simultaneous evaluations can alter how sensitive consumers' are to time. They further demonstrate the effect of such insensitivity on a variety of intertemporal decisions.

The third paper, by Janakiraman and Benson, examines the effect of duration of service on subjective estimates of a wait time. Their results show that longer experienced service duration (e.g., time spent while a cashier process items) significantly decreases consumers' estimation of the pre-service duration (e.g., waiting time on the cashier line and their subsequent satisfaction). They further show that this effect is mediated by perceived fairness and is moderated by prior expectations about the wait. The findings of these field and laboratory experiments demonstrate one important way in which sensitivity to duration influences actual consumer behavior.

Collectively, the three papers in this symposium provide new insights about consumer decision making, by focusing on the role of subjective time. Most of the prior research in this domain focused on the valuation of outcomes. Alternatively, these three papers show that consumers might be innately insensitive to time and have biased duration estimates, which affect a variety of consumer phenomena. The first paper illustrates that subjective time estimates are more compressed than objective time and that this difference is sufficient to account for hyperbolic discounting. Further supporting this idea, the results of the second paper indicate that insensitivity to objective time is unique to this dimension and does not present itself in others like money. Lastly, the third paper illustrates one very important consumer implication of malleable time perceptions, by showing that satisfaction with the service can be influenced by subjective estimates of pre-service and service time. Following the three papers, the discussant, Drazen Prelec, will comment on how the three papers inform and qualify the findings of previous research. He will also comment on some of the ways in which the three papers offer diverging perspectives on the common theme of the session. Discussant will then engage the audience by inviting questions, comments, and future research ideas.

## EXTENDED ABSTRACTS

### "Discounting Time and Time Discounting: Subjective Perception and Intertemporal Preferences"
*Gal Zauberman, University of Pennsylvania*
*B. Kyu Kim, University of Pennsylvania*
*Selin A. Malkoc, University of Minnesota*
*James R. Bettman, Duke University*

Research on intertemporal decisions has shown that people are biased towards current or near future events (e.g., O'Donoghue and Rabin 1999; Thaler 1981). In particular, one of the most important and robust findings in choice over time-hyperbolic discounting-demonstrates that the tendency to prefer a sooner-smaller outcome over a later-larger one (i.e., delay discounting) decreases as the time horizon gets longer.

Many models have been proposed to describe and explain preferences that show hyperbolic discounting (e.g., Ainslie 1975; Loewenstein & Prelec, 1992). Although varying in their specifications, all these models have two things in common: (1) incorporating objective time horizon in the model and (2) attributing present bias to changes in the valuation of outcomes at different points in time. That is, all models imply non-constant discounting of value in relation to objective (linear) time. Thus, these models overlook the possibility that how people perceive time (i.e., subjective time horizon) affects the valuation of outcomes over time.

Consistent with the Weber-Fechner Law, in this work we suggest that people are less sensitive to changes in objective time horizon and such insensitivity to time horizon leads to a declining rate of discounting with increased time intervals. Specifically, we predict that when examining individuals' implicit discount rates using subjective assessments of duration (compared to objective, linear duration), they appear more consistent and the discount rates implied in their preferences over time show a reduced level of hyperbolic discounting.

In study 1, we measured subjective mapping of prospective time horizons (3 months, 1 year, or 3 years) and discount rate for

deferring an outcome (i.e., $75 gift certificate) over these horizons. Subjective assessment of time horizon was measured by providing a 180mm continuous line. Results show that subjective time horizon is far more compressed and less sensitive to changes than objective time horizon (time horizon growth: $M_{3\ mos \rightarrow 1\ year}$=24%, $M_{1\ year \rightarrow 3\ years}$=32.33%). For discount rate, we replicated the standard pattern of hyperbolic discounting when objective time was used in the calculations ($M_{3\ mos}$=159.73%, $M_{1\ year}$=82.82%, $M_{3\ years}$=35.67%). However, when subjective estimates of duration are used, discounting no longer follows a hyperbolic pattern, but is instead more constant with time horizon ($M_{3\ mos}$=214.46%, $M_{1\ year}$=276.04%, $M_{3years}$=350.47%). In study 2, we replicated the findings with a within-subjects setting (i.e., 3 months and 12 months). As in study 1, subjective time horizon is less sensitive to changes than objective time horizon (time horizon growth: $M_{3\ mos \rightarrow 12\ mos}$=37%). Furthermore, discounting based on subjective estimates of time is not hyperbolic, but rather it shows the opposite effect ($M_{3\ mos}$= 111.64%, $M_{12\ mos}$=167.09%).

In study 3, we changed participants' perception of time by manipulating sensitivity to time horizon. Prior to the estimation and discounting task (1 month & 3 months), half of the participants in the long time horizon condition considered and estimated the duration of activities that take many years to complete (e.g., completing education including all degrees/breaks). The other half (the short time horizon condition) considered activities that take shorter times (e.g., taking a shower). Results show that participants compressed time horizon more with long time horizon than with short time horizon (time horizon growth: $M_{long;\ 1\ mo \rightarrow 3\ mos}$=50.28%, $M_{short;1\ mo \rightarrow 3\ mos}$=67.44%). Importantly, when discount rates were calculated with objective time, present bias was reduced in the long time horizon condition ($M_{short}$=231.05%$\rightarrow$138.90%, and $M_{long}$=176.57%$\rightarrow$143.22%). When subjective estimates of time horizon are used, discounting is constant with time for those who were primed with short time horizon and increasing with time for those who were primed with long time horizon. ($M_{short}$=295.81%$\rightarrow$250.05%, and $M_{long}$=232.99%$\rightarrow$327.44%).

In conclusion, we show that subjective estimate of time horizon is less sensitive to changes than objective time horizon. When discount rate is calculated using subjective estimates of duration, discounting is not hyperbolic but is either constant or increasing with time. These results imply that people show a hyperbolic pattern of discounting not because they discount outcomes hyperbolically over time, but because their perception of time is not sensitive to changes in objective time. In addition, when primed with long time horizon, hence compressing time horizon more, people show reduced present bias compared to when primed with short time horizon. But even more than the effect itself, these findings provide a different theoretical perspective than other current behavioral theories of intertemporal choice, which all focus on the psychology of perceived value of outcomes over different periods due to either affective or cognitive mechanisms. Our findings suggest that the psychology of time perception, and not simply outcome value, plays an important role in choice over time.

### "The Special Fragility of Time: Time-Insensitivity and Valuation of Near and Far Future

*Jane E. J. Ebert, University of Minnesota*
*Drazen Prelec, Massachusetts Institute of Technology*

The temporal dimension is an unavoidable but problematic component of many decisions. Managers choose between long-term and short-term goals; investors choose how much to put aside for retirement or for the deposit on a house in five years; people exercise to lose weight for an upcoming vacation or to remain healthy in later years; governments decide whether to drill for oil and satisfy demand in the near term or not to drill and preserve the environment for future generations. The value people place on different points in the future matters in such decisions, and evidence suggests that the value people place on the future is not quite what it should be.

Normative concerns often expressed in writings and research are that people are commonly myopic, not valuing the future enough (e.g., as discussed in Ainslie (2001) and Loewenstein (1992) and they discount future utility according to a hyperbolic, rather than compound, function (Ainslie and Haslam 1992; Green et al. 1994; Rachlin et al. 1991), showing dynamically inconsistent choices (Ainslie and Haendel 1983; Green et al. 1994; Thaler 1981), where an individual does not choose according to plans that were optimal from an earlier vantage point.

Here we provide a new theoretical diagnosis, supported by fresh experimental evidence, about the root cause of the problems with time. Consistent with other research that suggests that people are insensitive to or neglect some aspects of time (Frederickson and Kahneman 1993; Redelmeier and Kahneman 1996; Block and Zakay 1997), we propose that in the valuation of future events the temporal dimension is fragile in a dual sense. First, choices are insufficiently sensitive to the temporal dimension. Second, such sensitivity as exists is exceptionally malleable: certain manipulations can easily compromise it while others can easily enhance it. In this respect, we suggest that time behaves differently from other attributes, such as money or outcome quality. Unlike a money amount, which is difficult to ignore, the temporal dimension has an 'optional status' — it can be pushed into the background or become a key concern, depending on incidental aspects of the choice situation.

We conceptualize sensitivity as the impact of time variation on value variation, developing a discount function that allows the separation of impatience from time-sensitivity. In four studies, we show that time-sensitivity is susceptible to manipulations that draw attention to or facilitate processing of the time dimension, while impatience remains unchanged. As a result discounting changes in a characteristic way: with greater time-sensitivity people show less discounting in the near future and more discounting in the far future. In three of these studies, we also find that the time dimension seems especially vulnerable and susceptible to manipulation, relative to other dimensions.

In study 1, we show that time-sensitivity, rather than discounting per se, is enhanced in a within-subject design. Consequently, discount rates measured within-subject rather than between-subject are smaller for the near future, but larger for the far future. In study 2, time-sensitivity is compromised by requiring subjects to make a decision under time pressure. This selective vulnerability of the time dimension obtains even though in the baseline "unlimited time" condition the time dimension shows up as the most important (of three) dimensions in relative weight terms. Hence, time pressure does not simply cause subjects to focus attention on the most important attribute, as one might have supposed. Rather, with pressure, the time dimension becomes neglected in favor of an alternative dimension, one that was less influential with unlimited time.

In studies 3 and 4 we examine further this special vulnerability of the time dimension. Time-sensitivity is enhanced if subjects are asked to attend to the time dimension (Study 3), or are provided with an analogue visual cue (Study 4). However, when these same manipulations are directed toward the money dimension, we do not observe any increase in the influence of money. Hence, the money dimension is attended without specific instruction, or without

visual bolstering of magnitude. This is the case whether time or money is initially the more influential dimension, suggesting that time is naturally neglected in contrast to money, which is naturally carefully attended.

### "How Long You Received Service Determines How Long You Thought You Were in Line: Role of Fairness and Prior Expectations"

*Narayan Janakiraman, University of Arizona*
*Lehman Benson, University of Arizona*

Customers can wait before, during or after a transaction; that is pre process, in-process and post-process (Dube-Rioux, Schmitt, and Leclerc 1988). For example, in a retail checkout scenario, a pre-process wait would occur as one waits in line at a checkout queue; an in-process wait would occur as one has their items being scanned; and a post-process wait would occur after the items are scanned and one is waiting to leave the store. In most service contexts, pre-process waits are considered queue time where the customer is waiting to be served (e.g. call to CVS waiting to be answered), while in-process waits are termed service time (e.g. call time with the pharmacist).

While there exists prior research on the differential effect of delays on these stages of the waits on satisfaction; there exists no prior work on how consumers perceive their wait in queue (pre-process wait) based on how long they have been serviced (in-process wait). For example, imagine the following scenario: A customer calls IRS and waits on a telephone queue for 30 minutes (pre-process wait). Subsequently, she speaks to the IRS representative for either 2 minutes or 20 minutes (in-process wait). Would perceived duration of the time in queue (i.e. 30 minutes), vary due to the length of the service (i.e. 2 or 30 minutes)? Is so, why? In our research we hypothesize that duration of service time is likely to affect perception of queue waits. We base this on the notion that consumers hold norms that relate the length of wait for length of service. Violation of these norms we hypothesize leads to perceived unfairness that subsequently affects perceived duration (Katz, Larson, and Larson 1991).

A 2*2 pretest that tested for queue length (short/long) and service time (less/more) revealed support for the fact that shorter service times exacerbate perceptions of queue waits. A field study was then conducted at a leading supermarket chain. Using stopwatches, actual time spent waiting in line and at a teller was recorded. Customers exiting the line were then asked to provide response to a survey. We found support for the main effect that length of service time does affect perceived duration of wait in queue. We also found support for the fairness mediation hypothesis that the ratio of service time to length of wait in queue triggers differential perceptions of fairness. The second part of the field study at the supermarket asked customers before they entered a queue on a duration estimate for the queue they were in, and for a reasonable wait for the number of items they were carrying. Analysis revealed that prior duration estimates had no effect on subsequent satisfaction, while prior norms on length of wait for items in shopping basket had a large effect.

A lab experiment was then designed that varied the length of time that participants had to wait before they completed a study (pre-process: short/long), the actual length of the study (in-process: short/long) and whether prior knowledge was available about the length of the study (yes/no). This study was also designed to rule out recency effects i.e. all responses on retrospective duration estimates were collected at the same point in time for each condition. A hold out sample of respondents provided process feedback on what thoughts passed through their mind as they were waiting in line and as they were being serviced. Analysis revealed that when individuals had prior knowledge of the service time (i.e. duration of the study) they form norms of reasonable waits; and if individuals have no prior knowledge of the service time (i.e. duration of the study) they actively engage in comparing service time to queue time.

# Influences on Spending: Mental Accounts and Self-Control

Karen Stilley, University of Pittsburgh, USA

## SESSION OVERVIEW

Consumer spending is an under-researched area, which is unfortunate in light of mortgage foreclosures recently hitting an all time high (Knox 2007) and the American personal savings rate hitting a 73 year low (Associated Press 2007). Economists have traditionally assumed that consumers allocate their spending to rationally optimize their utility and that money is fungible. In contrast, the behavioral decision theory literature provides strong evidence that consumers employ a system of mental accounts. Considering the current trend towards overspending, it is important to understand whether consumers' mental accounting practices contribute to the problem or whether mental accounts are an effective method of self-control as has been previously suggested (e.g., Thaler 1985; Thaler and Shefrin 1981).

This session brings together a set of respected researchers to provide insight into the conditions under which mental accounting practices result in overspending vs. when they function as a self-control mechanism. The first two presentations examine mental accounting practices that are related to overspending. The first paper, co-authored by Juliet Zhu, Jack Chen, and Srabana Dasgupta (UBC), extends research on the endowment effect into the domain of multiple transactions by incorporating the notion of limited cognitive resources. Specifically, they show that individuals who are trading in a car pay a *higher* net price because they focus some of their limited resources on negotiating their trade-in rather than the sales price of the car. The second paper, authored by Amar Cheema (Wash U), finds that increases in income and assets affect purchase in a similar manner, while decreases in income decrease purchases more than asset value decreases. This research also shows that consumers tend to discount uncertain decreases, (but not uncertain increases) and that this tendency is correlated with debt.

In contrast, the third and fourth presentations examine consumers' use of mental accounting in an attempt to control their spending. The third presentation, co-authored by Karen Stilley, Jeff Inman (Pittsburgh) and Kirk Wakefield (Baylor), shows that consumers anticipate the occurrence of unplanned purchases and build these expectations into their mental budget for the grocery trip. The fourth presentation, co-authored by Leonard Lee (Columbia), Ziv Carmon (INSEAD) and Ravi Dhar (Yale), extends the work of Trope and Fishbach (2000) to show that priming shoppers to be aware of the potential for high spending activates counteractive self-control mechanisms.

While most prior studies in the mental accounting literature rely on hypothetical choices in a lab setting, the papers in this session cross methodological boundaries to provide robust results. Studies range from lab experiments (Zhu et al. and Cheema) to field studies (Stilley et al. and Lee et al.) to analysis of secondary data sets (Zhu et al. and Cheema). Providing strong external validity, each paper in our symposium supports findings with real world data. From a theoretical perspective, this session builds a bridge between research in mental accounting and more traditional psychological theories by incorporating research in cognitive processing (Einstein and McDaniel 1987), counteractive self-control (Trope and Fishbach 2000), and in-store stimuli (i.e., Heilman et al. 2002; Bettman 1979).

## EXTENDED ABSTRACTS

### "Exploring the Effect of a Trade-In on Consumers' Willingness to Pay for a New Product"

*Rui (Juliet) Zhu, University of British Columbia*
*Xinlei (Jack) Chen, University of British Columbia*
*Srabana Dasgupta, University of British Columbia*

Consumers commonly engage in replacement purchases, where they replace an existing product with a new product. In such situations, the existing or used product is often exchanged or *traded in* towards a reduction in the price of the new good. A distinctive feature of such trade-in transactions is that a consumer typically needs to negotiate two prices, one for the new product and another one for her existing product. This raises the question of whether the existence of the trade-in transaction creates any advantages or disadvantages for the consumer. For example, will the price that the consumer receives for the new good differ depending on whether there is a trade-in or not? Are consumers better off trading in their used product toward the purchase of the new one from the same retailer or should they keep the two transactions separate by dealing with different retailers? This paper promises to shed light on these questions.

We theorize that when a consumer engages in a trade-in, due to the endowment effect (Thaler 1980) and mental accounting principles (Thaler 1980, 1985), she is likely to perceive the trade-in value of the currently owned product to be highly important, and thus spend a considerable amount of resources on negotiating the trade-in price. Because individuals have limited resources at a given time, more resources allocated to the more important task would result in fewer resources available to respond to a less important task (Einstein and McDaniel 1987; Zhu and Meyers-Levy 2005). This implies that a trade-in consumer will have few resources left in negotiating the purchase price of the new good and should therefore be more tolerant of a high purchase price. In contrast, individuals who are involved in a single transaction, such as the purchase of a new good, only have one task to focus on and are simply looking for the lowest price possible. Thus, compared to individuals who are simply buyers, trade-in consumers may spend fewer resources on the new product transaction and perceive it as less important. As a result, trade-in consumers may be willing to pay a higher price for the new product than buyers alone. On the other hand, due to the endowment effect, trade-in consumers and sellers (e.g., a consumer who only sells her used good) are likely to perceive the used product transaction as equally important. Therefore, their WTA price for the used product should be equivalent.

We first test the above hypotheses through a series of lab experiments. Participants were asked to imagine engaging in either a trade-in or buying/selling alone transaction. For example, in one study, participants imagined one of the following three scenarios: trading in their used vehicle to purchase a new one, buying a new vehicle, and selling their used vehicle. Participants were provided with information regarding the new and/or used vehicle. After reviewing relevant product information, participants were asked to estimate a WTP price for the new product and/or WTA price for their used product. Across a number of different product contexts (e.g., automobile, house, piano), we consistently found that whereas sellers alone are likely to estimate a comparable WTA price for their used product as trade-in consumers, buyers alone are likely to

estimate a much lower WTP price for the new product compared with trade-in consumers. We further demonstrate that perceived importance toward the used car transaction is the underlying mechanism for the above effects. In addition, we demonstrate that the observed effects are not due to income effect (i.e., trade-in consumers pay more for new car because they have more cash due to the used car trade-in). Finally, to lend external validity to our lab findings, we examined real world field data from the automobile market. Specifically, after controlling for various other variables which may have an impact on the negotiated price, we were able to show that trade-in customers end up paying, on average, an amount of $452 more than customers who simply buy a new car from the dealer. This systematic difference in prices offers additional support to the hypothesis that trade-in consumers are willing to pay a higher price for the new vehicle than non-trade-in customers.

This research makes several important contributions. First and foremost, it advances the well-documented endowment effect by suggesting that it not only affects consumers' WTA for their currently owned product, but also their WTP for a new/upgraded product they intend to buy in a related transaction. Second, this research adds to the buyer-seller differences literature by investigating situations where consumers act as both sellers and buyers simultaneously and arguing that such trade-in consumers tend to place heightened importance on the trade-in value of their used product, and therefore exhibit a higher WTP for the new product compared to those who only buy the new product. Finally, this research promises to offer rich managerial implications as to how to better understand consumer psychology when multiple transactions are involved and thus offer implications for how to effectively manage the process.

### "A Reason to Spend? The Effect of Unexpected Price and Wealth Changes on Hedonic Purchases"
*Amar Cheema, Washington University in St. Louis*

#### Theoretical Background

Individuals often seek justifications for their decisions (Shafir, Simonson, and Tversky, 1993). This is especially true for purchases of hedonic items because such decisions evoke guilt (Kivetz and Simonson 2002; Prelec and Loewenstein 1998). Consequently, marketing activities that provide justifications for hedonic purchases prove to be highly effective. Indeed, research suggests that justifications such as price discounts and charity donations associated with hedonic products increase likelihood of purchases more than those associated with utilitarian products (Khan and Dhar 2007; Strahilevitz and Myers 1998). Using a motivated reasoning perspective, we argue that individuals considering the purchase of a hedonic product (e.g., a vacation package) will be more likely to purchase when price decreases provide them a justification to do so (Amir and Dawson 2007; Kunda 1990; Okada 2005). We also study how unexpected increases in wealth (i.e., windfall gains) affect individuals' purchase likelihood of hedonic products. Consistent with prior research on unexpected gains (e.g., Arkes et al. 1994; Heilman, Nakamoto, and Rao 2002; Soman and Cheema 2001), we propose that individuals use unexpected wealth increases to justify hedonic purchases in a manner similar to price decreases.

Furthermore, we explore the effect of unexpected price increases and wealth decreases on purchase likelihood of hedonic products. These changes provide individuals with a reason *not* to spend and are inconsistent with a motivation to purchase. Thus, motivated individuals may try to ignore these changes, when possible. We expect that individuals will be successful in mitigating the effect of these changes when the changes are more (vs. less)

uncertain (e.g., Shelley 1994). In the present research such a process of ignoring unexpected decreases reveals that uncertain wealth decreases (e.g., drops in stock value) are discounted to a greater extent than are relatively more certain wealth decreases (e.g., drops in income), even when both these assets are earmarked for the hedonic purchase to control for fungibility differences (Shefrin and Thaler 1988).

A consistent pattern of spending more when values of assets increase, while not decreasing spending when asset values decrease, would likely lead individuals to spending more than their means. Using the 2004 Survey of Consumer Finances, we study how the tendency to spend asset value increases is correlated with individual debt. We find that asset value spenders have higher overall debt, larger mortgages, and greater amounts of outstanding credit card debt, than do individuals who are unlikely to spend asset value increases. We conclude with implications of our results for individual finances.

#### Overview of Studies

We study the effect of unexpected changes in prices and wealth across three studies. Study 1 used undergraduate students who have funds earmarked for the hedonic purchase (thus controlling for fungibility differences). We find that an unexpected price decrease is sufficient to prompt purchase, irrespective of changes in individuals' wealth. However, among individuals faced with an unexpected price increase, individuals whose wealth increases are more likely to purchase (versus individuals whose wealth decreases). Furthermore, (less uncertain) income decreases lower purchase to a greater extent than (more uncertain) stock value decreases, while income and stock increases affect purchase in an identical manner. Study 2 replicates this asymmetric effect with relatively older, non-student individuals, using a budgeting scenario that manipulates the overall portfolio of individual assets. In addition, we identify an important individual difference measure (individuals' propensity to spend more when asset values increase) that is correlated with the effect of asset value increases on purchase.

Study 3 uses data from the 2004 Survey of Consumer Finances to study how individuals' propensity to spend asset value increases relates to measures of individual debt. We find that individuals who are more likely to spend asset value increases have higher overall debt than those who are less likely to spend asset value increases. More specifically, the former have higher credit card debt and mortgages than the latter. Taken together, these results suggest that individuals use a motivated reasoning approach to discount the impact of uncertain wealth decreases on spending, while allowing uncertain wealth increases to increase purchase likelihood. A consistent pattern of such motivated reasoning likely leaves individuals spending more than their means, contributing to greater individual indebtedness and higher interest payments.

#### Implications

*Increasing purchase likelihood.* Price discounts are one of the most popular tools used by marketers to increase store visits and purchase likelihood (Blattberg, Briesch, and Fox 1995), providing individuals with price savings as well as non-price benefits (Chandon et al. 2000). Recent research suggests that these non-price benefits may be more pronounced for hedonic versus utilitarian products (Khan and Dhar 2007). In addition to emphasizing price savings when individuals are considering purchases of hedonic products, another method of increasing purchase likelihood may be to emphasize unexpected wealth increases. Indeed, stores often allow individuals to file for tax refunds in-store, and use the unexpected

wealth increase to purchase products. Emphasizing other sources of unexpected wealth increases (e.g., stocks when the bourses are on the rise, or home values when real estate is appreciating) may also prompt higher individual spending.

*Individual debt.* Individuals often use mental accounts to control their spending and consumption (e.g., Thaler, 1999). However, unexpected asset and income changes may allow individuals to justify indulging in otherwise constrained activities. We find that motivated individuals use wealth changes selectively to justify purchases of hedonic products: while decreases in value of uncertain assets are discounted and affect purchase likelihood less than income decreases, increase in the value of uncertain assets affects spending in a manner similar to income increases. One consequence of spending asset value increases is higher individual debt when these increases cannot be supported by income increases, as demonstrated in study 3 by data from the 2004 SCF.

### "Planning to Make Unplanned Purchases? The Role of Discretionary Budgets In In-Store Decision Making"
*Karen M. Stilley, University of Pittsburgh*
*J. Jeffrey Inman, University of Pittsburgh*
*Kirk Wakefield, Baylor University*

Researchers and practitioners alike have commonly assumed that unplanned purchases (i.e., Heilman, Nakamoto and Rao 2002; Park, Iyer and Smith 1989) are largely due to consumer susceptibility to in-store stimuli. On the other hand, two major studies have reported the surprising finding that actual spending closely approximated spending intentions despite the fact that over 50% of purchases were unplanned (Kollat and Willett 1967; POPAI 1995). In this paper, we draw upon mental budgeting to provide an explanation for this paradox.

While economists have traditionally assumed that money is fungible, research has shown that consumers use a form of mental budgeting where they allocate money to mental accounts and resist further purchases when the budget is depleted (Heath and Soll 1996; Thaler 1985). While studies have found that consumers have budgets for groceries in general (Heath and Soll 1996; Heilman et al. 2002), we take this further to propose that consumers have a mental budget, even if implicit, at the shopping trip level. Furthermore, we posit that consumers anticipate the occurrence of unplanned purchases in their spending expectations because they realize they do not have enough time or cognitive resources to fully plan (i.e., Bettman 1979) and/or because they want to be able to make spontaneous decisions while in-store (e.g., Stern 1967).

Therefore, we first propose that consumers' shopping trip budgets are typically comprised of a *pre-allocated budget* (PAB) and a *discretionary in-store budget (DIB)*. We conceptualize the *PAB* as the amount of money that the consumer has allocated to spend on items planned to the brand or product level and the *DIB* as the amount she expects to spend on unplanned purchases. We then make predictions about how the size of the DIB will vary depending on trip and consumer characteristics.

We employ two field studies to test our hypotheses. In Study 1, we use data from 2300 in-store intercepts from the Point of Purchase Advertising Institute's (POPAI) 1995 Consumer Buying Habits Study. Before they entered the store, respondents were asked what items they planned to purchase and how much they intended to spend. After they had checked out, interviewers recorded information regarding the actual items purchased and the actual amount spent. Since this dataset does not contain a direct measure of the PAB or DIB, we employ a two stage approach to test our hypotheses. In the first stage, we conduct a multiple regression analysis with planned spend as the dependent variable and use these results

to generate estimates of each consumer's PAB and DIB. In the second stage, we use our estimates of PAB and DIB to simultaneously conduct two multiple regressions where the dependent variables are number of unplanned purchases and amount spent. In Study 2, we conduct a field study with 100 respondents. In this study, we replicate the method employed by POPAI, however, in addition to total planned spend, we also ask respondents to estimate the cost of the items they planned to purchase (i.e., their PAB). This approach allows us to measure the respondents PAB and DIB. In addition, we measure psychographics such as planning tendency and shopping task orientation.

In both studies, we find incidence of the discretionary in-store budget. Consumers' mental budget for the trip includes room for unplanned purchases and the size of the DIB is a strong predictor of amount spent on unplanned purchases. Furthermore, we find consistent support for our hypotheses that the size of the DIB varies depending on trip and consumer characteristics. As predicted, we find that the DIB is larger for major trips than for fill-in trips and that this difference increases as household size increases. We also find that while higher income households have larger DIBs, they still exceed their larger budget by a greater amount. In Study 2, we show that an individual's shopping task orientation and, on major trips, their planning tendency are negatively related to the size of their DIB. Finally, we show that consumers spend $0.50 per dollar in their DIB when they shop only the aisles where they need something, but spend $0.95 per dollar in their DIB when they shop most aisles.

Our results have implications for both retailers and consumers. For retailers, this research suggests that in-store stimuli may simply serve to redirect *what* items consumers purchase rather than to encourage incremental spending. As a result, in-store stimuli may not actually be generating incremental sales. For consumers, more research is needed to determine whether a DIB is an effective technique for constraining spending or whether the DIB is creating a self-fulfilling prophecy that consumers buy unplanned items that they do not really need.

### "The Prudent Shopper: Self-Control in Shopping"
*Leonard Lee, Columbia University*
*Ziv Carmon, INSEAD*
*Ravi Dhar, Yale University*

Consumers are often portrayed as victims of modern retail environments. They seem to respond readily to the arsenal of purchase triggers employed in retail stores, be they explicit marketing devices such as posters, sale signs, and product sampling (e.g. Anderson & Simester 1998), or more implicit cues within the shopping environment such as carefully selected background music and scents (e.g. Kotler 1973, North, Hargreaves, & McKendrick 1999). Indeed, much empirical research documents the substantial effectiveness of a wide variety of marketing actions at boosting sales (see, for example, Neslin 2002 for a comprehensive review of sales promotion effects).

In a series of field experiments conducted at a local convenience store, we demonstrate that consumers can sometimes oppose spending influence attempts: purchase inducing cues, instead of motivating consumers to spend, can sometimes backfire, making more salient the possibility of diverging from the higher-order goal of acting prudently by overspending, and putting consumers into a more frugal state of mind instead to the extent that these consumers can end up spending less than they otherwise would (Fishbach, Friedman, & Kruglanski 2003, Trope & Fishbach 2000). In each experiment, we monitored and analyzed consumers' spending behavior under different conditions. Across all three experiments,

we consistently employed an offer of a shopping basket as the primary vehicle via which we prompted store customers to spend, hence making salient the possibility of overspending to consumers and potentially triggering them to monitor their shopping.

Experiment 1 (*N*=356) was designed to investigate the basic effects of external spending triggers on consumer spending. Two hundred customers were randomly assigned to one of two experimental conditions. Upon entering the store, half of these customers were first offered a $1-off coupon by a research assistant disguised as a store clerk; immediately after the customers accepted the coupon, the research assistant offered them a regular shopping basket from the store ("basket-offered" condition). During the same time that we conducted this experiment, we also collected the shopping receipts of (156) customers who were offered neither the coupon nor the shopping basket (control condition). Whereas those who were offered only the coupon did not differ in average spending compared to control customers who were offered neither a coupon nor a basket (*p*=.94), customers who were offered both the coupon and the basket spent significantly less than those in the other two conditions (both *ps*<.05). In two follow-up prediction studies (using both a between-subjects design and a within-subjects design), we showed that this prudent shopping effect conflicts with lay beliefs: respondents in both studies mispredicted that customers offered a shopping basket would spend more, not less. Consistent with Fishbach, Friedman, and Kruglanski (2003), these studies also suggest that the activation of the prudent shopping goal (as a result of a spending prompt) is automatic.

An underlying assumption of our self-control account is that cognitive resources are required for deliberately exercising vigilance and prudence in spending (Baumeister et al. 1998, Shiv & Fedorikhin 1999) even if the initial activation of the prudent spending goal can be automatic (Fishbach, Friedman, & Kruglanski 2003). In our shopping context, this assumption implies that when consumers experience significantly reduced cognitive capacity, they should be less capable of exercising self-control when confronted with spending motivators and could perhaps spend even *more* than they normally would. We thus sought support for the self-control account in Experiment 2 (*N*=150) by manipulating consumers' cognitive ability to exercise prudence during shopping. In this experiment, customers who entered the store were approached before shopping for an experiment purportedly designed to study "the effects of shopping on memory." Half the customers were asked to memorize a random two-digit number ("low-load" condition), whereas the other half were asked to memorize a random eight-digit number ("high-load" condition); all participants were also given both a $2-off coupon and a shopping basket and told that they would have to reproduce the correct number upon exiting the store after shopping to qualify for the $2 coupon redemption. The results of this experiment revealed that customers under higher cognitive load spent significantly more, compared to both customers under lower cognitive load and those in the control condition who were not given the memorization task (both *ps*=.04), corroborating the self-control account in explaining the prudent shopping effect.

In Experiment 3 (*N*=120), we tested the self-control account more directly by examining both the situational and chronic mindsets of consumers after being prompted to spend. Specifically, using a post-shopping survey, we (1) examined consumers' attitudes toward spending (i.e. how frugally they spent) after receiving a basket offer (Lastovicka et al. 1999), and (2) considered the degree to which the prudent shopping effect depends on consumers' chronic impulsiveness to spend (Puri 1996). Consistent with our predictions, the results revealed that the prudent shopping effect was more pronounced among impulsive shoppers who would benefit more from external cues that reminded them to be cautious not to overspend (*p*<.05). Results from the post-shopping survey also indicated that customers who were prompted to spend with a shopping basket offer rated themselves as more frugal compared to those who did not receive the basket offer (*p*=.03), further supporting the self-control account.

Overall, our results suggest that some marketing initiatives designed to increase consumer spending may backfire with some consumers in that they might suppress rather than boost spending. Further research is needed to examine such implications as well as boundary conditions for this prudent shopping effect.

# The Ties That Bind: Transnational Families, Transnational Consumption
Mary C. Gilly, University of California, Irvine, USA

## SESSION OVERVIEW

The theme of this year's ACR conference is "Building Bridges." This session explores the theme from the perspective of bridging consumptionscapes across cultures and nations. The focus of this session is transnationalism and the effect on consumption in both an intra- and inter- national context. The three presentations together attempt to explore the impact and the consequences of "intranational and international cultural interpenetration" per Andreasen (1990, p. 848). Andreasen advocates that with the accelerating rates of immigration, it is the responsibility of consumer researchers, both for advancement of our knowledge and for societal benefit, to attempt to describe and explain both the nature of the cultural interpenetration and the consequences for both the immigrant and the penetrated cultural groups (Andreasen 1990). In this session we focus on families; families who have transcended the limitations of national boundaries, functioning in essence as bi-national units. As the authors examine these transnational families in three different settings and three different contexts, they analyze not only the effects of cultural penetration on consumption within the receiving or host societies, but take into account the impact on the originating or home countries as well.

The first paper examines bi-national households in the U.S., comprising two national combinations: specifically U.S. born spouses married to either Mexican or Filipino immigrants. In this study, bi-national households refer specifically to households with partners from two different countries of origin, where the country of residence is both the host and home country for the immigrant and native spouse respectively. It becomes clear that the intersection of the two cultures in these households exacerbate several of the decision making issues that come to play in any household, and has an impact on the bases of power, decision making influence and consumption preferences of the family unit.

In the second presentation, the authors narrow in on consumption behaviors in families that extend across national borders. The focus is on the flows of consumer products, services and capital which spans the economies of the U.S. and Mexico; the remittances sent by family members working in the U.S. to their families in Mexico. Peñaloza and colleagues explore the transnational consumptionscape of Mexican emigrant workers and their families in Mexico, specifically the manner in which these transmitted resources are consumed in Mexico and the impact on social relations within the family and within the families' wider social networks.

The final paper complements the first two as Üçok and Askegaard study transnational families in Denmark; Turkish immigrants who travel to and fro and have formed a link between their different worlds in Denmark and Turkey. In this paper, these Turco-Danish transmigrant consumers attempt to construct living spaces for themselves in both countries, as they move back and forth between the two cultural contexts. They go beyond the boundaries of nation states, creating in essence a transnational social and consumption space, based on the transference and conversion of economic, social and cultural capital between the two countries.

These three papers combined offer differing theoretical perspectives of the relative influence of capital resources within the family, drawing on Bourdieu's conceptualization of economic, social and cultural capital within a particular realm of consumption–that of the transnational family unit. This session thus provides an excellent cross-national and cross-contextual comparison of the

same phenomenon: examining consumption behavior in families who operate within, between and beyond different cultural frames.

## EXTENDED ABSTRACTS

### "For Better or For Worse: The Intersection of Cultures in Bi-National Homes"

*Samantha N. N. Cross, University of California, Irvine*

The bi-national family unit formed through the marriage of two individuals from different cultural backgrounds, can be seen as a crossroads, an "intersection" between two clearly delineated modes of thinking, patterns of beliefs and social constructs that define the concept of culture. This intersection of cultures is necessarily multidimensional in nature as manifested through the relationships between the spouses, the internal family dynamics, the external relational ties and support networks, and the consumption patterns of the household. Yet, despite the increasing globalization of markets and communication, the trans-national movement of knowledge and people, and the inevitable rise in the number of intermarriages between individuals from different countries and cultural backgrounds, the view of the family in decision making research has been as a homogeneous cultural unit. The culturally heterogeneous household has been virtually ignored by the literature.

Over the past 50 years, research studies in household decision-making have focused on marital roles, exploring the relative influence of gender on decision making roles (Davis 1970; Green and Cunningham 1975; Shuptrine and Samuelson 1976) and the decision-making process (Davis and Rigaux 1974; Putnam and Davidson 1987; Ford, LaTour and Henthorne 1995). Research has shown that the base of conjugal power in a particular household often drives gender differences in marital roles (Wolfe 1959; Blood and Wolfe 1960; Raven, Center and Rodrigues 1975), and that these gender differences have changed and evolved over time, as marital roles have become more egalitarian, with fewer traditional gender divisions (Qualls 1987; Lackman and Lanasa 1993; Belch and Willis 2002). Studies on household decision making have also been conducted in different countries (Davis and Rigaux 1974; Webster 2000), as researchers have discovered that marital roles and the bases of conjugal power differ across cultures and nationalities (Rodman 1967; Rodman 1972; Brown 1979; Green et al 1983; Webster 1994; Ford, LaTour and Henthorne 1995). However, this recognition of the importance of the cultural framework has been limited to the examination of "monocultural" families within a particular cultural context.

This research project addresses that gap in the literature, adding to the knowledge base on household decision-making, through an investigation of the effect of cultural diversity on decision roles, power dynamics and consumption within the bi-national household. This study makes a public policy contribution, adding to our overall understanding of the adaptation patterns of immigrant populations in the U.S. today, an increasingly important consumer segment. This analysis may also help managerial and political decision makers to appreciate some of the dynamics involved in cross-cultural interactions at the most fundamental group level–the level of the family.

The study answers the following key research question: How does cultural diversity within the family affect the decision making roles and bases of conjugal power in the household? Hence, the

purpose of this study is to explore the influence of culture of origin and culture of residence on purchase decision roles, decision influence and consumption within the family unit. This research focuses on bi-national households with partners from different countries of origin, particularly where one partner is an immigrant to, and the other partner is a native of, the U.S. This paper seeks to examine not only who makes the decision, but also the context in which the decisions come to be made, both during the formative and maintenance phases of the household. Thus an additional research question asks: What are the types of decisions that prevail in the formative stages of the household and how do they impact later decisions that support the maintenance of the bi-national household?

Since there are few studies within marketing on the impact of culture on the consumption decisions of monocultural immigrant families (Wallendorf and Reilly 1983; Peñaloza and Gilly 1986; Peñaloza and Gilly 1999; Webster 2000), and little to none on the role of culture within bi-national families, the author takes a discovery-oriented approach to data collection and analysis. The analysis focuses on data derived through short surveys and depth interviews with eighteen spouses. The survey data are mapped using a trio of feasibility triangles, based on the work of Wolfe (1959), Davis and Rigaux (1974) and Putnam and Davidson (1987). The results are then elaborated by the interview data.

Thus, this study makes both a methodological and theoretical contribution to the family decision-making literature. The combination of methods used to collect and analyze the data supports the notion that multimethod research can provide a richer view of the phenomenon of interest. In addition, this study augments the knowledge base in the family decision-making literature through an examination of the power dynamics and consumption decisions in intrinsically diverse households. While the established bases of conjugal power (French and Raven 1959, Raven et al. 1975) are still held as valid within this context, expertise as a source of power, is shown to have different dimensions. Cultural competence as a power base, both as a facet of cultural capital and as an aspect of expert power in family decision making, emerges as an overarching theme. Additionally, decisions relating to vacations, children's schools, and food consumption are seen as both exacerbated and constrained by the often starkly different backgrounds and preferences, and the need to maintain psychological and familial ties with family members in the immigrant spouse's home country. Decisions made in the formative phase of the household, e.g. where to live, also become more salient due to the need to factor in the differing national origins. These early decisions are also seen to have a significant impact on future levels of decision influence in consumption choices. These findings clearly have implications for family-decision making theory, specifically the bases of conjugal power and the dynamics of cultural diversity.

## "Within Families, Beyond Borders: The International Social Structuring of Consumption in Mexico"

*Lisa Peñaloza, EDHEC and University of Utah*
*Judith Cavazos Arroyo, Universidad Popular Autónoma del Estado de Puebla*

Over 15 years ago Appadurai (1990) characterized disjunctions and difference in the global cultural economy, with consumptionscapes as one of five substantive domains. This work explores the contours of one such transnational consumptionscape, that for Mexican emigrant workers and their families in Mexico. Mexican immigrants number approximately 12 million in the U.S., and collectively sent over 22.9 billion dollars to Mexico in 2006 (London Guardian 2006). Previous work has highlighted push and pull factors motivating Mexican migration, the contours of immigrants' consumption behaviors in the U.S., and its embeddedness in transnational economic, social, and cultural networks (Peñaloza 1994; Rouse 1992). This work brings together work on consumption behavior with work on the postmodern family and on transnational social class in better understanding family consumption in the increasingly global economy.

First, as transnational consumption scholars have noted, most of our foundational consumption knowledge is based on a single national domain, and requires significant conceptual and methodological work to examine transnational consumption phenomena (Üçok 2007; Askegaard et al. 2005; Ger and Belk 1996). In this research we build upon previous work charting the nature and scope of the flows of money, products and services, and people, as they pertain to the nature and impacts of international movements of consumption meanings and values for families that transcend Mexican and U.S. national borders.

Second, we view the family as a coping social structure, and seek to extend previous work theorizing family adaptations in composition and function in relation to changing social, economic, and historical circumstance (Chauncey 2004; Stacey 1990; Zaretsky 1976). Our focus is on members who move from Mexico to the U.S. for better jobs, education, and standard of living, etc., and who retain family ties in Mexico, as we examine their effort, capital, and consumer behavior in making their families work. Thus various consumption technologies are relevant, in the form of internet mediated connections, international financial transfers, shipping and transportation services that foster and/or inhibit emotional, economic, and cultural ties important in maintaining, reuniting, and reinscribing family in the U.S. and Mexico. Such consumption is marked by visits, participation in holidays and other cultural rituals and rites of passage such as weddings, birth, death, and graduation, or when visits are not possible or desirable, by the transmission of currency and/or gifts.

The third leg of our theoretical framework hones in on the recursive nature of consumption and social status (Bourdieu 1984), in exploring how national hierarchies change with such transnational family consumption. Analysis sifts through the malleable versus anchored nature of social distinctions within the nation-state, with attention to how they are affected by consumption that extends across national contexts. Our hope is to extend previous work emphasizing hybrid cultural forms as the result of globalization (Ger and Belk 1996) by mapping their particular patterns and processes. Of particular interest is tracing the impacts of forms of consumption (i.e., products/services, fashions, and ideas) informants associate with the U.S., as they circulate with and against forms of consumption associated with Mexican culture.

Our research design entails depth interviews with ten families living in Mexico that vary in relation to the Mexican emigrant worker, as well as in family composition, social class, age, gender, and rural/urban residence. Interviews begin with daily life in Mexico, particularly consumption of particular products and services, and then proceed through family, community, and national activities and events. We then inquire about family members working in the U.S., what they do, and how often they communicate and visit, ultimately turning to the types of items and amounts of money they send and its uses and significance to family members and in the community.

We hope to contribute to knowledge of transnational consumption behavior in better understanding how it manifests and operates in families and social class hierarchies that traverses national boundaries.

## "Capital Build-Up and Transfer: The Case of Turco-Danish Transmigrants"

*Mine Üçok Hughes, University of Southern Denmark, Odense*
*Søren Askegaard, University of Southern Denmark, Odense*

This research demonstrates how immigrants whose lives stretch between Turkey and Denmark allocate their financial resources between these two countries and the reasons behind these decisions. The point of departure for this investigation is the application of a transmigrant (Basch, Schiller & Blanc 1994) perspective on these immigrant consumers, stressing that they are trying to construct living spaces for themselves in *both* home and host cultures. They

thus differ from other types of migrating populations, e.g. cosmopolitans (Thompson & Tambyah 1999) in that they are generally not free movers in the global ethnoscape (Appadurai 1990) but firmly rooted in life and identity projects in only two cultural contexts, what we could call a home and a host culture using the standard terms of immigration research.

We adopt Bourdieu's (1984) notions of social and cultural capital as our main theoretical construct. In addition to the economic capital, which is central to most classical social and consumer research, Bourdieu integrates two more types of capital, cultural and social (which he also calls symbolic), into his analysis. The economic capital is one's financial assets, the social capital is the social networks and group memberships one has, and the cultural capital is mainly related to the general knowledge associated with arts and style of living that one acquires, usually through the family which one is born into and education acquired through formal institutions and family. He argues that, the 'cultural capital' and 'social capital' are often ignored as their transmission is more disguised than the economic one. To Bourdieu (1984) capital signifies power, and forms of capital can be transformed into one another under certain circumstances. Holt (1998) has demonstrated the usefulness as well as the need for contextualization of Bourdieu's conceptual apparatus for consumer research also outside the French context in which it was created.

Thirty-one informants consisting of families and single persons were studied using interviews, participant observations and photography in multiple sites in Turkey and Denmark. The multisited ethnography allowed us to observe the differences in lifestyles of informants in their home and host societies in terms of their economic, social capital and cultural capital. The study focused on economic dispositions, possessions and spending patterns in Denmark and Turkey respectively. Also included were themes on ethnicity and identity, the degree of transmigration present in the lives of the informants and their hopes and expectations of their future.

As indicated by our previously mentioned "transmigrant perspective", the discussion presented in this paper does not claim true for all Turkish immigrants included in the research. It is about a subgroup of the studied informants, with particular investment characteristics. These group of transmigrants, labeled as "myth of returners" in a previous related article by Ucok and Kjeldgaard (2006), tend to divert their investments mainly to Turkey. These investments include land, estate, bank deposits, shares in Turkish companies, and gold coins and jewelry.

The main reasons for investing in Turkey are historical, economical and social. Historically immigrants from Turkey migrated to Europe as guest workers, temporary workers that intended to save money and return to their countries. Initially, their temporary stay in Denmark was the main reason for investing in Turkey. Economically, the discrepancies between the economies of Denmark and Turkey make it attractive to invest in Turkey. While the high taxes supporting the Danish welfare system have been creating incentives for the immigrants to engage in black economic activities and yielding extra income, the Turkish financial system has been making it attractive for them to deposit their remittances in Turkish banks. Socially, the increase in their economic wealth, in other words their economic capital, means the increase in their social capital. Being a landowner and having economic wealth allow them to have a higher social status in their hometowns that they once left as poor peasants.

The economic capital of Turkish immigrants in Denmark is on a par with at least parts of the native Danish population due to a well functioning welfare state that allows a fair income distribution and equal job opportunities. However, Turkish immigrants often lack social and cultural capital in Denmark that would allow them to better integrate into the Danish society. What they lack in Denmark, they try to compensate in Turkey and they do this through accumulation of economic capital.

Based on our findings, we construct a model illustrating the flow and conversion of economic, social and cultural capital between the Danish and Turkish contexts. One of the main arguments is that economic capital gained in the host cultural context is transferred into social and cultural capital in the cultural context of origin. This flow is throwing new light on acculturation processes as they have been described in the consumer behavior literature (e.g., Peñaloza 1994, Askegaard, Arnould & Kjeldgaard 2005). It also extends the knowledge of the role of consumption for Turkish immigrants' identity construction (Ger & Østergaard 1998).

This model accentuates, how external and self-imposed barriers for capital conversion, especially between economic and social capital, in the host cultural context, lead transmigrants to engage in other kinds of capital transfer oriented towards the home culture, reinforcing the transmigrant character of their lives. The results thereby extend the findings of Ça?lar (1995) from the business market to private consumption sphere. Our results finally have implications for Danish immigration policy, since they point to the role of consumption patterns and capital build-up as central factors in relation to successfulness of political attempts to ensure a better integration of Turkish (and other) immigrants in Danish society.

# Alternative Perspectives on Consumer Judgment and Choice

Itamar Simonson, Stanford University; USA

## SESSION OVERVIEW

Consumer studies of judgment and choice, like decision research more generally, have tended to adopt a narrow point of view or a particular method of investigation, without trying to examine the same phenomena from different perspectives. As is well-established, the perspective (or frame) and approach that are adopted at the outset of a study can often have a major impact on the findings and conclusions derived from the investigation. Although one can contrast the findings of separate investigations in order to learn about a problem from different perspectives, variations in concepts and methodologies often limit our ability to make such comparisons.

Accordingly, the main objective of this session is to advocate and illustrate the application of different approaches and perspectives within the same investigations of judgment and choice phenomena. Each of the three papers in this session examines judgment and/or choice phenomena from two different perspectives, focusing on the implications of each perspective with respect to our understanding of the underlying processes and the derived predictions and explanations. We hope that the multi-perspective approach advanced in the session will have a broader impact on future investigations of consumer judgment and choice behavior.

The paper by Sood, Rottenstreich, and Trepel contrasts predictions from traditional approaches for studying anchoring and adjustment with predictions from a dual process perspective. Traditional models do not distinguish the types of stimuli that may engender greater or reduced anchoring effects. Using a dual process framework, they show that stimuli that are reliably judged by "System 1" are not subject to anchoring effects whereas stimuli that typically invoke "System 2" are subject to anchoring effects. Consistent with their analysis, they show, for example, that differences in anchoring effects depend on whether the judgments were regarding personal taste or more complex judgments.

The paper by Gao and Simonson examines two perspectives regarding the consumer decision making order and its impact on the resulting choices. One perspective focuses on situations in which consumers first decide whether to choose and then make a selection from a set of options; the other perspective reverses the order, with the option selection decision coming first followed by the decision whether to make any choice. Across a wide range of problems (e.g., asymmetric dominance, assortment size effect, vice vs. virtue choices), they show that the Option selection→No/Buy order is driven by the relations among options whereas the No/Buy→Option selection order highlights overall features of the set.

The paper by Simonson contrasts the currently dominant notion that consumer preferences are constructed with an alternative view whereby revealed preferences reflect both constructed and *inherent preferences*. Briefly, this paper proposes that much of the evidence for preference construction reflects people's difficulty in evaluating absolute attribute values and tradeoffs and their tendency to gravitate to available relative evaluations. A nonconstructive concept of *inherent preferences* is then presented, suggesting that it is often meaningful and useful to assume that people are non/receptive to certain object configurations, including those that may not yet exist. This notion may have far reaching implications for our understanding of preferences and for consumer research.

## EXTENDED ABSTRACTS

### "Exploring Boundary Conditions for Anchoring by Contrasting Traditional Approaches and Dual Process Models"

Sanjay Sood, University of California, Los Angeles
Yuval Rottenstreich, New York University
Christopher Trepel, Industry, USA

In this research we contrast predictions from the traditional approach for studying anchoring and adjustment with an alternative approach that stems from recent research in dual process models. Traditional approaches have not identified clearly the types of estimates that may be more or less susceptible to anchoring effects. We show how dual process models help to shed light on this issue by delineating the effect of anchors in different contexts.

Since it was first highlighted by Tversky and Kahenman (1974), anchoring and adjustment has been implicated in many important phenomena, including patterns as disparate as preference reversals (Lichtenstein and Slovic 1971), hindsight bias (Fischoff and Beyth 1975), and the effect of ambiguity on judgments (Einhorn & Hogarth 1985). Recent research by Strack and Mussweiler (1997) suggests that anchoring is a special case of semantic priming. On the other hand, work by Epley and Gilovich (2006) has emphasized that the anchoring process is a function of the anchor itself and differentiates between processes arising given self-generated versus other-generated anchors.

In this research, we study anchoring using dual process models such as that proposed by Kahenman and Frederick (2002; see also Stanovich and West 2002; Sloman 1996). These models propose an interplay between two systems or modes of thought. "System 1" is marked by rapid, automatic, and associative processing that provides an initial (and often final) response to stimuli. System 2 is marked by slower, more controlled, and deliberative processing and sometimes overrides, corrects, or supplements the response of System 1. A dual process framework may help explicate the types of stimuli and the conditions under which anchoring will or will not occur.

Earlier research characterized anchoring as less likely to occur when an individual holds a strong a priori attitude towards the stimulus being judged. We suggest a modification of this conclusion; in particular, anchoring may be less likely to occur for stimuli engendering a compelling reaction by System 1, a reaction that either does not need or cannot benefit from the supplemental processing provided by System 2. To illustrate, consider how much you like chocolate. System 1 provides an immediate response to this question; moreover, this response may not benefit much from more deliberative processing by System 2. That is, one "knows" how much one likes chocolate, yet one cannot "figure out" how much one likes chocolate. In sum, using a dual process view, judgments of personal taste (e.g., how much do you like chocolate?) and aesthetics (e.g., how attractive is the Eiffel Tower?) are unlikely to be susceptible to anchoring. On the other hand, more complex judgments involving these matters (how much would you pay for Godiva chocolates?) should be susceptible to anchoring.

Note further that in a dual process framework, adjustment is a System 2 process. Thus, cognitively taxing individuals should dilute anchoring effects for matters of taste and aesthetics, because

it will lead people to rely on their accessible System 1 response. On the other hand, cognitively taxing individuals, should accentuate anchoring effects for more complex matters that necessarily engender System 2 processing. In these cases, System 2 will operate but will adjust less than it would were it not taxed.

We examined these predictions in two experiments. In experiment 1, we find differences in anchoring effects depending upon whether the judgments were regarding personal taste or more complex judgments. In experiment 2 we use a cognitive load manipulation to suppress the use of System 2 and examine corresponding changes in the anchoring and adjustment process.

### "Perspectives on Consumer Decision Order and Their Impact on Purchase Behavior"

*Leilei Gao, Stanford University*
*Itamar Simonson, Stanford University*

A purchase usually involves two decisions and can be examined from both perspectives: a *selection decision* (which option I like most) and a *buy/no-buy decision* (whether or not to buy it now; see also Dhar and Nowlis 2004). The order in which consumers make the two decisions may vary across different shopping situations. For example, consumers tend to make the buy/no-buy decision prior to the selection decision when they have a shopping list or are facing a big sale. However, when consumers are simply browsing at a bookstore or visiting an antique shop, they tend to make the selection decision prior to the buy/no-buy decision. The two decisions may also be made simultaneously (e.g. many impulsive shopping decisions). Prior research on decision-making has either focused on the selection decision or examined the joint consequence of the two decisions. In the present research, we separate the two perspectives on consumer decision processes and show that different decision procedures lead to systematic differences in consumers' purchase likelihood.

Specifically, in a series of studies (based on the dissertation of the first author), we contrast consumers' purchase behavior under different decision orders. In one condition, participants are first asked to decide whether to choose and then make a selection from a set of options (the *buy-select decision procedure*). In another condition, participants are first asked to make a selection and then decide whether to make any choice (the *select-buy decision procedure*). To compare the two decision orders with the traditional way of examining choice deferral (e.g., Dhar 1997), we add a third condition where consumers are asked to make a selection when a no-buy option is treated as another choice option (the *one-step decision procedure*).

Building on the preference reversal literature (e.g., Tversky, Sattath, and Slovic 1988) and temporal construal theory (e.g., Trope

& Liberman 2000), we propose that although different decision orders provide logically equivalent end states, they activate a different evaluation focus, which in turn affects consumers' purchase likelihood. When the selection decision is made first, consumers focus on assessing comparative characteristics of alternatives and weighing relevant differences among them. When the buy/no-buy decision is made first, however, consumers focus more on assessing their need for the product and judging the overall features of the choice set. In other words, an initial focus on the selection decision limits the scale of comparison to alternatives within the set. But an initial focus on the buy/no-buy decision increases the scale of comparison to trading off benefits of purchase with that of deferral.

We explored the decision order effect across a wide range of problems based on the notion that factors that primarily affect the overall feature of the choice set would have stronger influence on the buy-select procedure, whereas factors that primarily affect the difficulty of comparing alternatives within the set would have stronger influence on the select-buy procedure. Following are brief summaries of the results of already completed studies:

(1) *Decision Order & Donation Behavior*: The buy-select decision order induced a higher donation rate (involving charities to save particular animal species) than the select-buy order.

(2) *Decision Order & Dominance Structure*: Including a dominant option in the choice set significantly increased purchase rate in the select-buy condition, but had no effect in the buy-select or one-step conditions.

(3) *Decision Order & Assortment Size*: Large (vs. small) assortment is found to decrease purchase rate in a select-buy decision order, creating a choice "overload" effect, but increase purchase rate in a buy-select decision order, resulting in a "reverse overload" effect.

(4) *Decision Order & Product Nature*: When choosing among "virtue" products, the select-buy order led to higher purchase rate than the buy-select order. When choosing among "vice" products, however, decision order has no effect on purchase rate.

We are currently running additional studies to explore the process underlying the effects of decision order as well as boundary conditions.

### "Will I Like a "Medium" Pillow? Another Look at Constructed and Inherent Preferences"

*Itamar Simonson, Stanford University*

There is a growing consensus that preferences are inherently constructive and largely determined by the task characteristics, the choice context, and the description of options. In this paper, I argue that much of the evidence for preference construction reflects people's difficulty in evaluating absolute attribute values and

tradeoffs and their tendency to gravitate to available relative evaluations. Furthermore, although some key demonstrations of constructive preferences involved rather unusual tasks and might have "benefited" from the effects they were demonstrating, the findings have led to rather sweeping, unqualified conclusions.

A nonconstructive, pre-contextual concept of *inherent preferences* is then presented, suggesting that it is often meaningful and useful to assume that people are non/receptive to certain object configurations, including those that may not yet exist. Inherent preferences are most influential when reference points and forces of construction are less salient, most notably, when objects are experienced. A series of specific research propositions will be presented. It is important to recognize that both constructed preferences and inherent preferences pose major challenges to the effectiveness of marketing research, in general, and to the prediction of consumer preferences, in particular. Thus, the final part of the presentation explores some of the implications of constructed and inherent preferences with respect to decision and marketing research.

# What's Your Motivation?
## Affective and Cognitive Processes that Motivate Behavior and Choices

Kelly Goldsmith, Yale University, USA
Monica Wadhwa, Stanford University, USA

### SESSION OVERVIEW

*"People's behavior makes sense if you think about it in terms of their goals, needs, and motives"*
*-Thomas Mann*

*Introduction*: What drives us to pursue our goals, what motivates us to behave in certain ways, how does our motivational system work have all been questions that have evoked considerable interest through the ages. Greek Philosophers such as Aristotle believed human behavior to be motivated by a desire to pursue goals that led to pleasurable outcomes or to the avoidance of painful outcomes. Hindu philosophy, on the other hand, perceived human behavior to be tied to intrinsic motivation. The importance of understanding what motivates human behavior and choices has been recognized by the consumer researchers as well. Extant research in social as well as consumer psychology has examined the mechanics of motivation through a variety of lenses including rewards and incentives (Deci 1971; Kivetz 2005), drive reduction theory (Hull 1951; Mowrer 1960) and hedonic versus utilitarian motives (Shiv and Fedorikhin 1999; Dhar and Wertenbroch 2000; Kivetz and Simonson 2002). The three papers in this session integrate some of these perspectives in presenting a dynamic view of goals and motivation.

*Session Objective and Overview*: The broad purpose of this session is to present work that adds significantly to the growing body of research on motivational factors underlying choices and behaviors. The more specific objectives of the proposed session are—1) examining how mental framing of choice alternatives and incentives can motivate choices and performance on a subsequent task and 2) shedding light on the process by which motivational states get satiated and the impact of satiated motivational states on subsequent consumption related behaviors. Keeping in mind the overall theme of the 2007 ACR ("Building Bridges"), the papers in this session explore the factors that impact the motivation underlying consumer behavior from diverse, yet related perspectives.

The session will begin with a focus on how framing an incentive in terms of gains or losses affects task-motivation. The first paper by Goldsmith and Dhar examines how the threat of a loss can enhance motivation on a task. Goldsmith and Dhar demonstrate that though people predict the incentives framed in terms of gains to be more motivating, incentives framed in terms of losses act as more powerful motivator in experience.

The second paper by Zhang and Fishbach builds on the first paper by extending the impact of mental framing on consumer motivation into the domain of consumer choices. Zhang and Fishbach's research explores how the mental framing of choice alternatives pertaining to goals and temptation motivates people's choices. To elaborate, Zhang and Fishbach demonstrate that when choice alternatives pertaining to goals and temptations are presented as a unified choice set, people assign a greater value to the temptation option. In contrast, when the same choice alternatives are presented in two different choice sets, people assign a greater value to the higher goal related option.

Finally, the third paper by Nowlis, Shiv and Wadhwa complements the first two papers by demonstrating the factors that satiate consumers' motivation to engage in consumption-related behaviors. Specifically, Nowlis, Shiv and Wadhwa demonstrate that being exposed to the odor of a food item can satiate the consumer and, therefore, reduce the subsequent consumption of not only the food item smelled to satiety but of other food and beverage items as well.

Collectively, the three papers provide cutting edge counterintuitive insights into the motivational processes that drive consumer behavior and decision making

### EXTENDED ABSTRACTS

#### "The Effect of Incentive Framing on Working Harder: Doing More Than We Predict"
*Kelly Goldsmith, Yale University*
*Ravi Dhar, Yale University*

Although it is well established that consumer behavior is goal driven, reaching a goal target often requires exerting effort on multiple tasks (e.g., the goal to lose 10 lbs. requires choosing healthy meals on multiple occasions). Much recent research has focused on self-regulation through changes in intrinsic motivation or goal commitment (e.g., Fishbach & Dhar, 2005). The role of extrinsic rewards on self-regulation and goal motivation has not received the same degree of attention in the academic literature, though extrinsic rewards have long been used as motivators (See Deci et al., 1999 for review) and firms often use rewards to motivate consumer behavior. For instance, a recent government initiative designed to motivate performance on advanced placement tests is now offering high school students $100 per test passed along with hedonic gifts (e.g., iPods) for attending test prep classes (Hechinger & Warren, 2007).

The current project makes an initial attempt at addressing the effectiveness of extrinsic motivation (e.g., monetary payment) on meeting a goal target depending on whether the incentive is framed as a gain or a loss from a reference point. Consider an individual has to perform a set of eight challenging tasks in order to meet her goal. In one scenario, she learns that she will receive $25 for each task successfully completed for a maximum payment of $200. Now imagine a scenario where she is given a $200 at the outset then learns that $25 will be deducted for each task which is *not* successfully completed. Under both incentive structures, the goal target is identical (completing the set of tasks) and the incentive is the same ($25 per task successfully completed). Building on the research on loss aversion in the formation of preferences (Kahneman et al., 1991), we posit that motivation to perform a set of tasks will be enhanced when task accomplishment allows one to avoid incremental losses in relation to when the same value framed in terms of incremental gains.

We further examine whether people's predictions of which monetary payment structure would be more motivating diverge from their real time persistence and performance. Specifically, while the real time motivation reflects the affective experience (e.g., the predicted pain or pleasure from the gain/loss of the external incentive), people's prospective evaluations are often based on general beliefs or intuitions. Therefore, we hypothesize that when making predictions about how motivating an incentive

would be individuals may overweight how *enjoyable* it would be to work on the task in one scenario versus the other based on a belief that enjoyment and motivation positively correlate, rather than considering the effectiveness of the incentive at motivating persistence.

These hypotheses were tested in a series of eight studies. The first two studies tested real time persistence and performance on challenging tasks, when incentives were framed in terms of gains or losses from a reference point. In the first study, participants were given a task to complete which involved unscrambling six anagrams, two of which were unsolvable. Time spent persisting at these unsolvable anagrams was used to measure motivation. Participants were either told that they would receive $0.25 per correct answer or they were given $1.50 at the outset and told that they would lose $0.25 per incorrect answer. Consistent with our predictions, people persisted longer when their incentive was framed in terms of losses. As Study 1 did not allow performance to vary with effort, Study 2 involved a task where increased effort was reflected in performance. In line with our predictions, performance was enhanced when the incentive was framed in terms of losses.

In order to test the participants' intuitions about the effect of incentive framing on motivation, we conducted prediction studies designed to parallel to our real time studies. Across different study designs (within vs. between participants), dollar amounts ($200 vs. $1.50) and tasks (anagram task vs. doctor's visits) people consistently and incorrectly predicted that the gain-framed incentive would be more motivating.

We next sought to test the underlying mechanism for this divergence, assessing if an overweighting of predicted enjoyment contributes to this discrepancy. Our results supported this. We presented participants with descriptions of both gain and loss framed incentives and asked them to indicate which would be more enjoyable to work towards ("no difference" was also an option). Participants believed it would be more enjoyable to work towards an incentive framed in terms of gains (Study 5) and believed that incentives which are more enjoyable to work towards were more motivating (Study 6). To test for the belief in a positive correlation between motivation and enjoyment, we presented participants with either an incentive framed in terms of gains or one which is framed in terms of losses and had them rate both how enjoyable and how motivating the incentive would be (Study 7), finding that predicted enjoyment and motivation did significantly positively correlate.

Having demonstrated this prediction/experience disparity and identified an overweighting of predicted enjoyment as one driver, we lastly sought to empirically test for de-biasing manipulations to bring predictions more in line with real time task persistence. We find that forcing participants to briefly work on difficult anagrams prior to making their predictions improved their predictions significantly. Relative to a control they were significantly more likely to indicate that loss framed incentive would be more motivating (Study 8).

This research achieves several goals: we extend what is currently known about how the framing of an external reward affects the motivation towards a goal which requires completing several challenging tasks. Further, we show that people erroneously predict the opposite would happen, based on beliefs about the relationship between motivation and enjoyment. We believe our findings are of particular importance to researchers who study consumer goals, as extrinsic incentives are often utilized to motivate consumer behavior however our understanding of their implications is limited. Future research explores additional prediction/experience discrepancies in motivation (e.g., people predict a small monetary award for oneself would be more motivating than the same amount for charity but in experience the reverse is the case).

### "Together and Apart: What Makes Choice Alternatives Compete Versus Complement"
*Ying Zhang, University of Chicago*
*Ayelet Fishbach, University of Chicago*

When browsing through a restaurant menu, how does the presence of fatty, yet tasty, courses influence the value of healthy menu items, or vice versa? In this research we propose that, when both goal- and temptation-related items are present, the value of these options will be influenced by the format of presentation as together in a unified choice set, or apart in two different choice sets sorted by the underlying goals. These presentation formats activate the corresponding dynamic of either balancing between goals and temptations or highlighting the high-order goal, which in turn influence value and choice.

Specifically, when goal- and temptation-related options are presented together in a unified choice set, they appear to complement each other, which justifies balancing between the options and increases the immediate value of temptations. For example, presenting tasty (yet unhealthy) candies and healthy fruits in the same plate elicits a sense that they complement each other and it is justified to consume temptation now and balance later. Consequently, the immediate value of candies increases, compared with fruits.

However, when choice alternatives are presented apart in two separate sets sorted by the underlying goals, they appear to compete with each other, which motivates highlighting the high-order goal and fosters a positive evaluation of goal-related options. For example, when candies and fruits are served in two separate plates, they appear to be in competition. This presentation format highlights the fact that fruits represent a more important goal and consequently the immediate value of fruits increases relative to candies.

To summarize, we expect that when goal- and temptation-related options are presented in a unified choice set, the plan to balance causes an increase in the value of tempting (vs. goal-related) alternatives and an immediate preference for temptations. Conversely, when goal- and temptation-related alternatives are presented in two choice sets organized by the underlying goal, people are motivated to highlight goal pursuits, and evaluate goal-related (vs. tempting) alternatives more positively.

Four studies tested this general hypothesis. The first study presented images of goal-related items (e.g., vegetables) and tempting items (e.g., burger) either together in one image ("together" condition), or in two separate images arranged next to each other ("apart" condition). Participants rated the extent to which each of the featured items was appealing. We found that when the items were presented together in one picture, participants rated the goal-related items to be less appealing than the tempting items, but when the items were presented apart in two separate images next to each other, they rated the goal-related item to be more appealing than the tempting items.

Our next study extended Study 1 by using menu courses with verbal descriptions to ensure that the items were understood the same across conditions. Participants in the "apart" condition received two restaurant menus: one contained exclusively healthy courses (healthy menu), and the other exclusively unhealthy courses (unhealthy menu). In contrast, those in the "together" condition received a menu that contained all courses from the healthy and unhealthy menus, and the order was mixed (mixed menu). Participants in the control condition received either the healthy or unhealthy menu. All courses in the menus were followed by a short description. For the dependent measure participants rated the appeal of each of the courses. We found that participants in the control

condition perceived the healthy and unhealthy courses as equally appealing. However, when the healthy and the unhealthy courses were presented apart in two separate menus, participants rated the healthy courses as more appealing than the unhealthy courses, but rated the unhealthy courses to be more appealing than the healthy ones when they were presented together in one mixed menu.

Our third study tested whether people indeed perceived the options to be complementing and planned to balance in the future when they were presented together, but perceived the same options to be competing and chose to highlight when presented apart. In this study participants were asked to hypothetically choose two magazines: one for immediate reading, the other for later. The options included equal number of high-brow (e.g., TIME, Newsweek) and low-brow magazines (e.g., Vogue, SI). We gave participants in the "together" condition one list that included all magazines in mixed order, and gave participants in the "apart" condition two separate lists, each containing only one type of magazines (high or low-brow). We found that presenting the options together (vs. apart) reduces an immediate choice of high-brow magazines but did not affect the subsequent intention to choose a high-brow magazine. In addition, participants were more likely to switch from a low-brow to a high-brow magazine when the options were presented together than when they were presented apart. The same pattern was found with menu courses.

Our final study tested whether these evaluations and plans influence people's actual choices. Participants, after a filler task, were asked to make a choice between a chocolate bar and baby carrots. In the *together* condition, the chocolate bars and carrot bags were scrambled together in one plate; in the *apart* condition, the two options were put in separate plates placed next to each other. We found that participants chose more chocolate bars when the options were presented together (vs. apart). Further analyses indicated that participants' dieting orientation predicted their choice when the options were presented apart from each other but not when these options were presented together.

In summary, in this research we found that when choice alternatives pertaining to goals and temptations appear together in a unified choice set, they seem to complement each other and prompt a self-regulatory dynamic of balancing. The result is that people assign greater value to temptation-related (vs. goal-related) options, and are more likely to choose them. However, when the same choice alternatives are presented apart from each other in two separate choice sets sorted by the goals they serve respectively, the options seem to compete against each other and prompt a self-regulatory dynamic of highlighting the more important goal. As a result, people evaluate goal-related (vs. temptation-related) more positively and are more likely to choose them.

### "Smelling Your Way to Satiety: Impact of Odor Satiation on Subsequent Consumption Related Behaviors"

*Stephen M. Nowlis, Arizona State University*
*Baba Shiv, Stanford Universtiy*
*Monica Wadhwa, Stanford University*

Imagine reading a book sitting in the Barnes and Nobles book store with the odor of freshly baked cookies wafting from the café inside the store. Would the odor of these freshly baked cookies enhance or reduce your subsequent consumption of food and beverage? Common intuition would suggest that the appetitive odor of cookies is likely to increase subsequent consumption of food. In line with the common intuition, marketers are increasingly encouraging the use of food related olfactory cues in restaurants and hotels to enhance their sales.

On the contrary, is it possible that being exposed to food odors will reduce subsequent consumption of food? An emerging body of work on sensory satiety seems to point to this possibility. Specifically, research in the domain of sensory satiety suggests that the sense of satiety is not only influenced by the macronutrient properties of the food (i.e., energy consumed in the process of eating food), but also by other sensory properties of the food such as the odor of food (Rolls 1989, 2005). Thus, according to this notion that we will refer to as "odor-satiety," it is likely that just being exposed to the odor of food for a long duration could reduce subsequent consumption of food.

In sum, the implications for odor-induced consumption behaviors arising from odor-satiety clearly contradict those arising from common intuition that seems to be reflected in the growing practice of using odors to stimulate consumers' appetites. A broad goal of this research, therefore, is to examine which of the two contradictory predictions would receive empirical support in the context of odor-induced consumption behaviors.

To test the aforementioned hypothesis, in study 1, we randomly assigned participants to either an odor- present or odor-absent conditions. To disguise the purpose of the study, participants were informed that they would watch a documentary, purportedly as part of a study conducted for TiVo. Participants were further told that as compensation for taking part in the study, they would be provided with food. In both the odor-present and the odor-absent conditions, participants watched the documentary for 12-minutes. In the odor-present-condition, the room was filled with the odor of popcorn. Following the purported study for TiVo, participants responded to mood and fatigue measures. Thereafter, participants left the first room and proceeded to another room, one person at a time. On reaching the second room, where food items were on display, each participant indicated his/her choice of food and drink on a checklist that contained the five displayed food items (chips, cookies, M&Ms, popcorn and pretzels). Food choices formed the main dependent variable in this study. The results of study 1 seem to support the odor satiety effect. Specifically, being exposed to an appetitive food odor led to a decrease in subsequent consumption behaviors related not only to the cued food item but food in general. No differences in mood and fatigue level were found across conditions.

Our second study aimed to achieve the following three objectives. Our first objective was to examine whether exposure to a food odor can have broader cross-modal effects wherein the effects extend to beverage items as well. Another objective of study 2 was to examine whether the diminished effects on consumption are mediated by a loss of appetite (i.e., wanting) for food and beverage or by a diminished liking for food and beverage. Finally, study 2 examines the odor-satiation effects documented in study 1 extend to non food related odors as well.

The basic procedure of study 2 was similar to that used in study 1. In study 2, however, we included a non-food odor condition. As in study-1, participants in all the conditions watched a movie in a room infused with either the odor of popcorn (food-odor condition), lavender (non-food odor condition) or no-odor (control condition). Participants subsequently indicated on 11-point (*not at all*/*very much*) scales their urge to drink and urge to eat. Thereafter, participants were ushered to another room with various food and beverage items on display. Participants chose the food item(s) and the size of the drink item(s) s/he desired to consume in the next room, while working on the remaining part of the study. Subsequent to making the food and drink choices, participants moved to the adjoining room, where they rated their liking for various utilitarian and hedonic products.

The findings of study 2 suggest that odor satiety effects are not restricted to appetitive food odors. Specifically, these findings suggest that not only exposure to appetitive food oders, but expo-

sure to appetitive non-food odors can also lead to a decrease in subsequent consumption behaviors related to food. Moreover, study 2 results indicate that odor satiety leads to a broader cross-modal effects, such that participants in the appetitive food and non-food oder conditions, as compared to the control condition, showed reduced behavioral tendencies toward not only food but also beverage items. Interestingly, our findings also show that there were no differences in the urge to drink and eat across conditions. In other words, these results seem to suggest that the documented odor satiety effects are engendered through an impact on the anticipated hedonic value (liking) of the food and beverage items and not through an impact on the appetitive value (wanting) for the food and beverage items. Thought not predicted, another interesting finding was that while odor satiety reduces consumption behaviors related to food and drink, it actually enhances liking for the utilitarian items.

Taken together, our findings provide support for the odor satiety effect at a cross-modal level, whereby exposure to food odors on one hand reduced subsequent consumption of food and drink, while on the other hand it enhanced a liking for utilitarian items. Our findings have important implications for the use of odors to promote the sale of products especially those in the food and beverage category. In a third study that is currently in progress, we are attempting to 1) better elucidate the impact of odor satiety on liking versus wanting for the food and non-food consumer items and 2) examine the impact of odor satiety on impulsive behaviors.

# There is a Time and Place and a Person to Vote for: Issues in Political Persuasion

Akshay Rao, University of Minnesota, USA

## SESSION OVERVIEW

The general topic of voter persuasion and voting behavior has historically attracted academic attention in several disciplines including journalism, political science, economics (specifically, public choice), and, more recently, psychology. But, with a few notable exceptions (e.g., Ahluwalia 2000, Klein and Ahluwalia 2005), the field of consumer behavior has largely been silent about political persuasion. This gap in our literature needs to be corrected for three fairly obvious reasons. *First,* based on the sheer volume of money spent on political campaigns, the Marketing of political candidates is an important economic activity.[1] *Second,* the field of consumer behavior has a unique intellectual basis from which to address the issue of political persuasion and choice. *Third*, studying consumers' choice of political candidate is arguably at least as important as studying which brand of carbonated soft drink they prefer or purchase. Therefore, in this special session, we bring together three papers that examine the factors that influence message persuasiveness, as well as voter choice.

In the first paper, Hedgcock, Rao and Chen examine whether the "attraction effect" can be employed to study three-person races. In particular, drawing from a recent episode in U. S. electoral history, they ask whether the *entry and exit* of a "decoy" (such as Ralph Nader) would have benefited a "target" (such as Al Gore) more so than if the decoy had never entered the race. That is, does a "phantom decoy" that is no longer available for selection still benefit the most similar of the remaining alternatives. Using a variety of stimuli, the authors report on three completed studies that show how the entry and exit of a decoy does in fact benefit the target. Further, they provide evidence for a process that explains the results.

In the second paper, Berger, Meredith and Wheeler report on two completed studies that underline the importance of situational cues in voting decisions. In light of the ubiquity of churches and schools as voting locations, their field and experimental findings that voters might support initiatives consistent with the mission of the polling place are noteworthy.

In the final paper, Kim, Rao and Lee report on three completed studies that consider temporal distance, message type, and audience properties on persuasion. Their premise is that swing voters are more likely to determine the eventual outcome of most elections, and these swing voters tend to be relatively "uninvolved" and "uninformed". It is these voters who are more persuaded by abstract messages when the choice is in the distant relative to the near future. Conversely, concrete messages are more persuasive when decisions are temporally proximal.

The objectives of our session are two-fold. *First*, each of the papers offers a theoretical advance on a consumer behavior issue. Hedgcock et al. provide evidence of the process underlying the attraction effect, Berger et al. demonstrate the impact of subtle environmental cues on malleable consumer preferences, and Kim and Rao successfully marry construal level theory with persuasion. *Second*, we bridge conceptual (BDT, psychology) and substantive (Consumer Behavior and Political Persuasion) perspectives in this session.

The importance of public choice as an area of study for consumer behavior scholars can not be overemphasized. Theoretically, voting behavior is an interesting topic of inquiry because it is infrequent but predictable, and requires a choice that *a priori* likely has little impact on the eventual outcome. Substantively, voting is critical to the functioning of our democracy and civil society. This topic therefore appeals to a broad array of scholars ranging from cognitive and social psychologists to those trained in the BDT tradition who are interested in processes underlying choice, as well as public policy oriented researchers who are interested in political choice as a phenomenon of interest in its own right.

## EXTENDED ABSTRACTS

### "Could Ralph Nader's Exit Have Helped Al Gore? The Impact of Decoy Entry and Exit on Consumer Choice"

*William Hedgcock, University of Minnesota*
*Akshay Rao, University of Minnesota and Hong Kong University of Science & Technology*
*Haipeng (Allan) Chen, Texas A & M University*

Individuals are frequently faced with making a new choice decision after a preferred option becomes unavailable. A preferred political candidate may lose in a primary, or a preferred vacation alternative may be sold out. Similarly, in software markets that feature "vaporware" (pre-announced but unavailable computer software), in the case of sold-out movies and shows, in the selection of dating partners or employees and jobs, in department stores where advertised items may be out-of-stock, in the case of pre-announced automobiles, and in the purchase of real estate, preferred options often either become unavailable or emerge during the choice process (Wedell and Pettibone 1996).

Prior research in marketing on the "attraction effect" has demonstrated how the *introduction* of an option into a choice set changes the choice shares of existing options, such that the share of an existing option *increases* following the introduction of a similar (generally dominated) option (Huber, Payne and Puto 1982). We examine the related but heretofore unaddressed issue of whether the *exit* of an option from a choice set returns the choice shares of the original options to the *status quo ante*.

In the first study, we examine support for our foundational prediction, that exposure to a selectable decoy influences choice shares even after the decoy becomes unavailable. The study was motivated by the speculation that Ralph Nader's entry and exit might have helped Al Gore more than if Nader had never entered the race. Therefore, in the first study we examine choices among unidentified political candidates. We observe that when an option ("the decoy") turns out to be unselectable following a decision problem in which it was selectable, the choice shares of the remaining options are predictably different, such that more people pick the target and fewer people pick the competitor, relative to a setting in which the option was unselectable to start with. That is, we observe an attraction effect even after a decoy has disappeared from the choice set.

Based on a review of the literature, we examine three potential explanations for this attraction effect. First, the initial availability of the decoy may increase the weight assigned to the attribute on

---

which the decoy excels, by increasing the frequency of options that score high on that attribute. Following a choice process that considers this increased weight, a subsequent choice process after the decoy turns out to not be available may still emphasize that attribute and therefore yield an attraction effect. Second, the consideration of the decoy in the initial choice stage may change the value of the two focal options by shifting the reference point against which the target and the rival will be evaluated. A decoy located closer to the target may shift the reference point towards the target, as a result of which the target becomes less of a loss on one attribute and more of a gain on the other attribute. Due to loss aversion, the target may become more attractive relative to the rival due to the shift of the reference point. Finally, the unavailability of the decoy might make a similar target appear more attractive, as people may pick among the remaining options based on how similar they are to the decoy.

To examine the various explanations for the observed attraction effect, in a second experiment we directly measure the weight shift, value shift and similarity heuristic based explanations. The approach we employed was similar to Study I, except the stimuli we used described unidentified brands of beer. We chose this product stimulus because it is relatively familiar to student subjects, and we were interested in assessing the process that underlies our phenomenon, an assessment that was likely to be easier for familiar products. Our results indicate that the attraction effect is mediated by weight shift and use of a similarity heuristic, but not by value shift. In the last study, we replicate the basic finding in five different setting. In addition, we measure the response time that is associated with different choices under different experimental conditions, in an effort to shed further light on the cognitive processes underlying this effect. This study was conducted on personal computers utilizing response time tracking technology (E-Prime[R]). In addition to finding support for the basic prediction, we also observe that the consideration of the additional option in the initial decision changes the speed of decision making in the subsequent decision, in a manner that is consistent with weight shift and the use of a similarity heuristic.

### "Can Where People Vote Influence How They Vote? The Influence of Polling Location Type on Voting Behavior"
*Jonah Berger, Stanford University*
*Marc Meredith, Stanford University*
*Christian Wheeler, Stanford University*

Voting decisions are some of the most important choices people make. They influence how money is spent, whether certain acts (e.g., gay marriage) are legal or illegal, and even whether or not the country is at war. Although many factors can influence voting preferences, political scientists have generally not studied influences on voting that operate after voters reach the polling place. That is, most research either implicitly or explicitly assumes that voters have stable voting intentions that are subsequently converted into a vote. Research on environmental cues, however, suggests that the cues prevalent in different environments can have significant effects on judgments and behavior. Building on such work, this paper examines the intriguing possibility that where people are assigned to vote (e.g. a firehouse, church, school, etc.) can influence how they vote. Supporting this proposition, we use precinct-level data from Arizona's 2000 general election and find that voting in schools increases the support for school spending initiatives.

Environmental cues prevalent at differing polling locations differ in systematic ways, and we argue these differences can influence voting outcomes. Research has shown that features of the environment can automatically activate associated representations in memory and affect behavior without the actor's intention or awareness (e.g., Bargh, Chen, & Burrows 1996). For example, exposure to business-related objects such as briefcases can make individuals act more competitively (Kay, Wheeler, Bargh, & Ross, 2004), exposure to stereotypes can make individuals feel and act like members of the stereotyped group (DeMarree, Wheeler, & Petty, 2005), and exposure to normative environments (e.g., libraries) can make people act in accordance with associated norms (e.g., speaking quietly; Aarts & Dijksterhuis, 2003). Based upon such research, we predicted that exposure to a school environment could increase activation of school-related norms, identity aspects, and stereotypes, which could then influence actual votes toward education-related initiatives (e.g., to increase school spending).

Using data from Arizona's 2000 presidential election, we found support for the notion that environmental factors can influence voting behavior. We collected precinct-level voting results, polling location data, and demographic data from all Arizona precincts, and focused on a ballot initiative that proposed raising the state sales tax to fund additional school spending. We used a Goodman regression framework and controlled for political views using votes for president and 13 other initiatives. Using this model specification, we found that those who were assigned to vote in schools were more likely to support the initiative to increase school spending. We also used a number of control group specifications to ensure the robustness of our results. The most stringent control group addressed possible non-random placement of voters into polling locations (e.g. people with children are more likely to live near and hence vote at schools) by comparing those who lived near schools and were assigned to vote at schools vs. those who lived near schools and were assigned to vote in a different location. We used 9-digit zip codes to identify polling locations near schools, thereby constructing two groups of voters who were similar in all characteristics (e.g. age, income, number of kids) except where they are assigned to vote. Our estimates show that using this quasi-experimental design, Arizonians who voted in schools were still significantly more likely to vote in favor of increasing the sales tax. These findings were generally robust across the several additional control group specifications we utilized.

In a follow-up experiment, we manipulated environmental cues by randomly assigning participants to view pictures of schools, churches (the other most common polling location), or generic buildings. Then, ostensibly as part of another experiment, participants indicated their voting preference on a number of initiatives, including the Arizona education initiative used in our field study. Results indicated that exposure to the school images increased support for the education initiative. Additional analyses showed that the effect of the images was larger among non-parents and among those opposed to taxes. Specifically, parents and those with favorable attitudes were likely to support the initiative regardless of which images they viewed. However, non-parents and those with negative attitudes toward taxes were more likely to support the initiative after viewing pictures of the schools. Hence, the effect of environmental cues on voting was strongest among those not already predisposed to favor the initiative.

This work highlights the fact that many voters may lack strong and stable intentions that guide their behavior and has implications for voting policy decisions. More broadly, this research illustrates the importance of simple environmental cues in directing behavior, even highly consequential behavior that occurs in "noisy" real-world environments.

### "It's Time to Vote: Fit Between Construal Level and Temporal Distance on Political Persuasion"

*Hakkyun Kim, University of Minnesota*
*Akshay Rao, University of Minnesota*
*Angela Y. Lee, Northwestern University*

With the increased penetration of cable television, talk radio and weblogs (popularly referred to as "blogs"), the coverage of political topics and campaigns now appears to be ubiquitous and incessant. This expansion of media outlets and the accompanying increase in media coverage has had a predictable effect on political expenditures as well. For instance, the most expensive Senate race in 2002 was in North Carolina, where the candidates spent a little over $27 million (roughly $3.20 per resident), whereas in 2004 over $37 million was spent by the candidates (about $525 per resident) in that year's most expensive Senate race (Daschle vs. Thune in South Dakota). When all the data come in, the figure for the 2006 mid-term elections is expected to reach $2.6 billion (Mooney 2006). Most of these campaign expenditures are incurred on marketing activities such as advertising and "get out the vote" efforts. These Marketing activities are designed to persuade undecided voters and assure the turnout of voters who are favorably inclined towards the candidate.

In political campaigns (as well as in several other Marketing communication settings), candidates communicate with voters for a long period of time before the actual choice decision. *What* these candidates say and to *whom* as well as *how* they say it, is likely critical to their success. Partisans (who are relatively brand loyal) are asked for money, time, and effort, while swing voters (who are not brand loyal) are asked for electoral support on Election Day. We draw from temporal construal theory to predict that the degree of abstraction ("why" laden appeals) versus concreteness ("how" laden appeals) of the message is differentially persuasive depending on the temporal proximity of the choice.

In a first study we empirically observe support for this foundational prediction. Stimuli featured an androgynous political candidate for U. S. Senate (Pat Darvell). Messages emphasizing high-level goals were more effective when the respondent expected to act in the distant future (action was needed six months from the present), whereas political messages focusing on low-level actions were more effective when the respondent expected to act in the immediate future (action was needed next week).

Two follow-up studies were conducted. In the first follow-up study, rather than manipulate temporal construal, we measured subjects' chronic construal level. And, in the second follow-up study, rather than manipulate temporal distance to the decision (as in the very first study), we asked subjects to imagine that they would need to vote using an absentee ballot either next week or a few months from now. These methodological variations were introduced to expand the scope of operationalizations of the focal construct. In the first of the follow-up studies we observe the effect to be strongest for subjects who were uninvolved. In the last study, we observe the effect to be strongest for subjects who were uninformed. Apparently, unlike politically involved and savvy subjects, uninvolved and uninformed subjects were more likely to be persuaded by peripheral cues.

The argument that the fit between temporal distance and message type is relevant to the persuasiveness of the message is a novel insight. Further, we observed the effect when temporal distance was manipulated (studies 1 and 3) and when the respondent's chronic tendency to represent events in either an abstract or concrete manner varied naturally (study 2). These results provide convergent evidence that it is the match between the message content and the *underlying* mental representation that yields the

effect on persuasion. Finally, that the construal fit effect is contingent on involvement is generally consistent with the finding that involvement moderates regulatory fit effects (Wang and Lee 2006). The finding that expertise plays a similar role is also noteworthy, particularly from a pragmatic perspective, since political campaigns appear to be focused on "swing" voters who are deemed to be either uninterested, uninvolved, or uninformed (Rao 2007).

# From Tools to Theories: How Different Methodologies May Impact Theory Development in Brand Relationship Research

Christie Nordhielm, University of Michigan, USA

## SESSION OVERVIEW

The topic of brand loyalty and brand relationship has been explored extensively in the consumer behavior literature for a number of years, and continues to be a vital research area in consumer behavior. Much of this work has concentrated on theory development regarding the nature of the brand-consumer relationship (e.g. Aaker, 1997, Kressman, et. al., 2006, Yoon, 2006). Crucial to furtherance of this understanding is the development of reliable and valid methods for assessing the relationship of consumer to brand. As suggested by Gigerenzer (1991), the emergence of cognitive theories is strongly influenced by the research tools available to theorist. In essence, different methodologies lead to different theories. Over the past twenty years the field of consumer behavior has witnessed an astounding proliferation of data collection and analytical methodologies, and it is certainly difficult to argue *against* the assertion that this proliferation has influenced the course of theory development. Presumably, it is this proliferation of both methodologies and theories that makes the theme of the conference, *building bridges,* so appropriate.

In this spirit, this session intends to present several methodological approaches to brand relationships with the overall objective of exploring the impact these different approaches may have on theory development. The session includes 1) research that utilizes depth interviews and structural equation modeling to develop a consumer brand-identification scale; 2) a set of studies that leverage qualitative depth interviews to develop a structural equation model of brand love, and 3) a videographic exploration of consumer-brand relationship that seeks to provide insight as to the influence of functional and emotional elements of brand relationships. While each paper is of course interesting in its own right, the key contribution of this symposium is the opportunity to present and discuss these different methodological approaches in light of their likely influence on theory development in the area of brand loyalty in a single session.

## EXTENDED ABSTRACTS

### "Antecedents and Consequences of Consumer-Brand Identification: Theory and Empirical Test"

*Nicola Stokburger-Sauer, University of Mannheim*
*S. Ratneshwar, University of Missouri, Columbia*
*Sankar Sen, City University of New York*
*Hans Bauer, University of Mannheim*

A key to the formation of strong relationships between consumers and brands is the concept of *identification*, i.e., a consumer's sense of oneness with a brand. This concept has a long history psychology and has been studied heavily in organization science; more recently, it has received the attention of academic researchers in the branding area (e.g., Bhattacharya and Sen 2003; Fournier 1998). It has been proposed that consumers identify with brands for cognitive as well as emotional reasons, and as in the work of Bhattacharya and Sen (2003), several different factors have been suggested as being conducive to consumer-brand identification (CBI).

Although the conceptual aspects of brand identification have received a fair amount of attention from academic researchers, empirical work in this area seems to have lagged behind. Scholars have proposed and tested scales for social identity and organizational identification (e.g., Mael and Ashforth 1992; Bergami and Bagozzi 2000), but such work does not address some of the unique aspects of the ties that potentially bind consumers to brands. Most fundamentally, brands are things we *consume*–thereby implicating the consumption experience itself as being integral to why we identify strongly with some brands and not others. Thus, for example, the affective traces left in memory by a certain brand consumption experience, or the social context in which a brand is consumed, can be among the factors leading to CBI. Further, as proposed in our conceptual model, variables such as product category involvement and product category symbolism are likely to moderate the impact of some of the influences conducive to consumer brand identification. Obviously, the aforementioned types of factors are quite unique to the consumption context and thus need to be taken into account in research on CBI.

Therefore, in the present research the construct of consumer-brand identification (CBI) is investigated in conceptual and empirical terms with two principal research objectives. The first objective is to develop a parsimonious scale for CBI with appropriate psychometric properties, including convergent and discriminant validity. The second and more important objective is to propose and test a model of the antecedents and consequences of CBI, including key moderating variables.

Our conceptual model for CBI is based on a synthesis of prior work in consumer behavior, organizational behavior, social psychology, and marketing. In regard to the empirical part of the project, we went through a multi-stage process. First, after gaining insights from an extensive literature review, initial item development was accomplished with the help of qualitative in-depth interviews and a test of a preliminary item pool. We then proceeded to conduct two main studies with the intent of further scale purification and nomological validation via a test of the overall antecedents/consequences model. The first study was carried out with a

Web-based survey administered to a panel of almost 800 German consumers and involved four product categories (athletic shoes, mobile phones, soft drinks, and grocery stores). Sample demographics were fairly representative of the German population (average age 40.6 years, 47% females). The second study was conducted with a Web-based survey of around 400 U. S. college students and involved two product categories (athletic shoes and soft drinks).

The results from several analyses of these data sets show that our CBI scale has satisfactory psychometric properties. In addition, the results from confirmatory factor analyses and structural equation modeling methods provide support for the hypothesized relationships between CBI and its antecedents/consequences. Importantly, we also find a great deal of consistency in the results across the two studies. In brief, CBI is influenced mainly by brand-self personality similarity, brand distinctiveness, brand prestige, the brand's social facilitation, brand warmth, and memorable brand experiences. Further, several of these relationships are moderated by product category involvement and product category symbolism. On the downstream side, CBI is found to explain a significant amount of variance in both brand loyalty and brand advocacy.

### "Brand Love: Towards an Integrative Model"
*Aaron Ahuvia, University of Michigan, Dearborn*
*Rajeev Batra, University of Michigan*
*Richard Bagozzi, University of Michigan*

Consumers' love of products and brands has become an increasingly popular research topic (e.g. Ahuvia 1993, 2005; Albert, Boyer, Mathews-Lefebvre, Merunka and Valette-Florence 2007; Carroll and Ahuvia 2006; Fournier 1998; Fournier and Mick 1999; Ji 2002; Kamat and Parulekar 2007; Keh, Pang and Peng 2007; Strahilevitz 2007; Thomson, MacInnis and Park 2005; Whang, Allen, Sahoury and Zhang 2004; Yeung and Wyer 2005). Love in consumption has also been drawing increased attention among practitioners (e.g. Roberts 2004). To see why love is relevant to marketing and consumer research, one need only think about the role it plays in relationships. Whether we are looking at romantic love or familial love, love is a powerful psychological process that brings and holds people together. For marketers who want consumers to be attracted to, and loyal to their products, love of products and brands is a topic of clear relevance.

Despite its growing popularity, consumer research on love is still in its infancy and much of the work centers around the basic question of what love is when applied to products and brands. Shimp and Madden (1998) adapted Sternberg's theory of love to

consumer behavior, and suggested that love in consumption was made up of three dimensions (see also Keh, Tat and Peng 2007); Kamat and Parulekar (2007) started out with Shimp and Madden's three dimensional model, but ended up with five somewhat different dimensions; building on Lee's (1988) research on interpersonal love styles, Whang, Sahoury and Zhang (2004) developed a three factor model; Carroll and Ahuvia (2006) developed a Brand Love scale with five dimensions; and finally Albert et al (2007) found a still different set of 7 dimensions. Thus we can see that past consumer research on love offers at least two dozen different dimensions that may, or may not, be part of love in consumption. To move forward on this important topic, we need more clarity about what the various aspects of love–in consumer behavior–are, and how they fit together. The extensive research literature on interpersonal love is one good place to start. However, Yoon and Gutchess (2006) have found that consumer-product relationships are processed in a different part of the brain from interpersonal relationships. This suggests the need for caution in assuming the direct transferability of interpersonal love theories to explain consumer behavior. The common practice of borrowing constructs directly from the interpersonal love literature and developing measures for these constructs, prematurely limits the data collected to information derived from those constructs, and thus does not give unique nuances of love in consumer behavior a sufficient chance to emerge.

The current research combines qualitative interviews and structural equation modeling to produce a theory of brand love rooted in consumer experience. We begin by interviewing 70 adult consumers about what, if anything, they love aside from another person. These qualitative interviews are analyzed to produce a rich description of love in consumer behavior. Having attained a clearer understanding of love in consumer behavior, we then address the issue of discriminant validity and discuss the relationship between love and other, similar constructs. Study 2 uses the results of study 1 and other insights from the literature, to build a structural equations model of brand love, and test that model for both a "loved" and a "mundane" brand from the same product category. We conclude with a discussion of the theoretical and managerial implications of our findings.

### Study 1: The Components of Love

Data collection took place in two stages. Initially, 70 structured interviews were conducted. From these 70 respondents 10 subsequently participated in follow-up depth interviews. Respondents for the first stage of data collection were contacted through a snowball sampling procedure (Lincoln and Guba 1985). Although the search for respondents began with personal contacts, the actual respondents had not met the researchers prior to the research. Seventy people were contacted and all of them agreed to participate in the research. The respondents were evenly split by gender (36 male and 34 female), predominantly white (white 57, black 10, Hispanic 2, other 1), ranged from 23 to 45 years of age (M=32), and were generally well-educated (graduate school 38, college 27, high school 5). Quotes from respondents are identified by gender, occupation, and age; e.g. M, lawyer, 42. Ten respondents were selected from the large sample study for 2- to 4-hour home interviews. A purposive sampling design (Lincoln and Guba 1985) provided coverage of commonly mentioned love objects and redundancy on some of the most frequently mentioned items.

In the large sample study, confidential taped interviews were conducted over the phone and lasted from 10 minutes to one hour, averaging 20-30 minutes. Respondents were asked, 'if there is something aside from people with whom you have a close personal

relationship that you love–what is it?' Respondents were then asked a series of open ended follow-up questions to learn more about their relationship with each item. The interview continued until the respondent ceased to name new loved objects. For the depth interviews, a questionnaire was developed to test the major findings of the phone interviews against a richer, more detailed data set. In addition to discussing loved objects mentioned in the phone interviews, respondents also discussed objects toward which they had a neutral or mundane relationship and people they loved. This allowed for a comparison between loved and mundane objects and activities, and for a comparison of interpersonal and non-interpersonal love.

Study 1 provides a description of the major components of love in consumer behavior, drawn from the experience of consumers. When consumers were given an open ended opportunity to talk about products that they loved, their comments went well beyond a particular emotion and encompassed a much larger and more complex psychological system. The things consumers loved were overwhelmingly seen as excellent. The emotional experience associated with these items was generally very positive, heightening positive moods and soothing negative experiences. However, consumers also made significant investments of time and money in the things they loved, and sometimes this work involved frustration or other kinds of sacrifice that were not altogether positive. Through these encounters and active involvement with the things they loved, consumers developed a strong sense of attachment to them. This stemmed at times from long histories of involvement with the loved items, and implied a sense of loyalty and commitment to the item in the future. In some cases this attachment was understood through the metaphor of an interpersonal relationship, and the product was seen as a friend, companion, etc. But these relational metaphors were not seen by all respondents as being part of love.

Respondents sometimes reported an experience akin to love at first sight, where they knew immediately at some intuitive level that this item was right for them. This was consistent with the desire and attraction for the item expressed in many cases. Respondents talked about the loved item meeting a wide variety of needs (Ahuvia 1993), but in particular love was associated with items that met consumers' higher order needs for existential meaning and helped them enact and clarify their sense of identity. This tied into the fact that consumers tended to find the things they loved intrinsically rewarding, rather than being a means to a future end. Because the loved items were intrinsically rewarding (i.e. directly provided a rewarding experience), and because of the intuitive sense of "rightness" that respondents felt about many loved items, the respondents saw them as authentic parts of their identity.

Now that we have an understanding of love in consumer behavior that emerges out of the lived experiences of consumers, we can address the issue of how love differs from other consumer behavior constructs such as attitudes, involvement and satisfaction. When love is seen as a larger psychological system, these constructs are not rival but rather constituent parts. Love includes being involved with the item, being satisfied (at least) with the item, and having a positive attitude about the item. But love cannot be reduced to any one of these constructs.

## Study 2: Structural Equation Modeling of the Brand Love Construct

Our second study began with the findings from the qualitative work in which aspects of brand love were identified. On the basis of the qualitative work, we generated 140 items measuring the 16 aspects of brand love. These items were administered to 230 consumers, and exploratory factor analysis was used to identify a set of items, as the basis for testing construct and nomological validity.

A total of 85 items passed the exploratory factor analysis stage of analysis. Because so many measures for the 16 factors would generate too many parameters to be estimated for the sample size at hand under confirmatory factor analysis, we parcelled items based on the factor loadings from the exploratory factor analysis so as to generate two indicators (parcels) per factor.

Confirmatory factor analyses show that convergent and discriminant validity of indicators were achieved for four subdimensions of cognitive brand love (i.e., beliefs related to self-identity, long-term use, life meaning, final quality, looking/feeling like one wants to look/feel), four subdimensions of affective brand love (i.e., feelings related to fit, emotional connection, positive affect, negative affect), three dimensions of cognitive brand love (i.e., willingness to spend resources, desire to use, things done in past), overall attitude valence, attitude strength #1, attitude strength #2, and loyalty. Tests of hypotheses on the relationships among these dimensions support a brand cognitive→attitude→loyalty sequence of effects. That is, attitudes mediate the effects of cognitive/affective/conative aspects of brand love on loyalty.

### "Head, Hand, Heart: A Videographic Exploration of Functional and Emotional Aspects of Brand Relationships"

*Christie Nordhielm, University of Michigan*
*Tonya Williams Bradford, University of Notre Dame*

The topic of brand loyalty and consumer-brand relationship has received substantial attention in the literature for many years. A long and important debate in this literature revolves around the question of how functional and emotional aspects of brand relationship relate to brand loyalty (see, e.g., Kressman et al. 2006). Emotional aspects of brand relationship reflect the assertion that brands have a "personality" and that consumers' relationship to these brands are similar to their relationships to people (Aaker, 1997, Yoon, 2006). In this context brands may engage the ego or bolster the self-esteem of the consumer. In contrast, functional aspects of brand relationship are presumed to involve the concrete, utilitarian aspects of brand performance; brand loyalty is based on consumers' evaluation of these functional criteria. In addition, involvement has been identified as a key factor that affects brand loyalty, and that both low and high-involvement relationships merit consideration (see, e.g. Hoyer, 1984).

There is presently a substantial body of research has been developed that leverages ethnographic methodologies to examine brand loyalty (see e.g. Belk, 1988). The primary focus of much of this work is on "high-involvement" brand loyalty, usually centered on one product category and/or one group of consumers. However, initial depth interviews on the topic of brand loyalty suggest that the same consumer may have a variety of brand relationships that vary in terms of both functional/emotional aspects as well as involvement level. From a brand perspective, it also appears that while certain types of brands may lend themselves more naturally to certain types of brand relationships, the same brand may indeed have consumers that relate to that brand in either an emotional or functional way, and at varying levels of involvement.

The purpose of the present research is to further explore the possibility and extent to which consumers may have different relationships with different brands, and that brands may have different relationships with different consumers. Based on depth interviews of approximately 30 consumers, three classifications of brand loyalty have been developed: *heart loyalty* is high involved, emotionally-based brand loyalty; *head loyalty* is similarly high-involved, but is functional in nature; and *hand loyalty* is low-involved loyalty where consumers exhibit neither functional nor emotional connections to the brand but remain (behaviorally) loyal nonetheless.

The videographic portion of this research seeks further explore these three types of loyalty. One purpose of this work is to further understand the multi-faceted nature of brand loyalty at the individual level; for example, one respondent indicated a strong emotional identification with Apple Computers associated with self-reported brand loyalty. This same respondent also reported being loyal to Toyota automobiles; however, when probed, the revealed nature of this relationship appeared to be much more functional in nature. Finally, she also reported a (behavioral) loyalty to Kleenex tissues, but, when probed, did not appear to have any strong emotional or functional ties to the brand. In contrast, another respondent also loyal to Kleenex tissues appeared to have a far stronger emotional connection to the brand, and responded in an extremely positive fashion to the recent Kleenex "Let it Out" campaign that has a strong emotional appeal (http://youtube.com/watch?v=E5fZ-dnmExE). Hence, it appears that the same person can have different types of brand loyalty, and the same brand can also have different types of brand loyal consumers.

Another purpose of this research is to explore the relationships between attitudes and behavior as they relate to these three types of loyalty. Raymond (1976) classified the behavior-learning hierarchy into learn-do-feel, feel-do-learn, and do-learn-feel. These three classifications map naturally onto the head, heart, and hand classifications discussed above. The videography will be used to explore whether or not these mappings hold.

Finally, we are interested in exploring the nature of consumers' resistance to competing brand proposals in each of the loyalty states. If, for example, some consumers have a strong emotional commitment to a particular brand, we should expect them to be highly resistant to competing offers. In fact, if this type of relationship is truly ego-involved, we might expect them to experience something of a personal affront at the suggestion that another brand is superior to theirs. In contrast, head loyals, by virtue of their functional relationship, might be expected to be more responsive to propositions that reveal functional superiority of competing products. In depth interviews this outcome was observed when consumers were given competing brand offers; we attempt to examine this further in the videography.

We believe this research represents an important contribution to the area of brand relationships in that it 1) reveals further insights regarding the emotional and functional aspects of brand loyalty, 2) examines these relationships in light of consumer involvement level by leveraging the videographic methodology, and 3) begins to examine how a single consumer might exhibit different types of loyalty to different products and a single product might engender different types of loyalty in different consumers.

SYMPOSIA SUMMARY
# The Social Nature of Consumer Behavior

Debora Viana Thompson, Georgetown University, USA
Michael I. Norton, Harvard Business School, USA

## SESSION OVERVIEW

In this session, we will discuss how and why the presence of others can affect consumption decisions, challenging a model in which consumer behavior is seen as a private activity (individuals making choices in isolation) by demonstrating the powerful and wide-ranging impact of social factors on a diverse array of consumption decisions and contexts, including both laboratory and field studies. The first three papers present evidence about three different ways in which social factors influence consumption: the presence of others and its effect on preference for feature-rich products (Thompson and Norton), the positive contamination effect from attractive others touching a product (Argo et al.), and the effect of the choice set provided by others (Goldstein et al.). In the fourth paper, Griskevicius et al. ground these findings in a framework which has thus far been overlooked in consumer behavior–evolutionary psychology–suggesting fundamental reasons for the impact of social influences on consumer behavior, an approach which provides new and interesting insights for future research. Finally, John Deighton, an expert in consumer privacy issues–in some sense the interesting flip side of the current symposium–will serve as discussant, integrating the presentations, as well as highlighting the contribution of these papers to the consumer behavior literature and their implications for marketing research and practice. This symposium should be of interest to researchers in the areas of persuasion, marketing communications, information processing, and consumer decision making, as well as serving to focus future research on the interesting differences between private and public consumer behavior.

## EXTENDED ABSTRACTS

### "The Social Utility of Feature Creep"
*Debora Viana Thompson, Georgetown University*
*Michael I. Norton, Harvard Business School*

A recent trend across several product categories is bundling a variety of product features into single, multi-purpose devices that perform several tasks. This trend towards offering a higher number of product features has been described as feature bloat or feature creep. Although adding features can indeed increase the value of a product to consumers, research shows that consumers tend to buy products with too many features, which after use do not maximize their satisfaction (Thompson, Hamilton, and Rust 2005). We investigate whether this seemingly suboptimal behavior may in fact serve a different–and at times more important–goal of obtaining social status. Specifically, we suggest that consumers may choose feature-rich options as a means of engaging in conspicuous consumption (Veblen, 1899) in order to impress their peers. This hypothesis requires two related phenomenon to be true: First, consumers should be more likely to choose feature-rich products when impression-management concerns are most salient (while preferences for basic products should be enhanced when privacy is highlighted), and second, individuals who choose high-feature products should be evaluated more favorably as a result of such conspicuous consumption.

In an initial study, participants were asked to evaluate two consumers, one who had purchased a product (either a cell phone or

a digital camera) with 30 features, and one who had purchased that product with 15 features. To control for inferences about wealth, participants were told that the two consumers had paid the same amount for the products. As we expected, participants ascribed more positive traits (e.g., intelligent, adventurous) to the consumer who bought a product with more features than to the consumer who bought the product with fewer features.

Next, in a series of four studies, we used several manipulations of impression management goals and measured product preference for products with varying number of features. In Study 2, we used a priming task to elicit either impression management or accuracy goals. After completing the priming task, participants were invited to participate in a survey about cell phones and digital cameras. Consistent with our prediction, participants primed with impression management goals were significantly more likely to select high feature products than participants primed with accuracy goals. In Study 3, we replicated this finding by manipulating product category, by choosing some products that were predominantly used in public (e.g., digital cameras and gas grills) and others used predominantly in private (hair dryers and treadmills). As expected, participants showed greater preference for high feature products for public products, such as digital cameras and gas grills, but this preference reversed for private products, where participants preferred options with fewer features. In fact, merely asking participants to think about using the same product (e.g. an espresso machine) in either private (making their morning coffee) or public (hosting a brunch) altered their preference for high- vs. low-feature versions of those products (Study 4). Finally, in Study 5 we used products whose consumption was perceived as balanced in terms of public and private usage situations (e.g., MP3 players) and varied the observability of participants' choices. As expected, preferences shifted significantly toward the high feature product in the public choice condition compared to the private choice condition. In addition, replicating results from study 1, participants perceived other participants who selected the high feature product as having significantly more positive traits than participants who selected the product with fewer features–and this was true even for participants who selected a low-feature option themselves.

Taken together, these results have interesting implications for theory and practice. First, these studies suggest that seemingly suboptimal behavior by consumers in isolation may in fact be rational if social concerns are taken into account. From a managerial standpoint, companies aiming at increasing or decreasing the share of feature-rich products can design marketing communications that heighten or attenuate impression management concerns (or, for example, designing channels with internet versus face-to-face sales). Additionally, adding features may have a positive effect on consumption that occurs in the presence of others. In public consumption situations, consumers may extract social utility (i.e., the possibility to signal positive personal traits to others) from the mere presence of product features; though when they leave that public setting and use that product at home, feature fatigue may begin to set in.

### "Positive Consumer Contamination: Responses to Attractive Others in a Retail Context"

*Jennifer J. Argo, University of Alberta*
*Darren W. Dahl, University of British Columbia*
*Andrea C. Morales, Arizona State University*

When it comes to physical touch in retail settings, consumers are faced with a paradox: they want to touch products because it helps them gather information and make better purchase decisions (Peck and Childers 2003) but they feel disgusted when other people touch the products they want to buy and view touched products as having been negatively contaminated (Argo, Dahl, and Morales 2006). Thus, consumers desire to touch products while shopping, but do not want others to do the same. But is this always the case? Are there situations where products touched by other individuals result in positive reactions? The central focus of this research is to determine when physical contact between a product and another individual creates positive outcomes for the consumer. Prior research along with current business practices, suggests that the beauty and attractiveness of other consumers may play an influential role in addressing our research question. Although the effectiveness of appeals that utilize themes of beauty and attraction on brand attitudes and purchase intentions has been mixed (e.g., Percy and Rossiter 1992), retail managers seem to believe strongly that beauty can be an extremely powerful persuasion tool. For example, Abercrombie & Fitch has been in the headlines for specifically trying to hire "young, attractive, athletic types, and the cheerleaders who might be their girlfriends" to work in their stores (Edwards 2003, p. 16).

Despite the prominence of the belief that beauty and attractiveness are important in the retail atmosphere, surprisingly little research has actually examined the impact that people who are high in attractiveness may have on consumers during a shopping experience. To date, most research has focused on the use of attractive models in advertising (e.g., Smeesters and Mandel 2006), but has neglected a possible role of attractiveness in the retail consumption experience itself. Thus, this research provides insight into the effects of an attractive social influence in the context of consumer touching and contamination of store products. Specifically, we investigate how consumers respond when they see other individuals of varying levels of attractiveness touching the same products they want to purchase.

Building on previous work in contamination that shows people have lower evaluations of products that are touched by other shoppers (Argo et al. 2006), this research proposes that consumer contamination can also have positive effects (e.g., raise product evaluations). This prediction is tested in an actual retail environment where a product is perceived to have been physically touched by another individual. In our investigation we examine both the attractiveness level of the individual and the role the individual plays in the shopping environment (i.e., shopper or salesperson) on consumer reactions. Further, we consider the moderating role that gender may have on consumer contamination by varying whether the other individual is a male or a female and whether this matches or mismatches the gender of the consumer. Finally, we investigate the process through which positive contamination operates to see whether it follows a residue model of contagion resulting from physical contact with the other individual (Morales and Fitzsimons 2007), or if instead it is the result of a symbolic interaction model based on the interpersonal/moral factors of the other individual (Nemeroff and Rozin 1994).

Three field experiments examined the impact of level of attractiveness, gender (of both the participant and the contaminator) and the contamination event. The first two studies found that male participants evaluated a product (i.e., a shirt) more favorably when they believed that a highly (versus average) attractive female shopper had previously touched the product while female participants' evaluations were equal regardless of the female shopper's level of attractiveness. Study 2 also found that the reverse was true when participants believed a male shopper had previously touched the product. Females evaluated the product significantly more favorably when a highly (versus average) attractive male shopper touched the product while male participants evaluated the product equally low regardless of the male shopper's level of attractiveness. Study 3 sought to identify which model of contagion explains the results while extending the contamination event to include a salesperson. The study demonstrated that the physical residue model best explains the results as participants evaluated a product significantly more favorably when a highly attractive salesperson had previously worn the product and had not cleaned it (versus cleaned). In contrast, when the product was previously worn by an average attractive salesperson, participants evaluated the product more favorably when the product was cleaned (versus not cleaned). The effects across all three studies are shown to be mediated by positive affect.

### "The Push Technique: Social Influence and Predecisional Bias Among Fluid Choice Sets"

*Noah J. Goldstein, University of Chicago*
*Vladas Griskevicius, Arizona State University*
*Robert B. Cialdini, Arizona State University*

Suppose that a car salesperson wants to get either Car A or Car B off the lot, but doesn't care which one sells next. Instead of showing all the cars on the lot to the next customer sequentially, what if he first paired Car A with Car B and asked the customer to form a preference for one over the other, only showing the customer Cars C, D, and E afterwards? We argue that the customer in such a situation would be disproportionately likely to choose the originally preferred car than if he had presented all of the alternatives sequentially to the customer.

Although consumers often make purchase decisions while considering a single choice set that contains all of the available alternatives, there are many instances in which they choose from a more expansive choice set after forming a preference from a more limited choice set. What effect will forming a preference for an alterative have on a consumer's final decision when the choice set is more fluid—that is, when it is expanded to include many other alternatives? Because the existing literature on predecisional biases is limited to static choice sets (see Brownstein 2003)— choice sets in which no new alternatives are added—the extant literature does not currently provide a clear answer.

Study 1 investigated whether consumers have a predecisional bias toward an initially preferred alternative such that they disproportionately choose that alternative when the final choice set is expanded to include several other, equally desirable alternatives. We also explored whether this novel type of predecisional bias might be moderated by consumers' knowledge or lack of knowledge that they will be able to choose from an additional set of alternatives later. In Study 1, participants were first asked to review two sets of CDs that were nearly identical to one another in terms of each participant's overall evaluation of the sets. Participants were asked to state which one of the two they prefer and then had an opportunity to choose from their preferred alternative and two new alternatives. The hypothesized bias toward the initially preferred alternative would be empirically found if participants tend to choose their initially preferred alternative among the other two alternatives at a rate statistically greater than chance—that is, at a

rate greater than 33.33% for a final choice set with three alternatives.

The data revealed that regardless of awareness condition, participants were disproportionately likely to choose the initially preferred alternative in the final expanded choice set, indicating that the predecisional bias effect does occur among fluid choice sets.

Study 2 examined the role of four potential mediating mechanisms of this bias by investigating the circumstances under which the bias exists and ceases to exist: First, individuals in such situations might be encouraged to use the heuristic of consistency (see Cialdini and Trost 1998). A second potential mechanism could be that when participants state their initial preference, they generate a set of reasons for that preference and then later rely on those reasons (e.g., Maio et al 2001). A third possible mechanism for this effect could be that when choosing among the final choice set, participants identify the originally preferred alternative and spontaneously generate reasons to support their original preference (see Kunda 1987). Such a thoughtful response likely necessitates the availability of sufficient cognitive resources during the final choice. A fourth possible mechanism could be cognitive dissonance (Festinger 1957).

In Study 2, we sought to uncover the mediating mechanisms of the effect by introducing a potential moderator of the effect: cognitive load. Using the experimental paradigm from Study 1, the introduction of a cognitive load manipulation occurred during the initial preference choice, during the final choice, during both choices, or during neither choice. Thus, the design was a 2 (First choice set: Load vs. No Load X 2 (Second choice set: Load vs. No Load) between participants design.

The results of Study 2 revealed that the bias failed to occur in the two conditions in which a cognitive load was induced during the final choice set, ruling out consistency, reason generation during the initial choice set, and cognitive dissonance as possible mediators—and pointing to the generation of reasons during the final choice set as the most likely mediator of the effect. These findings have implications for social influence strategies that can be utilized by influence agents to steer consumers toward particular alternatives as a function of how the alternatives are grouped and the sequence in which the alternatives are presented to consumers.

### "Fear and Loving in Las Vegas: Evolution, Emotion, and Persuasion"

*Vladas Griskevicius, Arizona State University*
*Noah Goldstein, University of Chicago GSB*
*Chad Mortensen, Arizona State University*
*Jill Sundie, University of Houston*
*Robert Cialdini, Arizona State University*
*Douglas Kenrick, Arizona State University*

Imagine you're charged with the task of creating a television advertising campaign for a new product. Knowing that people typically don't process ads very deeply, you craft the message using proven persuasion tactics that are particularly effective when people make heuristic evaluations. After learning that the ad tests well in a focus group, you purchase airtime during two perennially top-rated television programs: a police crime drama and a sexy romantic comedy. But exactly how will these programs influence the way people respond to the ad? And will an ad featuring common persuasive heuristics be effective during both programs?

Several well-established theoretical models make predictions regarding how romantic or fear-inducing programs should influence the effectiveness of persuasive heuristics. A general *arousal model* predicts that any show eliciting some arousal will tend to inhibit deep processing and increase effectiveness of a diagnostic heuristics (Sonbonmatsu and Kardes 1988; Pham 1996). A general *affective-congruence model*, however, differentiates between positive and negative feelings, and predicts a different pattern for each show: Romantic comedies should produce positive feelings, leading to shallower processing and increased effectiveness of persuasive shortcuts. Police dramas, in contrast, should produce negative affect, leading to more careful processing and decreased effectiveness of persuasive heuristics (Schwarz and Bless 1991).

In this research we investigated another possibility grounded in an *evolutionary* approach—one that predicts a different pattern of results. This approach suggests that television programs—or any kind of visual, auditory, or other sensory stimuli that precedes an ad—can activate qualitatively different motives and particular associated emotions, which in turn promote perceptions, cognitions, and behaviors conducive to the successful fulfillment of the active motive. Unlike models of general arousal or affect, this approach maintains that depending on which motive is currently active, a target will be tactically receptive to some messages and ignore others, selectively interpret the same information in completely different ways, and even respond negatively to some well-established persuasive strategies.

In three experiments we tested the influence of emotion-arousing contexts on two types of commonly used persuasion heuristics: *Social proof* and *scarcity* (Cialdini 2001). Social proof heuristics are based on the general heuristic rule that if many others are doing it, it must be good; social proof appeals tend to convey that a product is a top seller or is particularly popular. Scarcity heuristics are based on the general rule that if a product or opportunity is rare, it must be good; scarcity appeals tend to highlight features related to the distinctiveness, rarity, and uniqueness of a product or an opportunity.

According to an evolutionary perspective, the motives and emotions having the strongest effect on cognition and behavior are those most closely related to survival and reproduction. Following this logic, we investigated how social proof and scarcity heuristics are influenced by two such motives: the motive to *protect oneself from danger* and the motive to *attract a romantic partner* (Kenrick, Li, and Butner 2003). Given that self-protection motives produce group-cohesive processes and lead individuals to desire to join together with others, we predicted that (H1) Fear-inducing contexts should lead social proof heuristics to be more effective, but cause scarcity heuristics to be counter-persuasive. Given that romantic motives are likely to produce a desire to stand out from the crowd by positively differentiating oneself from one's rivals, we predicted that (H2) romantic contexts should lead scarcity heuristics to be more effective, but cause social proof heuristics to backfire.

Contrary to predictions made by general arousal and affective-congruence models, the first two experiments showed that fear-inducing and romantic contexts influenced the effectiveness of the two heuristics in a way consistent with an evolutionary perspective. Fear led scarcity heuristics to backfire, while leading social proof appeals to be more persuasive. In contrast, romantic content led social proof heuristics to backfire, while leading scarcity appeals to be more persuasive. Not only were these findings different from those predicted by general arousal or affect models, but they cannot be explained by a simple persuasion matching-mismatching models.

Overall, this work demonstrates the utility of an evolutionary approach in consumer behavior by showing that an evolutionary approach can produce unique and testable predictions. Although this rich theoretical perspective has successfully led to theoretical advancements in the fields of biology, behavioral ecology, anthro-

pology, psychology, and economics, evolutionary models have thus far been almost completely absent in research in consumer behavior. We believe that the present work—and an evolutionary approach—reflect only the tip of a data-rich iceberg that can serve as an impetus for novel research and theory-building in marketing.

# Consuming Uncertainty: Feelings, Expectations, and Wishful Thinking in Consumer Choice and Experience

Eduardo B. Andrade, University of California, Berkeley, USA

## SESSION OVERVIEW

Managers and consumers usually think of uncertainty as a negative—to-be-avoided—aspect of a given purchasing or consumption experience. The four papers presented in this symposium challenge this intuition. *Andrade and Iyer* show that in a scenario where they must "pre-commit" to a sequence of 2 gambles, consumers choose to lower their bets after anticipated losses (vs. gains). When losses are eventually experienced, they bet more than they had initially planned. Dynamic inconsistencies are not observed after gains. The authors discuss potential underlying processes and the role of feelings. *Nelson, Galak, and Vosgerau* investigate the potential (mis)matching between forecasting and experiencing excitement. In prospect, people seem to put a substantial premium on the excitement of outcome uncertainty in televised sporting event, but it remains unclear if this actually improves the experience. The authors show that in many cases, uncertainty operates much different than consumers predict. Although people enjoy a live game more than a taped game, the benefit is eliminated if people also place a bet in the game. Moreover, people enjoy the uncertainty that comes with wagering on games, despite the added anxiety it brings. Furthermore, though people believe that knowing the outcome in advance will ruin the experience, it actually has no negative effect, and knowing the game play ahead of time actually improves the experience of watching the game.

*Mazar and Ariely* expand the relationship between uncertainty and excitement by investigating probabilistic discounts. When will a probabilistic discount (i.e., gambling-type) be preferred over a fixed discount? Why would it be preferred? The authors show that probabilistic discounts are more appealing than fixed discounts of the same expected value. Moreover, this preference results from a desire to "avoid the pain of paying" rather than to "enjoy the excitement of the gambling". Finally, *Goldsmith & Amir* also show that there are motivational advantages to uncertain cues. They find that promotions offering uncertain rewards are more persuasive than those which offer certain rewards with a higher expected value. For example, lotteries between smaller and larger rewards can be as attractive as larger certain rewards. Consumers tend to show intuitive wishful thinking, a tendency that may be mitigated through elaboration and a-priori attitudes.

In short, consumers occasionally seek uncertainty, even when it seems strictly suboptimal. Although they may derive direct utility from it (Goldsmith, Amir; Mazar & Ariely) they might also overestimate its benefits (Nelson, Galak, & Vosgerau). On other occasions consumers will to endure its costs (Andrade and Iyer) in pursuit of a distal benefit. Regardless, whether in the context of gambling, product promotions, or televised sports, it seems clear that consumers will frequently incorporate the anticipated levels of uncertainty into their decision making process.

We are pleased to have Tom Meyvis as our discussant, whose expertise across the entire field should help to integrate the four papers and place them in the context of the ongoing theory, research, and practice of consumer research.

## EXTENDED ABSTRACTS

### "Dynamic Inconsistencies in Gambling: The Role of Feelings"

*Eduardo B. Andrade, University of California, Berkeley*
*Ganesh Iyer, University of California, Berkeley*

Anecdotal evidence suggests that in a gambling environment people might violate pre-commitments, and bet more than they had initially planned. In this paper, we investigate this phenomenon in a scenario where (i) participants have full information about the characteristics of the gamble prior to a planning phase (ii) the time period between the planning and actual phases of the gambles is very short (around 1 minute), (iii) and participants are reminded of the planned bet right before the actual bet. The research paradigm follows a two-stage process. First, during the *"pre-commitment" phase*, participants are asked to pre-commit to a series of 2 fair gambles. In gamble 2 they are given the opportunity to bet contingent on winning/losing the previous bet. Then, during the *actual phase* of the gambles participants are unexpectedly allowed to confirm or revise the "pre-committed" bets. In other to increase external validity, participants are authorized to use their own participation fee in the experiments and bet any amount within a pre-determined budget (i.e., $0 to $5 per gamble).

The results throughout all three experiments show that, on average, participants plan to bet less after an anticipated loss and the same amount after an anticipated gain. Also, asymmetric dynamic inconsistencies emerge during the actual phase of the gamble, as participants bet on average more than initially planned after experiencing a loss and the same amount after experiencing a gain.

Experiments 2 and 3 address the mechanisms leading to the systematic deviation after losses. Following the hot-cold empathy gap, we hypothesize that people underestimate their negative feelings and its impact on subsequent behavior. It has been shown that people eat more, shop more, take more drugs, and report riskier sexual behaviors than they had initially planned in a cold state. Whether deprived from food, information, drugs, sex, or money individuals will react, and usually exaggerate, in an attempt to reestablish the prior state. Translated into gambling contexts, it means that during the pre-commitment phase (cold state) participants underestimate the impact of the feelings during actual phase (hot state). Precisely, negative emotions generated by losses lead people to "over bet" (i.e., positively deviate from the initial plan) in a visceral attempt to restore a current affective state in the prospect of winning.

In experiment 2, therefore, an affective correction manipulation is used, where a subset of participants is asked to avoid using their post-outcome feelings generated in gamble 1 during the subsequent bet. Consistent with the hot-cold empathy gap, the asymmetric dynamic inconsistencies disappear when people are requested to correct for the potential impact of post-outcome feelings of gamble 1 on bet decisions in gamble 2.

In experiment 3, we assess whether participants underestimate their negative feelings after a loss. Following the pre-commitment phase but before the actual phase, participants are asked to forecast their feelings after a potential gain and after potential loss in gamble 1. Once the outcome 1 is realized participants are asked to report

current feelings. The results show that participants on average underestimate how bad they will feel after a loss in gamble 1 and are on average accurate about their positive feelings after a gain. Moreover, most participants who deviate from the plan after a loss are also the ones more likely to underestimate their negative feelings after the loss is experienced. No such contingency is observed after a gain.

### "The Unexpected Enjoyment of Expected Events: The Suboptimal Consumption of Televised Sports"

*Leif Nelson, University of California, San Diego*
*Jeff Galak, New York University*
*Joachim Vosgerau, Carnegie Mellon University*

Sometimes uncertain events are more exciting than their certain alternatives. Consistent with this excitement-seeking drive, when watching sporting events people put a substantial premium on the feeling of uncertainty by experiencing them live (as opposed to taped) or by placing wagers on the outcomes (Vosgerau, Wertenbroch, & Carmon, 2006). Does all this extra uncertainty and anxiety actually improve the experience? Recent work suggests that it might not, instead suggesting that the added uncertainty may come at a cost to the enjoyment of the experience (Mandel and Nowlis, 2007). Four studies investigate the influence of prediction and outcome knowledge on the experience of watching sports programming. We derive two types of uncertainty, process and outcome, in order to manipulate and identify which factors make televised sports most enjoyable to watch. Inclusive in this analysis is a consideration of sports betting, which had been previously shown to have a negative influence on enjoyment, but which in these studies we show can have a highly variable influence.

In our first study, American participants watched the final few minutes of closely contested women's European handball match. Some participants were told that the game was being streamed live from Germany, whereas the remainder were told that it was a previously taped game. Additionally, approximately half of the participants in each group were given an opportunity to predict the winner of the game (after reading some basic information about the teams). All participants then watched the game and indicated how much they enjoyed it. As people have forecasted in previous research (Vosgerau, Wertenbroch, & Carmon, 2006) participants enjoyed the game more when it was 'live.' However, this difference only held for people who did not bet on the game; the difference was eliminated for people who had an additional stake in the outcome. Though some uncertainty improves the consumption of televised sports, when coupled with the arousal of a bet on the outcome, uncertainty has no additional impact.

Study 2 compared three different viewing conditions (this time of the overtime period of a professional basketball game): A control condition, a betting condition, and a condition in which the participants knew the final score beforehand. All of these Experiencers watched the entire 15-minute clip and reported their enjoyment. We were particularly interested to know if people were well calibrated to the influences of these factors, so we asked Forecasters to read a description of the each condition the Experiencers faced and to predict their enjoyment. Forecasters accurately predicted that people would enjoy the game more when they bet on the outcome, but they incorrectly predicted that people would enjoy the game less when they knew the outcome. Forecasters universally thought that eliminating outcome uncertainty would ruin the viewing experience, but it had no impact whatsoever.

But is all uncertainty the same? When people think of uncertainty in sports they instantly think of the outcome, but fail to consider the uncertainties of each event leading up to the game outcome. It may be the case that, in fact, the cumulative impact of those smaller uncertainties may outweigh the outcome uncertainty when determining the overall enjoyment. When this process uncertainty is reduced or eliminated, the anxiety associated with it is also removed leaving people to experience only the excitement associate with the experience. Study 3 sought to show that process uncertainty, rather than outcome uncertain was the driver of enjoyment. When watching the same overtime period as in Study 2, half of the participants were told which team would win the game (outcome certain) and half were not (outcome uncertain). Furthermore, for about half the participants the audio channel was offset so that the announcers reported on the game play 3 seconds ahead of time (process certain) versus 3 seconds delayed (process uncertain). In accordance with our hypotheses, Forecasters thought that they would enjoy watching the game less when either outcome or process was certain. But, in fact, Experiencers enjoyed watching the game equally whether the outcome was certain or not. Viewers enjoyed the game more when the process was certain than when it was uncertain. So, while viewers think uncertainty generally enhances enjoyment, process uncertainty actually dampens it.

Is it always the case that process uncertainty is aversive? Study 4 addressed this question by having participants watch the same overtime period as in Studies 2 and 3. Approximately half of the participants bet on the outcome of the game and the other half did not. Additionally, we again manipulated process uncertainty by offsetting the audio channel either 3 seconds ahead of time (process certain) or 3 seconds delayed (process uncertain). We reasoned that bettors were actually deriving hedonic value from the feeling of anxiety, and so their enjoyment should go down with increased certainty. For non-bettors we replicated our finding from study 3: process uncertainty is aversive. However, for bettors, process certainty was aversive. Furthermore, by collecting continuous measures of excitement throughout the entire viewing experience we were able to determine that this variability was only present in the second half of the experience, when the outcome was looming. Though betting on sports can make them more enjoyable, that enjoyment is predicated on the uncertainty of the entire event.

### "Probabilistic Discounts: When Retailing and Las Vegas Meet"

*Nina Mazar, Massachusetts Institute of Technology*
*Dan Ariely, Massachusetts Institute of Technology*

People love to gamble. Recent numbers provided by Christiansen Capital Advisors CCA and the American Gaming Assocation (http://www.americangaming.org) support the notion of gambling as a mammoth phenomenon in our society: Consumer spending on traditional gambling including commercial casinos, racetracks, card rooms, and lotteries generated a $85 billion input to the U.S. economy in 2005 and Internet gambling has been estimated to reach $25 billion in global revenues by 2010. Given these observations we were wondering whether we can design a new type of discount that combines retailing with gambling such that it becomes more attractive for both consumers and retailers.

Imagine that you are at the checkout of your local video store and they offer you one of two discounts: What would you choose?

A fixed discount that offers a guaranteed 10% off your purchase OR

A probabilistic discount that offers a 10% chance to get your purchase for free and 90% chance to pay the full price

Choices among gambles have been the "fruit fly" of research on decision-making. In the current work we examine gambles in context of purchases and in particular in context of discounts. There are several reasons why a probabilistic discount is likely to work.

First, there is the attraction of the gamble itself, due to excitement, curiosity, wishful thinking, or variable schedules of reinforcement. Second, getting something for free (i.e. zero price) seems to not only reduce cost, but also add benefit such that people are disproportionally attracted to free items (Shampan'er and Ariely, forthcoming). Finally, recent evidence suggests that paying–part of the buying transaction–is psychologically painful and people therefore try to avoid paying (Prelec and Loewenstein, 1998).

The questions we examine are: 1) Under what conditions do consumers prefer risky / probabilistic discounts? 2) Under what conditions would consumers spend more money if they were given probabilistic discounts? 3) What is the cause for the attraction of the probabilistic-discount? 4) Finally, we use this type of data to examine whether consumers think of purchasing more as a gain or as a loss in terms of their risk attitude.

We examine these questions in four experiments. First, in a field experiment we offer customers of a local video store at checkout a choice between a fixed discount and a probabilistic discount on one video rental with equal expected value. We examine the preference between these two discounts at a 10%, 33%, 50%, 67%, and 90% chance of getting one rental for free and find that in general customers significantly prefer the probabilistic discount over the fixed discount.

Next, we designed an online store in which students were able to spend their own money and buy items ranging from $0.50 (candy) to $15 (Amazon Gift Certificate). We had three different versions of the store manipulated between subjects, offering a 10% fixed discount, a 10% probabilistic discount, and a choice between these two types of discounts. Our results show that customers in the probabilistic discount store purchased significantly more of the cheaper items but significantly less of the expensive items. Customers shopping in the store that offered both types of discounts showed a pattern of behavior that was somewhere in the middle although they showed a strong preference for the probabilistic discount.

In a third experiment, we repeated the first experiment in the local video store but this time varying the probabilistic discount such that it would not always offer a chance to get the item for free but instead to buy it for a small, insignificant amount (probabilistic discounts: 11% chance to pay $0, 12% chance to pay $0.38, 13% chance to pay $0.69), while keeping the expected value the same. Again we find that in general customers significantly prefer the probabilistic discount over the fixed discount and that it does not matter whether the probabilistic discount involved a chance of getting the item for free or for a small $ amount. This result suggests that the attraction of the probabilistic discount is not due to the special role of a zero price.

Finally, we contrast consumers' preference for risky options over sure options in context of purchases for a designer pen with purchases of gift certificates for Amazon.com (a product that comes relatively close to money) and with their preferences in context of gambles involving money-prizes of equal expected surplus. Our results suggest that the attraction for risky options is higher for product purchases than for gift certificate purchases, and even higher than for monetary gambles. Together these findings suggest that the probabilistic discount is significantly driven by the pain of paying involved in a purchase and not (only) by the gamble and the excitement of winning something.

By bringing probabilities to the marketplace we are able to examine how consumers react to probabilities in settings that they are more used to, and hopefully expand our understanding of decision-making under risk more generally.

### "Wishful Thinking: How Uncertainty Can Improve Promotions"

*Kelly Goldsmith, Yale University*
*On Amir, University of California, San Diego*

Advertisements for consumer incentives often contain varying degrees of certainty as to the nature of the incentive. For example, one advertisement might promise a generous gift with purchase. Another might offer a gift with purchase which could be either a generous gift or a more modest gift (the latter incentive being comparably more uncertain). As wishful thinking is only free to operate when the value of an incentive is not explicitly delineated, it seems possible that appraisals of an uncertain incentive's value could be boosted by wishful thinking and might even exceed those aroused by a more specific incentive.

Most conceptualizations of consumer behavior suggest that people tend to be risk averse over gains, that is, they prefer a sure good to a lottery of equivalent expected gain. In particular, because receiving a free gift in a promotion is a gain for consumers, Prospect Theory argues that consumers should be risk averse and favor the more "certain" outcome (Kahneman & Tversky, 1979). However, research has also shown that uncertainty can allow consumers to wishfully think that a superior outcome will emerge and use that as an "elastic justification" (Hsee, 1995). Thus the results on uncertainty are mixed and the question of when wishful thinking aroused by greater uncertainty can boost the perceived value of an incentive above its expected value remains unresolved.

The key hypothesis of this paper is that such instances exist. We claim that uncertain incentives can be appealing when our natural wishful thinking is allowed to operate. This premise relies on the following assumptions about judgments in the domain of gains: 1) People intuitively demonstrate wishful thinking; 2) This wishful thinking holistically increases the perceived value of uncertain rewards; 3) When the judgment is not intuitive, or when factors that inhibit wishful thinking exist, this effect will not occur. We test the theoretical and empirical foundations for these premises in a series of experiments by altering the degree of certainty in the incentives which consumers are shown and assessing consumers' judgments of those incentives.

Our pilot study demonstrates that uncertain promotions can be more motivating than their expected value, and consequently may be as motivating as certain high value rewards. In one condition we offer either a high value reward (a free iTunes song download) and in another condition a low value reward (a point towards a future prize). In a third condition we offer the lottery between the above-mentioned rewards. In line with our predictions, our results show that the lottery between the high and low value rewards is just as effective at generating interest as the high value reward.

Experiments 1-5 explore the process behind this effect. The results of these studies demonstrate that our intuitive wishful thinking is what colors an uncertain incentive with a rosy glow. Thus when we are told that the incentive is a lottery between a high value and a low value reward, our automatic, intuitive response is to perceive the value of this uncertain offer as being greater than its expected value.

We find that this intuitive wishful thinking is different from generalized optimism and is not driven by a biased understanding of base rates. Experiments 1 and 2 illustrate the intuitive nature of these assessments: when any elaboration is encouraged before judgments are made, the positive effect of uncertainty is significantly diminished. Calling into question one's likelihood of receiving the high value incentive (Experiment 1), or simply encouraging participants to "think carefully" before responding (Experiment 2) negates the operation of automatic wishful thinking. In both instances, interest in the uncertain incentive dropped significantly and was on par with interest in the low value reward, as opposed to the high value reward. Interestingly, ratings of one's likelihood of receiving the high value incentive made ex-post were statistically indistinguishable from those made ex-ante, supporting the claim that this effect is not driven by a biased understanding of base rates.

While we demonstrate that when allowed to operate wishful thinking can increase the perceived value of an uncertain gain above its expected value, one may question if the participants evaluating the lottery incentive are actually engaging in wishful thinking or if they are simply focusing their attention on the more extreme of the two outcomes. Experiment 3 rules out this alternate account by assessing consumers' interest in receiving a flu shot when the side effect is either negative (extreme option), moderately negative (preferred option), or a lottery between the two. In line with our contention that consumers employ innate wishful thinking, interest in this lottery condition does not resemble interest in the extreme alternative, but rather resembles that of the preferred alternative with interest in each being higher than that of interest in the extreme option.

Experiments 4 and 5 manipulated antecedents of optimism to further explore what drives interest in uncertain offers. The results demonstrate that when affect is manipulated, uncertain incentives can be as motivating as high value incentives offered with certainty when a positive mood is induced (Experiment 4). As prior research has demonstrated the correlation between mood and optimism (Marshall et al, 1992), these results illustrate how heightening wishful thinking can increase the positive impact of uncertainty on a promotion's effectiveness, while dampening it has deleterious consequences for interest in uncertain incentives. Experiment 5 replicates these findings using a-priori trust in the retailer to manipulate wishful thinking. Again, when wishful thinking is allowed to operate it increased the effectiveness of the uncertain promotion beyond its rational value. These results illustrate a boundary condition which should read as cautionary to some retailers: uncertainty might not be positive when the nature of the retailer promotes skepticism; on the other hand, trusted brands and established venues may benefit by adding uncertainty to their promotions.

Our results contribute to a growing body of literature on how and when uncertainty can be motivating. We believe the research enriches our understanding of how consumers react to retailer promotions and has clear practical implications for marketers.

# Doing Family: The Temporal and Spatial Structuring of Family Consumption
Linda Price, University of Arizona, USA

## SESSION OVERVIEW

The purpose of this session was to bridge sociological and family research on the temporal and spatial dynamics of the ideologically laden enterprise of "doing family" with family consumption research. The session broadly contributed to our understanding of family consumption, a neglected and vital topic for consumer research. In addition, we enhanced understanding of how consumption, time and space interplay and are constitutive of the structures of domestic life. Relatively little consumer research addresses this interplay. The session was of broad interest to consumer researchers interested in family, identity, mundane consumption, time and technology. The presentations confronted challenges of doing family in contemporary consumer culture, challenges many of us encounter in our own family lives.

The family is a fundamental building block of society that impacts numerous areas of life and represents an important consumption unit intermediate between individuals and society (Netting, Wilk and Arnould 1984). Despite its importance, compared to the vast array of studies focused on individuals, there is still relatively little work on families in consumer research and important research questions remain (Commuri and Gentry 2000). One important yet neglected aspect of family consumption is the micro spatial and temporal dynamics of everyday family life—the coming together and moving apart in time and space that characterizes doing family (Daly 1996, 2001; DeVault 2003). Consumer researchers have focused on transitional episodes such as divorce, moving and aging on family consumption and have also explored the structural life cycle of families. However, the micro movements of family members together and apart in space and time have been almost wholly neglected in consumer research.

A burgeoning array of social science research is dedicated to examining family time as "the central organizing feature of family activities" (Presser 1989, p. 536; Daly 1996; Folbre and Bittman 2004; Zvonkovic, Manoogian and McGraw 2001). Nevertheless, "the meaning of time for families has been insufficiently problematized," generally residing in the recesses of discussions about caregiving, work-family balance and socialization (Daly 1996, p. 2). One area deserving of more attention is how space and time interplay in the material and symbolic organization of family experience (Silverstone 1993; 287). Family time might even be theorized as "transsituational or spatially dislodged," with family activities mobilized over cell phones, computers and on-line environments (Daly 1996, p. 221; Gillis 2001).

Family activities in space and time are heavily freighted ideologically. Key tensions among family members and between families and broader ideological currents are often played out over family dinners and family vacations. Yet, there is little appreciation for nontraditional and conflictual aspects of family time and space (Winton 1995). For example, family meal times are traditionally cast as positive experiences central to family preservation and reproduction, but research shows that dinners are a site for conflict (Vuchinich 1987). Similarly, Larson and Richards (1994) discovered that tired and hungry adolescents and parents together struggle with "the 6 o'clock crash." Likewise, family vacations intended as a temporal oasis, may instead become a conflictual performance of irreconcilable individual and relational goals (Daly 1996).

Discussions of family activities and "quality-time," almost always implicate consumption (Daly 1996; English-Lueck 2002; Schor 2005). However, with few exceptions, sociological research shows little understanding of how consumption and family identity interplay across a spectrum of possibilities—sometimes contributing to fragmentation of family life but other times facilitating family togetherness (Daly 1996; English-Lueck 2002). Family problems are attributed to a lack of "family time" driven by consumption desires (Schor 2005), but there is little information about consumption strategies families employ to contend with barriers to spending time together.

Previous research has shown an explosion of technology into family space. Some argue consumer technology from televisions to computers and cell phones challenges the traditional temporal and spatial boundaries between work life, home life and leisure in myriad ways (Jackson 2002). But research is needed to examine whether and how families experience technologies as threats and resources in relationship to family time and space (Daly 1996; English-Lueck 2002).

The first paper by Kelli, Linda and Eric examined family dinner as a mundane but problematized spatial and temporal juncture for "doing family." The second paper, presented by Amber investigated coming together as a family on family vacations and the dynamic interplay of individual and relational identities enacted in this idealized "temporal oasis." The third paper by Fleura, Robin and Meera considered the problematic challenges of enlisted military families confronting centripetal and centrifugal movements associated with military deployment. Each of the three papers incorporated the passive and strategic roles of marketplace resources in the movement of families apart and together and examined the role of consumption in family activities. All the projects are ongoing multi-year endeavors and presentations were based on substantial data. Our discussion leader, Robert Kleine who has research interests in identity and mundane consumption engaged our audience in a thoughtful discussion that complemented the composite of papers in the session as well as added a different perspective.

## EXTENDED ABSTRACTS

### "Consuming Family Dinner Time"
*Kelli Gutierrez, University of Arizona*
*Linda L. Price, University of Arizona*
*Eric J. Arnould, University of Wyoming*

What do families do together? According to recent research, family members still predominantly use their limited time resources during shared meals (with TV a close second on weekdays, and travel a close second on Saturdays) (Robinson and Godbey 2000). However, the amount of time spent on family meals, especially weekday family dinners, has declined significantly during the past thirty years (Mestdag and Vandeweyer 2005; Jones 2001; Schor 2005). Simultaneously, this particular kind of family time, time spent over family dinner, is positively correlated with benefits such as reduced childhood obesity, aiding literacy development and reduced speech impairments, language socialization, lower levels of behavioral problems, higher academic achievement and reduced drug and alcohol use among teens (Califano 2005b; Fiese, Foley, and Spagnola 2006; Hofferth and Sandberg 2001; Neumark-Sztainer 2006; Ochs and Shohet 2006; Snow and Beals 2006). However, as with time-use diaries, these correlational data based on self-reports provide little insight into whether and why family dinner is actually important to families and how it is

experienced by them (Daly 1996; 2001). For example, in these studies, "weekly dinners together" may be the only measured indicator of family time, leaving unanswered the question of whether other kinds of family time (hiking, playing games or even watching TV together) would have equivalent benefits. Moreover, this measure may map more closely to what families believe they should do rather than what they actually do.

By contrast with the rosy portrait of family meals in some research, others argue that dinner time is an experience when parents and children come together with all the stress and fatigue induced by their participation in the outside world. Hence, energies are low, needs for nutrient and emotional energy high making reentry into the cohesive ideal of family life precarious. Family members may exert pressure on others to perform family roles in conformance with ideals provoking a backlash or may fail to perform as they themselves would wish, provoking dissonance and regret (Daly 2001, 207).

Our study examined whether and how family dinners are embedded in the centrifugal and centripetal dynamics of everyday family life, the diversity of meanings they have for families and the intentions and practices surrounding their enactment. We uncovered whether and why families attach importance to this particular use of scarce family time and whether and how family dinner practices coalesce with their ideological representations of their social value. In this way we provide a more nuanced conception of the relationships between the enactment of family, time and consumption.

Our ongoing project is comprised of participant observation and depth interviews with a diverse group of North American families including dual-income households with multiple children, blended families, single parent families, and dual-income couples without children. We sampled a diversity of informant families in order to uncover commonalities and differences in the meanings and experience of family time and family dinner. The project is conducted in the homes of informants before, during and after weekday evening meals and consists of approximately six hours of participant observation with each family including an average 60-90 minute depth interview with one or both parents, with follow-up interviews as needed. Using a modified time-diary approach, care was taken to situate a particular observed family meal within a weekly time-frame of family meals and time. Projectives were also employed to explicitly inform understanding of policy initiatives such as the "Family Day" campaign.

Findings reveal that family dinner is viewed as a priority family project fundamental to the identity of the family, but often at odds with individual and other relational identity projects. Informant families believe that they should have dinner together and intend to do so. Nevertheless, we uncovered substantial variance in what constitutes a family dinner as well as a diversity of meanings and enactments. Negative cases of families that favor other uses of scarce family time provide interesting points of contrast.

Why is family dinner a preferred way to spend scarce family time? Our findings suggest that as compared with other family time, the proxemic conventions of the family dinner table, norms for behavior, and the structured consumption sequence are viewed as facilitating and enforcing disclosure, intimacy and collective identity. In addition, the time of the weekday evening meal as compared to other times represents a symbolic coming together and cleansing of the family consistent with a nostalgic rendering of family time as a refuge from the outside world.

Paradoxically, while gathering for dinner seems responsible for most of the benefits (some home-cooked nutritional appeals aside), the problem of "what's for dinner," afternoon energy deple-

tion, combined with a steady stream of daily "emergencies" and technological intrusions creates a disjuncture between intentions and enactments of family dinners. In addition, although the actual components of a meal may be difficult to recall and unremembered the next day by participants, a complex array of conflicting norms implicitly constrain what is acceptable to serve as a family meal and may disrupt the intent of family dinner. These norms also constrain the portfolio of marketplace resources that families look to as a way of gaining control over this family time (i.e. pizza is okay in an emergency, pizza is okay once a week or so, pizza together is better than nothing and so on). Blaming daily "emergencies" plays a special role in maintaining the dream of family time against a reality of "failed" enactments.

## "Idealized Family Time: Collective Identity Interplay in Vacations"

*Amber M. Epp, University of Nebraska-Lincoln*

Contemporary families face diverse challenges to engaging in collective identity projects. Families such as blended, divorced, single-parent, and co-parenting from separate households sometimes result in family separation in both time and space (Daly 1996; Smart and Neale 1999). In addition, to some extent, the privatization of family possessions—evidenced in family members having their own televisions, computers, cell phones, and other personal technologies—may encourage individual interaction at the expense of collective interaction. Technology presents a paradox that leads both to assimilation and isolation effects (Mick and Fournier 1998), transforming family interaction in ways that reconstitute family relationships while simultaneously limiting time spent as a collectivity. Further, overbooked families spend much time engaging in separate activities such as work, after-school activities, music lessons, or sports, leaving less time for families to spend together (Elkins 2003).

As one result of these challenges, family identity practices spill out of the household as families find ways to interact purposively in time set aside just for family. Specifically, idealized family vacations are "culturally viewed as a temporal oasis away from rigid demands and schedules" (Daly 1996, p. 74). Vacations represent an increasingly relevant activity to both families and service providers. "Travel and tourism generates $1.3 trillion in economic activity in the U.S. every year" (TIAA 2006). In addition, families indicate that traveling with their families has become more important over recent years and gives time-poor families much needed time to bond (Gardyn 2001). Family vacations also offer a theoretically enlightening context. Staging collective experiences, particularly family leisure activities, helps families develop a sense of family identity (DeVault 2000; Shaw and Dawson 2001). Further, within this consumption milieu bounded in a particular time-space, families manage multiple identity projects and highlight the complexity of collective goals, choices, and actions that occur in families.

Family identity represents a co-constructed, collective identity that exists in action (Blumer 1969) and may diverge from the individual and relational-unit identities of its members. These relational units such as parent-child, couple, or siblings construct unique identities, discourses, rituals, symbols, and experiences that they enact as complementary, overlapping and competing consumption practices. Consumer studies reveal that marketplace resources offer solutions for managing identity tensions within individuals (c.f. Ahuvia 2005; Murray 2002; Oswald 1999; Schau and Gilly 2003; Thompson and Hirschman 1995; Thompson and Tambyah 1999; Tian and Belk 2005). Despite the noteworthy contributions of these studies, we have virtually no understanding of how collectivities manage the bundles of identities that coexist

in families. As co-producers of family experiences, service providers would benefit from such an understanding by indicating potential roles of firm resources in identity-constituting practices. The following research question guided my study: How do families use marketplace resources as they constitute and manage interplay among family, relational, and individual identities?

Based on semi-structured, group interviews with 22 families representing diverse family forms, this study uncovers a range of families' identity goals and practices that draw on marketplace resources. The interviews took place in families' homes to facilitate auto-driving techniques using vacation photos, videos, and artifacts and were designed to expose and discriminate among aspects of individual, relational, and family identity as enacted in this context.

Study findings revealed that despite idealized notions of vacations as strictly family time, families highlight not only collective practices involving the entire family, but also emphasize multiple relational bundles in their vacation experiences. Families used vacations as a bounded time-space context to construct, revise, and manage multiple identities. Among the participants in this study, families fell along a continuum of synergy and discord among displayed collective, relational, and individual identity projects. For instance, in some families, each combination of relational units (the whole family, subsets of family, and individuals) employed marketplace resources similarly and selected comparable activities to define themselves—demonstrating synergistic identity projects across groupings.

In the case of managing discord across groupings, voluntary displacement of one identity project for another was a common theme. Examples include a husband known as the family chef relinquishing the kitchen in a shared condo to his wife and her sisters to revitalize sibling identities; a grandfather supporting his wife and grandchild in their quest to explore gendered relational identity by having tea at American Girl Place; and an extended family encouraging a couple with multiple children to go out and do something they used to enjoy together. One contribution of this study is that it shifts the focus of group decisions away from relative influence (as most frequently studied—c.f. Filiatrault and Ritchie 1980; Litvin, Xu, and Kang 2004; Su, Fern, and Ye 2003) and instead considers the interplay of collective identity projects by examining identity goals, enactments, and discourses that might shape sub-decisions in the vacation context.

Prevalent across families, I observed an array of identity construction practices. In several families, participants' explicit purpose of taking the vacation was to establish new collective or relational identities. One newly-formed stepfamily indicated they took the trip as a bonding experience for their two daughters and stepfather, and all agreed that the vacation was a turning point: "we were able to accept him into our lives" (daughter). For a widowed, single father with two boys, the family vacation offered a shared time-space to "get out and build some light memories" together and establish a new family identity following this difficult transition.

In some cases, families draw on vacation experiences to revise boundaries around relational units. The most recurrent strategy families demonstrated involved integrating additional family members into existing subgroup identity practices. In many cases, parents established vacation traditions, such as visiting the same special place year after year or going out to breakfast every morning, which they extended to their children or to new members that joined the family. For one family, defined internally and by others as heavily involved in community service, a mother invited her son to join her on a "volunteer vacation" to build a recreational center for a poor village, an experience the mother participated in regularly.

### "Domesticating Technology to Build Army Family Identity"

*Fleura Bardhi, Northeastern University*
*Robin Coulter, University of Connecticut*
*Meera Venkatraman, Suffolk University*

Recently researchers have examined family identity practices (Commuri and Gentry 2000; Moore, Wilkie, and Lutz 2002; Price, Arnould and Curasi 2000). A related stream of research has suggested that new technology impacts physical and socio-cultural spaces in the home, and is changing popular conceptions of home and family (Venkatesh, Stolzkoff, Shih, and Mazumdar 2001). In this research, we focused on military families, nested within US Army subculture and confronted with the centrifugal-centripetal stressor of episodic deployment of family members into harm's way. Our work contributes to literatures on family, family roles and life projects and their associated conflicts, and the interplay of technology and family identity.

We conducted depth interviews with 18 wives (aged 24-44) of Army enlisted men, with children, living in on-post housing at two deployment Army posts. The interview was focused around two topics, home and technology, but the flow of the interview emerged in relation to characteristics of informants' experiences, and meanings (Thompson 1997). We then visited the homes of 14 informants to better appreciate their personal circumstances, their living space, and understand how the family locates technologies in their home space. Interviews were transcribed and scrutinized by hand and with the aid of a computer-based text analysis package, NVIVO. A narrative analysis enabled us to better understand technology's facilitating role in the creation and maintenance of family identity (McCracken 1988).

Army families experience special centripetal-centrifugal conflicts. Although in principle the Army enlists soldiers, in fact it enlists families; and Army spouses (94 percent of whom are wives) are expected to fully integrate into Army culture (Houppert 2005; Leyva 2003). Army families of enlisted men face many challenges– they are of low socio-economic status, are typically blended families, they relocate Army posts every two to three years, and for the past four years, they have contended with a spouse's deployment to military danger zones overseas. When their husbands are on post, Army wives fulfill traditional familial roles of wife and mother. When their husbands are deployed, the wives facilitate and sustain "family togetherness" over time and space. In some ways, these women become single moms, responsible for all household activities, and dual parental roles. Yet, they must determine how and when to involve their husbands in the family's daily life. They are cautious and think carefully about whether something is worth "burdening" or "distracting" their husband from his assigned duty– the war (see also Houppert 2005). These wives increasingly utilize information and communication technologies (ICTs) during husband deployment to sustain the family as well as manage their everyday household duties.

Recent work has considered the domestication of technology, the process by which public and pre-formed technology narratives are appropriated into the family, inscribed with private meaning and transformed into acceptable symbolic objects (Berker, et al. 2006), ultimately articulating particular family values (Silverstone 2006). The metaphor of domestication suggests that technology is a wild animal that is tamed through household agency which exerts control of domestic space and time and through which both the family and technology are altered (Morley 2006).

Consistent with previous research, we find technology has a multi-faceted impact on the family (Hoffman, Novak, and Venkatesh 2004, Mick and Fournier 1998). Our findings substantiate the domestication of technology—"the co-production of the social and

the technical" (Sørensen 2006, p. 46). Herein, we focus on two aspects of domestication–objectification which is concerned with the spatial aspects and incorporation which deals with the temporal aspects of domestication (Silverstone et al. 2006). An overarching theme that emerges from our data is "control," related to the space and time needed to create family identity and cohesion.

With regard to objectification, our informants deliberately and strategically locate technology in the home to facilitate family togetherness. In many homes, computers, webcams, and other information and communication technologies are placed in the public space of the living area and often serving as a center for family togetherness (e.g., a family movie or game night). In some instances, placement of technology is an artifact of the lack of space in "old" on-post housing units. However, in "new" on-post housing units with extra space, families make conscious decisions to locate ICTs and orchestrate space around ICTs. Consistent with other work (e.g., Mick and Fournier 1998), our informants acknowledge that ICTs have the ability to disrupt family identity if they are not carefully monitored and managed, a factor which partially drives the integration of ICTs into central spaces.

Our findings also document incorporation of technology into daily life. ICTs induce changes in the management of temporal patterns in domestic life. Family unity is particularly relevant when the family's soldier is deployed, and ICTs offer a metaphorical bridge between the physical space of home and the front, and family's "control." Through ICTs, informants make their husbands "present" for the birth of babies, birthday parties, and other family events. ICTs are an important tool for building not only the immediate Army family (see also Kosova 2007), but also constitute a social, bonding space for extended kin relationships. Family photo websites, emails and other computer-mediated communication constitute an important relationship maintenance infrastructure not only for the immediate family but also for neighbors, other military wives, and Army support staff who, on occasion, or with some regularity, become part of the family unit. Despite the positive aspects of ICTs in sustaining and building family, informants are mindful of the "evils of technology" that have the potential to degrade the family unit. Army mothers monitor not only the content of, but also the time allocated to computers, XBox, television, and other technologies. Many set a timer, others keep written records. A key concern is having their children "get lost" in the technology.

Consistent with domestication research, we find that meanings of technology in the home are neither positive nor negative, but rather are negotiated by the family(Bakardjieva 2006). Indeed, the family, its rituals, scripts and dynamics, as well as values and goals impact not only the acquisition of technology, but also the nature of the objectification and incorporation of ICTs within the household.

# The Role of Power In Consumer Behavior: New Perspectives and Insights

Derek D. Rucker, Northwestern University, USA

## SESSION OVERVIEW

Power, defined as the capacity to control one's own and others' resources and outcomes (Hunt and Nevin 1974; Keltner et al., Gruenfeld and Anderson 2003), is perhaps one of the most omnipresent forces in consumers' lives. Throughout the day consumers likely have experiences of feeling both powerful and powerless. For example, meeting with one's boss might evoke feeling powerless, but interviewing a potential employee may evoke feeling powerful. What is the role of power in consumer behavior? Does feeling powerful lead to an increased willingness to pay a premium price for products, or might it have the opposite effect? Do momentary states of power affect consumers' response to persuasive messages? Does power activate a single goal, or could there be different goals associated with power? This symposium unites under a common theme of providing understanding of the role of power in consumer behavior.

The first paper by Rucker and Galinsky examines how states of power affect consumers' spending behavior. Recognizing powerlessness is an aversive state, these authors propose that powerlessness may serve a previously unexplored role of motivating consumers to restore power. Because status is one source of power, they suggest consumers would be willing to pay a premium for status-related products in an effort to restore power. In three experiments, these authors find evidence that placing consumers in a state of low power provokes a greater willingness to pay for products associated with status, but not with products unassociated with status. This work provides insights into the role of power in consumer behavior, and provides evidence for a new compensatory process evoked by power.

The second paper by Briñol and colleagues explores how power affects consumers' attitudes towards a persuasive message and whether this is dependent upon *when* power is induced— before or after a persuasive communication. Briñol and colleagues suggest power validates whatever mental constructs are accessible to consumers. They hypothesize that before persuasion power produces a general sense of confidence in one's views that leads consumers to process subsequent information less carefully. However, after persuasion, they suggest power enhances consumers' reliance on their thoughts. These authors provide evidence for both of these effects and demonstrate how power can differentially affect persuasion depending on whether it is induced before or after persuasion. This stream of research provides an important insight into how power affects consumers' attitudes, intentions, and information processing.

The final paper by Torelli and Shavitt enhances our understanding of power by distinguishing between notions of power as status and power for the benefit of others. In three experiments, the authors find that consumers' information processing efforts are not dependent solely on the activation of power, but the particular notion of power held by consumers. Specifically, those who are relatively high in vertical-individualism engage in more stereotyping, presumably to preserve their power identity, whereas those who are relatively high in horizontal-collectivism engage in more individuating, presumably in order to form careful impressions that could be helpful to others.

This session discusses a topic that has received little prior research attention in the consumer behavior literature, but has amazing potential to both inform consumer research and stimulate future research efforts. We anticipate this session will attract not only those interested in attitudes and information processing, but those interested in studying the topic of power that is beginning to emerge in consumer research. Joseph Priester, an expert in information processing and persuasion, will weave together the implications of the three streams of research and paint a picture of the future research questions for research in power and consumer behavior.

## EXTENDED ABSTRACTS

### "The Role of Power in Consumer Spending"
*Derek D. Rucker, Northwestern University*
*Adam D. Galinsky, Northwestern University*

How does power affect consumers' spending habits? Past research suggests that power tends to be associated with action (Galinksy, Gruenfeld, and Magee 2003) such that states of feeling powerful prompt greater action and greater risk-taking (Anderson and Galinsky 2006) Thus, one potential role for power in consumer spending is that power would lead to greater spending (i.e., paying whatever it takes to acquire an item). Indeed, such a prediction might also be hypothesized based on a general association of power with resources (e.g., Keltner et al. 2003), indicating those feeling powerful may perceive themselves as having more resources to allocate to obtaining consumer products.

We propose, however, that power may play a very different role in consumer spending. Several research streams suggest that power is an aversive state such that people often have a more negative response when in a state of low power (Keltner et al. 2003). As an aversive state, we hypothesize that consumers are likely to want to reduce feelings of powerlessness. Past research suggests that status is one form of power (e.g., French and Raven 1959). Furthermore, research suggests that consumer products serve the function of communicating information about one's status (e.g., Belk, Bahn, and Mayer 1982). For instance, Belk and colleagues (1982) discuss the notion that consumer products may signal or convey one's status. Belk and colleagues note, "It may be that concern with *demonstrating* status to others comes to dominate other consumption message interests sometime after the eighth grade and that this concern then continues."

*Power and Consumer Spending: The Compensatory Hypothesis.* Given low power is often an aversive psychological state, we hypothesize that consumers may seek to compensate for feelings of powerlessness by obtaining or signaling status. Further, we suggest acquiring consumer products and goods represent one means by which consumers may attempt to restore their lost power. Status has often been viewed as one basis of power (French and Raven 1959) and indeed, status often determines the resources or control one is given or able to allocate within a group (Kemper 1991). Consequently, we hypothesize that, when placed in a psychological state of low power, consumers may be attracted to and seek to acquire products that are naturally associated with status (e.g., business attire, executive pens). By acquiring products associated with status, consumers may compensate for their feelings of powerlessness. If true, we hypothesize that consumers' willingness to spend money on products associated with status should increase when they are in a state of low power. This increased expenditure should stem from a greater perceived psychological benefit of the product in addressing their needs.

In experiment 1, we examined the extent to which power affects participants' willingness to pay for products that have an association to status. Power was induced by instructing participants to write about a time they either had low or high power, a manipulation clearly established to affect participants' state of power (Galinsky et al., 2003). In addition, a control group was included where participants simply described their last trip to the grocery store. Then, as part of an ostensibly unrelated study, participants were asked to indicate their willingness to pay for various consumer products. Results revealed that low-power participants compared to high-power or control participants, indicated a greater willingness to pay for items associated with status (e.g., Italian suit, briefcase, silk tie) but there were no differences in items unassociated with status (e.g., sofa, t-shirt, minivan).

In experiment 2, we examined whether the effects hold for the same consumer product by simply framing the product as being associated with or unassociated with status. Specifically, after receiving the power manipulation used in experiment 1, all participants were asked to indicate their willingness to pay for a portrait of their university. However, the product was either described as common and conveying no status or special association or as rare and conveying prestige and status. Replicating experiment 1, we found participants placed in a state of low power, compared to high power and control conditions, were significantly higher in their willingness to pay for the same item, but only when the product was framed as having status.

In a third experiment, we found that consumers' increased willingness to pay for items associated with status is due to the perception that obtaining those items will provide a sense of power to them. In addition, throughout the experiments we included items to assess competing interpretations of the data (e.g., mood), and find little evidence for alternative accounts.

*Conclusion and Contributions.* The present research provides evidence for a new mechanism by which power can affect behavior. We believe the present findings offer advances in understanding the role of power in consumer behavior and, more generally, the various processes that are activated by changes in one's psychological state of power. Theoretical and practical implications of this work in understanding power in consumer behavior are discussed.

### "The Validating Effects of Power: Implications for Consumer Persuasion"

*Pablo Briñol, Universidad Autonoma de Madrid*
*Richard E. Petty, Ohio State University*
*Carmen Valle, Universidad San Pablo Ceu*

Building on previous research demonstrating that power is associated with approach tendencies (Galinsky, et al. 2003), we argue that greater levels of power might be associated with increased confidence in whatever mental constructs are accessible at the time. We provide an initial experiment to demonstrate the existence of a power-confidence link. We subsequently hypothesized power, via its relationship with confidence, would have divergent effects depending on whether power was induced before or after persuasion because of the mental constructs likely activated.

First, we hypothesized before information processing consumers' must decide how carefully to process information. As a consequence, we anticipated that inducing power before information processing would affect consumers' decision of how carefully to process subsequent information. Feeling powerful, compared to powerless, should induce confidence in one's position, and past research has shown that states of confidence lead people to process subsequent information less thoroughly (e.g., Tiedens and Linton

2001). If consumers' process information less carefully when they feel powerful, this should lead to a poorer discrimination between weak and strong arguments (Petty and Cacioppo 1986) due to differences in information processing.

Second, we hypothesized that after information processing consumers' no longer need to decide whether to process but whether to rely upon or trust their own thoughts in response to the message. As a result, we hypothesized that feeling powerful, compared to powerless, should induce greater confidence in one's thoughts, and past research has shown that people are more likely to rely upon their thoughts when those thoughts are held with confidence (Briñol, Petty, and Tormala 2004). Importantly, if consumers' rely upon their thoughts more when they are feeling powerful, this should lead to a great distinction between weak and strong arguments (Briñol et al., 2004) due to differential thought reliance.

*Experiment 1: Linking Power and Confidence.* Participants were randomly assigned to the high-power or low-power conditions. Power was manipulated by asking participants to play the role of a supervisor or an employee in a work simulation game (Galinsky, et al. 2003). Following this induction, participants rated their confidence and feelings of power. We predicted and found that participants in the high-power condition felt more confident and powerful that low-power individuals. This supported our hypothesized link between power and confidence.

*Experiment 2: Manipulating Power Before Information Processing.* Power was manipulated between participants using the same manipulation as in experiment 1. After completing the power induction task, as part of a supposedly unrelated study, participants were asked to evaluate a printed advertisement promoting a new cell phone containing either strong or weak arguments. Argument quality was varied in this study to assess consumers' information processing activity. Specifically, the greater information processing, the more (less) favorable consumers should be when receiving strong (weak) arguments. Finally, all participants reported their attitudes toward the product. If power does influence participants' confidence in their views when deciding whether to process a message, participants who are powerful should show less information processing than participants who are less powerful. Consistent with predictions, we found that the effect of argument quality on consumer attitudes was smaller when consumers had been induced into a state of high, as opposed to low, power.

*Experiment 3: Manipulating Power After Information Processing.* Participants were first exposed to a printed advertisement promoting a new cell phone containing either strong or weak arguments. Prior to providing their attitudes, however, participants were told the experimenter need to make copies of the dependent measures and thus they should work on a new experimental task. Power was then experimentally induced using the same role-playing technique described in prior experiments. After completing the power manipulation, the experimenter returned with the final measures and participants reported their attitudes toward the product. If, when induced after information processing, power does influence the confidence with which people hold their thoughts, we would expect high power to increase the argument quality effects, that is, more persuasion with the strong than the weak ad. In line with this hypothesis, we found that the effect of argument quality on consumers' attitudes was greater when consumers had high rather than low confidence in their cognitive responses. Thus, with relatively high confidence, consumers relied on their thoughts in forming attitudes, but with relatively low confidence, consumers did not use their thoughts to judge the product (producing a lower attitude-thought correspondence).

*Discussion.* In the present work we not only demonstrate a link between power and confidence, but demonstrated that power could have different effects on persuasion depending on when power is induced. Specifically, when induced prior to information processing power affected how carefully consumers processed a message. However, when induced after information processing power affected the confidence consumers placed in their thoughts. As a result, a strong message was more persuasive for low power participants when power was induced before information processing, but a strong message was more persuasive for high power participants when power was induced after information processing. Taken together, these findings are important because they identify new roles for power in the persuasion process.

### "Culture and Mental Representations of Power Goals: Consequences for Information Processing"
*Carlos J. Torelli, University of Minnesota*
*Sharon Shavitt, University of Illinois*

This research investigates the consequences of activating different types of power goals on consumer information-processing strategies. People's culturally-related values and beliefs are used to predict the types of power-goals activated when power is made salient. We examine the role of cultural orientation in consumer contexts that make power salient, the types of power goals that individuals bring to mind in those contexts, and the information processing consequences of activating those goals.

In the present research, we focus here on 2 types of power goals: 1) *personalized* power (i.e., self-focused) goals of seeking status in order to gain recognition and admiration from others and, 2) *socialized* power (i.e., other-focused) goals of helping and having a positive effect on others (McClelland 1973). In previous studies, we have found that whether people pursue personalized vs. socialized power goals is predicted by their culturally-related values and beliefs. We separate different cultural orientations using the *vertical-horizontal* distinction nested within the broader individualism-collectivism classification (Triandis and Gelfand 1998). We find that individuals high in vertical-individualism (VI) associate power with personalized goals of seeking status, whereas individuals high in horizontal-collectivism (HC) associate power with prosocial goals of helping others. We use the goals that high-VI and -HC individuals associate with power to better predict how they process information when power is salient.

Previous research indicates that powerholders frequently use stereotypes for their judgments. Stereotyping protects relevant beliefs about who should have control and protects existing power identities (e.g., Fiske 2001). However, powerholders who focus on their effects on the well-being of others often attend to individuating information (Goodwin et al. 2000). We propose that the way in which people process information when power is salient will be impacted by the culturally-nurtured associations they have established with power. Powerholders relatively high in VI, who associate power with personalized goals of seeking status, would engage in more stereotyping. In contrast, powerholders relatively high in HC, who associate power with prosocial goals of helping others, would attend more to individuating information.

Results from 3 experiments support the notion that, when power is salient, individuals relatively high in VI stereotype more. They attend more to and remember better information that is congruent with their prior expectations about target products, whereas such effects are absent among low-VI participants. In contrast, individuals high (vs. low) in HC attend more to and remember better the information incongruent with their prior expectations about target products. In all experiments, cultural orientation was measured using Triandis and Gelfand's (1998) scale.

In experiment 1, we examined the effects of personalized (status-enhancing) versus socialized (helping-others) power cues embedded in product messages on the way participants processed the messages. Participants read initial information about either a status enhancing (i.e., facilitates achieving high-status) or a nurturing product (i.e., that impacts others positively). Along with this initial information, participants read additional information both congruent and incongruent with the initial description of the product. After a filler task, they received a surprise recognition task for the product information. As expected, people high in VI stereotyped more after reading information about the status-enhancing (and not about the nurturing) product. That is, they remembered better the congruent (relative to incongruent) information, whereas such effects were absent among participants low in VI. We argue that status-seeking goals activated by the product description led high-VI individuals to stereotype more. In contrast, individuals high (vs. low) in HC processed in a more individuating manner after reading information about the nurturing product (but not the status-enhancing product). That is, high-HC individuals had higher recognition for incongruent information. We argue that prosocial goals activated by the product description led high-HC participants to individuate more.

In experiment 2, participants recalled events associated with exercises of either personalized or socialized power. Subsequently, they received messages about a known brand (McDonald's). We measured attention and memory for attributes congruent and incongruent with the McDonald's stereotype of unhealthiness and convenience. Results showed that individuals high (vs. low) in HC, after being primed with socialized power, were more likely to emphasize the incongruent attributes when writing a product review about McDonald's and had higher recognition for these attributes. We argue that helping-others goals activated by high HC participants after being primed with socialized (and not with personalized) power led them to individuate more. In contrast, participants high (vs. low) in VI stereotyped more after being primed with personalized power. They emphasized more congruent (relative to incongruent) attributes when writing a product review about McDonald's. In addition, they were the only ones who showed an advantage in recognition of information congruent with McDonald's stereotype.

Finally, experiment 3 followed a similar procedure to experiment 2, but used alternative power primes. The same pattern of results from the previous experiment emerged using new power primes. Furthermoe, the results were contrasted with a control (no power) condition in which the stereotyping and individuating effects were absent. In summary, this research addresses the information processing strategies used by individuals with different cultural orientations in consumer settings that make power salient. It highlights the important role of culturally-nurtured associations with power for determining the effects of power primes on basic cognitive processes. Ultimately, a focus on the distinction between personalized and socialized power goals can enhance our understanding of the role of power in consumer behavior. We discuss consequences for consumers' judgments, preferences, and influence attempts.

# How Stock Prices Influence Investment Behavior

Susan Jung Grant, University of Colorado, Boulder, USA

## SESSION OVERVIEW

Prices are commonly assumed to reflect the value or utility of a good or service. Similarly, modern asset pricing theory assumes that, in the stock market, share prices reflect the value of a firm. We consider prices in terms of other information they convey in a stock investing context. These three papers find that the shifting price level of a stock, rather than serving as a merely passive indicator of changes to underlying value, is often taken as a dynamic signal. This session investigates how this price signal can lead to a variety of consumer judgments, inferences, and behaviors.

The first paper, by Jung Grant, Xie, and Soman, examines how consumers use reference prices to evaluate their stock portfolios and how those reference prices get updated. In the second paper, Gal investigates the influence of a stock's nominal price level on the stock's price response to news events and other information. The third paper, by Raghubir and Das, examines how the graphical display of stock price information affects assessments of risk and return.

The proposed session integrates three distinctive approaches to understanding how share price is perceived in the stock market setting. The papers draw on evidence from laboratory experiments and empirical data. This symposium offers an opportunity for scholars interested in behavioral finance to discuss the implications of the current findings as well as for consumer researchers to consider pricing in a new context.

## EXTENDED ABSTRACTS

### "Asymmetric Updating of Reference Prices"

*Susan Jung Grant, University of Colorado, Boulder*
*Ying Xie, Washington University*
*Dilip Soman, University of Toronto*

This research seeks to understand how a pattern of price fluctuations of a given stock holding alters the way reference prices are updated. Instead of comparing stock performance strictly to a stable reference price, such as initial purchase price, investors have a tendency to "reset their reference price" on a frequent basis (Thaler 1999).

In this research we examine how stock performance history influences investors' tendency to update. In particular, we consider two performance contexts–one in which the stock rises but then breaks even with the initial level of investment and a second in which the stock falls but again breaks even. Because the two contexts we have selected are economically equivalent, the investor should assess his outcomes comparably. However, we find an asymmetry to the extent that investors report feeling significantly worse in the first sequence than in the second.

We explore two theories to explain this asymmetry: 1) differential counterfactual availability and 2) a level-of-ownership bias. Counterfactual theorists suggest that negative affect enhances the availability of more positive alternatives (Roese and Hur 1997). Therefore, looking retrospectively at the stock's zenith, investors may kick themselves with the upward social comparison: "If only I had sold my stock at that point." According to the counterfactual literature, people are less likely to invoke negative comparisons. Therefore, with the second sequence, investors may not consider the downward social comparison: "What if I had sold at the low?" Thus, there is no updating when stocks recover after reaching a low.

Despite the intuitive appeal of the counterfactual account, we find evidence that the asymmetry is not due to the differential invocation of counterfactuals. Instead our data indicate that investors feel a higher level of involvement with gains and greater ownership for a stock that achieves a record high. Research from the behavioral finance literature provides a starting point for this hypothesis. For instance, the ostrich effect suggests that investors are more engaged in their stock when it is performing well than when it is performing poorly (Karlsson, Loewenstein and Seppi 2004). These investigators find that investors choose to be less informed about their portfolios when they anticipate losing money but seek out definitive information about the value of their portfolios in rising markets.

In Study 1, we asked investors and gamblers how they felt about their investment outcomes based on a chart showing their stock rose but dropped back to the original level over 10 periods or a chart showing their stock dropped but rose back to the original level over 10 periods. The investors whose stock followed the first sequence reported updating their reference prices significantly more than investors whose stock followed the second sequence. The gamblers, however, updated no more than investors whose stock broke even after reaching a low. This suggests support for the ownership hypothesis. We find that investors and gamblers had the same level of negative affect, however, which suggests that differential availability of counterfactuals was not driven by the impact of negative affect. If the counterfactual account were operative, we should have observed worse-off feelings among investors but not among gamblers, which we did not.

In Study 2, we employed the same patterns of stock performance with investors as in Study 1 but measured investor reactions after each of the 10 periods of stock performance results. Again, we found that investors whose stock followed the first sequence reported by the end feeling they were worse off than when they started, whereas investors whose stock followed the second sequence said by the end they felt they were no worse off but also no better off. This result replicates our previous finding, which we interpret as further support for our hypothesis that reference prices are updated when investors observe a rise followed by a drop but not when investors observe a drop followed by a rise.

We also varied whether investors could monitor their stocks by providing an informational table that tracked the weekly performance or not. We found that when the stock was on the decline, investors felt significantly worse about their stock performance if they had no informational table than if they did. This held true regardless of whether the pattern of stock prices dropped after reaching its record high or before reaching its record low. This suggests that the table grounded investors in the reality of their stock's performance but that without the table, investors exaggerated their sense of loss. In contrast, investors with or without a table reacted consistently when the stock price was on the rise–regardless of whether the pattern of stock prices rose after reaching its record low or before reaching its record high.

In a third study, we explore whether similar asymmetries in reference price updating extend to a consumer pricing context. We

found consumers who observe a series of increasing gas prices (coded as a loss) are less likely to update their reference price than consumers who observe a series of decreasing gas prices (coded as a gain). This result mirrors the effect we observe for stock prices and corroborates our hypotheses.

This research not only provides some insight into a phenomenon that impacts how investors may react in response to market fluctuations, but it also proposes an explanation for the tendency that investors have of selling "winners" in the portfolio while maintaining "losers." When investors observe a rise in the performance of their stock, they perceive the stock as theirs and have a strong desire to pocket the money. However, when investors observe a decrease in performance, they are less likely to perceive the stock as theirs and are inclined to leave the money in play. This explanation is posited as a complement to other existing explanations for selling "winners" and maintaining "losers" (Odean 1998).

### "Stock Price Level and Price Response"
*David Gal, Northwestern University*

Modern asset pricing theory assumes that investors determine a company's value based solely on their expectations for the company's future earnings, and their individual preferences for risk and time. Thus, the nominal price of a share of a company's stock is considered a merely cosmetic variable, with no influence on a company's valuation. For instance, it is considered immaterial whether a company valued at $1 Million is comprised of 10,000 shares of stock priced at $100 or of 100,000 shares of stock priced at $10 (barring microstructure considerations).

This paper, however, posits that nominal share prices will have a significant impact on stock values, and, particularly, that stocks with nominally cheap share prices will be more impacted by events and information than those with nominally expensive share prices. This proposition derives from the hypotheses that (1) investors are likely to use the nominal price of a share of a company—not just the market value of a company—as a proxy, or reference price, for the share's value; and (2) investors are likely to be sensitive to absolute—not just relative—differences in share prices.

For example, assume that, due to new information, an investor decides she is willing to pay "a little more" for a stock than its current price. If she (1) uses the nominal price of a share as her reference price and (2) is sensitive to absolute differences in the price of a share, then she will likely translate "a little more" into a larger percentage increase in price if the stock she is evaluating is nominally cheap than if it is nominally expensive. For instance, "a little more" than $2 may translate into $3 (a 50% increase), whereas "a little more" than $100 may translate into $110 (a 10% increase).

The first study employed a 2 (nominal price: cheap vs. high) X 2 (information valence: positive vs. negative) between-subject design. Experimental participants were provided with the initial nominal price of a hypothetical stock and a new piece of either positive or negative information about the stock. Based on this new piece of information, participants were asked to provide their evaluation of what the stock should be worth. Consistent with predictions, participants determined that the stock should be worth *more* (in percentage terms) in response to positive information and *less* (in percentage terms) in response to negative information when its shares were nominally cheap than nominally expensive. That is, the nominally cheaper stocks manifested a more pronounced reaction to *both* positive and negative information.

The second study analyzed stock price volatility by price level for all stocks listed on the NYSE, AMEX, and NASDAQ stock exchanges between 1972 and 2003, with volatility measured monthly for each stock as the standard deviation of daily price changes. In order to control for market value, I first sorted the stocks into deciles by market valuation, and then sorted stocks into deciles by price level within each of the market valuation deciles. Thus, I obtained 10 different price level deciles for each of 10 different size deciles. Consistent with predictions, I observed that within each of the 10 size deciles, stock price volatility increased as price level decile decreased. The effect of price level decile—from lowest to highest—on volatility was highly significant in all ten size deciles. Additional analyses ruled out alternative market microstructure explanations for these findings.

The third study analyzed the stock price response to positive and negative earnings announcements by price level for all stocks listed on the NYSE, AMEX, and NASDAQ stock exchanges between 1972 and 2003 that had matching earnings announcement date data in the COMPUSTAT database. An earnings announcement was considered positive if the stock price increased in the three day window around the announcement date and negative otherwise. As in Study 2, stocks were sorted into deciles by market valuation and then into deciles by price level. Consistent with predictions, the price response to positive earnings announcements was more positive, and the price response to negative earnings announcements was more negative, as price level decile decreased. This effect was significant in all ten size deciles.

The findings described in this paper bear several implications. First, the significant influence of nominal price, a transparently cosmetic variable, on a company's market value casts doubt on the modern asset pricing theory assumption that each stock has a unique true value. Instead, these findings suggest that investor psychology cannot be disentangled from a stock's true value, but that investor psychology is *inherent* to asset prices. Second, the support obtained for the notion that individuals are sensitive to absolute as well as to relative differences in prices (and that this effect does not depend on share-of-income as assumed by classical choice theory), suggests that price elasticity of demand will be greater for more expensive goods than for cheaper goods, independent of any share-of-income effect.

Third, and perhaps of broadest interest to consumer research, investors' use of a share as a proxy for a company can be thought of as a manifestation of the more general situation in which consumers can use a part of a good as a proxy for evaluating a whole good. It is likely that a part or unit of a good is often more accessible and easier to manipulate mentally than a whole good, and, thus, that similar effects to those observed in the context of stocks in this paper may extend to many consumer contexts.

### "Processing Graphical Information: Perceptual Illusions of Risk and Return"
*Priya Raghubir, University of California, Berkeley*
*Sanjiv Das, Santa Clara University*

Individuals' financial decisions are amongst the most important decisions they make. They frequently use graphical data to make such decisions. This paper examines how consumers process graphical information as a function of their mode of presentation. Prior literature suggests that the choice of a sample point is a function of its salience (Raghubir and Krishna 1996). Applying this idea to the domain of graphical data of financial returns, we propose that investors need to *i)* identify trends over a period of time; and *ii)* identify the extent of noise around the trend line. The former (trend estimate) is a proxy for the average return (mean) of a stock, and the latter (noise estimate) is a proxy for the risk of the stock. The trend can be estimated by using the starting and ending points of a series. The noise can be estimated by choosing a sample of prices between these two points. This sample could be biased if the prices surround-

ing a point change its likelihood of being sampled. The mode of presentation of information systematically affects the price points that will be sampled and used to make financial judgments.

The different aspects of mode of presentation that are examined include: digital versus graphical information (Studies 1 and 2); X-axis choices (Studies 3, 5, and 6), presence of reference indices that follow or diverge from the target stock (Studies 4, 5 and 6), and the salience of local maxima and minima (Studies 7-9). Across studies, results converge to a theory that consumers process visual graphical information by sampling salient data points to assess the trend and noise of a price series. This leads to systematic biases in the estimates of risk and return of different graphs that are equivalent in terms of their information content. Theoretical implications for the processing of visual and financial price information, and practical implications for the communication of financial products and consumer welfare are discussed.

Specifically, Study 1 shows how the presentation of stock prices as a series of digital numbers versus a visual graph leads to different choices between pairs of stocks that have the same mean return. This leads to choice reversals when given digital numeric versus visual graphical data that range from 27% of the group to as high as 51%.

Study 2 shows that when identical information about the S&P index is presented digitally in tabular format (showing returns for the last quarter, last 1 year, 3 years, 5 years and 10 years for the S&P 500 index versus 11 other indices), the mere presence of graphical information about the historic performance of the S&P (provided prior to the table, after the table, or not provided at all) affects the estimated return for the index in the following year. Presenting the historical graph prior to the table significantly increases estimated return.

Study 3 examines how the manner of presentation of graphical information through the choice of X and Y axes affects perceptions of risk and the estimate of return. While Y-axis effects are contingent on expertise with financial markets, the effects of the X axis (e.g., the length of time for which historic data is provided) are robust. The longer the period for which data is provided in markets that have been rising the higher the estimates.

Study 4 examines how the perception of risk of a stock presented using a line graph is affected by the presence of a reference graph. We presented the last one year's data on the NASDAQ composite index with either a 50-day moving average line which followed the original data but smoothed it out or a 200-day moving average line that increased the perceived variance of the stock from the average. The NASDAQ was perceived to be a worse investment when presented with a 200-day moving average.

Study 5 presenting information about the Dow (for 1, 3 and 5 years) with or without the presence of a reference S&P index replicated Study 3 effects for the X-axis in a domain where the stocks had not been rising: the greater the period for which information was presented, the greater the estimated return of the Dow. It also replicated Study 4 effects showing that the presence of a reference index (that diverged from the Dow by trending up as opposed to following its pattern) affected the forecast for the Dow.

Study 6 using the natural experiment of the NASDAQ index with or without Dow and the S&P over a period of 1 year, 5 years and since inception to show that when indices track the target stock, their trends are assimilated into judgments, and when they diverge from the target stock they are used to contrast the target. Either way, their presence or absence systematically affects the manner in which people estimated the risk and return of graphical information.

Finally, a set of three studies (7-9) examine the effect of run length. The run length of a stock is the number of consecutive periods over which a stock continues its upward or downward movement. Run length affects price extrema: the longer the run length of a stock, the greater the price extrema, controlling for the statistical moments of returns. If people anchor on the local maxima and minima, then stocks of longer runs with higher local maxima and lower local minima may be perceived to be more risky than stocks of shorter runs. Three studies test the hypothesis that a stock with a longer run length is perceived as riskier than one with a shorter run length with the same start and end points, and identical mean, variance, skewness and kurtosis of returns.

## Symposia Summary
# Considering the Alternatives: Cognitive Mechanisms Underlying Choice Processes
### Karim Kassam, Harvard University, USA

## SESSION OVERVIEW

In today's society, choice pervades every aspect of our lives, and the number of alternatives is staggering. Recent research has shown that consumers' reactions to a given decision outcome depend significantly on the number of alternatives: Rather than boost confidence and raise satisfaction, large numbers of alternatives end up making us less convinced of our decisions and less happy with our outcomes.

Though this phenomenon is well established, less is known about the psychological processes underlying these effects. The present symposium investigates different cognitive mechanisms relating to both the selection of and the reaction to different set sizes to understand how, why, and when increasing the alternatives will reduce consumers' well-being. This knowledge of the cognitive mechanisms will allow researchers and marketers to make informed predictions of what a consumer might do or how she might feel in any given situation.

In the first presentation, Lee and colleagues investigate how adaptation leads to the selection of choice sets of varying size. Hedonic adaptation to changing surroundings is a well-established phenomenon, and how we adapt may have important consequences for how we subsequently choose. Their studies suggest that adaptation to one's own physical attractiveness has implications for the partners that one seeks. Specifically, they find that less attractive people consider a larger pool of potential mates, but place less weight on attractiveness when making selections. The results indicate that adaptation can be an important factor in set size selection.

Next, Botti and colleagues explore how the extent of cognitive elaboration on the choice-set options interacts with set size to influence the choice-making experience. Elaboration has previously been shown to have beneficial effects on choice, leading to greater confidence; however, relative to a limited set, elaborating on an extensive set reduces positive affect. Taken together, these two effects pose a dilemma to consumers confronted with extensive choice: While elaborating on their options will diminish their positive mood, failing to elaborate will diminish their confidence in the outcomes they choose. This paper also investigates a possible solution to this dilemma: preference learning through repeated choice from the same set maintains a high level of confidence while at the same time reducing the need for elaboration and the associated negative influence on affect.

Finally, Kassam and colleagues examine how rationalization affects consumers' satisfaction after a choice is made. The paper suggests that increasing the number of choice-set alternatives impacts happiness by hampering our ability to rationalize. The process of rationalization involves shifting our perspectives on a situation in such a way as to present it in a more positive light, and frequently depends on favorable comparison with alternatives. They find a non-linear relationship between satisfaction and number of alternatives. When the number of alternatives is small, comparison is easy and people are happy. With moderate numbers of alternatives, comparison maintains its allure but loses its effectiveness, and people end up less happy. When the number of alternatives is very large, people don't attempt comparison and instead rationalize in other ways. Though large numbers of alternatives are detrimental during the process of choice, moderate numbers may actually result in less happiness after the fact.

*Potential Audience*. Researchers interested in consumer judgment and decision making, in choice theory and alternatives, or in the effect of choice-set size on product perception and preference. The three papers should also be of interest to marketing practitioners because they provide a more detailed explanation of how set size impacts consumer satisfaction which can be used to make predictions of consumer behavior in natural environments.

*Providing a Bridge*. The importance of set size when examining satisfaction from choice has recently been established in a variety of domains, but little is known of the cognitive mechanisms underlying these effects. In studying these mechanisms, we aim to provide a more detailed account of the phenomenon that can be used to more effectively predict consumer choice and satisfaction. In making this connection between theoretical psychology and marketing practice, we are aided by the diversity of perspectives of our contributing authors, which include academics in psychology, marketing and management, as well as practitioners from industry.

## EXTENDED ABSTRACTS

### "If I'm Not Hot, Are You Hot or Not? Attractiveness Adaptation and Dating Preferences"
*Leonard Lee, Columbia University*
*George Loewenstein, Carnegie Mellon University*
*Dan Ariely, MIT*
*James Hong, HOTorNOT.com*
*Jim Young, HOTorNOT.com*

It is well established that people adapt to diverse circumstances, such as chronic health problems and low income, quickly reporting roughly similar levels of happiness to those in more objectively advantageous situations. Such 'hedonic adaptation' serves important functions, increasing the motivation to change what can be changed and decreasing the motivation to change what cannot be changed. If the "why" of adaptation is relatively well understood, the "how" is much less well understood; there has been relatively little research into the psychological processes that support adaptation. For example, do people adapt to a lowered income by cultivating inexpensive hobbies and tastes, by persuading themselves that their income isn't, in fact, low, or by simply deciding that income isn't very important in the scheme of things? As the question suggests, different possible mechanisms can support hedonic adaptation.

In this work, we examine adaptation to one of the most important dimensions on which people vary–physical attractiveness. Specifically, we investigate whether individuals' own physical attractiveness affects the number of potential mates they see as viable, as well as their perception of the attractiveness of others.

It should not take much persuading that beauty is highly valued in our society; physically attractive people are not only popular romantic targets but also benefit from a 'halo effect', whereby they are seen as possessing a wide range of other favorable traits and personal qualities such as social and intellectual competence. If beauty is considered a benefit, then one benefit of beauty is the capacity to bond with others who are also beautiful. Studies of assortative mating find very strong correlations between the attractiveness of dating and marital partners. The phenomenon of assortative mating raises the question of how people adapt to the attractiveness of individuals they may marry. Do people adjust their

aspirations for whom they will accept as dating or marital partners based on their own attractiveness? If so, do they adjust their perceptions of the attractiveness of those potential partners? Or do they assign different importance weights to the various desirable qualities in their prospective partners?

In Study 1, based on the analysis of three unique datasets from HOTorNOT.com, we found that the attractiveness of decision makers does impact their likelihood of dating another individual: less attractive people tend to be less selective in the rated physical attractiveness of potential dates. However, the results also suggest that, whereas people tend to give higher attractiveness ratings to others who are judged to be more attractive by other individuals (and males, in particular, tend to give higher ratings), people, regardless of how attractive they themselves are, seem to judge the attractiveness of others in similar ways. With almost 450,000 observations, the latter result is rather stunning; if there was any connection between own-attractiveness and the perceived attractiveness of others, we should have ample statistical power to detect it. Thus, overall, the results from analyzing the HOTorNOT data sets in Study 1 imply that, whereas less attractive people are willing to accept less attractive others as dating partners, they do not delude themselves into thinking that these less attractive others are, in fact, physically attractive. There is no evidence of adaptation at this level.

Yet, possibly, adaptation could take other forms. Perhaps, instead of wearing a different pair of lens when judging the attractiveness of others, people of different physical attractiveness levels might instead vary the importance they place on different desirable attributes in their romantic partners. Drawing from cognitive dissonance theory, we hypothesize that people might adapt to the unlikelihood of attracting a more physically attractive partner by placing less weight on physical attractiveness and more weight on other attributes such as intelligence and sense of humor. To test this hypothesis, we ran a speed dating event in Study 2 where participants were asked to (1) complete a short survey in which they indicated how much they weighed each of six criteria (physical attractiveness, intelligence, sense of humor, kindness, confidence, and extroversion) when selecting a potential date prior to the speed dating event; and (2) rate each participant whom they speed dated on his or her physical attractiveness during the actual event. Correlation analyses between the participants' own-attractiveness and their self reported standardized weights for each of the six criteria revealed that less attractive people tend to place less weight on physical attractiveness in date selection and greater weight on other non-attractiveness-related attributes such as sense of humor.

The results of Studies 1 and 2 highlight one plausible mechanism underlying hedonic adaptation: when faced with a range of options (e.g. potential partners) or life situations (e.g. states of health) of varying (objective) hedonic value, instead of adopting a "sour grapes" mindset and deluding themselves that what is unattainable isn't as great as what it looks, people divert their focus to the merits of options that are attainable to them. Such motivated changes in dating preferences not only supports hedonic adaptation, but also increases the pool of potential mates, reducing the likelihood that physically unattractive people will end up without partners, and supporting assortative mating. Much like the famous line from a Crosby Stills Nash and Young song, people find a way to love the one they are with.

**"Thinking Deeply: The Affective Costs of Elaborating on Too Much Choice"**
*Simona Botti, Cornell University*
*Sheena S. Iyengar, Columbia University*

As consumers, we are often confronted with abundant choice, from the many options we encounter on a trip to buy groceries to the hundreds of options we encounter on a trip to the mall. In response to this explosion in choice, a growing body of research has found that the provision of choice can elicit a host of undesirable effects, such as lower satisfaction with the decision outcome and more negative affective responses (Botti and Iyengar 2006). However, there has been little research on how the size of the choice set interacts with additional factors to produce these effects. In the present studies we address this issue by examining the moderating role of elaboration, an effortful mode of cognitive processing marked by thoughtful analysis and a thorough scrutiny of the options. We propose that, although elaboration enhances confidence in the chosen outcome, elaborating on extensive options worsens choosers' affective response to the decision process. This negative effect of elaboration is however tempered when consumers repeatedly choose from the same sets as the amount of elaboration is reduced by learning.

Research has found that positive affect is generally enhanced by the act of choosing (Taylor and Brown 1988) but it is worsened by the increased elaboration associated with cognitively difficult tasks and emotionally difficult trade-offs (Garbarino and Edell 1997; Luce 1998). Building on prior research showing that choosing from larger, as opposed to smaller, choice-sets is more cognitively and emotionally challenging (Iyengar and Lepper 2000) we hypothesize that consumers who choose from abundant options will experience lower positive affect than those who choose from limited options.

As a preliminary investigation of this hypothesis we conducted a pre-test in which participants chose a restaurant from either a larger (30) or a smaller (10) list of restaurant advertisements. The advertisements included the restaurants' name and location; their Zagat ratings for food, décor, service, and average cost; and the written reviews of the restaurants from Zagat and City Search. To measure the extent to which participants elaborated on their options we asked them to list all the features that they took into account when making their choice; we then coded these features as either salient or non-salient attributes, where salient attributes (i.e., Zagat ratings and average price) were easier to discern and compare than non-salient attributes (i.e., style of décor and type of clientele). We expected that whereas participants at all levels of elaboration would utilize salient attributes, participants at high levels of elaboration would be more likely to broaden their search and utilize non-salient attributes than participants at low levels of elaboration (Petty and Wegener 1998). Results confirmed these predictions: Increased reliance on non-salient attributes was associated with decreased positive affect for participants in the extensive choice condition. Conversely, the use of salient attributes did not differentially impact positive affect for participants in the two choice conditions.

Study 1 replicated these results by manipulating the extent of both choice and elaboration and examined the effect of elaboration on decision confidence. This effect is particularly relevant because prior research has shown that elaboration enhances consumers' confidence (Cialdini, Petty, and Cacioppo 1981) posing a dilemma to consumers confronted with extensive options: They can mitigate decreased confidence in their choice by elaborating while they choose—but only at the expense of their positive mood. As in the preliminary investigation, participants in Study 1 chose a restaurant from either a limited (15) or an extensive (45) set of options. Extent

of elaboration was manipulated by using time constraints so that participants had either a limited (3 minutes) or an extended (15 minutes) amount of time to make their choice. To check this manipulation, we asked participants to describe their thought process during the decision task and coded these thoughts to measure the extent to which participants both relied on non-salient information and confronted trade-offs. This manipulation check confirmed that, relative to those in the limited time condition, participants in the extended time condition were more likely to consider non-salient features and to weigh trade-offs when making their choice. Results show that, as predicted, in the high elaboration condition participants experienced lower positive affect when choosing from an extensive as compared to a limited array; this difference was however not significant in the low elaboration condition. In addition, participants who had ample time to elaborate on their options felt overall more confident in their choices than participants who had little time to elaborate.

These two effects suggest a double bind for consumers facing extensive choice: While elaborating on a large number of options may diminish their positive mood, failing to elaborate may diminish their confidence in the chosen outcomes. Study 2 solved this dilemma by looking at situations that can mitigate the negative effects of elaboration on positive affect. Prior research has shown that preference learning reduces the amount of elaboration required to make a choice (Alba and Hutchinson 1987) but not the level of decision confidence (Chernev 2003). Hence, if consumers faced with larger choice sets were given the possibility to learn their preferences they might still enjoy decision confidence while at the same time avoid the emotional suffering associated with elaboration. In Study 2 preference learning was achieved by having participants make repeated choices from the same sets over a period of two weeks. Participants were asked to select ten consecutive songs from the same list of either a limited (30 songs from 10 albums) or an extensive (300 songs from 100 albums) number of unfamiliar mp3 music files. Results show that, as predicted, choice repetition decreased the amount of time and the extent of elaboration, and increased perceived expertise. As a result, both decision confidence and positive affect increased in the extensive choice condition, causing participants faced with a larger choice set to be more confident and happier with their choice than those faced with a smaller set.

### "Stuck in the Middle: The Effect of Number of Alternatives on Adaptation to Outcomes"

*Karim S. Kassam, Harvard University*
*Carey K. Morewedge, Carnegie Mellon University*
*Daniel T. Gilbert, Harvard University*

We tend to go through life with fewer regrets than an objective observer might imagine. Not everyone is admitted into their preferred college, we may not get the job we really want, and the beautiful woman we ask on a date may well say no, but in the end we love our alma maters, are happy with our jobs and can't imagine having married anyone else. Research suggests that one reason for our ability to adapt to any situation is rationalization. We rationalize automatically and unconsciously, even when it seems there's no way to construe the facts to make a horrible failure look like an incredible victory.

One way that people create satisfaction with their outcomes is by favorably comparing those outcomes to their alternatives. By focusing on positive aspects of a given outcome and negative aspects of alternative outcomes, we are able to frame the situation in the best possible light. Consumers use comparison to make their selections look better than the alternatives (Brehm, 1956), voters

use comparison to make the election winner look better than other candidates (Beasley & Joslyn, 2001), and high school seniors use comparison to make colleges that have admitted them look better than those that haven't (Lyubomirsky & Ross, 1999).

Though are abilities to adapt to even extreme situations are formidable, there are factors that can slow the process. The reliance of rationalization on comparison suggests one such factor. Comparing two outcomes is relatively straightforward, but as the number of outcomes increases comparison quickly becomes difficult or impossible. When the set of alternatives grows from small to moderate, the number of pair-wise comparisons necessary to establish that a given outcome is best may overwhelm our psychological abilities and thus hinder adaptation. When the number of alternatives gets very large, direct comparison quickly becomes impossible. We might not be able to keep ten or more possibilities in mind, let alone compare them. Taken together, this suggests a non-linear relationship between number of alternatives and happiness. Both very small and very large numbers of alternatives may result in positive affect changes that are not seen when a moderate number of alternatives is considered. While we might expect hedonic adaptation to proceed similarly regardless of the number of alternatives, both the underlying mechanisms and the results may change when alternatives go from few to moderate to many. We conducted three studies which provide evidence for this non-linear relationship.

In Study 1, we compared participants who knew the alternative to the prize they won, to those who knew the alternative comes from a set of four possible alternatives, and those who had no knowledge of the possible alternatives. All participants won the same prize, the best in the set. Those unable to make the comparisons are likely to be less happy. In addition, those with no knowledge of potential alternatives were expected to rationalize other than by comparison, and thus become relatively happy. Participants were least happy when they compared the prize they won to a moderate number of alternative prizes (i.e., four other prizes). In other words although all participants won the same prize, those who saw a single, salient alternative to the prize they won, and those for whom the alternative could have been anything were significantly happier than participants who knew the alternative was from a moderate-sized set.

Study 2 extended the results and provided an even stronger test of our hypothesis. All participants saw the entire set of prizes, and all won the prize they had previously ranked lowest. Subsequently, after winning the worst prize, some participants saw that the alternative to the prize won was the prize they had ranked next-to-last in the pre-ranking. These participants were objectively in the best situation, they may not have won the prize they wanted, but the prize they almost won was similarly undesirable. Others saw that the alternative to the prize won was the prize they had ranked highest in the pre-ranking. These participants were objectively in the worst situation, not only did they win the worst prize, but the prize they almost won was the prize they wanted most. A third group knew only that the alternative was one of a set of four possible prizes. Even though all participants won their lowest ranked prize, those who saw a single, salient alternative were significantly happier than those who knew the alternative was from a moderate-sized set. Interestingly, this difference persisted even for those who had almost won the prize they wanted most, i.e. those faced with the most difficult comparison.

Study 3 provided further support for a non-linear relationship. Participants pre-ranked a set of twenty possible prizes, and all won the prize they had rated lowest. Some participants saw a small number of alternatives (two), others a moderate number (four), and others a very large number (nineteen). Once again, even though

everyone won the worst prize, those who saw the prize together with a moderate number of alternatives were significantly less happy than those who saw it together with either a very small or very large number of alternatives.

Our abilities to rationalize outcomes have a profound affect on our well-being. Whatever we choose, we find reasons after the fact suggesting that whatever we ended up with was for the best. Though these abilities are formidable, the present research suggests that they are also vulnerable. Comparison may be a favored method of rationalization, but in cases where there are a moderate number of alternatives, comparison becomes difficult while maintaining its allure. That difficulty limits our ability to adapt and consequently limits our happiness.

# Real Consumers Have Curves: The Effects of Body Esteem and Weight on Consumer Responses to Marketing Stimuli

Elizabeth Gelfand Miller, Boston College, USA

## SESSION OVERVIEW

This session includes three papers that seek to understand how body issues, such as consumer weight and body esteem, impact consumer responses to marketing stimuli, such as advertising, package design, and retail atmosphere, as well as consequent consumption behavior. Approximately 59% of Americans (www.census.gov) and 40% of Europeans (www.epha.org) are overweight or obese. Furthermore, self-esteem and body esteem can be important factors in determining happiness (Baumeister et al. 2003; Cheng and Furnham 2004) and subjective well-being (Paradise and Kernis 2002). In these three papers, we find that consumer weight, body esteem, and dieting behavior can interact with marketing variables in several interesting and unexpected ways. By bringing together these three papers and the discussant, we expect that this session will enhance our understanding of how body issues impact responses to marketing stimuli and consequent consumption behavior.

Each of these papers examines a different aspect of this question. The first paper examines the effects of consumer body weight on responses to media images in advertisements, focusing on the impact of media exposure on consumers' self-esteem. Furthermore, this paper investigates the impact of the resulting shift in self-esteem on consumption behavior, as well as dieting and fitness intentions. The second paper examines the effects of chronic dieting behavior on responses to packaging, focusing on how the consumption behavior of dieters and non-dieters is affected by package size. The third paper explores the effects of body esteem on shopping behavior, focusing on approach/avoidance behavior in retail stores and preferences for store décor. By understanding the role these factors play in consumers' decisions, marketers can better cater to their customers' needs. In addition, an understanding of how weight interacts with marketing stimuli (such as responses to media images and package size) can lead to important public policy recommendations and help consumers better manage their behavior, likely leading to improved body image and self-esteem.

The first paper, co-authored by Smeesters, Mussweiler, and Mandel, examines how body weight changes consumers' responses to media images. Specifically, the paper examines how advertisements containing thin and/or heavy models influence the self-esteem of overweight and underweight consumers. In three studies, the authors find that underweight consumers' self-esteem shifts upward while overweight consumers' self-esteem shifts downward when they are exposed to any models, regardless of whether the models are thin or heavy. The results are explained in terms of differences in the two groups' comparative processes. The authors find that shifts in self-esteem have implications for consumers' consumption behavior, as well as their dieting and fitness intentions.

The second paper, co-authored by Scott, Nowlis, Mandel, and Morales, examines how dieting impacts consumers' responses to packaging. Across three studies, these authors demonstrate that dieters consume more calories from diet-sized packages compared to regular-sized packages, while non-dieters consume fewer calories from diet-sized packages compared to regular-sized packages. In addition, they demonstrate that even though dieters know they

will overeat the diet food, they are unable to prevent the over-consumption without the assistance of external cues.

The third paper, by Miller, examines how body esteem affects consumers' responses to retail environments. This paper examines how consumers' preferences for different aspects of store design, such as brightness, are affected by body esteem. Results from a survey and an experiment indicate that consumers with low and high body esteem respond differently to salespeople, have different preferences for store décor, and have different motivations for shopping. Implications for better managing customer experiences are addressed.

At the end of the session, LJ Shrum will lead the discussion to integrate the individual presentations into a more general framework. LJ is an expert on the topic of media effects on consumer perceptions, as well as the cognitive processes underlying such effects. He will involve the audience members in a discussion in order to develop a more overarching understanding of how consumer body issues interact with marketing stimuli, as well as the potential managerial implications of the authors' findings.

Given the current interest in transformative consumer research topics, we expect this symposium to appeal to a significant portion of the ACR membership. In particular, we hope to draw people who are interested in research on advertising, packaging and/or retail effects, gender issues, social cognition, self control, and even public policy issues.

## EXTENDED ABSTRACTS

### "The Effects of Thin and Heavy Media Images on Overweight and Underweight Consumers"
*Dirk Smeesters, Tilburg University*
*Thomas Mussweiler, University of Cologne*
*Naomi Mandel, Arizona State University*

We examine how advertisements containing thin and/or heavy models influence the self-esteem levels of overweight and underweight consumers. Overweight individuals represent a significant and growing segment of consumers. If exposure to thin media images can result in low self-esteem and eating pathologies among average-sized women (Polivy and Herman 2002), it is possible that overweight women will be even more vulnerable to these effects. Furthermore, although underweight consumers comprise only 2% of the American population, they are often victims of eating disorders, and therefore might also be especially vulnerable to thin media images.

The success of Dove's Campaign for Real Beauty (which features full-figured models) suggests that viewing heavy or imperfect models will raise women's self-esteem, especially when the viewers are overweight themselves (Wasserman 2005). On the contrary, Smeesters and Mandel (2006) showed that, among average-sized women, exposure to moderately heavy models actually lowered self-esteem, rather than raising it. However, they did not examine the effects of such ads on overweight or underweight consumers. Moreover, our research contributes to the existing literature by offering a better understanding of how comparison processes occur when consumers are exposed to advertising mod-

els. In all studies, we concentrate on consumers' informational foci after exposure to an advertising model. Informational foci reflect the judgment of one's similarity or dissimilarity to a comparison other (Mussweiler, Rüter, and Epstude 2004). Shifts in foci determine which self-knowledge becomes accessible (Mussweiler 2003), thereby shifting the consumer's self-esteem, and ultimately his or her eating behavior, dieting, and workout intentions.

Our first study used a 3 (participant body mass index (BMI): low, normal, high) x 2 (size of the model: thin, heavy) x 2 (extremity of the model's size: moderate, extreme) between-subjects design. The results indicated that participants with normal BMI levels demonstrated higher self-esteem after exposure to moderately thin and extremely heavy models than after exposure to extremely thin and moderately heavy models, replicating Smeesters and Mandel's (2006) findings. For low BMI participants, exposure to all models led to a general high level of self-esteem compared to high BMI participants, for whom exposure to all models led to a general lower level of self-esteem. These results appear to be due to differences in comparative processes. Low BMI participants demonstrated a stronger similarity focus after exposure to thin models than after exposure to heavy models (regardless of extremity), while high BMI participants demonstrated a stronger similarity focus after exposure to heavy models than after exposure to thin models (regardless of extremity). These findings suggest that underweight consumers show higher self-esteem because they feel similar to thin standards and dissimilar to heavy standards, while overweight consumers show lower self-esteem because they feel similar to heavy standards and dissimilar to thin standards.

One of our most intriguing results was demonstrated in study 2. Low BMI and high BMI individuals started out with similar levels of self-esteem (as measured by a control, no-model condition), but after exposure to *any* models (thin or heavy), self-esteem increased for low BMIs and decreased for high BMIs. Importantly, the effects of one's own BMI and exposure to the models on self-esteem were statistically mediated by one's perceived (dis)similarity with the models.

The third study measured the effects of exposure to models on behavioral variables, such as cookie eating behavior, and dieting and fitness intentions. Normal BMI participants ate fewer cookies when demonstrating low self-esteem (i.e., after viewing moderately thin or extremely heavy models) compared to when demonstrating high self-esteem (i.e., after viewing moderately heavy or extremely thin models). In contrast, low BMI participants ate fewer cookies when exposed to heavy models than when exposed to thin models. Additional measures showed that this effect was mainly due to the fact that low BMI participants wanted to avoid becoming heavy in the future. High BMI participants ate fewer cookies when exposed to thin models than when exposed to heavy models. Additional measures revealed that this effect appeared because high BMI individuals felt more ashamed after being exposed to thin models, compared to heavy models. The results for dieting and fitness intentions followed the same pattern as those for cookie eating.

Our findings contradict the notion, suggested by Dove and others, that overweight individuals should have higher self-esteem after looking at heavy models than after looking at thin models. Therefore, we recommend that overweight consumers attempt to avoid looking at ads with *any* models, thin or heavy (perhaps by avoiding women's magazines). Furthermore, our research contributes to the literature by revealing which cognitive processes (i.e., informational foci) occur during social comparison in an advertising context, how these processes determine shifts in self-esteem, and behavioral responses (such as cookie eating, fitness and dieting intentions).

## "Do Diet Foods Make Consumers Heavier? The Effect of Reduced Calorie Packages on the Consumption Behavior of Dieters and Non-Dieters"

*Maura L. Scott, Arizona State University*
*Stephen M. Nowlis, Arizona State University*
*Naomi Mandel, Arizona State University*
*Andrea C. Morales, Arizona State University*

With obesity at an all-time high, many consumers are fighting this epidemic by dieting and buying diet foods to help them self-regulate (Hoch and Lowenstein 1991, Stunkard 1980). From food to cigarettes and alcohol, consumers attempt to ration their consumption quantities to exert increased control (Wertenbroch 1998). In response to consumers' demands for rationed portions, diet foods of varying sizes, calories, and packages have been introduced. For instance, in 2004, Kraft launched "100 calorie packs," miniature versions of snacks enclosed in small packages (Horovitz 2006), which sold over $100 million by 2005 (Thompson 2006). In this research, we investigate whether consuming smaller food morsels from such packages is an effective eating restraint strategy, particularly for consumers attempting to manage their weight. Our research questions are: 1) Do dieters consume fewer calories from a configuration of smaller food morsels in smaller packages or from a typical configuration of larger food morsels in a larger package?, and 2) How do perception and self-control influence the amount of food dieters and non-dieters consume?

Dieting is "the deliberate effort to combat the physiologically-based urge to eat in order to lose weight or maintain a reduced weight," (Fedoroff, Polivy, and Hermann 1997, 34). Non-dieters have a balanced response to internal and external stimuli (Nisbett 1968; Schachter, Goldman, and Gordon 1968), and use physiological cues as satiety indicators (Tom and Rucker 1975). Alternatively, dieters possess eating patterns consistent with obese individuals (Herman and Polivy 1975) and may be more responsive to external cues (Fedoroff et al. 1997). Therefore, it is possible that presenting dieters with reduced-calorie packaging may backfire, resulting in overeating or even binge eating.

Existing research suggests consumers eat more calories when presented with larger sized food than smaller sized food (Wansink, Painter, and North 2005, Geier, Rozin, and Doros 2006), and more calories from larger packages relative to smaller ones (Wansink 1996, 2004; Wansink and van Ittersum 2003). However, when dieting behavior is introduced, it is not obvious how consumers will respond. Our four studies provide evidence that while non-dieters consume fewer calories from diet food configurations, dieters consume more from them, when compared to non-diet configurations.

Study 1 was a 2 (food configuration: diet, regular) x 2 (dietary restraint: dieter, non-dieter) between subjects experiment (*N*=96). We operationalized food configuration to include diet food (eight small cookies distributed across four small packages) and regular food (four large cookies in one large package), with each configuration totaling 240 calories. We found that dieters consumed more from the diet food packages than from the regular food packages, while non-dieters consumed more from the regular packages than from the diet food packages. Furthermore, when examining the percentage of people eating the entire 240 calories, we found that dieters were more likely to eat everything in the package(s) when eating the diet food compared to the regular food, while non-dieters did the opposite, supporting the idea that dieters experience self-control lapses with diet food.

Study 2 was a similar design to study 1, but with either 200 calories of mini-M&Ms evenly distributed across four small bags (diet configuration), or 200 calories of regular-M&Ms in one large bag (regular configuration). Consistent with study 1, dieters con-

sumed more M&Ms (and were also more likely to eat the entire package) from the diet configuration than from the regular configuration, while non-dieters consumed more (and were more likely to eat the entire package) from the regular configuration than from the diet configuration. In study 3, we examined the effect of providing participants with nutrition information, such as the number of calories, on the package. We found that dieters dramatically reduced their consumption when they were given nutrition information on the diet packages, while the reduction was less marked when they were given nutrition information on the regular packages.

The purpose of study 4 was to examine whether the differences in behavior between dieters and non-dieters are due to perceptual differences or self-control differences between the two groups. We presented participants with one of the two food configurations at a time and asked them to estimate the caloric content. Among both dieters and non-dieters, the diet configuration was perceived to have significantly more calories than the regular configuration. This distorted perception of higher calories in diet configurations is consistent with extant theory, and helps non-dieters consume fewer calories overall; but for dieters, it is a trigger for self-control failure, causing greater caloric intake. Study 5 is underway to examine the moderating roles of factors such as self-control depletion and hot/cold system activation on the effect of package configuration on eating behavior among dieters and non-dieters.

Many diet plans encourage configurations of smaller food morsels in small packages to help dieters reduce their overall caloric intake. Our research provides some evidence that dieters overconsume these configurations and often experience self-control lapses with them, which might explain why these products are so profitable for firms. Therefore, dieters may be better served by avoiding such diet configurations when attempting to lose weight.

### "Body Esteem and Shopping Behavior"
*Elizabeth Gelfand Miller, Boston College*

In order to effectively build relationships with customers and to best manage customer experiences, marketers must understand the consumer characteristics that influence their responses to the store environment. While numerous researchers have highlighted the role of the physical environment in impacting relationship building (e.g., Bitner 1992) and the ability to create and maintain positive customer experiences (e.g., d'Astous 2000; Michon et al. 2000), fewer researchers have examined how individual personality traits affect reactions to the environment and shopping behavior more generally, even though such characteristics likely influence reactions to one's surroundings (Bitner 1992). Indeed, several researchers have highlighted the need to locate consumer characteristics which influence responses to and expectations about the environment (e.g., Babin and Darden 1995; Chen-Yu and Seock 2002; Turley and Milliman 2000).

One characteristic likely to affect consumers' responses to the environment and their shopping behavior more generally, particularly for high body-involving products (Rosa et al. 2006) such as clothing, is body esteem. Body esteem has been defined as a deeply held and generalized like or dislike of one's body (Rosa et al. 2006). Although body esteem has been previously linked to consumer purchase decisions (e.g., Ferraro, Shiv, and Bettman 2005), such inquiries have focused on how body esteem influences assessments of how products enhance or preserve personal well-being, the types and styles of products consumers favor, and responses to digital stimuli (Rosa et al. 2006; Rosa and Malter 2003), but not in-store shopping behavior. Given that mood has been identified as an important driver of retail experience (Gardner 1985) and that consumers with varying degrees of body esteem likely feel different

ambient levels of affect and arousal when considering social products, it seems likely that body esteem may be one characteristic which may explain individual differences in reactions to environmental stimuli as well as in shopping behavior more generally. In particular, given that "cool" store interiors–those which use colors with short wavelengths (Babin et al. 2003)–have been found to soothe and relax, while dark interiors often harm one's spirits and morale (Bellizi et al. 1983), I expect consumers with low and high body esteem to be differentially affected by such environments. Specifically, I posit that the environment could serve as a coping mechanism for low body esteem consumers, leading low body esteem consumers to show increased approach behavior in a light environment. I expect such effects will be moderated by the presence of pictures of models on the walls, as such images may heighten body dissatisfaction (Cafri et al 2005).

To test these hypotheses, I conducted a 2 (brightness: light, dark) x 2 (wall décor: pictures of models, pictures of landmarks) x 2 (body esteem: low, high) between-subjects experiment in conjunction with a larger survey to assess shopping preferences more generally (e.g., ideal shopping environment, general shopping enjoyment). Participants were presented with colored pictures of a hypothetical clothing store along with a brief written description and asked to rate their patronage intentions, purchase intentions, salespeople perceptions, store perceptions, and other measures related to approach / avoidance behavior. Body esteem was measured using the Body Esteem Scale (Franzoi and Shields 1984).

The results indicate that body esteem does influence shopping behavior. Those with higher body esteem reported higher levels of positive affect than those with lower levels of body esteem. Those with higher levels of body esteem were also more likely to try on clothes and more likely to interact with salespeople. However, there were no differences between these groups in their purchase intentions or levels of shopping enjoyment. Consistent with expectations, I also found that body esteem influenced preferences for store design and interacted with the environment to determine behavior. Consumers with low body esteem were more uncomfortable in a dark store, while those with high body esteem seemed to prefer dark stores. However, the relative preference low body esteem consumers felt toward a light store was mitigated when pictures of models were hung on the walls; consumers with low body esteem felt the most positive affect and expected to spend the greatest amount of time in stores that had a light feel with landmarks (non-people) on the walls. Finally, I found that consumers with low and high body esteem may have different motivations for shopping.

As a whole, the findings suggest that consumers with high body esteem may perceive the environment in terms of whether it aids or deters them from achieving their shopping goals, while low body esteem consumers may evaluate the environment more in terms of its ability to soothe already high anxieties. Consequently, the use of soothing colors and quiet music may be particularly beneficial for attracting low body esteem consumers. Moreover, high body esteem consumers appear more likely to browse in a store, while low body esteem consumers may only decide to enter a store if they are already committed to buying something. These findings suggest that when targeting low body esteem consumers, managers should focus more on enticing consumers to enter the store, while when targeting high body esteem consumers, managers should focus more on enticing consumers to buy (once in the store).

# Symposia Summary
## Exploring The Evolving Terrain of Consumer-Generated Brand Content

Susan Fournier, Boston University, USA
Frédéric Brunel, Boston University, USA

## SESSION OVERVIEW

Many studies have discussed how consumers create brand meaning in order to make sense of and align the product/service within their lives (Fournier 1998; Ritson and Elliot 1999). Besides these negotiation and (re)interpretation roles, recent studies have exposed consumer's ability to create original content for the brand. Although we have long noted a penchant for advertising parodies that make mockery of a brand and brand bricolage by counter-consumers (Handleman 1999), the recent trend is for brand-supportive activities that mimic marketing messages and strategies. Such content creation capabilities of brand community members sharing a passion and ethos for the brand have been especially noted (Brown, Kozinets and Sherry 2003; Schau and Muniz 2006). The "creative consumer" actively participates in the customization of product features and designs (von Hippel 1986, Moreau and Dahl 2005), refinements to packaging, and the generation of branded communications (Ives 2004). Web-based technologies that enable the creation and dissemination of branded content have fueled the creative consumer trend. Per media pundits, the ascendancy of empowered and passionate consumers as brand content creators is a marketplace reality that transforms the discipline of brand marketing at its core (Flight 2005).

Practitioners have been quick to recognize the likely power and benefits of consumer-created content. Interest in citizen marketing that takes the form of advertising message creation—so-called "homebrew ads", "folk ads", VCAMs (viewer-contributed advertising messages), or more generally, "open source" branding—has been especially strong. Most recently, mass market manufacturers Frito-Lay, Unilever, and Chevrolet have taken gambles in this arena by airing consumer-generated ads (CGAs) on the 2007 Superbowl and Academy Awards. Most firms, however, remain wary of the risk-reward trade-offs involved with consumer-generated content. Chevrolet's Spring 2006 campaign as a CGA first-mover gave a significant cause for concern, when invited consumers created anti-Chevy ads showcasing Tahoe's destructive role in the environment. While some firms now include token amounts of consumer-authored content in their own advertising, and others pursue controlled CGA experiments via venues such as Gore's CurrentTV, the full strategic leverage of consumer- generated content as an integral and systematic part of brand strategy has yet to be obtained.

Inarguably, management indecision centers on reservations concerning the nature and effectiveness of consumer-generated branded content, and uncertainty concerning the best tactics for this new phenomenon. For example, CGA presents a role reversal of sorts in the process of advertising creation and consumption. Consumers—who were once conceived as receivers of company-created messages, or, more recently, as active translators and co-creators of the meanings that these messages contain—now serve a new function as self-motivated originators of advertising content. Firm roles, too, are shifted. Firms are now becoming facilitators of the creation and/or dissemination of consumer-created messages. They are involved in filtering and selecting nationally-exposed CGAs. They are even becoming consumers of CGA content itself. Although potentially attractive and beneficial to business, these marketplace shifts bring new concerns and questions. Does CGA present a fundamentally different advertising paradigm, or does it operate to persuade in much the same way that fifty years of research on company-sponsored advertising has exposed? Do CGAs even possess the benefits of authenticity, credibility, and insight that managers assume they hold? How can a firm best design a CGA campaign to control the risk/reward tradeoff, assuming that company involvement does not deny the very benefits of CGA? Without a solid base of research, the rules of engagement in the new terrain of consumer-created content remain unknown.

This session addresses the pressing need for research on consumer-generated content by presenting three completed empirical investigations along three complementary perspectives. The paper by Schau and Muniz considers consumer content creators and the products of their efforts as the units of analysis. Leveraging netnographic information from the Firefox user community, Schau and Muniz ask: are consumers capable of creating branded content that resembles—in form, function, quality/professionalism, and intent—what we know of as traditional company created brand artifacts? The second paper by Brunel, Fournier and colleagues concerns viewers' responses to consumer-generated ads. Their multi-method inquiry includes (1) an experiment to contrast the effects of advertisements identified either as having been created by consumers or companies, and (2) a qualitative analysis of posted viewer responses to milestone CGAs (e.g., Superbowl and Academy Awards 2007) to probe persuasion processes in a natural viewing environment. Research by Berthon and Pitt provides an important third perspective: that of the firm as a potential collaborator in the process of consumer-generated content. A survey of 178 marketing managers illuminates practitioner awareness of, attitudes toward, and actions concerning the creation of message content by consumers. The authors developed a typology of firm stances on consumer-generated content in order to guide marketing strategy and research.

Our session closes with integrative comments and facilitation of audience participation from our discussant, John Deighton. Deighton offers invaluable perspective on the emergent CGA phenomenon through his experiences not only as editor of *JCR*, but also through his involvement in the development of cases on lead-user companies in the CGA space.

Collectively, the first-ever empirical investigations of CGA presented in this session, as extended through discussant and audience comments, provide not only a holistic perspective on the phenomenon, but a contextual one that considers synergies between and divergences from traditional advertising concepts and frames. It is our hope that these empirical studies provide some stakes in the ground that can service and guide future consumer research on CGAs.

## EXTENDED ABSTRACTS

### "Share the Brand: Communally-embedded Consumer Generated Content"
*Hope Jensen Schau, University of Arizona*
*Albert M. Muniz, Jr., DePaul University*

Studies have demonstrated that members of brand communities can create extensive brand content (Brown, Kozinets and Sherry 2003) and that the ascendancy of communally-embedded, empowered consumers is now a marketplace reality (Flight 2005).

Although several marketers have played lip-service to the idea of consumer-generated messages, and a number have included token amounts of user-authored content in advertising campaigns, few have made extensive efforts to include consumer-created content in their advertising strategies and campaigns. Part of the problem may center on uncertainty concerning the professionalism of the resulting advertising. Indeed, little work has examined how successful consumers can be in their advertising creation endeavors. In other words, what is the quality of consumer-generated content (CGC)? Are consumers capable of creating content that resembles, in form, function and intent, advertising? Can CGC rival and/or exceed the quality of firm produced brand content? Does CGC gain new persuasive traction simply by being consumer-created? Do the ideals of brand content shift with the emergence of consumer-generated brand content? Can CGC be successfully integrated into larger firm objectives, where brand content is harmoniously co-produced, as recommended by proponents of the new service-dominant logic (Vargo and Lusch 2004)?

In order to assess these issues, we investigate consumer-generated, commercially-centered artifacts in two brand communities and compare them to existing firm-produced brand content. We conducted a netnographic study (Kozinets 2002) of the Jones Soda and Mozilla Firefox brand communities. We employ naturalistic and participant observation within these communities, close examination of consumer-generated artifacts, careful scrutiny of current firm-authored brand content, and depth interviews with community members and firm employees regarding brand content, brand positioning and CGC as an element of the brand strategy. Jones Soda relies heavily upon its community of loyal users for the creation of branding content. From product innovations (flavors) to packaging (labels, cap quotes), promotions (stickers, web content, price points) and advertising, Jones Soda gives its 12-24 year old target consumers considerable input into the brand's attributes and personality (Underwood 2005). Mozilla's Firefox is an open-source web browser. It, too, relies entirely upon users for innovations, modification and promotion. Firefox users are encouraged to be evangelical and to get users of other browsers to switch to Firefox. As part of these efforts, consumers are encouraged to create short television-commercial-length videos.

We find the Jones Soda and Mozilla Firefox communities possess the three markers of brand community identified by Muniz and O'Guinn (2001) and provide ample room for personal transformation and consumer empowerment. Our data demonstrate effective consumer-generated communications for both brands that are collectively created, disseminated and distilled within a strong consumer controlled brand community. The data reveal much about consumer-to-consumer communications, including consumers' sophistication and agility in mimicking the conventions of advertising in order to invest brands with the meanings they seek. We find consumers quite adept at appropriating and mimicking the styles, tropes, logic and grammar of advertising. Consumers in both communities demonstrate mastery of intertextuality (O'Donohoe 1997) by utilizing the permeable boundaries between advertising and other cultural texts via their appropriation of content from those texts. They demonstrate mastery of polysemy (Kates and Goh 2003; Ritson and Elliott 1999), creating artifacts with different meanings for different groups. The consumers also demonstrate a grasp of the importance of oppositional brand loyalty (Muniz and O'Guinn 2001), crafting advertising like objects that play up intra-brand rivalries. Both Jones Soda and Mozilla Firefox recognize the potential of CGC and actively leverage their loyal, evangelical users to create artifacts that are woven into the fabric of their strategy for the brand.

In conclusion, this study demonstrates that consumers can mimic the conventions of advertising and produce consumer generated ads comparable to those produced by professionals. Owing to cheaper desktop audio, video and animation software, consumers can easily create promotional content that rivals that which is produced professionally. Moreover, via the Internet, such creations can be quickly and inexpensively shared with a multitude of others. Consumers, especially those who are members of brand communities, are more than able to be skillful, proficient and prolific in the creation of vigilante advertising content. Likewise, our findings show that some firms successfully outsource brand content and persuasive marketing communications to their consumers, harnessing these efforts toward long-term marketing objectives. There is no reason to doubt that the practice of utilizing consumers as both operant and operand resources in this way will spread. These findings have important, perhaps revolutionary, implications for advertising theory and practice.

### "Consuming the Consumer-Generated Ad"

*Frédéric Brunel, Boston University*
*Susan Fournier, Boston University*
*Ben Lawrence, Boston University*
*Courtney Guzman, Boston University*
*Eliza Papavasileiou, Boston University*

Although decades of research have yielded significant knowledge regarding consumers' responses to ads designed by firms or their agencies (Vakratsas and Ambler 1999), little is known about the emergent phenomenon of consumer generated advertisements (CGAs). In this presentation, we report on two studies designed to investigate viewers' reactions to CGAs. We seek to understand if and how consumers' responses to CGAs compare to those for company/agency produced ads. Specifically, our research informs three goals.

First, we explore whether CGAs present advantages as branded communications. Based on media pundits' opinions and case studies of CGA lead-user companies, we argue that viewers will have more favorable reactions towards ads which are identified as CGAs versus those identified as having agencies/firms as the source. Second, we study the processes that cause CGAs to be received more favorably. We investigate the roles of credibility and viewer involvement and predict that CGAs are more persuasive due to increased credibility and involvement with these ads. Third, we augment our understanding of the micro-psychological processes that explain reactions to CGAs through a holistic exploration within the natural viewing environment. We study the social discourse around the creation and use of CGAs in the commercial space. Our first two goals are informed through a laboratory experiment; our third leverages qualitative analyses of a series of field events.

For the experiment, we first identified a brand -Toyota Yaris-for which consumers had created ads and for which the target audience was aligned with our student respondents. Thirty Yaris CGAs were reviewed along two dimensions known to affect advertising response: executional quality and information content (Mitchell, 1986). Based on assessments by four judges, we selected four 30-seconds CGAs with varying (high vs. low) levels of executional quality and information content. In a controlled pretest where the source of the ad was not identified, 119 undergraduates viewed these ads and completed a battery of ad-response measures. Results confirmed our 2 by 2 factorial design: two ads with high brand information content and two with low content ($F_{4,119}=20.48$, $p<.000$), and two ads with perceived executional quality and two with low ($F_{4,119}=6.70$, $p<.000$). The main experiment involved a 2 (high-low information content) by 2 (high-low executional qual-

ity) by 2 (source condition: ad identified as created by a consumer versus by the firm/ad agency) between subjects design. Two hundred and eight undergraduates provided a series of reactions to and evaluations of these ads.

Results confirmed our hypotheses, with one exception. As expected, CGAs were more persuasive: attitude toward the brand was higher when the ads were identified as CGAs (F1, 208=5.37, p<.05). Further, there was a significant interaction of information content and ad source (F1, 208=5.72, p<.05): when information content was high, consumers' attitudes toward the brand were higher if the source of the ad was identified as CGA. This result suggests that viewers in the CGA condition were more engaged in the experience and processed more advertising message claims. Indeed, additional analyses showed that viewers' attitudes towards and involvement with the ad resulted from a significant 3-way interaction between the experimental factors. In particular, we found that viewers' involvement was greatest in the experimental conditions in which we found higher attitudes for the brand. This result pattern confirms our hypotheses concerning the added persuasiveness of CGAs, and the enhanced involvement that drives their effectiveness. We also found consistent result patterns for additional dependent measures, including motivations for social networking around the ad (e.g., saving the ad, forwarding it to friends) as well as behavioral intentions (e.g., seeking more product information or considering it for purchase). Finally, contrary to expectations, credibility was not a significant factor in explaining responses to CGAs.

In part two of our research, we sought a deeper, more natural, and holistic understanding of the processes underlying CGAs' effects. We studied (1) milestone CGAs created in response to company-sponsored competitions for the Super Bowl 2007 (Frito-Lay Doritos, Chevrolet HHR, and NFL) and the 2007 Academy Awards (Unilever's Dove Cream Oil contest winner and two finalists), and (2) CGAs created organically by evangelists for four community-intensive brands (Harley Davidson, iPod, Facebook and VW). Traditional company ads in these venues were also used as benchmarks. Our research pursued a multi-pronged analytic approach deriving grounded themes from analyses: viewer comments posted on Youtube.com, uncutvideo.aol.com, and company contest sites; secondary research surrounding the details of CGA contests; and interviews with CGA creators.

Our research revealed a key and previously unidentified driver of consumer response to CGAs: the professional skills of CGA creators versus their perceived authenticity as brand consumers. We found dramatic differences in viewer responses for "crowd-sourced" versus "authentic" CGAs. Responses to crowd-sourced CGAs mirrored those for "typical company ads," and focused on entertainment value, positive attitudes toward the advertising, and judgments of executional quality. Responses to "authentic" CGAs, in contrast, were driven by interdependent conversational activities among viewers: consumer-to-consumer conversations and one-to-one messages to and among ad creators that at times constituted overt relationship advances. These conversations created a multi-faceted engagement experience consisting of viewer involvement, ad involvement, creator involvement, brand involvement, contest process involvement, emotional engagement, and cognitive elaboration of the messaging. Responses to authentic CGAs also appear driven by brand characteristics, notably the brand's capability for and support of a strong community base. This study stresses the complexity of the CGA setting that must be accommodated in future research, and helps illuminate the processes underlying the effects of different "forms" of CGAs.

## "Managing The Creative Consumer Conundrum"

*Pierre Berthon, Bentley College*
*Leyland Pitt, Simon Fraser University*

Creative consumers represent an intriguing paradox for business. On the one hand they can be a black hole for future revenues, with breaches of copyright and intellectual property, while on the other hand they represent a potential gold mine for generating brand, product and business ideas. This duality poses a fundamental challenge to traditional consumer management processes. In order to create and capture value from creative consumers, firms need to adapt their mindsets and business models, and implement new strategies that accommodate and leverage the brand marketing artifacts generated by consumers in the field.

Although the pace and importance of consumer creation is fueled by the new networked economy and thus accelerating overall, the notion of consumers creating marketing artifacts has a long and illustrious history. The automobile serves as an excellent example of a product which, since its inception, has lived in a generally symbiotic relationship with creative consumers. The early Model T Ford was regularly adapted by farmers as a power source for driving generators, mills and lathes (Nye, 1998). Yet, although the phenomenon is old, it has received limited inspection by consumer researchers and leaders in the business press. Only recently has the phenomenon received focused attention in the management literature. For example, Mollick (2005) refers to creative consumers as "underground innovators". He provides an excellent framework that helps researchers and managers alike understand and categorize creative individuals. Unfortunately, the framework leaves us guessing about what management should do to approach and manage creative consumers– apart from encouraging them to perform.

In consumer research, there exists a long stream of research that has focused on consumer creativity, beginning with the work of Hirschman (1980) who defined it as problem-solving capability applied toward consumption-related problems. The focus of consumer researchers has tended to be on the behavioral traits of creative consumers, and especially the factors that influence the process of consumer creativity. For example, Moreau and Dahl (2005) studied, in an experimental setting, how input and time constraints influence the ways in which consumers process information during a creative task, and how those processes, in turn, influence the creativity of the solution. Also using experiments, Burroughs and Mick (2004) investigated the antecedents and consequences of creativity in a consumption context. Their findings suggest that both situational factors (i.e. time constraints, situational involvement) and person factors (i.e. locus of control, metaphoric thinking ability) affect creative consumption, and that there exists an interaction between these constructs as well. These research efforts are laudable, yet they shed little light on what managers should be doing to become aware of content generated by creative customers, how they should feel towards it, and what actions they should embark on to either encourage or discourage it for value creation and capture by the firm.

In this presentation, we define the concept of creative consumer, develop a typology of firms' stances toward this phenomenon, and examine the steps that are involved in the approach and management of creations by consumers. Our theoretical developments and considerations build from empirical results of research conducted among 178 marketing managers (representing a 30% response rate) concerning their handling of creative customers.

We define the creative consumer as an individual or group who generates branded content through creation, adaptation, modification, or transformation of proprietary offerings (such as products/

services and ad messages). We emphasize that creative consumers are different from 'lead users' (von Hippel, 1986), with creative consumers comprising a more general category of innovators than the lead user group.

Having defined and differentiated creative consumers, we develop a typology of firms' stances to the phenomenon. The typology is based upon managers' attitudes about and actions towards consumer-generated innovation in their businesses, as derived from factor analyses. Attitude toward consumer innovation concerns the firm's espoused policy or philosophy towards the phenomenon in principle; it can range from positive to negative. The espoused philosophy typically reflects the mental mindset of top management, but can also range from a subtle form of politicking to poor organizational communication. Action on consumer innovation comprises what a firm does once the phenomenon has actually been detected. This can range from active to passive. Based on our research, these dimensions yield four distinct stances: resist, discourage, encourage and enable. For example, some firms see creative consumers as threatening and try to prevent them from innovating with their products and brands; others see creative consumers as an opportunity and actively facilitate creativity efforts on their part.

We consider implications of our typological model for corporate strategy, and empirically derive, via factor analysis, a three-step approach for dealing with creative consumers: awareness, attitude and action. Overall, results indicate a relatively low level of awareness of creative consumer activity concerning the brand, a generally negative attitude toward the process, and a passive tendency towards incorporating the products of creative consumers into brand and marketing plans. More sophisticated analyses reveal the relationship between awareness, strategic stance, and firm performance, and the role that market turbulence plays as a moderator of responses in this realm. Our presentation concludes with a discussion of avenues for future consumer research.

# Politics and Consumption

Yesim Ozalp, York University, Canada

## SESSION OVERVIEW

In the past, consumer researchers have studied various dimensions and practices of consumerist politics including boycotts (Klein et al, 2004; Sen et al, 2001), the critical/reflexive consumer (Murray and Ozanne, 1991; Ozanne and Murray 1995; Firat and Venkatesh 1995), consumer activism (Kozinets and Handelman, 2004), consumer resistance (Kozinets 2002, Kozinets et al 2004), countervailing strategies for commercial mainstreaming (Thompson and Coskuner-Balli, 2007) and oppositional meanings of global brandscapes (Thompson and Arsel, 2004). A related yet substantially different stream of research on the politics of consumption has evolved in the field of political science. Discussions of what political theorists call political consumerism (see e.g. Micheletti 2003; Micheletti, Føllesdal and Stolle 2004) focus on broad issues ranging from the existence and role of the postmodern political agent to the meaning of forest stewardship in the age of privatization. At the center of many of these writings are analyses of the condition and effects of global corporate capitalism, especially when fuelled by new information and communication technologies. The objective of this body of literature is to theorize the political consumerism movement as an individual and collective quest for political virtue in consumption and the market in the age of postmodern consumer culture, unfettered neo-liberalism, and rising neo-conservativism (Saltman 2006). Heeding the call of the conference theme, we would like to advance the budding debate on the politics of consumption in consumer research by 'building a bridge' to the theoretical work done in the field of political consumerism and by sketching out new directions for research on the politics of consumption within the canon of consumer culture theory.

Within the scope of this session we would like to achieve two main objectives. First, we revisit and critically interrogate some (often implicit) assumptions that posit the market as a sphere for political action and consumer agency. Second, we present two growing domains of consumption activity that traditionally have not been considered by researchers of the intersection of politics and consumption: first, the interrelationship between consumers' political orientation and collective consumer decision making and second, tourism. Partly due to a lack of comprehensive theoretical and historical analyses of political consumerism in CCT, our discussions have been limited to explorations of the motivations, the role, and the actions of various anti-global and anti-corporatist consumer movements. In this session, we not only present a number of different contexts in which to investigate political consumer action and move forward theorizations of political consumerism, we also question the theoretical and practical limits of political consumerism by presenting the contradictions that persist (and arguable become more accentuated in the age of neo-liberal globalization) between the market and the public (political) sphere. Hence, our agenda goes beyond the well-known consumer activism/resistance literatures by theorizing the political conditions of possibility of markets, consumption, and consumer subjects.

The first paper by Ozalp and Zwick investigates the implicit assumptions inherent in positing the market as a domain for enacting political action (collective and individual) and performing political consumer agency. From a public sphere perspective inspired by Habermas and others, the authors build a case against seeing the market as a useful site for political action as its logic goes against the main principles of enlightened and emancipated political debate: concern for the common good, concern for complete inclusion, and a desire to resolve inequity and injustice. The paper concludes with thoughts on the future of consumer resistance and the public sphere in the age of the Internet. Ozalp and Zwick argue that as the market becomes a transnational public the already rather limited ability of consumers to constitute and govern markets as a public sphere is diminished further vis-à-vis other political bodies such as firms, supra-national institutions, and governments. Yet, the condition of possibility for emancipated political consumerism is a market functioning as a public sphere. Otherwise, such acts of resistance are merely momentary and cannot be considered political and emancipatory.

The second paper expands on what has been considered part of the politics-market nexus by focusing on a specific type of anti-consumption activity: politically motivated brand rejection (PMBR). Sandikci and Ekici define PMBR as the refusal to purchase and/or use a brand on a permanent basis because of its perceived association with a particular political ideology that the consumer rejects. Based on interview data, the authors present three different types of ideologies that can lead to PMBR: predatory globalization, chauvinistic nationalism, and religious fundamentalism.

The third paper studies the volunteer vacation context in order to understand how political consumers have sought re-enchantment, communitas, and public virtue. Leonard presents results of an ongoing empirical project that investigates how volunteer vacations become a domain for political identity projects by presenting a space for engaging with the Other/Difference. She discusses how the motivations of political consumerism enter one of the more unlikely areas, global tourism, a site conventionally associated with the consumption of leisure and escape. Collectively these papers aim to provide a richer understanding of the intersection of politics and consumption.

## EXTENDED ABSTRACTS

### "Market and Public Sphere: Unpacking Political Consumerism"

*Yesim Ozalp, York University*
*Detlev Zwick, York University*

Today, consumers are actors in increasingly politicized market. Even international relations between countries are enacted in part through the market as instances of country-based calls for buycotts demonstrate (for example, many Muslim countries called for a boycott of Danish products after the cartoon incident and many popular right-wing media pundits in the US called for a consumer boycott of French products after the President Chirac-led government around President Chirac refused to support the Iraq war). More typically perhaps, the market has been politicized by the critics of global corporate capitalism who routinely call for consumption boycotts when companies fail to uphold ethical, social, economic, or environmental standards. Although these practices resulted in a growing interest in studying consumer activism, the notion of whether the market can serve as a legitimate site for emancipatory political action and agency has remained largely unquestioned. In this paper, we would like to investigate this take-for-granted assumption. To this end we first introduce two different conceptualizations of the modern public sphere that we find useful for theorizing political consumerism: modern public sphere and

counter publics. We then proceed to discuss under what conditions the market could be considered a public sphere that provides a legitimate area for political action and agency. Finally, we discuss how the Internet and the changing nature of a transnational public sphere may affect political consumerism.

Standard practices of political consumerism involve boycotts, buycotts, culture jamming, stewardship certification schemes, labeling schemes, and socially responsible investments. Micheletti and others (Micheletti et al, 2004) see the global market as a site for ethics and citizen action. They suggest that the disassociation of individual citizens from the political life turned the market into a site for "confronting the transnational corporations directly in the global marketplace, [where consumers] accuse them of violating human rights, and criticize them for their lack of dedication to sustainable development" (Micheletti et al, 2004, p. x). The capacity to resist corporate power *qua* consumer power has been discussed in the marketing literature as well, including boycotts (Klein et al, 2004; Sen et al, 2001), consumer enlightenment (Murray and Ozanne, 1995; Firat and Venkatesh 1995), consumer activism (Kozinets and Handelman, 2004), countervailing strategies for commercial mainstreaming (Thompson and Coskuner-Balli, 2007) and oppositional meanings of global brandscapes (Thompson and Arsel, 2004).

Despite such vivid interest in the politics of consumption, the question whether the market in fact constitutes a site for emancipation and deliberation remains unaddressed. In pursuit of an answer, we refer to the works of Habermas (1984; [1959] 1989) and Arendt ([1958] 1998) to develop a concept of the modern public sphere. Even though both authors consider the market as a social 'space', the recent rise of what has widely been called neo-liberalism calls into question whether the market form can uphold the key pillars of a public sphere (presence of rational-critical discourse and common goal), since there is an increasing power imbalance and unequal distribution. As a result, researchers of political consumerism and consumer resistance/activism focus on how the market can enable a free speech situation in Habermas's sense. Although the ideal speech situation developed by Habermas (1984) is central to the reflexive-defiant consumer of Murray and Ozanne (1991; 1995) and also rather implicitly present in the conceptualizations of the postmodern consumer subject by Firat and Venkatesh (1995), these authors focus on theorizing the consumer subject rather than developing a conceptualization of the market as public sphere for consumer emancipation. Arguments similar to Murray and Ozanne can be found in the political science literature on political consumerism. Specifically, as ideal democracies and public spheres are inclusive rather than exclusive; equating political consumerism with democracy and equating the [political] consumer subject with the democratic individual and citizen (see Micheletti et al. 2004, for different perspectives on this argument) calls for an in depth analysis of the inclusiveness of the political consumerism. As Stoole and Hooghe (2004, p.284) state "political consumerism like many other forms of participation is not all-inclusive". Given the exclusivity of market and consumer resistance as well as the absence of a cultural and social mechanism that will ensure the pursuit of a common good, serious doubts arise about the market as a modern public sphere (Barber 2007).

Within public sphere literature, the issue of exclusivity has resulted in the development of the concept of counter public. A counter public excludes or self-reflexively sets itself against the wider public (Asen, 2000). A counter public shares an understanding of a common good that is different from the wider public (Warner, 2002). The counter public exists as long as the exclusion is articulated in the discourse (Asen, 2000). The objective is to end the exclusion. Again, while references to a counter public can be found in the CCT literature (see e.g. Kozinets 2002; Kozinets and Handelman 2004) a theorization of this concept is missing with important implications for the theorization of consumer resistance as a counter public. Theories of counter publics require the articulation of resolution (of exclusion) (Asen, 2000). Such a perspective is yet to be included in the consumer resistance work in the CCT literature.

Hence, our analysis suggests three problem areas to which CCT researchers interested in the field of consumer resistance need to pay more attention: the common good, exclusivity, and the possibility of articulating a resolution to exclusion. Finally, we provide some thoughts on the future of consumer resistance and the public sphere. The meaning of the public has changed with the Internet, which has also affected the idea of the market as public sphere. Similar to Bohman (2004), we argue that even though the market turns into a transnational public as a result of the Internet, the existence of institutional support becomes ever more critical. The role of consumers in constituting the market as a public sphere is diminished vis-à-vis other forms like firms, supra-national institutions, and governments. As a result we argue that the possibility of a deliberate and emancipated consumer is not the result of acts of resistance but of a market functioning as a public sphere. Otherwise, such acts of resistance are merely momentary and cannot be considered political and emancipatory.

### "Politically Motivated Brand Rejection"
*Ozlem Sandikci, Bilkent University*
*Ahmet Ekici, Bilkent University*

Both anecdotal and scholarly accounts indicate that anti-consumption attitudes and behaviors have become more diversified and widespread. The term anti-consumption spans a wide continuum, ranging from relatively harmless beliefs, such as negative perceptions of fast-food, to violent and illegal behaviors, such as the acts of vandalism and arson targeted at companies such as McDonald's, Nike, and the Gap. This study contributes to the existing literature by introducing and discussing an emergent form of anti-consumption behavior, which we refer to as "politically motivated brand rejection" (PMBR). We define PMBR as the refusal to purchase and/or use a brand on a permanent basis because of its perceived association to a particular political ideology that the consumer is opposed to. By political ideology we refer to a "belief system that explains and justifies a preferred political order for society, either existing or proposed, and offers a strategy for its attainment" (Christenson 1971, p.5). Movements such as anti-branding/anti-globalization, green/ethical consumption, and voluntary simplicity exemplify consumption behaviors that are shaped by various political and ideological commitments. As problems such as environmental destruction, human rights violations, and unfair business practices become issues that states have difficulty controlling and governing, marketplace choice emerges as a new form of political participation through which citizen-consumers can exercise their agency (Micheletti 2003). However, contemporary political-social landscape is also characterized by increasing conservatism, fundamentalism, and nationalism. It is likely that, similar to the environmental and ethical concerns that promote anti-consumption behaviors, concerns over nationalism or fundamentalism can also foster anti-consumption behaviors.

The study draws from data collected through qualitative methods in Ankara, Turkey, between March and December 2005. Data collection process involved two stages. First, semi-structured interviews with consumers of different age, gender, and social groups were conducted. The goal was to find out whether they

deliberately refused any brands and products in their consumption choices, and if they did so, to identify the reasons underlying their behavior. Analysis of the first stage data indicated that consumers may reject brands and products for a variety of product, health, environment, and ethics related reasons. However, there were also some consumers who reported rejecting a brand because of politically-motivated reasons that were not discussed previously. Although a number of local and global brands were mentioned, the brands most frequently cited as subject to such rejection behavior were Coca Cola and Cola Turka, a Turkish cola brand. At the second stage of data collection process, interviews with exclusive Coca Cola or Cola Turka consumers were conducted.

The analysis indicates that informants refrain from drinking Coca Cola or Cola Turka for a number of reasons. These include product related as well as politically oriented reasons. The analysis of the politically oriented reasons mentioned by our informants suggests that these consumers perceive an association between the brand they reject and a particular political ideology that they personally oppose. We identified three distinct sets of political ideologies that underlie rejection behavior. A brand can be rejected by some consumers if it is associated with a hegemonic and imperialistic form of globalization, or what Falk (1999) refers to as "predatory globalization". Many of the Cola Turka consumers in our sample perceive Coca Cola as a symbol of the hegemony of the United States operating under the guise of globalization. Some of them state that they refuse to drink Coca Cola because they consider it represents American cultural imperialism. However, although these consumers reject Coca Cola due to its perceived association with American cultural imperialism, their rejection behavior is distinct from consumer animosity. They do not feel animosity toward all American products; rather they selectively reject certain brands that they believe are associated with the hegemonic nature of the American culture.

A brand can also be rejected if it is associated with chauvinistic nationalism and is seen as manipulating nationalist feelings for financial gains. Contrary to the expectations of the literature on consumer ethnocentrism, our analysis indicates that a domestic brand can be rejected by local consumers because of its strong identification with nationalism. Almost unanimously, those who reject Cola Turka perceive the consumers of Cola Turka as nationalistic people who resent foreign brands and give importance to using domestic products, and disassociate themselves from the type of nationalism that they think Cola Turka represents. Moreover, many of the Coca Cola users believe that the managers of Cola Turka brand take advantage of the political context that fosters anti-American sentiments in Turkey and attempt to convert nationalistic feelings into cash.

Finally, a brand can be rejected if it is associated with religious fundamentalism and perceived as representing a threat to contemporary lifestyles. Almost all of the informants who refuse to consume Cola Turka point at the religious undertones of the brand and/or the parent company and perceive the brand as a symbol of Islamic fundamentalism. They believe that those who consume Cola Turka do so not because of its taste but as an expression of their support for the political ideology that the brand and its parent company advocate. Many consumers who reject Cola Turka believe that the Cola Turka represents radical religious groups whose hidden agenda is to abolish the secular regime in Turkey and throw her back into the dark ages. The findings reported in this paper provide preliminary evidence for politically motivated brand-rejection behavior. We argue that PMBR differs from other related forms of brand rejection. First, unlike political consumption, PMBR appears to be a sporadic activity which is not necessarily accompanied with a heightened and enduring sensitivity toward objectionable business practices in general. Second, unlike political consumers who participate in boycotts with the goal of pressuring the target company to correct its bad business practices, consumers who engage in PMBR do not expect a change in the market and business practices.

## "Virtuous Vacations: When the Global Citizen Consumer Hits the Road"
*Hillary Leonard, University of Rhode Island*

Volunteer vacations offer the opportunity to join a travel program, typically organized by a non-profit or nongovernmental organization, and spend one's holiday doing volunteer work. The work of the tourists on these "Volunteer vacation," "alternative tourism," or "working holiday" programs range from assisting scientists in conservation research to building homes and schools to assisting disabled, orphaned, street children to repairing trails in wilderness parks. Programs take place all over the globe in both the developed and developing world with international casts of characters. The work does not come cheaply. Costs for these holidays can equal those of some of the most high-end luxury vacations with land-only costs for a one or two week program running several thousand dollars. Despite the expense, the amenities rarely approach the hedonic, luxury vacation image so widely distributed by the cultural industries. For many volunteer tourists part of the authenticism of the experience is derived from "roughing it" or denying themselves the indulgence of a sumptuous vacation. The work of the volunteers can be tedious, even grueling, leaving volunteers with little time or energy for activities beyond the program nor relaxation. Yet the niche is growing quickly and many mass tourist vacation programs are incorporating elements of volunteer vacations into their mainstream packaged holidays.

This paper draws from interview data to investigate the experiences and motivations of the volunteer vacationer. Particular emphasis is put on the question of how such forms of tourism provide citizen consumers the opportunity to share in the responsibility for a wide-range of environmental, social, and political issues in our complex risk-ridden world. As these working holidays offer diverse groups of individuals the opportunity to engage with fellow tourists and their hosts, fascinating political, social, and cultural dynamics play themselves out often translating in a type of worldly solidarity with the plight of others and a sense of collective identity through, or perhaps despite, difference.

Volunteer vacations resist some common models and typologies of tourism and tourists available in the literature. Tourism is frequently contrasted to the everyday, the ordinary (Graburn, 1989) and work (Cohen, 1984) and is commonly conceived of in parallel to pleasure (Rojek, 1995). Further tourism is often categorized by the amount of exposure or protection it provides from the local environment provided by the "tourist bubble" of the tourist infrastructure (Cohen, 1984). The organized tour is the type of tourism most removed and protected from the local host environment, a categorization with lower social status, deemed the most inauthentic. However, the volunteer vacationer joins the organized tour of a working holiday in an effort to gain otherwise unattainable access to the locals and their culture. For many vacations are a time to indulge oneself, an occasion for well-deserved pleasure (Urry, 1990). Contrary to this view of tourism, the volunteer vacation is defined by its objective of benefiting others. As such, volunteer vacations represent a form of political consumerism where citizens take responsibility, balance self interest with helping others, and an enact virtue through consumption (Micheletti, 2003). On the self-interest side, tourists commonly join volunteer vacations for the

chance to meet and connect with a group of like-minded tourists. Perhaps alienated at work, the volunteer program offers tourists access to community and solidarity. Although the community bonds tend to be formed between co-tourists within the packaged volunteer program, volunteer tourists typically choose these holidays to intimately encounter local hosts.

The desire to encounter and "help" the Other has commonly been derided as patronizing at best and perhaps an attempt to reify colonialist, elitist power. However these views have been challenged with the charge that the self/other dichotomy might be refigured (Wearing and Neil, 2000). Although Western views privilege self in *opposition* to Other, in different cultures self may be defined through *connection* to others (Wearing and Neil, 2000). By offering volunteer tourists and local hosts the occasion to cooperate and find unity with each other, volunteer vacations build bridges between these groups and bonds them as common citizens of the world. In this way, the other becomes integral and important rather than minimized and contrasting.

# The Role of Cognitive Processes in Overcoming Self-Control Failures

Sabrina Bruyneel, Carnegie Mellon University, USA

## SESSION OVERVIEW

The capacity to exert self-control is an important feature of human nature. Given the adaptive benefits of being able to control inner states and behavioral responses, self-control is of significant importance for achieving success in life (cf. Baumeister and Heatherton 1996). Self-control has also been studied from a consumer perspective, and particularly the self-control strength model has been gaining ground in consumer research (Baumeister 2002). According to this model, exerting self-control temporally depletes self-control in the same way as in which using a muscle temporally depletes its capacity to exert power. This vision presents a rather grim view on the consumer, who will find herself making decisions going against her long-term self-interest all too often. Accordingly, the empirical focus in recent years has been on consumer choices not conducive to long-term self-interest (e.g., Shiv and Fedorikhin 1999; Vohs and Heatherton 2000; Vohs and Faber 2007). The purpose of this symposium is to present ongoing research that sheds light on the cognitive processes underlying self-control, thereby providing insights in how consumers might proactively overcome temptations.

Recent research has focused on consumer self-control failure (Shiv and Fedorikhin 1999; Vohs and Faber 2007). Self-control is typically shown to break down after the prior exertion of effort, for instance when resisting temptations. Some work attempted to shed light on the nature of depletion (e.g. Vohs and Schmeichel 2003; Webb and Sheeran 2002). Beyond its theoretical impact, such research has direct relevance to consumer research because it provides insights that may help to dampen the negative impact of the depletion state. The papers in this symposium fit into this stream of research in that they demonstrate the importance of cognitive processing in helping consumers to exert self-control. Thereby, all papers offer new insights in the nature of self-control, and simultaneously provide consumers with strategies that may help them to successfully deal with self-control dilemmas.

In the first paper, Vosgerau, Bruyneel, Dhar, and Wertenbroch argue that the scarce resource on which all acts of self-control draw according to depletion theory is not self-control specific but rather of a more general nature, and that cognitions play an important role in the processes underlying depletion. In the second paper, Bruyneel and Dewitte argue that exerting self-control induces a concrete mindset, which subsequently drives depletion effects. The amount of effort exerted during the first task seems to be less important in producing depletion effects than the level of concreteness on which people process task-related information. In the third paper, Fishbach, Zhang, and Myrseth argue that goals decrease the motivational strength of tempting alternatives and prior exposure to temptations increase the motivational strength of goal-related alternatives. As a result of these counteractive shifts in evaluations, adhering to the goal is more valuable than yielding to the temptation and the initial conflict between the two is more likely to be resolved in favor of the goal. The underlying theme is that the three papers offer new insights in the nature of self-control, and hence in its applicability to consumer research.

## EXTENDED ABSTRACTS

### "Ego Depletion and Cognitive Load: Same or Different Constructs?"

*Joachim Vosgerau, Carnegie Mellon*
*Sabrina Bruyneel, KULeuven*
*Ravi Dhar, Yale University*
*Klaus Wertenbroch, INSEAD*

The theory of ego depletion states that all acts of self-control draw on a common limited resource that is akin to energy or strength. Hence, exertion of self-control is necessarily followed by a period of diminished capacity to exert subsequent self-control. Eventually, with sufficient rest, the resource should build up again (e.g., Muraven and Baumeister 2000). Researchers have demonstrated depletion for behaviors as diverse as thought suppression (Muraven, Tice, and Baumeister 1998), persistence at strenuous tasks (Baumeister, Bratslavsky, Muraven and Tice 1998), emotion control (Vohs and Heatherton 2000), response inhibition (Wallace and Baumeister 2002), intellectual performance (Schmeichel, Vohs, and Baumeister 2003), self-presentation (Vohs, Baumeister, and Ciarocco 2005), and active choice-making (Bruyneel, Dewitte, Vohs, and Warlop 2006). This pattern of findings raises the question as to what extent these behaviors actually involve *self-control* conflicts, given that many researchers define self-control conflicts much more narrowly as conflicts between smaller, immediate versus larger, delayed rewards (e.g., Loewenstein 1996; Metcalfe and Mischel 1999; Trope and Fishbach 2000; Wertenbroch 1998; Wertenbroch et al. 2008). In other words, is ego depletion *self-control* specific, or might it be just another form of mental fatigue?

The concept of cognitive capacity has played an important role in the literature on (consumer) decision-making. One way to reduce cognitive capacity is to cognitively load participants, resulting in similar effects as ego depletion (Dhar, Nowlis, and Sherman 2000; Drolet and Luce 2004; Shiv and Fedorikhin 1999). Given that cognitive load can produce similar effects as ego depletion, the question becomes whether depletion can produce similar effects as cognitive load, and if so, whether and how depletion differs from cognitive load.

In the first study, we investigated whether depletion and cognitive load produce differential effects on memory for previously presented product information. The experimental design is a 2 (depletion vs. no depletion) by 2 (cognitive load vs. no cognitive load). We used a variation of the Stroop task as depletion manipulation (Wallace and Baumeister 2002). Participants were asked to indicate the ink color of 50 color names. In the non-depleting condition, words and ink colors were matched (e.g., RED in red ink). In the depleting condition, words and ink colors were mismatched (e.g., RED in yellow ink). In addition, when a word in blue ink appeared participants were instructed to indicate the word rather than the ink color. Subsequently, participants saw information on a luxurious Italian holiday resort, while at the same time had to keep either a one-digit (no cognitive load) or a nine-digit number (cognitive load) in mind (Chun and Kruglanski 2006).

After the depletion and cognitive load manipulations, we administered a memory test consisting of free recall and recognition

of holiday resort features (Lynch, Marmorstein, and Weigold 1988). We found a main effect of both depletion and cognitive load on free recall, indicating that depleted participants recalled fewer holiday resort features than participants who were not depleted, and that cognitively loaded participants recalled fewer holiday resort features than participants who were not cognitively loaded. The depletion by cognitive load interaction was not significant. Cognitively loaded participants also recognized fewer holiday features, however no such effect was found for depletion.

In the second study, increased the number of holiday features to test whether the same pattern of recall and recognition can be found for depletion as for cognitive load. The design of Study 2 is similar to the one of Study 1. We replicated the effects found in Study 1, such that cognitively loaded participants recalled fewer holiday features than participants who were not cognitively loaded. A similar effect was found for correct recognition of holiday features. However, an interaction of recall and recognition indicated that cognitive load impaired recall to a greater degree than recognition. The same interaction was found for depletion. Depleted participants recalled and recognized fewer holiday features than non-depleted participants, but the effect was more pronounced for recall than for recognition. The overall effect of depletion was much weaker than the overall effect of cognitive load.

Our findings demonstrate that cognitive load and depletion can produce similar effects on variables unrelated to self-control exertion. So, the scarce resource producing depletion effects is not self-control specific, as is typically suggested in the depletion literature. Depletion and cognitive load produce similar effects, suggesting that they recruit the same underlying processes. However, depletion effects are weaker than cognitive load effects on memory recall. Depletion is an after-effect because learning is impaired *after* participants are depleted, whereas cognitive load is an immediate effect because learning is impaired *while* participants are cognitively loaded. Future studies are planned to look whether depletion and cognitive load are moderated by the same factors. If so, we would have further evidence that depletion and cognitive load both recruit the same underlying psychological processes.

### "To Have One's Mind Set on it: Mindsets and Self-Control Dilemmas"
*Sabrina Bruyneel, KULeuven*
*Siegfried Dewitte, KULeuven*

The self-control strength model (Muraven and Baumeister 2000) states that exerting self-control taxes a limited resource akin to energy or strength, and thus brings people in a state of resource depletion. This state reduces people's capacity to exert self-control subsequently. Although the basic finding is undisputed and several moderators and mediators of the depletion effect have been proposed (Martijn et al. 2002; Muraven and Slessareva 2003; Vohs and Schmeichel 2003; Webb and Sheeran 2003), the nature of the scarce resource remains elusive. The aim of this paper is to gain more insight in the processes underlying depletion. We claim that depletion effects result from being stuck in a concrete mindset that is adopted during initial self-control exertion.

It has been argued that concrete processing is associated with performance on challenging tasks (Mischel, Cantor, and Feldman 1996; Norman and Shallice 1986; Scheier and Carver 1988; Vallacher and Wegner 1987; Vallacher, Wegner, and Somoza 1989). As tasks that experientially have been shown to evoke concrete processing have important features in common with typical self-control tasks (Vohs and Baumeister 2004), we propose that the exertion of self-control will also evoke concrete processing, and will even induce a concrete *mindset*, in that the state of concrete processing will linger

and influence how people deal with subsequent tasks. Indeed, the transfer of cognitive procedures from one task to an unrelated task is the hallmark of mindset priming (Gollwitzer 1990). We suggest that the resulting difficulties in organizing and reorganizing cognitive resources may explain self-control failures observed in typical depletion studies.

If we are right in assuming that exerting self-control induces a concrete mindset, we should observe carry-over effects of self-control manipulations on concreteness of processing while engaging in subsequent unrelated tasks. We investigated this in the first study. Participants were asked to engage in a thought-listing task. They were instructed to write down their thoughts and either to avoid thinking about a white bear (self-control condition) or to think about anything they wanted, including a white bear (no self-control condition). A similar task was a successful self-control manipulation in earlier research (Muraven and Slessareva 2003). Subsequently, participants imagined themselves in one of three situations (e.g., having a yard sale) and classified objects related to each situation (e.g., books, cutlery) in as many categories as they deemed suitable. This task is one of the standard measures of level of concreteness of categorization (Liberman, Sagristano, and Trope 2002). We found that participants who had exerted self-control formed more groups than participants who had not exerted self-control, suggesting that exerting self-control induces a concrete mindset.

In the second study, we manipulated the extent to which participants engaged in concrete processing while exerting initial self-control, and investigated whether this influenced the depletion effect. Participants were randomly assigned to one of three conditions. In the control condition, participants were presented with a series of products and rated how often they had been using each product in the past. In the choice condition, participants were presented with a series of binary product choices. A similar choice task was shown to produce depletion effects in previous research (Bruyneel, Dewitte, Vohs, and Warlop 2006). It also induced concrete processing as products in each binary choice set had to be compared on the attribute level (e.g., chocolate chip cookie versus raisin bran cookie; Johnson 1984). In the goal condition, participants were also presented with a series of product pairs, but they were asked to come up with a common goal that could be fulfilled by the products in each pair (e.g., a book and a pair of glasses both satisfy the goal of reading). This task was depleting as it required complex thinking (Schmeichel, Vohs, and Baumeister 2003). It also induced abstract processing as it required participants to focus on goals (Freitas, Gollwitzer, and Trope 2004). Subsequently, participants were asked how much they would be willing to pay for several products. We found that choice participants were willing to pay more than control participants, replicating the typical depletion effect. Choice participants were however also willing to pay more than goal participants. We found no differences between control and goal participants. Interestingly, choice and goal participants indicated that they had exerted a comparable amount of effort during the first phase of the study, and that they had exerted significantly more effort than control participants.

In the third study, we attempted to replicate the findings of study 2 using different depletion and mindset manipulations. Participants were randomly assigned to one of four conditions. In the control and the thought suppression conditions, participants engaged in the same thought listing task as in study 1. They were asked to list their thoughts and were either or not allowed to think of a white bear, respectively (Muraven and Slessareva 2003). In the choice condition, participants engaged in a similar depleting binary choice task as in study 2 (Bruyneel et al. 2006). The double

condition was the most informative one. In this condition, the task requirements of the other two depletion conditions were combined. Participants were asked to not think of a white bear while actively making binary product choices. We hypothesized that it would be harder for participants in this condition to engage in concrete processing than it would be for participants in the other two depletion conditions, as they could not entirely focus on the task characteristics of one particular task. Our dependent measure again was willingness to pay for several products. We found that control participants were willing to pay less than thought suppression and choice participants, the latter two conditions not being significantly different. This finding replicated the typical depletion effect. In addition however, participants in the double condition were also willing to pay less than participants in the other two depletion conditions. Participants in the double condition did not differ from control participants. Participants in the three depletion conditions indicated that they had exerted a comparable amount of effort during the first phase of the study, and that they had exerted significantly more effort than control participants.

Overall, our data provide support for the claim that exerting self-control induces a concrete mindset, which rather than the effort exerted subsequently drives depletion effects.

### "Asymmetric Effects of Counteractive Control"

*Ayelet Fishbach, University of Chicago*
*Ying Zhang, University of Texas at Austin*
*Kristian Myrseth, University of Chicago*

Counteractive control theory describes the conditions that activate self control processes, the nature of those processes, and how they enable individuals to overcome temptation (e.g., Fishbach and Trope 2005; Trope and Fishbach 2000). According to this theory, when individuals feel that tempting alternatives threaten the attainment of their high order goals, they proactively employ self control strategies, designed to offset the influence of those temptations on their behavior. The stronger the temptation, the more likely are individuals to engage in counteractive control.

 Our recent research on counteractive control addresses asymmetrical shifts in motivation: Goal-related cues undermine the value of temptations and lower the amount of time people plan to invest on tempting activities. Temptation-related cues augment the value of the goal and increase the amount of time people plan to invest on goal-related activities. Specifically, exposure to temptations increases the value that people assign to an overriding goal. In this respect, making individuals aware of pleasurable alternatives to a goal may make the goal seem more positive. Correspondingly, reminding individuals of an overriding goal renders the value of tempting alternatives less positive. In themselves, temptations represent desirable outcomes that individuals would otherwise pursue. However, when these outcomes steer individuals away from an overriding goal, they would be devalued. As a result of counteractive shifts in evaluations, adhering to the goal is more valuable than yielding to the temptation and the initial conflict between the two is more likely to be resolved in favor of the goal. We present three studies that support these asymmetric shifts in motivation.

The first study tested for implicit evaluation of goals and temptations using an evaluative priming paradigm (cf. Bargh, Chaiken, Govender, and Pratto 1992). In the domain of healthy eating and overcoming food temptations, this study finds that dieters undermine the implicit value of fatty foods (e.g., chocolate) in response to cues for dieting, and they augment the value of healthy foods (e.g., apple) in response to cues for indulging. Such changes in the implicit value of healthy and unhealthy foods help dieters maintain their commitment to healthy eating when they encounter tempting foods.

The second study examines whether counteractive evaluations are elicited by available (rather than unavailable) temptations. According to our self-control perspective, making temptations available should make them less valuable, whereas making goals available should make them more valuable. Following a procedure developed by Simpson et al. (1990), we specifically tested how individuals in dating relationships versus not (i.e., singles) perceive the sexual attractiveness of others who are either in dating relationships and hence, they are unavailable, or not and hence, they are available. We find that those in dating relationships undermine the attractiveness of single (available) targets compared with (unavailable) targets in a dating relationship. In addition, they boost the perceived attractiveness of their own partners after evaluating available (vs. unavailable) potential partners. A devaluation of the attractiveness of a potential partner by a person in a dating relationship is therefore, a matter of availability.

Our final study examines asymmetric effects on the amount of time or resources that individuals plan to invest on a goal-related activity versus a tempting activity. We predict that in respond to temptations, individuals set higher performance standards to maintain their level of performance on goal-related activity. In addition, in respond to a goal, individuals underestimate the amount of time and resources that they would like to devote to a tempting activity. We explore these overly optimistic predictions in the domain of academic goals and overcoming leisure temptation. We find that students augment the predicted amount of time that they will spend on academic activities (e.g., completing their coursework) when they first consider the time spent on leisure activities (vs. not). We also find that students undermine the amount of time that they will spend on leisure activities (e.g., watching TV) if they first consider the time spent on academic activities (vs. not).

Taken together, these studies document asymmetric changes in motivation for goal pursuing and giving in to temptation: augmenting the goal value while undermining the temptation value, and setting optimistic expectations for more goal pursuit and less time spent on succumbing to temptation.

# What Do You Think: The Role of Others' Opinions in the Marketplace

Rohini Ahluwalia, University of Minnesota, USA

## SESSION OVERVIEW

Past consumer behavior research has typically focused on how other people's opinions tend to *influence* consumers–e.g., in the form of expert opinions (e.g., Petty and Cacioppo 1991), as consensus cues (Aaker and Maheswaran 1997), as reference groups (Bearden and Etzel 1982), and word-of-mouth communications (Godes and Mayzlin 2004). This session takes a unique and broader perspective on this topic by bringing together research from several diverse streams (as per this year's conference theme) to launch a productive discussion on how research from these areas can be integrated to provide a more complete picture of the role of other's opinions in the marketplace—not only from the vantage point of how they influence consumers, but also how and when are consumers more likely to be influenced by these opinions, how do consumers attempt to influence other's opinions, and how do they estimate these opinions.

The three papers represent the main aspects and approaches to understanding the role of others' opinions. The Gershoff, Mukherjee and Mukhopadhyay paper attempts to understand how people estimate other's opinions and the extent to which biases operate in this process. They examine this issue in the context of the false consensus effect. The Kaikati and Ahluwalia paper focuses on the issue of when, how and which of the other's opinions are likely to influence consumer buyer behavior. These issues are examined in an interpersonal setting, using the context of word-of-mouth effects and relationship ties. The Kirmani and Dorokhina paper uses interpersonal sales setting to understand when consumers are likely engage in deceptive behaviors, in attempting to influence the opinion of others (buyers in this context).

As such, each of these papers approaches the topic of other's opinions, but from a different perspective: how are these opinions estimated (Gershoff et al); how and when do they influence consumer evaluations of products (Kaikati and Ahluwalia); how do consumers attempt to influence other's opinions (Kirmani and Dorokhina).

Margaret C. Campbell (University of Colorado-Boulder) served as the discussion leader. She brought to bear her breadth of knowledge in this area to engage the participants and the audience in an enriching discussion on this topic.

## EXTENDED ABSTRACTS

### "What's Not to Like? Preference Asymmetry in the False Consensus Effect"

*Andrew D. Gershoff, University of Michigan*
*Ashesh Mukherjee, McGill University*
*Anirban Mukhopadhyay, Hong Kong University of Science and Technology*

Individuals often need to predict other people's likes and dislikes (Hoch 1987; West 1996). For example, when individuals offer advice to friends about movies, buy a gift for a loved one, or recommend a restaurant to a colleague, they first have to assess the recipient's likes and dislikes. Yet, extensive research indicates that people tend to overestimate the extent to which their own attitudes, beliefs, and behaviors are shared by others, an effect variously referred to as false consensus, egocentric bias, social projection, and assumed similarity (Hoch 1987).

One explanation for false consensus, based on the availability heuristic, is that individuals estimate the prevalence of views in the population by relying on the availability or ease with which either examples of others who hold an attitude come to mind, or the ease with which reasons for holding the attitude come to mind (Ross et al. 1977; Mullen et al. 1985; Tversky and Kahneman 1973).

Recent research finds an asymmetry in the attribute ratings of alternatives, such that people are less likely to dislike attributes in an object they like compared to liking attributes in an object they hate (Gershoff, Mukherjee, and Mukhopadhyay 2007). Notably, such asymmetry in the quantity of these counter-valence attributes between disliked and liked alternatives has been empirically demonstrated in a number of product categories, including movies, wall posters, and ice-cream sundaes (Gershoff, Mukherjee, and Muhopadhyay. 2006, 2007).

We propose that this asymmetry in counter-valence attributes between disliked and liked alternatives leads to a moderation of the false consensus effect, such that the effect is weaker for disliked alternatives and stronger for liked alternatives. Since it is relatively easy to think of positive aspects of disliked alternatives, individuals are likely to be sensitive to the possibility of others liking, or at least being neutral toward, an alternative that they personally dislike. This, in turn, should dampen individuals' overestimation of population consensus for disliked alternatives, thus reducing the magnitude of the false consensus effect. In contrast, since it is relatively difficult to think of negative features of a liked alternative, the false consensus effect is likely to be stronger for liked alternatives. Four studies support these results.

Two-hundred and twenty-two individuals participated in study 1 by providing their estimates of the percent of other people who would like, give a neutral rating to, or dislike, each of a set of 27 ice cream sundaes (n=113), or a set of 50 images of posters (n=109). Participants also provided their own ratings of each sundae or poster. Consistent with predictions, in both data sets, in addition to the basic false consensus effect, there was moderation by one's own preference. Specifically, those who liked an alternative estimated a greater percent of others would share their opinion compared to those who disliked the alternative. The same results also held when the dependent variable was the difference between participants' estimates and the actual liking and disliking percents in the population, a measure of the 'truly false consensus effect (Krueger and Zeiger 1993)

Study 2, directly explored the mediating role of availability counter-valence attributes on the relationship between preference and false consensus. Sixty participants provided names of movies they either liked or disliked as well as estimates of the percent of others who liked, were neutral toward, or disliked the movie. Participants also provided ratings of the acting, directing, plot, writing, and music. As in prior research, greater counter-valence attributes were found in the disliked compared to liked alternatives, with the average number of liked attributes in the disliked movies exceeding the average number of disliked attributes in the liked movies. Replicating study 1, those who liked a movie estimated a greater percent of others share their evaluation than those who hated a movie. More importantly, supporting the role of availability of counter-valence attributes, the quantity of counter-valence attributes mediated the relationship between ones' evaluation and the estimate of the percent of others who share that evaluation.

Studies 3 and 4 manipulated the availability of counter-valence attributes. In Study 3, was a 2 (preference valence) X 2 (availability) design with one hundred participants providing esti-

mates of the percent of others liking, disliking, and neutral toward a poster that was either liked or disliked by the participant, depending on condition. Availability of counter valence attributes was externally manipulated by providing the participant with either 1 or 4 statements indicating reasons for liking or for disliking the poster, said to be from another person in the study. As in studies 1 and 2, there was a main effect for preference valence, with those liking a poster estimating a greater percent of others would hold the same opinion as they do compared to those who dislike a poster. However, as expected, this effect was moderated by the availability of counter-valence reasons. Making available a greater number of counter-valence attributes decreased the false consensus effect. Further, as in study 2, the reported ease of thinking of counter-valence attributes mediated the relationship between preference valence and false consensus.

Finally study 4, manipulated availability internally, by forcing participants list either 3 or 8 aspects of a movie that ran counter to their overall evaluation. As predicted, those forced to list more reasons indicated that it was more difficult to think of reasons that were opposite their own evaluation. As in the prior studies, the degree of false consensus depended on one's preference, with more false consensus for liked versus dislike alternatives. However, consistent with the role of availability of counter-valence attributes in driving the effect, the degree of false consensus decreased when participants found it easier to generate the counter-valence attributes. Again, mediation provides further support for the role of counter-valence attributes.

In summary, across multiple studies and multiple product categories, it is shown that the false consensus effect is moderated by one's own preference valence, such that there is more false consensus when a person likes and object than when he or she dislikes it. The studies also show the role of availability of counter-valence attributes in this effect. Specifically, measured availability of counter-valence attributes are shown as mediators (studies 2, 3, and 4) and manipulations of availability are show to moderate the effect (studies 3 and 4).

### "Examining the Effectiveness of Firm-Sponsored Word-of-Mouth Communications: The Role of Disclosure and Relationship Tie Strength"

*Andrew M. Kaikati, University of Minnesota*
*Rohini Ahluwalia, University of Minnesota*

Prior research has found that interpersonal word of mouth (WOM) is more persuasive than other forms of media communication (Blackshaw and Nazzaro 2005; Godes and Mayzlin 2004; Katz and Lazarsfeld 1955). Consequently, firms are relying more on WOM communication (Godes et al. 2005), and are actively recruiting consumers to be WOM agents (Kaikati and Kaikati 2004). The objective of consumer WOM agents is to talk to other people they know (e.g. friends and acquaintances) about firms' products, and in return they often receive points that are redeemable for prizes. For instance, P&G's Tremor group has over 300,000 consumer WOM agents, and BzzAgent has over 60,000 (Wells 2004).

In response to consumer advocate concerns about surreptitious advertising, the Federal Trade Commission has stated that consumer WOM agents are required to disclose their affiliation with product manufacturers (Shin 2006). However, these agents fall in a "grey area," such that they can still choose whether to disclose their affiliations with firms when recommending products to other consumers. It is not clear whether disclosure of firm affiliations will have a positive or negative effect on evaluations and persuasion. On the one hand, it may increase agent credibility, and thus persuasiveness. On the other hand, it may increase consumer skepticism of the agent and the message (Friestad and Wright 1994). There are also several different types and "moments" of disclosure (e.g., forewarning before the persuasive message, post-warning after the message); past research has yet to examine how their nature might influence the persuasion outcomes.

Additionally, many companies try to encourage their agents to approach their close friends and family, while others tend to focus on tapping into the casual acquaintances of their agents. It is also largely unclear at this point, how these different types of relationship ties might moderate the relationship between disclosure and persuasion. Here again, past literature presents a mixed picture. Although it can be argued that information provided by a trusted friend (versus acquaintance) may be perceived as more credible and might be more persuasive even when the source is known to be a company agent (e.g., Friestad and Wright 1994); it can also be argued that people might be more suspicious, less forgiving and more angered by a sales attempt by their friend versus an acquaintance (Fein and Hilton 1994). Our research attempts to examine these issues further. In a series of two experiments we examine the effects of communications from WOM agents who had either strong (friend) or weak (acquaintance) ties with participants, under different types of disclosures.

Study 1 had a 3 (disclosure: forewarn, post-warn, none) x 2 (relationship tie strength: strong [friend], weak [acquaintance]) between-subjects design. Participants were asked to imagine themselves in a given new product recommendation scenario–where they received a product recommendation from either a friend or an acquaintance, and then completed the dependent measures. The no disclosure condition was used as a baseline for making the contrasts. The difference between two disclosure conditions was the point at which the source made a disclosure of his/her participation as a WOM agent. In the forewarning condition, it occurred before the product recommendation, while in the post-warning condition this information was disclosed after the product recommendation.

Results of the first study revealed that, as expected, a friend was perceived as more persuasive than an acquaintance (more favorable brand and agent attitudes), in the baseline (no disclosure condition). Inclusion of a post-message disclosure, however, proved to be highly detrimental for the friend-agent, but not to the same extent for the acquaintance-agent–whose message was better able to withstand the disclosure of a relationship with the company. Not only was the friend-agent's recommendation less persuasive than the baseline, it was also no more persuasive than an acquaintance-agent's recommendation. More importantly, the ill-effects of post-warning were attenuated, and a clear and significant advantage of the friend-agent emerged, simply by changing the timing of the disclosure to before (forewarning) instead of after the message. We argue that this might be a more effective strategy when friend-agents are used because of the communal character of close relationships (Clark and Mills 1979).

The second study was conducted to gain a better understanding of the underlying processes. Since consumer's expectations from their relationships appeared to be an important driver of the outcomes, in this experiment, we assessed the participant's extent of relational-interdependent self-construal (RISC), which is defined as the tendency to think of oneself in terms of relationships with close others (Cross, Bacon and Morris 2000). This study focused on the post-warning condition, where the strength of tie had backfired, to gain a better understanding of what might be driving this effect. To examine generalizability of our findings, a different variant of the post-warning disclosure was examined–where the agent did not volunteer the disclosure, but provided it upon a query by the target.

The study was a 2 (disclosure: none, post-message) x 2 (strength of tie: strong vs. weak) x 2 (RISC median split: high vs. low) between subjects design. In addition, measures of purchases intention were included in this study. The overall patterns of data from experiment 1 were replicated when the data were combined across the RISC conditions. However, when data were examined with a median split on the RISC variable, the results revealed that participants who scored high in RISC, that is, those who defined themselves in terms of their close relationships, reacted very differently from their counterparts who scored low in RISC. As such, participants who were high in RISC demonstrated a significant drop in their evaluation of the target brand and agent, and their purchase intention, when provided with the post-message disclosure from a friend-agent–similar to the findings of study 1. In contrast, no such drop was observed for the participants who were lower in RISC, who continued to evaluate the brand and corporation as highly as the baseline condition, even after the disclosure.

The findings of these studies suggest that the point at which the disclosure of a consumer agent's relationship with a company is an important determinant of brand and agent evaluations. Furthermore, a consumer's inclusion of others in his/her sense of self determines, to a very great extent, whether using a friend as a product agent is likely to backfire or help in selling process.

### "I'm Fair, Therefore I Deceive"
*Amna Kirmani, University of Maryland*
*Olga Dorokhina, University of Maryland*

What is the relationship between a concern for fairness and the likelihood of deception? There is little research on this topic in marketing or psychology. Since the two constructs are morally conflicting, one would assume that a sense of fairness would attenuate the likelihood of engaging in deception. However, that is not always the case. In this paper, we examine conditions under which consumers who are concerned about fairness are *more* likely to engage in deception than consumers who are not concerned about fairness.

We examine deception in the context of an interpersonal marketing interaction, e.g., an interaction between a buyer and a seller. We examine several factors that may affect consumers' likelihood of deceiving others, including the relationship between the seller and buyer, social value orientation and the type of deception. The relationship between the buyer and seller is characterized by cooperation (mutual interests) vs. competitiveness (conflicting interests) (Deutsch 2000). Deception may be considered less appropriate in a cooperative than competitive relationship (Kirmani and Campbell 2004). The second factor, social value orientation, is a stable dispositional variable that reflects a preference for own vs. other outcomes (Kuhlman and Marshello 1975). Those with a prosocial orientation seek to maximize joint outcomes along with equality in outcomes (Van Lange 1999); those with an individualist orientation maximize their personal outcomes; and those with a competitive orientation seek relative advantage over others. These three types of social value orientation are predictive of cooperative and competitive behavior patterns in a variety of settings, such as experimental games and social dilemmas (e.g. Kuhlman and Marshello 1975). Prosocials tend to be concerned with fairness and reciprocity, while individualists and competitives have more selfish motives; thus, researchers collapse the latter two groups into a category called pro-self. Finally, type of deception refers to whether consumers withhold information (omission) or actively lie (commission). Lies of commission are typically perceived as worse than lies of omission, since the former are perceived as more effortful and causal (Spranca, Minsk and Baron 1991).

Research shows that compared to consumers with a pro-self orientation, consumers with a prosocial orientation will be less likely to deceive opponents in a cooperative relationship. In a competitive relationship, however, consumers with a prosocial orientation will be *more* likely to deceive opponents (Steinel and De Dreu 2004). We extend this hypothesis in the first study, by examining all three levels of orientation. We predict that faced with a competitive buyer, prosocials will be more deceptive than individualists but not more deceptive than competitives.

Study 1 is a 2 (Buyer: Cooperative/Competitive) X 3 (Orientation: Individualist/ Competitive/ Pro-Social) X 2 (Type of Deception: not telling the truth/actively lying) X 4 (Scenarios) mixed design. The first two factors are between subjects and the last two are within subjects. One hundred undergraduate students imagined themselves in the role of a seller of a used car. Social value orientation was measured, while the buyer was described as cooperative or competitive. Participants were given private information about different aspects of the car they were selling (e.g., mileage, brakes, stereo system, and availability) and were asked how likely they would be to tell the truth or actively lie to the buyer about each of the different aspects. Consistent with the hypothesis, the results showed that when faced with a competitive buyer, prosocials were more likely to actively lie than were individualists, but as likely to lie as competitives. However, there were no differences across the three types of orientation in terms of reactions to a cooperative buyer.

To show that a fairness motive underlies these findings, we directly manipulated fairness in study 2 through priming. According to the might over morality hypothesis (Liebrand et al., 1986), social value orientation influences the relative weight individuals attach to the dimensions of morality (or fairness) and might (or power). Prosocials tend to frame decision making in terms of fairness, whereas individualists (and competitors) tend to frame decision making in terms of power. The design was a 2(Buyer: Cooperative/Competitive) X 2 (Prime: Fairness/Power) X 2 (Type of Deception: not telling the truth/actively lying) X 4 (Scenarios) mixed design. As before, the first two factors were between subjects and the other two were within subjects. Results are similar to those in study 1, suggesting that priming with fairness leads to greater deception than priming with power when dealing with a competitive opponent. A third study will examine further the underlying processes of prosocial motivation. Specifically, it will try to answer the question of whether different types of prosocial motivation, such as fairness and empathy have different effects on buyer's decision to lie.

Two of the three studies have been completed and the data have been analyzed. The third study will be finished before the ACR conference. The paper makes a contribution to research on deception, fairness, social value orientation, and persuasion knowledge. In the literature on social value orientation, individualists and competitives are considered one group; however, our study shows that their motivations are different, leading to different behavior in the context of deception.

# Symposia Summary
# Homo Consumicus: Emerging Research in Evolutionary Consumer Behavior

Nicole L. Mead, Florida State University, USA
Vladas Griskevicius, University of Minnesota, USA

## SESSION OVERVIEW

Evolutionary approaches to studying human behavior have led to broad theoretical advancements in the fields of biology, economics, anthropology, and psychology. In consumer behavior, the year 2007 marks the release of two books on evolutionary approaches to consumption: a textbook (*The Evolutionary Bases of Consumption*) and a forthcoming popular science book (Faking Fitness: The Evolutionary Origins of Consumer Behavior*). Yet empirical research utilizing evolutionary models in our discipline's top journals have thus far been almost completely absent. Are we as a scientific discipline missing out by potentially neglecting this vastly under-explored theoretical perspective?

The objective of this symposium is to bridge the gap between evolutionary approaches to studying human behavior and mainstream consumer behavior research. Four papers—each consisting of a series of programmatic experiments—will demonstrate how novel insights into consumer behavior can be gained by drawing on an evolutionary perspective. The papers and the discussion that follows aim to demonstrate how an evolutionary approach can be useful for developing novel, unique, and testable consumer behavior hypotheses. Moreover, the session and discussion will emphasize the fact that evolutionary approaches do not aim to replace other theoretical approaches—but instead offer a wide-reaching theoretical framework that can help integrate a number of existing models of consumer behavior, and to explicitly connect them with broad theoretical developments in other disciplines.

While the four papers presented in this symposium use diverse experimental methodologies to test specific hypotheses, all of the papers center on a core evolutionary theme: How consumer behavior and consumption experience is influenced by two evolutionary human motives—the motive to attract romantic partners (papers 1 and 2) and the motive to affiliate with others (papers 3 and 4). Examining the motive to attract a romantic partner, Griskevicius, Tybur, Sundie, Cialdini, Miller, and Kenrick draw on costly signaling theory from biology to examine conspicuous consumption, altruism, and philanthropy. They find that activating a romantic motive leads people to strategically spend money on flashy conspicuous purchases to display wealth. Van den Bergh and Dewitte examine the effects of "sexy" ads on consumer behavior, showing that the consequences of sexual imagery in advertising extends much further than merely to the evaluation of the product or brand—including that seeing attractive members of the opposite sex in an ad leads men to display resources and leads women to display physical attractiveness.

Mead, Vohs, Baumeister, and Rawn examine how social exclusion, which can trigger the motive to affiliate, leads people to consume in a way that enhances their chance of forging new social bonds. For example, they find that participants threatened with social exclusion are more likely than others to mimic the consumption patterns of a new peer. Ramanathan and McGill examine the motive of affiliation by simultaneously tracking the second-by-second evaluations of individuals' shared consumption experience. They find that shared consumption experiences foster affiliation between strangers via the emergence of mimicked non-verbal cues.

Finally, Darren Dahl will draw on his expertise in consumer behavior research and marketing practice to initiate a dialogue between the audience and the presenters. Particularly, researchers from myriad backgrounds are invited to engage in a discussion on whether and how an evolutionary approach could be integrated into consumer behavior research and practice. We hope to particularly emphasize that although evolutionary models clearly need more rigorous testing by consumer behavior researchers, an evolutionary approach provides fertile ground for a wide range of novel hypotheses and theoretical insights in consumer behavior.

## EXTENDED ABSTRACTS

### "Blatant Benevolence and Conspicuous Consumption: When Romantic Motives Elicit Strategic Costly Signals"

*Vladas Griskevicius, Arizona State University*
*Joshua M. Tybur, University of New Mexico*
*Jill M. Sundie, University of Houston*
*Robert B. Cialdini, Arizona State University,*
*Geoffrey F. Miller, University of New Mexico*
*Douglas T. Kenrick, Arizona State University*

On Valentine's Day 2003, Donald Trump pledged a million dollars to charity. A few years earlier, Ted Turner pledged a billion dollars to humanitarian causes. While such valiant spectacles of public philanthropy are actually fairly common, they seem somewhat puzzling. Trump and Turner, for example, epitomize many people's stereotypes of self-interested and self-serving capitalists; both men appear to obtain great satisfaction from lavish lifestyles and openly flaunt their extravagant private jets, luxurious yachts, and chauffeured limousines. Yet each of these seemingly selfish tycoons chose to give away a phenomenal amount of their own money to complete strangers. What motives might underlie such costly and apparently selfless deeds?

In the current research we investigated the idea that self-sacrifice might actually be self-presentation. Although it may have been a mere coincidence that Trump's donation was announced on Valentine's Day, there may indeed be a connection between philanthropic displays, lavish spending, and courtship. Deriving specific hypotheses from costly signaling theory, in three experiments we tested whether merely activating romantic motives in individuals might indeed elicit public philanthropy, conspicuous consumption, and blatant benevolence.

Donating one's own resources to a stranger is the essence of altruism. From an evolutionary perspective, altruism has always been somewhat of a puzzle—natural selection would not favor people to give away resources to people who aren't family members or to strangers who are unlikely to reciprocate such gifts. From an evolutionary perspective, for instance, it's difficult to understand why 70% of U.S. households give money to charity or why nearly 10 million Americans each year give blood to strangers whom they'll never meet.

A theory that may help explain such benevolent and often expensive behaviors is costly signaling theory (Miller 2000; Zahavi and Zahavi 1997). This theory was developed in biology and has garnered empirical support in studies of animals and of hunter-gatherer societies. Costly signaling theory suggests that individuals often engage in behaviors that are costly—behaviors that involve significant amounts of resources, energy, risk, or time—as a way of signaling to others useful information about themselves. According to costly signaling theory, such signals are ultimately adaptive

because they increase an individual's probability of attracting a mate.

According to a costly signaling theory, public philanthropy is a costly signal that displays two important features about an individual: That the person has abundant *resources,* and that the person is *prosocial.* According to the theory, just like a peacock's tail, such displays might ultimately serve to increase the signaler's ability to attract and retain mates. Following this logic, we examine whether merely activating mating motives in individuals would indeed lead people to produce displays of conspicuous consumption, blatant benevolence, and public philanthropy.

Three experiments found results consistent with costly signaling theory and with research on mate preference. Specifically, a romantic desire led men to increase their spending on conspicuous purchases—products that are luxurious, frivolous, and publicly consumed. But a romantic desire did not lead men to spend more on inconspicuous purchases—products that are necessities and are consumed in private. For women, a romantic desire increased blatant benevolence—helping that is social and public. However, mating motives did not increase women's inconspicuous helping—helping that is non-social and unlikely to be observed by one's friends or acquaintances. Romantic motives also led both men and women to increase their conspicuous financial generosity—to spend more money in publicly charitable ways.

The present research supports the hypothesis that blatant benevolence and conspicuous consumption are costly signaling displays that can function to attract and retain mates. That is, merely putting men and women in romantic state produce a cascade of strategic (although often non-conscious) behaviors such as conspicuous spending, public helping, and philanthropy. We believe that the present work and an evolutionary approach reflect only the tip of a data-rich iceberg that will serve as an impetus for novel and promising consumer behavior research.

### "When do Men Pay the Bill and Women Advertise Physical Attractiveness?"

*Bram Van den Bergh, Katholieke Universiteit Leuven*
*Siegfried Dewitte, Katholieke Universiteit Leuven*

Advertisers search for a way to break through the clutter by using sexually oriented appeals in marketing campaigns. Advertisements became much "sexier" in past decades and the percentage of less-than fully dressed models in commercials continues to increase. Previous research on the use of sexual imagery in advertising has focused on consumers' brand recall and recognition, appeal evaluation, attention, purchase intentions, product perception, persuasiveness, and communication effectiveness. The present investigation differs from earlier work by showing that the consequences of using "mating primes" extend much further than the evaluation of the product or brand. Deriving specific hypotheses from an evolutionary framework, two experiments tested how exposure to opposite-sex advertisements influences consumption geared towards mate-attraction.

Given the centrality of reproduction in the evolution of humans, sensory stimuli from opposite sex individuals act as input cues that prime a psychological orientation directed toward attracting a mate (Roney 2003). We hypothesize that exposure to mating primes instigates consumption patterns that closely match prefer-

ences of the opposite sex. Women are more likely than men to seek non-appearance-related factors in a mate, such as cues to resource possession or acquisition, while men more than women seek attributes associated with reproductive value or fertility (Buss 1988, 1989; Schmitt and Buss 1996). Following this logic, after exposure to mating primes, men should be more willing to pay the bill, since this is an indicator of resource possession. In contrast, women should be more willing than men to display physical attractiveness to advertise their reproductive value.

Our results supported the basic cognitive model of mate attraction (Roney 2003). Ads featuring desirable women led to an increase in mate-attraction tactics among men: Levels of financial investment in a romantic relationship were dependent on exposure to advertisements featuring opposite sex individuals. Following mating primes, men desired to invest more in a romantic relationship in an effort to increase their romantic appeal. In contrast, after exposure to desirable men, women advertised their feminine morphology. Using a breast rating scale, consisting of five drawings of women ordered by increasing breast size, women indicated that they preferred larger breasts after exposure to desirable opposite sex individuals.

We investigated the interaction between relationship preference style (committed versus uncommitted) and type of advertisement (parenting versus 'sexy'). Research indicates that individuals with a preference for committed relationships seek out romantic partners who will be likely to be good parents for their offspring. In contrast, individuals with a preference for brief uncommitted relationships prefer romantic partners who possess characteristic associated with physical attractiveness (Simpson and Gangestad 1992). Following this logic, we predicted that parenting primes (i.e., advertisements featuring individuals in positive interaction with a child) should affect individuals with a preference for committed relationships to a greater extent than physical attractiveness primes (i.e., advertisements featuring 'sexy' individuals). The opposite should hold for individuals who prefer brief uncommitted relationships. As predicted, commitment-focused men were more willing to invest in a romantic relationship (i.e., pay for a date) after exposure to parenting primes, whereas brief-relationship-focused men were more willing to pay after physical attractiveness primes. Similar effects were observed among women. Brief-relationship-focused women prefer larger breasts after exposure to physical attractiveness primes, whereas commitment-focused women prefer larger breasts after parenting primes.

The present research differs from earlier work by showing that the consequences of sexual imagery in advertising extend further than the evaluation of the product or brand. Two experiments demonstrate that advertisements featuring opposite sex individuals instigate consumption patterns geared towards attracting a romantic partner. Depending on the qualities one seeks in a potential partner, opposite sex individuals displaying specific desirable qualities (parenting vs. attractiveness) produce the strongest effects.

## "Reconnection Through Consumption: Socially Excluded People Adapt Consumption Patterns to Serve Affiliation Needs"

*Nicole L. Mead, Florida State University*
*Kathleen D. Vohs, University of Minnesota*
*Roy F. Baumeister, Florida State University*
*Catherine D. Rawn, University of British Columbia*

Humans have evolved as a hyper-social species and have a fundamental need for affiliation (Baumeister and Leary 1995; Buss and Kenrick 1998). When this need for affiliation is thwarted (e.g., by social rejection), people search for ways to forge new connections with others to re-establish social ties (Maner, DeWall, Baumeister, and Schaller 2007). The present research examined how the motivation to affiliate with others influences consumption. Specifically, in three experiments we examined whether people who are socially rejected (compared to people who are not socially rejected or who are socially accepted) would use consumption to forge new social bonds and promote affiliation.

Much research indicates that people use consumption behaviors as a way to form impressions of others. People's clothing serves as cue to their personality, people ascribe personality traits to users of specific products (Shavitt and Nelson 2000), and people form impressions of others based on cultural tastes (Belk, Bahn, and Mayer 1982). Recent research also indicates that people use consumption as a means to try and help achieve a temporarily activated goal. For example, using an evolutionary theoretical framework, Griskevicius and colleagues (2007) demonstrated that after activating men and women's motive to attract a romantic partner, people's consumption patterns shift in a specific manner that could help them fulfill their motive. Men with a romantic goal, for instance, signal their desirability as a potential mate through increased conspicuous consumption that can display wealth. Conversely, inducing a mating motive in women resulted in increased public helping to display prosociality.

Although an evolutionary perspective suggests that affiliation motives are likely to be a particularly strong driver of human behavior, little work has examined the influence of affiliation goals on consumption. To begin redressing this imbalance, we examined whether merely activating a motive to affiliate would influence people's consumption behavior. Specifically, in three experiments we tested whether people who had been socially excluded (compared to those who received negative non-social feedback or who had been accepted) would engage in consumption behaviors that could enhance their chances of affiliation.

In experiment 1, participants were led to believe that their partner declined to have a face-to-face interaction with them. The reason for the partner's departure constituted the rejection manipulation. Participants in the non-rejected condition were told that their partner had forgotten about an appointment, whereas participants in the rejected condition were told that their partner left the experiment because of a dislike for the participant. After the rejection manipulation, participants were given $10 (ostensibly for their participation) and were allowed to peruse products for sale in a laboratory store. Results indicated that rejected participants were more likely than non-rejected participants to purchase school spirit wristbands, a product symbolic of group affiliation and loyalty.

In experiment 2, participants were asked to indicate how much money they would be willing to pay for 10 products that were categorized as either conspicuous consumption items that are usually displayed in public (e.g., Rolex, Audi) or utilitarian items (e.g., rug, coffee maker). As predicted, socially excluded participants (compared to controls) were willing to pay more for conspicuous consumption items. However, there was no difference between the groups in willingness to pay for utilitarian items, suggesting that the effect of affiliation motives are specific to products that would be consumed publicly and could therefore be used as symbols of status and group membership. Additional data indicated that these findings could not be explained by differences in emotion or mood between the experimental groups.

In experiment 3, participants were led to believe they could anticipate a life devoid of social connections (social exclusion condition) or a life full of strong social connections (social acceptance condition). After the manipulation, participants were told that they would be having a discussion with another person. Before the discussion, however, participants reviewed a questionnaire that was purportedly completed by their partner—the partner was depicted as either a lavish spender or a frugal spender. Participants' desire for an expensive watch (lavish product), a Sam's Club Membership (frugal product), and Netflix service (neutral product) were then assessed. As predicted, for participants expecting to meet a lavish spender, social exclusion increased desire for a luxurious watch. In contrast, for participants expecting to meet a frugal spender, social exclusion increased desire for a Sam's Club Membership. There were no differences in willingness to pay for Netflix service between groups.

In sum, the present studies indicate that people who are socially excluded adjust their consumption patterns in a manner that could increase their chance of forging social bonds. The present research highlights how social motivations such as affiliation can influence consumption patterns, and how an evolutionary theoretical perspective can provide a useful framework for understanding, predicting, and testing consumption behaviors.

*Ann L. McGill, University of Chicago GSB*

Imagine going on a blind date to a movie with someone. Your partner in the experience may have very different goals during the experience compared to you. The question that we address in this paper is whether people are so sensitive to non-verbal cues during the experience that they can sense whether they share the same or different goals in the experience, and whether such a sense of rapport can predict subsequent evaluations of the experience.

Consistent with an evolutionary perspective on the goal of affiliation and social mimicry, recent work has shown that people tend to adopt others' moods and feelings upon observing their emotional expressions. A common finding in this research is that people's expressions of emotions may rub off on each other so that people acting together come to catch each others' moods, eventually even moving up and down together in a shared emotional rhythm (Neumann and Strack 2000; Totterdell et al. 1998). Further, people can often sense and adopt the goals of others outside of awareness (Aarts, Gollwitzer, and Hassin 2004). Thus, even if people do not initially know the goal that a partner is pursuing, they obtain emotional feedback that confirms or disconfirms their expectations of their partner's goal pursuit, which in turn leads to a feeling of being matched or mismatched. Thus, emotional expressions carry information not just about what a partner is feeling, but also about the goals that he or she is currently pursuing.

In our first study, we manipulated the goals that participants had during a viewing experience, whereby the goals were either matched or mismatched. Specifically, we instructed participants to observe a humorous video clip with the goal of enjoying it or evaluating it. These instructions thus created three possible combinations of goals that people might have while sharing an experience–a) both individuals may have a consummatory motive of enjoying the experience, b) both individuals may have an instrumental motive of critically evaluating or judging the experience, and c) one of the individuals may want to enjoy the experience while the other may want to evaluate it. Participants were not told what goal had been assigned to their partner. Online ratings on a continuous scale (0=dislike very much, 10=like very much) were collected every second for both participants via a joystick. We ran a cross-spectral analysis on the resultant time series to determine how people's evaluations covaried at different frequencies–that is, whether evaluations converged in short (every 2 to every 28 seconds) or long cycles (every 30 seconds or less often). Short cycle covariation would suggest that people were picking up non-verbal cues through frequent glances at each other, while long-cycle covariation would suggest that the effects were more subtle and indicative of long-run affiliation.

We found that matched goals (regardless whether goals were instrumental or consummatory) led to greater covariation in both the short and long cycle range. However, when both forms of covariation were included as predictors of retrospective evaluations (controlling for individual level peak and end affect), only long cycle covariation was significant, suggesting that the enjoyment of a shared experience depends on subtle affiliation rather than overt agreement or disagreement on the goals one brings to the experience.

In a second study, we included an individual difference variable (self-monitoring) to see if the effects obtained above were moderated by the degree to which people were sensitive to social cues. Once again, we used the same humorous video clip and captured online evaluations via a joystick. The resultant time series were analyzed using cross-spectral analysis, which yielded measures of short and long cycle covariance. In the short cycle range of frequencies, we found two main effects–people with matched goals had a greater covariance compared to those with mismatched goals, and high self-monitors had a greater covariance compared to low self-monitors. In the long cycle range of frequencies, we obtained the same main effects, and also found an interaction such that for people with matched goals, covariance was higher for high versus low self-monitors; while for those with mismatched goals, there was no difference in covariance across levels of self-monitoring. It thus appears that high self-monitors seem especially adept at sensing subtle affiliation cues when they share the same goals with others.

# Advances in Regulatory Focus and Regulatory Fit Theory: Effects on Consumer Search, Consumer Satisfaction, and Self-Control

Michel Tuan Pham, Columbia University, USA
Remi Trudel, University of Western Ontario, Canada

## SESSION OVERVIEW

There has been a renewal of interest in motivational explanations of consumer behavior. A primary driver of this renewed interest has been the field's recognition that consumer motivation should be conceived not only in terms of motivational *intensity* (cf. the popular concept of involvement) but also in terms of motivational *content*. As recently outlined by Pham and Higgins (2005), regulatory focus theory (Higgins 1997) provides a powerful framework for studying the role of motivational content in consumer behavior. *Regulatory focus theory* suggests fundamental differences between two modes of self-regulation called promotion and prevention that primarily differ in terms of strategic means during goal pursuit. Whereas promotion uses primarily approach means to attain desired end-states, prevention uses primarily avoidance means to attain desired end-states. This theory has achieved a great deal of attention from consumer researchers, and has proven to be a powerful predictor of how consumers respond to marketing communication and how they make decisions.

Recent research on the concept of *regulatory fit* (Higgins 2000) indicates that the pursuit of a goal in a manner that "fits" the person's regulatory orientation creates a subjective experience of "feeling right" that increases the person's motivational engagement and enhances the perceived value of the goal pursuit (e.g., Avnet and Higgins 2006; Wang and Lee, 2006). Regulatory fit theory implies a broader conception of the notion of value. Whereas value has historically been associated with the hedonic experiences of pleasure and pain, there is growing evidence that value also accrues from the *strength of engagement* (Higgins 2006). A person's strength of engagement, and the perceived value, increases under conditions of regulatory fit

The four presentations in this session further extend our understanding of how regulatory focus and regulatory fit influence consumer decision making, self- regulation and value. The first presentation by Tory Higgins, the father of regulatory focus and regulatory fit theory, examines value as not only a hedonic experience but also as an experience of motivational force whereby strength of engagement contributes to the intensity of the motivational force experience. The contribution to value by strength of engagement provides important new insights on what value is and how it is created. Tory Higgins will consider two sources of engagement strength in his presentation—the *use of proper means* when making a decision (What *is* right), and *regulatory fit* between the regulatory orientation of decision makers and the strategic ways they make their decision (What *feels* right). Experimental evidence demonstrates how these sources of engagement strength can intensify people's value reactions to their choices, including how much money they are willing to offer to buy their choices.

The second presentation Michel Pham and Hannah Chang examines the effects of regulatory focus on consumer search and consideration sets in decision environments with a large number of alternatives. The findings from four experiments show that promotion- and prevention-focused consumers do not differ in total amount of information searched, but promotion-focused consumers tend to search for alternatives in a more global, top-down fashion, whereas prevention-focused consumers tend to search for alternatives in a more local, serial fashion. In addition, promotion-focused consumers tend to have larger consideration sets than prevention-focused consumers. Finally, they find found that aligning the decision environment with the search and consideration inclinations of promotion- and prevention-focused consumers produces an experience of regulatory fit that increases the subjective value that the consumers attach to the offer.

In the third paper, Remi Trudel, Kyle Murray and June Cotte investigate the relationship between motivation and satisfaction-more specifically-how consumer satisfaction with a product is affected by an individual's regulatory focus. In two experiments, the authors demonstrate that differences in regulatory focus ultimately influence consumer satisfaction, and that post-consumption evaluations are different under promotion than under prevention. The results from both studies show a significant disconfirmation x goal interaction. More specifically, participants reported greater levels of satisfaction as a result of a positive product experience under promotion than under prevention, and greater levels of dissatisfaction with a negative product experience under promotion than under prevention. The findings from this research demonstrate the importance of motivation and goal orientation on post-consumption evaluations of products and consumer satisfaction.

Finally, Jiewen Hong will report an investigation on how regulatory fit contributes to self-regulatory success. The findings form four studies demonstrate how regulatory fit improves self-regulatory performance whereas nonfit decreases and impairs self-regulatory performance. Convergent evidence as demonstrated by participants' physical endurance, their willpower to resist temptation, and their intention to comply with disease detection behaviors support the hypothesis that regulatory fit improves self-regulation whereas regulatory nonfit impairs self-regulation. This research highlights the impact and importance of regulatory fit on self-regulation and further sheds light on how self-regulation effectiveness may be improved or impaired.

All presentations will be 15-20 minutes long with 3 minutes of questions after each presentation. The empirical work for all four presentations has been completed and all authors have agreed to attend and present their work. We believe that the session will appeal to a broad range of consumer researchers. In particular it should appeal to those interested in: (a) regulatory focus and regulatory fit theory, (b) more broadly, motivational approaches to consumer behavior, (c) consumer judgment and decision making, and (d) consumer self-control and self-regulation processes.

### "Where Does Value Come From"
*E. Tory Higgins, Columbia University*

What is value? Where does value come from? For centuries, these questions have been central to understanding people's motivation and decision-making. Not surprisingly, there have been many different answers to these questions, including that value is the experience of pleasure and pain. I propose that value is, indeed, a hedonic experience, but it is not only that. It is also an experience of motivational force-experiencing the force of attraction toward something or repulsion away from something. Because it is a *motivational force* experience and not only a hedonic experience,

there can be contributions to the overall experience of value other than hedonic experience. Specifically, I propose that *strength of engagement* contributes to the *intensity* of the motivational force experience-the intensity of attraction to or repulsion from something. The hedonic properties of a value target contribute to engagement strength, but there are also other factors-separate from the target's hedonic properties-that influence engagement strength and thus contribute to the intensity of attraction or repulsion. Because their contribution derives from their effect on engagement strength, these additional factors can contribute to a value target's attractiveness or repulsiveness regardless of whether they themselves are pleasant or unpleasant. For example, the unpleasant experience of opposing an interfering force while moving toward a positive target, such as removing a barrier that is blocking the path to a goal, can intensify the target's attractiveness. It is the contribution to value of these additional sources of engagement strength that provides new insights on what is value and how it is created.

In conceptualizing value, my starting point is the position of Kurt Lewin. For Lewin, value is a force that has direction and strength. I follow Lewin's lead but postulate a force experience that has direction and strength or intensity. Experiencing something as having positive value corresponds to experiencing attraction toward it (i.e., trying to move in the direction toward it), and experiencing something as having negative value corresponds to experiencing repulsion from it (i.e., trying to move in a direction away from it). The directional component of the value force experience (i.e., attraction versus repulsion) is critical to the psychology of value. This is why the hedonic experiences of pleasure or pain are so important. "Cognitive" sources of value can also influence the experience of direction. For example, shared beliefs about what is desirable and what is undesirable-both social values and personal ideals and oughts-directly determine what has positive value and what has negative value. But value experiences have more than direction. They also vary in strength or intensity so that the experience of attraction can be relatively weak or strong (low or high positive value), and the experience of repulsion can be relatively weak or strong (low or high negative value). The contribution of strength of engagement to the value force experience is not through an influence on direction but through its influence on the intensity of attraction or repulsion. The hedonic nature of a value target also contributes to value intensity through its impact on engagement strength, but it is not the only determinant of engagement strength. The purpose of this paper is to highlight the contribution to engagement strength, and thus to value intensity, from sources other than the value target's hedonic properties.

What is critical here is the notion that value is not just an experience of pleasure or pain but an experience of the force of attraction toward or repulsion away from something. Value involves an experience of the intensity of a motivational force and not just a directional experience of pleasure versus pain. *Although the hedonic nature of a value target contributes to the intensity experience through its influence on engagement strength, there are other sources of engagement strength that are independent of the value target's hedonic properties.*

Two sources of engagement strength are investigated; the *use of proper means* when making a decision (What *is* right), and *regulatory fit* between the regulatory orientation of decision makers and the strategic ways they make their decision (What *feels* right). Experimental evidence of how these sources of engagement strength can intensify people's value reactions to their choices, including how much money they are willing to offer, are presented.

### "Regulatory Focus and Regulatory Fit in Consumer Search and Consideration of Alternatives"
*Michel Tuan Pham, Columbia University*
*Hannah Chang, Columbia University*

Regulatory focus theory (Higgins 1997) provides a powerful framework for studying the role of motivational content in consumer behavior. The theory has proven to be a powerful predictor of how consumers make decisions. However, such investigations have generally focused on the later stages of the decision making process, especially the formal evaluation and the choice stages. Much less is known about the effects of promotion and prevention on *earlier* stages of the decision making process. This research examines the effects of regulatory focus on consumer search and consideration of alternatives in decision environments with a large number of alternatives. We focus on these environments because they are becoming increasingly common and by their very nature make the analysis of search and consideration processes particularly instructive.

Consistent with theoretical propositions recently advanced by Pham and Higgins (2005), results from four experiments show that (a) promotion- and prevention-oriented consumers do not differ in sheer amount of information searched, but (b) promotion-oriented consumers tend to search for alternatives in a more global, "top-down" fashion, whereas prevention-oriented consumers tend to search for alternatives in a more local, serial fashion, and (c) promotion-oriented consumers tend to have larger consideration sets than prevention-oriented consumers. In addition, making the decision environment more consistent with the search and consideration inclinations of promotion- and prevention-oriented consumers increases the subjective value that these consumers attach to the offer, apparently because of the decision environment "feels right"—a phenomenon known as *regulatory fit* (Higgins 2000).

In the first experiment, participants who were put in a promotion or prevention focus by a situational prime were asked to make a three-course dinner selection from a fictitious restaurant's "prix-fixe" menu. The selections were done with a computerized version of the menu that allowed unobtrusive tracing of participants' search. As predicted, promotion- and prevention-focus participants searched equivalent amounts of information, but allocated their search effort differently. Promotion-focus participants searched the menu in a more global, "top-down" manner, whereas prevention-focused participants tended to search in a more local, serial fashion. In addition, promotion-focused participants had larger consideration sets than prevention-focused participants. The second experiment successfully generalized the results of the first experiment (a) with a separate and even more subtle prime of regulatory focus, asking participants to reflect on their personal ideals or personal duties (see Pham and Avnet 2004), and (b) in a different product domain: movie choices, asking participants to search for two movie rentals from the actual Blockbuster.com website.

Experiment 3 tested the prediction that promotion-focused consumers would value alternatives more when presented in a decision environment conducive of a global, top-down search than when presented in an environment consistent with a local, serial search, and the opposite pattern for prevention-focused consumers. As in Experiment 1, participants who were put in a promotion- or prevention-focus were asked to make a three-course dinner selection from a restaurant's prix-fixe menu. Two versions of the menu were used, presenting the same dishes either (1) in its original hierarchical structure (as in Experiment 1), or (2) in a list format. It was predicted that, among promotion-focused participants, the hierarchically-structured menu would "feel right," which would lead them to assign greater values to menu offering than an

equivalent menu organized in a list format. In contrast, among prevention-focused participants, it is the menu in a list format that would "feel right" and lead them to assign greater value to the offering compared to a hierarchically structured menu. As predicted, respondents in either regulatory focus were willing to pay significantly more when the offered menu was structured in a way that fit their search inclinations than one that did not fit these inclinations.

Experiment 4 demonstrated that promotion-focused consumers value alternatives more favorably when part of larger sets of offerings than when part of smaller sets, whereas prevention-focused consumers exhibit the opposite pattern. As in experiment 1, participants who were put in a promotion- or prevention-focus were asked to make a three-course dinner selection from a restaurant's prix-fixe menu, featuring either 3 possible dishes per course or 12 possible dishes per course. (A careful counterbalancing scheme was followed to ensure that the dishes remain statistically equivalent across conditions.) Results showed that participants in either regulatory focus were willing to pay a higher price when given a menu offering option set sizes consistent with their consideration set sizes than inconsistent ones.

### "The Effect of Regulatory Focus on Satisfaction"
*Remi Trudel, University of Western Ontario*
*Kyle Murray, University of Western Ontario*
*June Cotte, University of Western Ontario*

The extant satisfaction literature offers little insight into the effects of motivation and consumer goals on satisfaction. Yet it should be obvious that motivations and goals are important antecedents to any purchase; we argue these antecedents also ultimately effect consumer satisfaction. The purpose of our research is to investigate the relationship between motivation and satisfaction. More specifically, this research investigates how consumer satisfaction with a product is affected by an individual's regulatory focus.

Higgins (1997) distinguishes between two types of regulatory focus: promotion and prevention. The two types of regulatory focus result in fundamentally different goals toward a desired end state-satisfaction. Promotion is characterized by approach-oriented regulation, and the eager pursuit of goals of advancement, aspiration and accomplishment (what Higgins calls "maximal" goals). Prevention, on the other hand, is characterized by avoidance-oriented regulation, and the vigilant pursuit of goals of security, protection and responsibility ("minimal" goals). Its argued that pleasure from a positive outcome is more intense under promotion than under prevention, based on the notion that the attainment of maximal goals should lead to higher levels of satisfaction than the attainment of minimal goals. Regulatory focus theory also suggests that post-consumption evaluations of dissatisfaction and regret will be different under promotion versus prevention. Outcome-regret levels are expected to be different, depending on regulatory orientation, since promotion-focused individuals are more concerned with errors of omission and prevention-focused individuals are more concerned with errors of commission (Pham and Higgins 2005). Prevention should therefore lead to conservative evaluations in both positive and negative outcome situations in an effort to avoid errors of commission. In two experiments we demonstrate that these differences in regulatory focus ultimately influence consumer satisfaction, and that post-consumption evaluations are different under promotion than under prevention. Both experiments use a priming manipulation of ideals and oughts developed in prior research to access the participant's temporary promotion and prevention focus (Pham and Avnet 2004). Both experiments also employ the confir-

mation/disconfirmation paradigm commonly used in prior satisfaction research (Fournier and Mick 1999).

In experiment one, satisfaction with a common consumption good, coffee, was investigated using a 2 (disconfirmation: positive vs. negative) X 2 (goal orientation: ideals vs. oughts) between subjects design. The positive disconfirmation (PD) manipulation involved serving a *hot* cup of premium coffee. The negative disconfirmation (ND) manipulation involved serving very weak *warm* coffee to which baking soda had been added. As hypothesized, the results showed a significant disconfirmation x goal interaction. More specifically, participants reported greater levels of satisfaction with good coffee under promotion than under prevention, and greater levels of dissatisfaction with bad coffee under promotion than under prevention.

In experiment two, participants reported their satisfaction with a camera by evaluating photos allegedly taken with the camera. Three key attributes were selected and manipulated: color, clarity, and sharpness. Each attribute varied on only two levels to operationalize performance, and hence disconfirmation. In the positive disconfirmation condition photo quality in all three photos was consistently good, whereas in the negative disconfirmation condition photo quality was consistently poor. The results from experiment two are consistent with the findings of our initial experiment, and provide more convincing evidence that motivation and goal orientation influence post-consumption evaluations of satisfaction. Participants reported higher product performance evaluations, were happier with the product, and more satisfied with a positive product experience under promotion than prevention. We also found that participants reported lower product performance, were less happy with the product, and less satisfied with a negative product experience under promotion than prevention.

The central tenets of regulatory focus theory suggest that individual decision makers assign different importance to the same decision, depending on their regulatory orientation or their means of goal pursuit. For the first time, the findings from our research demonstrate how this effect carries over into the domain of consumer satisfaction. This research provides strong support for the need to integrate motivational dimensions of decision-making in future research investigating consumer satisfaction.

### "Be Fit and Be Strong: Mastering Self-Regulation through Regulatory Fit"
*Jiewen Hong, Northwestern University*
*Angela Y. Lee, Northwestern University*

Regulatory fit (nonfit) occurs when the manner of goal pursuit sustains (disrupts) the individual's regulatory orientation; as a result, their motivational intensity during goal pursuit is intensified (Idson, Liberman, and Higgins 2004). Recent research shows that motivation plays an important role in successful self-regulation. Motivation can compensate for a depletion of regulatory resources (Muraven and Slessareva 2003); and when people are de-motivated, they show a deficit in self-regulation (Baumeister et al. 2005). The current research extends prior research by examining how regulatory fit contributes to self-regulatory success. Four studies tested the hypothesis that regulatory fit improves self-regulatory performance whereas regulatory nonfit impairs self-regulation.

Study 1 tested this hypothesis using a physical endurance task. Regulatory fit is operationalized using the regulatory fit questionnaire (Freitas and Higgins 2002). Participants were first asked to squeeze a handgrip and hold it for as long as they could. They were then instructed to do a free thought-listing task with the condition that they were to not think about a white bear during the task

(Wegner et al. 1987), which served to deplete their regulatory resources. Afterwards, participants performed the handgrip task again. The regulatory fit manipulation was introduced at this point, after which participants performed the handgrip task again. Results showed that participants' handgrip performance was facilitated by the fit manipulation, but impaired by the nonfit manipulation.

Study 2 replicated the findings in the context of resisting temptations. Participants were randomly assigned to one of three conditions: regulatory fit, regulatory nonfit, or control. The same regulatory fit manipulation as in study 1 was used. After participants completed the manipulations, they were offered a choice between a chocolate bar and an apple for a snack as a token of appreciation for their participation. Consistent with our hypothesis, participants in the fit condition were more likely to choose the apple over the chocolate bar as compared to those in the control condition, whereas participants in the nonfit condition were more likely to choose the chocolate bar.

Study 3 tested our hypothesis using a different operationalization of regulatory fit in a consumer-relevant context. Another objective was to examine whether individuals would naturally choose goal pursuit strategies that fit with their regulatory focus. Research has shown that promotion-focused individuals experience fit when they make decisions based on feelings whereas prevention-focused individuals experience fit when they make their decisions based on reasons (Avnet and Higgins 2006; Pham and Avnet 2004). We first measure participants' chronic regulatory focus, and then asked them to evaluate an advertisement based either on their feelings or on reasons. Some of the participants were given the opportunity to choose how they evaluate the advertisement, and others were assigned to one of the two conditions. After evaluating the advertisement, participants were offered a choice between a chocolate bar and an apple, which served as our dependent variable. We found that in the free choice condition the probability of participants choosing to evaluate the advertisement in a "fit" way was no better than chance. However, regardless of whether they were assigned or chose the evaluation strategy, those who evaluated the advertisement in a (non)fit way were more (less) likely to choose the apple over the chocolate bar compared to the control.

Finally, study 4 examined the mechanism and the boundary conditions of the fit effect in a health-related context. We hypothesized that the effects of regulatory fit on self-regulation operate through increased motivational intensity. This suggests that the effect of regulatory fit should be most apparent when people are less involved. Thus, we manipulated involvement by varying participants' perceived risk of contracting hepatitis and observed how regulatory (non)fit influence their willingness to get tested. All participants first read a message regarding the importance of being tested for hepatitis, which contains the perceived risk manipulation. This was followed by the same regulatory fit manipulation as in study 1. Persuasiveness of the message did not differ across the four conditions. Finally, participants' intention to get tested for hepatitis was measured. Consistent with our hypothesis, when participants perceived themselves to be at risk, regulatory fit had no effect on their intention to get tested for hepatitis. However, when participants did not perceive themselves to be vulnerable, those who experienced fit were more likely to get tested for hepatitis than those who experienced nonfit. We found that this effect was mediated by intensified motivation and could not be explained by message persuasiveness.

SYMPOSIA SUMMARY
# Advances in Judgmental and Inferential Heuristics
Xianchi Dai, INSEAD, France
Klaus Wertenbroch, INSEAD, France

## SESSION OVERVIEW

To deal with the complexities of the world and with the cognitive constraints in facing these, people use heuristics to facilitate their everyday judgments and decisions. Since Tversky and Kahneman's (1974) seminal work, much progress has been made in research on heuristics and biases, as shown, for example, by two classical volumes of selected papers on this topic (Kahneman, Slovic, and Tversky, 1982; Gilovich, Griffin, and Kahneman, 2002). Within the consumer behavior field, a large body of research has examined the impact of various judgmental and inferential heuristics on consumer decisions. For example, availability or ease of retrieval has been shown to affect consumer judgments of product failure (Folkes, 1988), consumer recommendations and purchase intentions (Menon and Raghubir, 2003), and consumer evaluations of products (Tybout et al, 2005). Consumers also use their affect as information in making product and other consumer related evaluations (Adaval, 2001; Bickart and Schwarz, 2001; Pham, 1998). Furthermore, anchoring systematically affects consumer valuations (Ariely, Loewenstein, and Prelec, 2003; Simonson and Drolet, 2004), quantity purchase decisions (Wansink, Kent, and Hoch, 1998), and attitude formation (Cohen, Reed II, 2006; Lynch, 2006), to name just a few.

Despite the extensive research done in this field over the years, this session demonstrates that it remains a fertile area for continued research. The session presents three papers, each of which introduces a previously undiscovered heuristic that consumers use in their judgment and decision processes. The first paper examines how consumers' valuations of objects and experiences affect judgments of frequency, supply, and duration. The second paper studies consumers' use of a metaphoric link between vertical position and cardinal direction to infer traveling costs, which in turn systematically affects consumers' preferences and choices. The third paper shows how the consequences of events affect consumers' inferences of the causes of these events.

Dai, Wertenbroch, & Brendl demonstrate in seven studies that consumers use the value of things to infer their relative frequency, quantity, and duration. Specifically, they judge what is more valuable as relatively scarcer. In the first four studies, they show that both inherent as well as experimentally induced value affect consumers' relative frequency judgments. Another three studies extends these findings to quantity as well as duration judgments. The results suggest that consumers underestimate the supply of what they value and thus make suboptimal purchase decisions.

Nelson & Simmons show that the metaphoric link between cardinal direction and vertical position affects consumers' price expectations and shopping decisions. Specifically, consumers implicitly associate "north" with "up" and "south" with "down," which is corroborated by IAT results. Furthermore, this association systematically affects consumers' expectation of traveling costs, consumer's intention to redeem coupons at shops located in the south versus north of a reference point, as well as consumers' store choice decisions.

Finally, LeBoeuf & Norton discuss consumers' inferences of the causes of events from their outcomes. They find that consumers use an outcome-cause matching strategy to make causal inferences. That is, a given event has a large cause if that event has a large outcome, but a small cause if the outcome is small. Across a series of studies, this outcome-cause matching effect is shown to hold along the magnitude and valence dimensions, with events in various domains.

Overall, the three papers were chosen for this session because (1) they unearth previously undiscovered strategies of consumer judgments and inferences that can cause surprising and serious biases and (2) they all share the same underlying process–attribute substitution-proposed by Kahneman and Frederick (2002). That is, whenever an attribute (the target attribute) of the judgmental object, which one wants to assess, is less readily assessed than a related property (the heuristic attribute), people may unwittingly substitute the simpler assessment of the heuristic attribute for the assessment of the target attribute. In the first paper, the target attribute is the relative frequency, quantity, or duration of a category, the heuristic attribute is the relative value of the category. In the second paper, the target attribute is the traveling cost to the shopping destination and the heuristic attribute is the cardinal direction. In the third paper, the event cause is the target attribute and the event outcome is the heuristic attribute. In most situations, the heuristic attribute and the target attribute are correlated. However, as demonstrated in the papers in this session, when the heuristic attribute is not diagnostic of the target attribute, the substitution process can bias judgments and thus lead to suboptimal consumer decisions. Together, the three papers form a cohesive set of explorations into some fundamental characteristics of consumer judgments and decision making. The session shows that research on heuristics and biases is alive and well by providing evidence of three completely new heuristics.

## EXTENDED ABSTRACTS

### "The Value Heuristic"
*Xianchi Dai, INSEAD*
*Klaus Wertenbroch, INSEAD*
*C. Miguel Brendl, Northwestern University*

Research in psychology and economics has shown that people tend to judge what is scarcer as more valuable, which Cialdini (2001) called scarcity principle. We demonstrate a reversal of this scarcity-valuation link. That is, people heuristically infer what is more valuable as relatively scarcer. Across seven studies, we demonstrate the operation of this value heuristic in consumer judgments of relative frequency, quantity, and duration.

In study 1, respondents underestimated the proportion of portraits of the opposite gender after they had seen and evaluated a series of male and female portraits appearing in a random order on a computer screen. Assuming that people prefer to look at portraits of the opposite gender, our respondents underestimated the relative frequency of the more valuable portraits. In study 2, we manipulated stimulus value directly, using two subsets of portraits, each with equal proportions of female and male faces. One subset included only attractive faces of both genders, the other only unattractive faces. Consistent with the value heuristic, both male and female respondents underestimated the frequency of portraits of the more desirable category (i.e., of attractive faces of the opposite gender) relative to the frequency of the less desirable category (i.e., of attractive faces of the opposite gender), whereas there was no such difference for unattractive faces.

To test whether these findings arose from an inferential retrieval heuristic rather than from a perceptual encoding effect, studies 3 and 4 induced a value difference only at the point of retrieval. In study 3, we first asked participants to evaluate a series of 50 bird and 50 flower pictures, one at a time, appearing in a random order. Subsequently, we told them that they would receive ¢2 for each occurrence of the target category (either birds or flowers); respondents flipped a coin to decide for which category they would get paid. After that, they estimated the number of pictures in each category. Those who were paid for flower pictures estimated that they had seen fewer flower pictures than bird pictures, whereas those who were paid for bird pictures estimated that they had seen fewer bird pictures than flower pictures. Study 4 tested the value heuristic for stimuli presented simultaneously rather than sequentially. Participants were first asked to memorize nonsensical blue and red letter combinations, presented to them on a computer screen. After that, participants again flipped a coin to determine whether they would get paid ¢2 for each red or each blue letter combination they had been presented. Finally, we asked participants to estimate the frequency of the two categories. Again, participants estimated the more valuable category as relatively scarcer.

We also examined the value heuristic in quantity and duration judgments. In study 5, we asked respondents to estimate how many units of an attractive item (a $50 offer of an almost new Sony TV set) were available on ebay.com at a given moment. We manipulated the salience of the value of this offer by varying whether or not respondents rated its attractiveness before estimating the supply. Respondents who provided attractiveness ratings estimated a lower supply than those who had not rated the attractiveness of the offer; making stimulus value salient lowers quantity estimates. In study 6, participants first listened to a 90 second music clip. To manipulate respondents' valuations of the clip, we then asked them either for their willingness to accept (WTA; to induce a negative perception) or for their willingness to pay (WTP; to induce a positive perception; see Ariely, Loewenstein, and Prelec, 2006) to listen to the clip. Next, respondents estimated the duration of the music. As predicted by the value heuristic, duration estimates in the WTP condition were shorter than those in the WTA condition. Finally, study 7 manipulated value by asking participants to rate their liking of a music clip either before or after the duration estimation task. Similar to study 4, we predicted that liking ratings would make value salient and thus affect subsequent duration judgments. The results confirmed our hypothesis. For attractive music clips, rating liking before the duration estimation task decreased duration estimates; interestingly, for unattractive music pieces, rating liking increased duration estimates, which may point to a "negative value heuristic," such that consumers estimate unattractive objects to be more abundant than they are.

The value heuristic may have functional origins as valuable things are typically scarce, prompting us to work harder to obtain them. However, our findings have possible implications of dysfunctional behavior in a number of areas. For example, the value heuristic may yield an intuitive misunderstanding of the basic economic relationship between value and supply, giving rise to market inefficiencies. If people heuristically use their subjective valuations as information to estimate supply, they may well underestimate the supply of what they value. Second, it is well established in economics and psychology that perceived scarcity enhances stimulus valuation. Coupled with these scarcity effects, a value heuristic may turn people into value pumps. If scarcity increases valuation, and if, in turn, value enhances perceived scarcity, then repeatedly alternating between valuation and frequency estimation might turn people into value pumps. Finally, the value heuristic may

impact search behavior; consumers may stop searching for valuable alternatives too soon if they underestimate their true frequency of occurrence (e.g., during an online search of attractive hotels).

## "On Southbound Ease and Northbound Fees: Literal Consequences of the Metaphoric Link between Vertical Position and Cardinal Direction"

*Leif Nelson, University of California, San Diego*
*Joseph Simmons, Yale University*

Consumers' price expectations and shopping destinations are informed by judgments of distance and time. For example, to inform their purchasing decisions, people often try to identify which store is closer, which mode of transportation will be faster, and which freeway will have less traffic. Indeed, the minimization of distance and time plays a critical role in consumer decision making (Bell, Ho, and Tang 1998).

Different lines of research have emphasized how consumers fail to minimize travel, even when presented with an accurate map of the travel route. For example, when presented with a schematic map for airline travel, consumers show a preference for a route that continuously progresses towards the final goal, even if it takes longer than a comparable indirect route (Soman and Shi 2003). Furthermore, when shown a map featuring a number of stops on a possible shopping trip, consumers minimize the distance between stores even when it means traveling further from home and lengthening the total trip distance (Brooks, Kaufmann, and Lichtenstein 2004).

Particularly pertinent for the research presented here are findings suggesting that consumers may show consistent biases in their time and distance estimates even when presented with accurate maps of the trip. One set of findings, for example, showed that people underestimated distances in part because they were encoding travel times instead (Kang, Herr, and Page 2003). Another set of findings showed that underestimations of distance can be due to heuristic spatial processes that overemphasize direct distance (Raghubir and Krishna 1996). Indeed, a diverse set of studies show that consumers use a variety of psychological mechanisms to assess time and distance, and that these mechanisms often lead to counter-normative assessments.

In this paper we extend these findings by identifying a thus far undocumented influence on consumers' spatial perceptions. Across all of the studies detailed above, researchers identified perceptual processes by using an objective source of spatial information (e.g., a map) to evaluate consumer estimates of, and preferences for, different times and distances. Nevertheless, a long line of research has emphasized that consumers are not merely imperfect processors of useful information; they are also prone to improperly using useless information (Bastardi and Shafir 1998; Carpenter, Glazer, and Nakamoto 1994; Meyvis and Janiszewski 2002). With that in mind, we suggest that the metaphors that people use to describe spatial relations can affect their judgments of distance and time.

Whether making reference to living "up north" or "down south," we often use the language of vertical position to describe cardinal direction. Such a metaphorical link may not be merely linguistic; rather, it may alter our mental representations of spatial relations, and consequently influence our beliefs and judgments. As a result, we hypothesize that consumers may rely on this metaphor to infer that destinations to the north are slightly uphill, and therefore harder to get to. Further, this inference may increase price expectations for northward services, and decrease the willingness to shop at northward destinations.

In Study 1, response latencies in an IAT paradigm demonstrated a strong implicit association between "north" and "up" and "south" and "down." In Study 2, people were more likely to infer

that stimuli moving or facing downhill were oriented southward, despite the absence of any honest signals about cardinal direction. In Study 3, a secondary feature of downhill travel (i.e., ease of travel) showed similar effects. When people read about someone walking with ease, they were more likely to infer that she was walking south than when they read about someone walking with difficulty.

Next, we showed that these effects have consequence in consumer contexts. If people associate cardinal direction with slope, and slope with effort, then we expected to find corresponding effects in consumers' price expectations and choices. Consistent with this, people thought that it would be more expensive to ship to a northern city than to a southern city (Study 4) and they expected a moving company to charge more to move an apartment north than to move it south (Study 5). Study 6 investigated the implications of this metaphoric relationship for marketers' promotional efforts, finding that consumers expressed higher intentions to redeem a coupon that described an ice cream shop as south of a reference point than as north of a reference point. Finally, these effects were shown to depend on preferences for convenience. When people were choosing where to purchase an inexpensive item they were much more likely to choose a store to the south, presumably looking for the lowest effort option. When shopping for a much more expensive item, people were indifferent between the two options, reflecting a willingness to go to the higher effort northern location (Study 7). Taken together, these findings strongly suggest that the metaphor linking cardinal direction and vertical position can consequentially influence consumers' judgments, choices, and preferences.

### "Effects That Lead to Causes: Using an Event's Outcomes to Infer Its Causes"

*Robyn LeBoeuf, University of Florida*
*Michael I. Norton, Harvard University*

Imagine an event, such as a computer crash. That event could have many possible causes, ranging from the minor (e.g., a malfunctioning cooling fan) to the extreme (e.g., deliberate sabotage by a hacker). The event could also have many possible outcomes, ranging from mere inconveniences (temporary loss of email) to large-scale disruptions (loss of important documents). We examine how an event's eventual outcomes influence perceptions of its most likely cause, even when the outcomes are completely uninformative about the event itself.

In Study 1, participants read that a small country's beloved president was assassinated by one of his countrymen; a British newspaper then criticized the late president, sparking global protests. Some then read that Britain responded aggressively to the protests, triggering war, whereas others read that Britain peacefully resolved the issue. Participants were then asked whether the initial assassination was more likely to have been perpetrated by one man or by a conspiracy internal to that country. As predicted, participants more often chose the conspiracy (large cause) when Britain triggered war (large outcome) than when peace prevailed, even though Britain was unconnected to the assassination. A follow-up study showed that perceptions of whether United States President John F. Kennedy's assassination involved a conspiracy could similarly be manipulated by describing "large" versus "small" effects of his death.

To investigate this effect's generality, in Study 2, participants read about a zoo in which the animals caught a disease. Some learned that the disease had a large outcome (almost all of the animals died) whereas others learned that the outcome was minor (few animals died). Participants also learned that the zoo had recently acquired a "small new rabbit" and a "new fully-grown

bear" and were asked to choose which had most likely introduced the disease. The large cause (bear) was chosen more often when the disease's outcome was large than when it was small. Again, people think that large outcomes have (even literal, physical) large causes.

To examine this tendency in a consumer (product-failure) setting, in Study 3 participants read about a computer crash that destroyed a file containing a student's term paper. Participants either learned that the crash's outcome was severe (the professor did not grant an extension, so the student could not graduate) or mild (the professor granted an extension, and the student graduated as planned). Participants next indicated whether they thought the crash was more likely caused by an incorrectly installed cooling fan (small cause) or by an undetectable malicious virus (large cause). More selected the virus when the outcome was severe than when it was mild, even though the outcome was uninformative about the crash itself. Thus, the assignment of blame for a product failure may depend not just on the "local" circumstances of the failure itself, but also on the cascade of events that follow.

Having established widespread outcome-cause matching for size, we next explored whether people also match along another dimension: valence. Study 4's participants learned that a man was late for work because he did something thoughtless (started a fight with his wife) and then something thoughtful (stopped to buy his wife flowers). When the man was fired for being late, participants blamed his thoughtlessness for his lateness, but they blamed his thought*ful*ness for the lateness when his day turned out quite positively, even though the absolute amount of "lateness" was the same in each case. This finding suggests that outcome-cause matching may be connected to "just world" beliefs (e.g., Lerner and Miller 1978), inasmuch as people may attempt to justify bad (good) outcomes by attending more to the bad (good) aspects of prior behavior. Indeed, Study 5 revealed that participants high in just-world beliefs are more likely to select a cause that matches an outcome's valence than are those low in such beliefs. Thus, there may be a motivational component to the current effects, with outcome-cause matching arising more often among those who are motivated to see the world as a "just" and predictable place.

Study 6 further examined the underpinnings of the current effects. Some participants saw a film clip illustrating the butterfly effect (the idea that small changes can have large future consequences) but others saw a neutral, control clip. Participants then read the severe-outcome version of Study 3's computer crash. Those exposed to the butterfly effect were less likely to select a large cause for the severe outcome than those not so exposed, suggesting that outcome-cause matching (which may naturally be an accessible principle) can be supplanted if another causal schema is evoked instead. Interestingly, priming the butterfly effect had a larger impact among those high (versus low) in need for closure, suggesting that those who are most motivated to see the world as predictable are also the most likely to use the salient causal schema to explain the world, whether that schema involves matching or some other pattern (see Kruglanski 1987).

We thus suggest a regularity in causal reasoning: people rely upon an event's eventual outcomes to help them infer the event's prior causes, especially if they are motivated to make sense of the world and unless another causal schema is primed. This pattern is often reasonable (many large effects indeed have large causes), but such outcome-cause matching (reminiscent of the representativeness heuristic and referred to as the "resemblance criterion" by Nisbett & Ross, 1980, but never tested empirically) can lead people astray when outcomes are uninformative about potential causes. The current results have implications for theories of causal reasoning, and the implications for consumer behavior seem clear: for example, when a given product failure (*e. coli* contamination) has

a large outcome (many people die), consumers may be more likely to search for a large cause (corporate malfeasance) than when the failure is the same but the outcome is, for arbitrary reasons, smaller (many are sickened, but timely medical treatment prevents fatalities).

# The Best Offense is a Good Defense: Consumers' Defense-Motivated Strategies and their Effects on Memory, Choice, Preferences and Tastes

Martin Zemborain, Austral University, Argentina

## SESSION OVERVIEW

In what ways are people strategic about maintaining their ability to recall previous special memories? Which are the psychological processes driving consumers' choice-motivated shifts in their preferences for product features? What role does motivation play in one's preferences regarding physical characteristics of a product, such as taste? The three lines of research presented in this symposium seek to answer these questions, which share the same underlying mechanism: consumers' defense-motivated strategies. This symposium provides a novel view and a deeper understanding of fundamental issues in the consumer research field, such as memory preservation, taste formation and choice. On a methodological note, the symposium also bridges between the "Behavioral" and "Empirical modeling" data analysis methodologies used in marketing research by showing how Bayesian techniques can be successfully used to analyze experimental data (paper 2).

As mentioned above, the three papers presented here are focused on defense-motivated strategies developed by consumers. These defense-motivated strategies usually serve a self-preserving goal. People may engage in attitude change to justify their choices (Brehm 1956), or may prefer to distort their memories in order to feel better about their past behavior (Mather, Shafir and Johnson 2000, 2003). Support for this contention is found in studies of cognitive dissonance (Festinger 1957) and the motivated reasoning framework (Kunda 1990), which proposes that motivation affects people's reasoning through their reliance on a biased set of cognitive processes (Chernev 2001). An extensive body of literature has analyzed these defense-motivated strategies and their effects on information processing (Russo, Medvec and Meloy 1996), choice (Chernev 2001, Kivetz and Simonson 2000), repeated purchase (Sen and Johnson 1997), information search (Hoch and Ha 1986, Klayman and Ha 1987) and memory distortions (Mather, Shafir and Johnson, 2000, 2003), to name a few. However, as pointed out above, there are important questions that remain unanswered, some of which will be addressed in this symposium.

In paper 1, Kim, Zauberman and Ratner test the *memory protection through acquisition* hypothesis, a novel view on how consumers try to preserve their memories for special occasions in their lives. This hypothesis proposes that people seek to obtain products that they think will help them remember a special experience, even though they would forego these same items in the context of a non-special experience. Results from three studies suggest that individuals prefer products that are uniquely associated with a special memory rather than those that would not be associated with the memory or associated with both a special memory and a memory that is less special. In addition, consumers' desire for these memory pointer products is enhanced when people are led to believe that their memories are weaker.

Paper 2 (Zemborain, Johar and Ansari) analyzes the psychological processes governing choice-supportive distortions, or the defense-motivated mechanisms used by consumers to justify their choices. Unlike previous research based on dissonance theory (Festinger 1957) which focused on how people tend to justify their choices by increasing their liking or ratings to favor their chosen products (i.e., the spread of alternatives effect), in this paper the authors analyze how choice may shift consumers' preferences at the product feature level. Results from the first experiment show that after making a choice, people prefer positive features of their chosen products and negative features of their not chosen options, presumably to justify their choices. Previous research showed that people may distort their memories for past options in a choice supportive fashion; such that positive features are attributed to chosen products and negative features are attributed to forgone alternatives (Mather, Shafir and Johnson 2000, 2003). These findings, together with results from study 1, led the authors to hypothesize that based on these attributions people would change the attribute weights such that positive features attributed to chosen products and negative features attributed to forgone alternatives would become more important. Furthermore, if these changes in attribute weights implied a choice-defensive strategy, then such modifications should take place only when individuals were highly confident about their feature source attributions. Results from study 2 support these predictions. The moderating effect of confidence in the individuals' attributions suggests that these changes in attribute importance weights are indeed a defense-motivated strategy used by consumers to justify their choices.

Paper 3 (Riis and McClure) seeks to answer the question regarding whether taste change can be facilitated by motivation. Specifically, this research explores the possibility that consumers' concerns about health may lead to an actual change in the liking of a product. Results from the first experiment show that regular Coke drinkers who are highly concerned with health-related issues (i.e., motivated) expect to improve their liking for Diet Coke if asked to drink this soda during a hypothetical two week consumption period whereas regular Coke drinkers who are not concerned with health-related issues (i.e., unmotivated) expect to like Diet Coke even less when exposed to the same hypothetical situation. In study 2, heavy drinkers of regular cola refrained from drinking that soda for two weeks, consuming instead daily servings of Diet Coke. Results from a blind test showed a marked increase in liking for Diet Coke for all participants. However, in non-blind tests only participants who had a high concern for the health consequences of sugared soda consumption reported increased liking for Diet Coke. Furthermore, this group reported a greater increase in intention to purchase Diet Coke in the future.

Taken together, the three papers investigate how people develop defense-motivated strategies in fundamental aspects of their behavior, such as memory preservation, taste formation and choice. This symposium offers a novel and comprehensive view of the topic, and contributes to the field delivering a deeper understanding of this phenomenon. The symposium also benefits from the participation of Professor Fishbach as discussant. Her expertise on motivation and self-control ensures rich conclusions and suggestions for future research based on the work presented here.

The three papers contribute to a research area that is relevant to ACR members interested in memory processes, motivation, intertemporal choice, preference formation, taste change, information processing, and judgment and decision making. Regarding the organization of the symposium, we plan to make 15 minutes presentations, with about 5 minutes of questions following each presentation and a 15-minute discussion at the end of the session (total: 75 minutes).

## EXTENDED ABSTRACTS

### "Memory Pointers: Strategic Memory Protection through Acquisition of Recall Cues"

*B. Kyu Kim, University of Pennsylvania*
*Gal Zauberman, University of Pennsylvania*
*Rebecca K. Ratner, University of Maryland*

In this work, we focus on individuals' desire to engage in what we call strategic memory protection; that is, behaviors that people think will allow them to protect their ability to derive utility from memory. We focus here on a particular type of memory protection and propose the memory protection through acquisition hypothesis, where people seek to obtain products that they think will later help them remember an earlier special experience, even though they would forego these same items in the context of a non-special experience.

Study 1 examines this hypothesis in a situation where a special experience is to be followed by a second experience that could interfere with individuals' ability to retrieve the initial experience. We ask all respondents to imagine having a special vacation trip to a San Diego resort and ask half of them to imagine that they will be returning to the same city for a business trip soon afterward, staying in a different hotel. Consistent with our memory protection through cue acquisition hypothesis, among respondents who expected an upcoming business trip to the same city, participants were more interested in the resort-specific cue (i.e., the bungalow magnet; likelihood of buying on an 11-point scale, M=8.57) than in the generic cue (i.e., the San Diego magnet; M=6.87). However, in the vacation-only condition, participants reported a similar likelihood to purchase the magnet when offered the resort-specific magnet vs. the more generic California magnet (Ms=8.44 and 8.97, respectively).

Study 2 further tests whether people seek to obtain physical objects that they think will later help them to remember an earlier special experience (i.e., a memory pointer), even though they would forego these same items in the context of a non-special experience. All respondents imagined going to a resort in Cancun, Mexico with their significant other. Those in the special experience condition imagined that the weather was excellent and they had a wonderful vacation. Those in the non-special condition imagined that a huge storm passed through the region and they had an unpleasant vacation. Participants were asked to indicate their preference to buy either a traditional Mayan wooden sculpture (i.e., a product that would be thematically closely associated with the vacation) or a limited version of a music CD of their favorite band (i.e., a product that would not be closely associated thematically with the vacation) on an 11-point scale. Results show that participants' preference for the sculpture was higher with the special experience (M=6.36) than with the non-special experience (M=3.58), but preference for the music CD did not differ significantly across experiences (M=7.04 with special experience and M=6.02 with non-special experience). In addition, when imagining that they lost the sculpture after having purchased it, they were upset more after the special (M=8.05) than after the non-special resort experience (M=6.10), consistent with the notion that they wanted it to serve as a recall cue only after the special experience. However, when they imagined having lost the music CD, no difference emerged between those considering special vs. non-special experiences. This study also examines whether they would be interested in replacing the lost sculpture if they found an identical product at a local store. Content analysis shows that whereas people perceive the item purchased as the resort to be a good memory pointer, they perceive that a replacement item from a local store would not be.

Study 3 seeks more direct evidence about the extent to which being able to retrieve special memories plays a causal role in guiding consumers' behaviors. It has been shown in psychology and consumer research that experienced ease or difficulty (compared to content) of tasks affects evaluations and judgments in decision making (Schwarz 1998; Wänke, Bohner, and Jurkowitsch 1997). In the context of the current research, we expected that participants who were required to recall many past experiences that are particularly special (e.g., 10 experiences) would experience recall difficulty (and lack of processing fluency) and therefore prefer a product that might serve as a cue to facilitate recall following a special experience. However, those who were required to recall only a few special experiences (e.g., 2 experiences) would experience ease in the recall task (and greater processing fluency), and this would lead to a reduced perceived need for a memory pointer product. Results show that indeed participants who are manipulated to believe that recalling past experiences is difficult show stronger preference for a memory pointer product following a special than non-special experience. Specifically, participants who were induced to think that recalling past experiences is difficult (i.e., recall 10 experiences) showed higher preference for a product closely associated with the experience when the experience was special (M=5.51) versus non-special experience (M=2.95). However, participants who were manipulated to think that recalling past experiences is easy (i.e., recall 2 experiences) did not show any difference in preference for this product that was closely associated with the experience across the special vs. non-special experiences (Ms=4.05 and 3.50).

In conclusion, we show that individuals prefer products that are uniquely associated with a special memory rather than those that would not be associated with the memory or associated with both a special memory and a memory that is less special. We further show that individuals' desire for these memory pointer products is enhanced when they are led to believe that their memories are weaker. These results all confirm our memory protection through acquisition hypothesis. Whereas research in cognitive psychology examines the actual impact of exposure to new information on one's ability to remember past experiences (e.g., retroactive interference), our research program examines people's lay theories about the extent to which they might experience retroactive interference. Our work demonstrates the behaviors that people engage in to facilitate the retrieval of those past experiences that they most want to remember without interference from other experiences.

### "Choice-Motivated Changes in Consumers' Preferences"

*Martin Zemborain, Austral University*
*Gita V. Johar, Columbia University*
*Asim M. Ansari, Columbia University*

It has been shown that people may strategically distort their memories and evaluations about past choices in order to justify them (Tetlock, Stitka and Boettger 1989; Mather, Shafir and Johnson, 2000, 2003; Festinger 1957). Although this phenomenon has been reported extensively in the literature, little research analyzed the psychological process governing these choice-supportive distortions, which is the focus of this research.

If after making a choice people develop a strategy to support their decision, they should show a higher post-choice preference for positive attributes of the chosen products (i.e., reasons to choose) and for negative attributes of the not chosen products (i.e., reasons to reject). Results from study 1 confirmed this assumption.

In study 1 we asked 39 participants to imagine that they were planning to buy a house and they narrowed their choice down to two houses. Then, the participants were presented with two options, which were described in terms of eight features (four positive features and four negative features) each. After they made their choices, participants went through a filler task and then were exposed to a list of 30 house attributes, of which sixteen corresponded to the features of the houses they chose from, and fourteen were new. Beside the attributes were two columns, one labeled 'Check your 15 "must be positive" features in this column' and the other one labeled 'Check your 15 "can be negative" features in this column'. The participants' task was to describe their preferred house using exactly 15 positive and 15 negative features. They were asked to place a check mark in the "Must be positive" column beside each of the 15 corresponding features, and in the "Can be negative" feature column beside each of the 15 corresponding features. A test of proportions showed that people tended to choose to be positive those attributes that were positive and belonged to their chosen houses more than those that were positive and belonged to their not chosen options (positive-chosen=58% vs. positive-not chosen=46%,

p<.05). Also, participants tended to pick to be positive those attributes that were negative and belonged to their not chosen houses more than those that were negative and belonged to their chosen alternatives (negative-not chosen=51% vs. negative-chosen=39%, p<.05).

Although results were consistent with our predictions, they did not tell much about the psychological process governing this choice-defensive mechanism. Results from study 1 and previous research showing that people may distort their memories for past options in a choice-supportive fashion (Mather, Shafir and Johnson 2000, 2003), led us to hypothesized that based on these distorted memories people would change the attribute importance weights such that positive features attributed to chosen products and negative features attributed to forgone alternatives would become more important. Furthermore, if these changes in attribute weights implied a choice-defensive strategy, then such modifications should take place only when individuals were highly confident about their feature attributions. Results from study 2 supported these predictions. Upon arrival, participants were asked to rate the importance of thirty attributes for each of three distinct product categories (houses, restaurants and used cars). After a filler task, the students were asked to make binary choices in those same three categories. Each option was described in terms of four positive and four negative features, all of which corresponded to the attributes rated before. After an unrelated questionnaire; for each product category participants were presented with a list of thirty two features (the sixteen features that belonged to the choice options and sixteen new features) and were asked to indicate whether each feature belonged to their chosen product, to their not chosen product, or if it was new. They also indicated how confident they were in their attributions, on a seven-point scale anchored at 1 (Not at all confident) and 7 (Extremely confident). After indicating the sources of each feature, participants were asked to recall which product they chose in each category (we only report the results for the 126 students who correctly remembered all three choices). Following another filler, students were asked to rate again the importance of the attributes for each of the three categories. Finally, and after another unrelated questionnaire, participants completed the same choice task as in experiment 1, for each of the three categories; and rated the valence of each of the product features for which they reported the source.

To tap on the psychological processes driving consumers' choice-defensive strategies, we analyzed the data in two different ways. Our first main dependent variable was the difference between participants' post and pre-choice attribute importance ratings. To properly account for the repeated measures design and individuals' heterogeneity, we used a hierarchical Bayesian linear regression of the main DV on participants' reported feature source (i.e., chosen product, not chosen product, or new feature), participants' reported confidence in such source attributions, and participants' reported feature valence (i.e., positive or negative). As expected, we found a significant three-way interaction among the independent variables, such that attribute importance ratings were increased for positive features attributed to chosen products and for negative features attributed to not chosen products, only when participants' confidence in their feature source attributions was high.

Our second dependent variable was the participants' probability of choosing a particular attribute to be positive in their preferred product. We ran a hierarchical Bayesian probit in which we modeled participants' utility as a function of the change in the attribute importance ratings, the participants' reported feature source and the participants' reported feature valence. Results showed that individuals were more likely to choose an attribute to be positive if the attribute importance weight increased after choice, if the attribute

corresponded to a positive feature attributed to a chosen product or if the attribute corresponded to a negative feature attributed to a not chosen alternative.

Our results support our theorizing regarding the psychological processes governing consumers' choice-supportive distortions. Interestingly, consumers' preferences seemed to shift toward their choices, suggesting that these distortions may go beyond choice justification and have an effect in shaping consumers' preferences.

### "Motivated Taste Change for Diet Coke"
*Jason Riis, New York University*
*Samuel McClure, Princeton University*

While a number of studies have shown that changes in preference can occur with changes in consumption and exposure (Rozin, 1999), the question of whether taste change can be facilitated by motivation is more controversial (Loewenstein & Angner, 2003). Evidence for motivated taste change comes mostly from studies of dissonance, whereby people are thought to reduce negative feelings of disappointment by shifting their preferences to objects that happen to be in their possession (Brehm, 1956). In the present work, we investigate taste change that is motivated by concerns about health, and find that such concerns can influence awareness of taste change, and that this awareness has implications for future choice intentions.

The particular source of motivation that we investigate is the widespread concern about the health effects of sugared soda consumption. Obesity is considered by some public health experts to be the second leading cause of preventable death in America, and at least a third of American adults are attempting to lose weight (Kruger et al., 2004). Sugared sodas are thought to be one of the major contributors to the obesity epidemic, and diet sodas are rapidly gaining market share from sugared sodas.

Interestingly, many people claim that not only do they prefer diet soda because it is healthier, but that they also prefer the taste. In a pilot study with participants drawn from a paid, nationally representative panel, we found that 85% of the 120 frequent Diet Coke drinkers in the sample said that Diet Coke tasted better than regular Coke. More impressively, however, 70% of those who preferred the taste of Diet Coke said they used to prefer the taste of regular Coke. They also cited concerns about health and fitness, and not taste, as their original reason for switching to Diet Coke. These data are consistent with the possibility that concerns about health (i.e., motivation) led to an actual change in the liking of a product.

In the present studies we sought to test this possibility. In Study 1 we examined whether or not motivation is related to expectation of taste change. We hypothesized that it would be. People tend to be optimistic in their estimates of the likelihood of good outcomes (Weinstein, 1980). Since health-motivated people would be more likely to consider a taste improvement for a healthy product to be a good outcome, they should thus be more likely to expect this

outcome to occur. This is indeed what we found. We asked 58 regular Coke drinkers (drawn from the same panel as the pilot study) to indicate their agreement with the statement, "my consumption of sugared soda is having a bad effect on my health and fitness". We considered people who agreed with the statement to be "motivated" to change their taste, and people who disagreed with the statement to be "unmotivated". Both groups were similar in their soda consumption and in their self reported liking of Coke and Diet Coke. All participants were asked to imagine that they were to drink Diet Coke daily for two weeks. The motivated people predicted that their liking of Diet Coke would improve during such a trial, while the unmotivated people predicted that they would come to like Diet Coke even less.

In Study 2 we actually examine taste change by exposing both motivated and unmotivated Coke drinkers to Diet Coke for two weeks. Based on previous mere exposure studies (e.g., Bertino et al., 1982, 1986), we expected blind taste tests to reveal increased liking of Diet Coke in both groups. In branded tests, however, we expected the groups to differ, with the motivated participants being more likely to report increased liking.

Undergraduate participants were selected based on a pre-screening survey for heavy consumption of Coca Cola (mean of 3.8 cans per week) and for their level of concern about the effects of sugared soda on their health. Half of the participants were highly concerned (i.e., "motivated") and half were minimally concerned (i.e., "unmotivated"). The two groups did not differ in their soda consumption habits. Both groups were given a two week supply of Diet Coke, with the instruction to drink one can each day, and to refrain from drinking sugared soda. (Compliance, reported anonymously, was very high.) Participants were not asked about their expectations of taste change for fear that this would influence their subsequent reporting. Two kinds of taste tests were given, both at the beginning and end of the two week consumption period. In blind tests, participants drank several colas in clear, unlabelled plastic cups, and then rated the taste of each one on a 9 point scale (anchored at "dislike very much" and "like very much"). In "branded" taste tests, participants opened a can of Diet Coke, poured approximately one ounce into a clear plastic cup, tasted it, and then rated the taste using the same 9 point scale.

Both high-concern and low-concern participants revealed a large (4/5ths of a standard deviation) increase in liking of Diet Coke following the two-week consumption period. However, with the branded test, only the high concern participants revealed an increase in liking. Furthermore, the high concern subjects reported a greater increase in intention to purchase Diet Coke in the future. These results suggest that motivation for taste change may be independent of its actual occurrence, but that it may be required for awareness of its occurrence, and, importantly, for the intent to act on that taste change. The results do not isolate expectation as the mechanism of the motivational effect, although the results of Study 1 are consistent with this possibility.

# Truth or Consequences: The Ups and Downs of Perspective-Taking on the Accuracy of Predictions

Katherine Burson, University of Michigan, USA

## SESSION OVERVIEW

Accurately predicting other people's behavior and preferences is critical for consumers as well as managers. This is particularly relevant when people need to satisfy other people's needs and preferences (managers-customers, husbands-wives) as well as when people's own welfare partly depends on what others would do (e.g., negotiations). Prior research has suggested that taking the perspective of another person or other forms of mental simulation can improve the accuracy of such predictions. Perspective taking efforts are also common in the market place. For example, managers sometimes take the role of consumers or employees, aiming to gain consumer insight that would bridge the gap between the company and its consumers. This session explores when and how perspective-taking can improve the accuracy of predictions and effectiveness of subsequent behavior. Four papers investigate the processes by which consumers assess others' preferences and identify the mixed consequences of intervening in the manner in which they generate these assessments.

These four papers investigate the effects of changing perspectives (interpersonally or intrapersonally) on the quality of predictions. The first two papers examine the benefits of perspective-taking on the accuracy of predictions while the second two papers look at the costs of such interventions. The first paper, by Kruger and Evans, examines the tendency to seek out information that one is better off without. The authors find that, while people appear to not appreciate the downside of their own curiosity, they clearly see the negative consequences for others. While satisfying curiosity takes precedence over their own long-run happiness, not so when predicting what others need. Thus, decisions made for others are more realistic and better than those made for oneself. The second paper, by Tanner and Carlson, examines the role of unrealistic thinking in misprediction about oneself. The results show that, because consumers tend to predict idealized behavior rather than realistic behavior (e.g. downloading less music than is likely), they are willing to pay more for relevant products (e.g. iPods). But, simply asking consumers to change perspectives by imagining their ideal behavior before reporting a more realistic estimate debiases both the estimate and valuation of the product. However, perspective-taking can also have a negative effect on consumers' behavior and predictions. The third paper, by Caruso, Epley, and Bazerman, investigates the cost of taking another person's (like a retailer's) point of view in exchanges with that person. Though perspective-taking makes people more realistic about how they *should* behave, it encourages even more selfish behavior because people assume the same from others. Finally, Burson, Faro, and Rottenstreich show that two opposing errors occur when someone predicts another's preferences under uncertainty, but these errors tend to cancel out when left unchecked. When one of these errors is corrected by manipulations that aim to bridge the gap between the predictor and the target, overall predictions end up inaccurate.

These four papers feature research that connects research in psychology with issues important to marketers. They also explore seemingly incongruent findings to help us understand why sometimes perspective-taking helps and why it sometimes hurts the decision-making process and predictive accuracy. Taken together, these four papers suggest that the psychological processes underlying mispredictions about self and other are complex. Therefore,

seemingly sensible interventions such as various types of perspective taking can at some times improve accuracy and in others worsen it. It is thus important to recognize both the underlying psychological processes leading to accurate predictions and the consequences of altering this process on both predictions and subsequent consumer behavior. Overall, our findings add to marketing and psychology researchers' growing efforts to understand and improve accuracy in predicting people's preferences and behavior.

## EXTENDED ABSTRACTS

### "You Can't Handle the Truth! A Self-Other Difference in the Pursuit of Unpleasant Information"

*Justin Kruger, New York University*
*Matt Evans, DePaul University*

In his "confessions," Saint Augustine described a friend named Alypius who, though "utterly opposed to and detesting" gladiatorial shows, was nevertheless persuaded one day to visit a coliseum. Although determined to keep his eyes closed throughout the contest, upon hearing the cries of the audience at the brutal killing of one of the gladiators he was overcome with curiosity. Alypius opened his eyes, and in so doing "was struck with a deeper wound in his soul than the other…on whose fall that mighty clamor was raised" (St. Augustine 1943).

What is paradoxical about the story of Alypius is not merely that he did not know the consequences of his actions. After all, knowledge typically helps more than it hurts, and individuals can hardly be expected to perfectly predict the exceptions. An individual who opens a window expecting to see a rainbow, for instance, can hardly be faulted for merely seeing rain. Instead, what is paradoxical about Alypius' fate—and, for that matter, that of Pandora, Eve, and, in case Christians did not get the hint, Lot's (nameless) wife—was that it was voluntary. In his writings, Saint Augustine makes it clear that Alypius opened his eyes despite knowing that he would regret it later. In other words, Alypius pursued knowledge that, in some sense at least, he did not want to have.

We suspect that the story of Alypius rings true for most people. Who has not at one time or another insisted that the bearer of bad tidings—a doctor, a family member, or a disinterested date—"give it to us straight" without "sugar-coating" it, only to find that the truth can be a "bitter pill to swallow"? To be sure, such pursuits are occasionally premised on the hope that the information will turn out to be less dire than it appears. As well, there are clearly other occasions in which individuals expose themselves to unpleasant information because the perceived benefits outweigh the perceived costs. But there are also other occasions, we offer, in which individuals seek knowledge that they believe has *no* foreseeable benefit; knowledge that, as in the case of Alypius, they believe will cause more harm than good. Indeed, this is precisely the contention of Weiner (1986) and Loewenstein (1994), both of whom have argued that curiosity can cause individuals to seek information that they know they are better off without.

This research examined this tendency. We conducted a series of studies in which individuals were given the opportunity to gain knowledge—some hypothetical and some real—that was of ques-

tionable value (such as the content of a conversation about one's faults or a photograph of one's spouse caught in an act of infidelity). In each case, we found that people tended to expose themselves to information that they themselves believed they were better off without.

Of key importance, this tendency was reduced when deciding the fate of someone else. This finding is analogous to the influence of other visceral factors on judgment and decision making. Whereas one's own visceral factors tend to have a large and sometimes overwhelming influence on judgment and decision making, the visceral factors experienced by others tend to have a much smaller influence (Loewenstein 1996). Whereas one's own cravings for a cigarette can cause one to "light up" despite one's sincere desire to quit, the cravings of others have much less an influence on behavior. Applied to curiosity, this suggests that individuals ought to be much less likely to expose others to unwanted information than they are to expose themselves to the same information—precisely the pattern we observed. Paradoxically, this can lead consumers to make better decisions for others than they do for themselves.

The implications for firms are just as paradoxical. Marketers frequently manage consumer (and public) opinion with careful control of the information about their firms (and the goods and/or services they provide) they make public. The researcher presented here suggests that firms may actually overestimate the negative impact of "full disclosure."

### "From Ideal to Real: How Taking an Idealized Perspective Can Undo Optimism"
*Robin Tanner, Duke University*
*Kurt Carlson, Duke University*

Individuals tend to make overly optimistic self assessments about themselves relative to others. While little studied in marketing, such optimism may have negative consequences for both marketers and consumers themselves (Kahn and Dhar 2007). Consider, for example, a middle aged man who expects to start exercising more next week. Given his expectations, he might allow himself a second dessert or he might buy a home exercise bike. However, if his expectations are optimistic (i.e., he will not actually live a more healthy life in the future), the second dessert may have been ill consumed and the money spent on the exercise bike largely wasted. Thus, we suggest that consumers would be better off if they could make more realistic self assessments.

This research takes as its central premise the idea that optimistic bias in self assessments can cause consumers (and marketers relying on their assessments) to make poor decisions. We advance the idea that an over overlooked contributor to unrealistic optimism is that consumers selectively test a tentative hypothesis of idealistic behavior when estimating their future behavior. As such, one means to helping consumers make more realistic predictions derives from getting them to test more realistic hypotheses about their behavior. To examine this idea, we have consumers estimate their ideal behavior (e.g., "In an ideal world, how many times would you exercise next month?") before estimating their actual behavior (e.g., "How many times will you exercise next month?"). We reason that requiring consumers to explicitly test an idealistic hypothesis before providing an estimate of actual behavior will cause them to adopt a more realistic hypothesis when contemplating their actual behavior.

In a series of studies participants estimate a variety of future behaviors, including blood donation, exercise frequency, willingness to pay for a product, completion time for a project, and saving for retirement. We consistently find that participants who first estimated their ideal behavior subsequently give more realistic estimates of their behavior (both objectively and compared to estimates of peers) than those in a control group. Furthermore, standard self assessments are largely indistinguishable from idealized ones, supporting our contention that the default process is to test a tentative hypothesis of ideal behavior.

We also find that the reduction in optimism brought about by first taking an ideal perspective influences downstream consumer decisions. For example, we find that prior consideration of idealistic usage leads participants to estimate a lower capacity utilization for an iPod (i.e., to estimate they will store fewer songs on it) than do participants in a control group. Consistent with the former group thinking in a less idealistic fashion about future iPod usage, they subsequently indicated a lower willingness to pay for an iPod. Finally, providing further support for our selective hypothesis account, we demonstrate that the observed attenuation of optimistic thinking is both mediated by an increase in accessibility of realistic thoughts and moderated by expertise.

### "When Perspective Taking Increases Taking: Reactive Egoism in Social Interaction"
*Eugene Caruso, University of Chicago*
*Nicholas Epley, University of Chicago*
*Max Bazerman, Harvard University*

People often fail to achieve efficient solutions in social interactions partly because they tend to reason egocentrically about the appropriate allocation of limited resources. For instance, homeowners routinely demand more for their properties than home-buyers think is fair to pay, and spouses often disagree about the merits of spending now versus saving for later. Such divergent interests can lead to divergent perspectives, and failing to understand an opposing side's viewpoint can exacerbate such egocentric assessments of fairness and create interpersonal conflict (Babcock & Loewenstein 1997; Messick 1995).

A seemingly simple and effective solution to such problems would be to reduce the egocentric biases by actively considering an opposing side's perspective (e.g., Paese & Yonker 2001). In the present research, however, we suggest that the consequences of considering others' perspectives may have a more complicated effect on social interaction. Although reducing an egocentric focus on one's own concerns may make an optimal solution more readily available, we suggest it can ironically lead people to behave in an even less optimal fashion because considering others' concerns may highlight self-interested motives in others' perceptions or likely behavior. Because people tend to assume that others' behavior is guided by their self-interest with relatively little concern about fairness or justice (Kramer 1994), this belief often exaggerates the impact of self-interest on others' attitudes and thoughts (Miller 1999; Miller & Ratner 1998).

A person selling a house, for instance, might become even more focused on a buyer's interest in obtaining a low selling price after considering the buyer's perspective. Although this seller may now recognize that her house may be worth less than originally thought, she may also now feel compelled to demand an even higher selling price to balance out a presumably low offer from the opposing side. We suggest in this paper that perspective taking may inadvertently highlight cynical theories about how selfishly others are likely to behave. In three separate experiments involving both simulated and actual resource allocation tasks, we predicted that considering others' perspectives in social interactions—namely competitive social interactions—would decrease egocentric or self-centered biases in judgments of what is objectively fair, but would also increase egoistic or self-interested behavior, compared to those who remain more egocentrically focused and do not consider others' perspective.

In study 1, participants representing different fishing associations in a simulated social dilemma met to determine how much each association should reduce its current harvesting level to preserve fishing stocks. In study 2, undergraduates were asked to decide the appropriate amount of limited funds they should request from the Dean to improve life in their college dormitory. In study 3, participants baked cookies in cooperative or competitive groups, ostensibly sharing key ingredients with their other group members. Roughly half of the participants in each study were asked to consider the perspective of their fellow group members before making their judgments, whereas the other half were given no such instructions.

In all studies, participants asked to adopt the perspectives of their other group members claimed it was fair for them to take significantly less of the limited resource (fish, funds, or chips), but actually took more in competitive contexts than the groups who did not engage in perspective taking. Beliefs about how much other group members were likely to take predicted how selfishly the perspective takers themselves behaved. In marketer-consumer situations, such cynical theories about the motives of a perceived enemy are likely to be highly ingrained in the minds of both sides, which may increase the chances that attempts at perspective taking may do more harm than good. Because considering others' perspectives can sometimes increase the very egoistic and detrimental behavior that it was designed to reduce, care should be taken when suggesting that people should look beyond their own perspective. Those who look into the minds of others may not always like what they see.

### "Can Two Wrongs Make a Right? Accidental Accuracy in Predictions of Others' Preferences Under Uncertainty"
*Katherine Burson, University of Michigan*
*David Faro, London Business School*
*Yuval Rottenstreich, New York University*

The prediction of other people's preferences is an integral component of much decision making under uncertainty. Consider a manager at an innovative firm specializing in medical products. Among his or her many tasks, this manager may have to select between disparate product offerings. For instance, the manager may need to decide whether to offer the consumer a medical solution that is relatively safe but offers only limited recovery, or a treatment that offers greater recovery but is contingent, among other things, on consumers' ability to persist with the treatment. In making this decision, the manager must predict how consumers would react to the relevant uncertainty: Would they prefer and be more motivated by the prospect of greater but uncertain recovery or prefer the relatively safer solution?

What steps are entailed in forming a prediction of others' preferences? In our example, the manager must of course have some sense of how attractive different recovery outcomes would be to consumers. Beyond this most basic point of departure, at least two key steps are required. First, the manager must understand consumers' *beliefs* about the likelihood of reaching a successful recovery. Second, the manager must understand the *impact* of these beliefs on consumers' decision making. We present several experiments which suggest that in many contexts people systematically err at both of these steps. They both misunderstand others' beliefs about the likelihood of successful completion of any task and misunderstand the impact that beliefs have on others' decisions.

The first error is driven by egocentricism. Research on "better-than-average" and "worse-than-average effects" reveals that when tasks are easy, people estimate their own chances of success as high. However, they estimate that others' chances are *not as high*. When tasks are difficulty, people think their chances of success are low, but that others' chances are *not as low* (e.g. Moore and Small 2007). Therefore, people's predictions of others' beliefs about their likelihoods of success (e.g. medical recovery) are *less extreme* than those that others would actually report.

The second error is in predictions of the impact of others' beliefs and is driven by affective reactions to risk and the frequent inability to emphasize with such reactions (see Loewenstein 1996). Though people overemphasize deviations from certainty and impossibility when making their own risky decisions, they believe that others will show this tendency to a lesser extent (Faro and Rottenstreich 2006). Thus, people's predictions of the impact of beliefs on others' decisions are *more extreme* than their actual impact on others' decisions.

Data and analyses from three studies suggest that, although people may frequently err at both key steps of the prediction process, their errors may tend to offset each other. Therefore, people's errors may often "cancel out" to yield predictions that are "accidentally accurate" overall. In predictions of others' preferences under uncertainty, two wrongs can make a right. Our data also shows that, ironically, improving predictions at one step can worsen predictions overall, because a right and a wrong will combine to make an overall wrong.

In additional experiments, we demonstrate an important application of our analysis outside the domain of prediction. In particular, our analysis implies a specific pattern by which principals will diverge from optimal hiring strategies for agents. Our findings suggest that, especially in domains where principals and agents are on average equally able, principals will diverge from optimal hiring strategies and will engage in less extreme choices. When choosing whether to perform a difficult task on their own or to hire an agent, people will tend to overinvest in agents: the first error will lead them to believe that the agent's chances of success are higher than their own, but, now as the principal, the second error will not correct for this misperception. When deciding about an easy task, people will tend to underinvest in agents: the first error will lead them to believe that the agent's chances of success are lower than their own, but the second error will not correct for this misperception either. Thus, where the principal's decision turns on the opportunity cost of his or her time, we might expect more frequent reliance on agents for difficult tasks than for easy tasks.

# Resolving Dilemmas Posed by Personal Sacrifices: Facilitators and Hindrances to Charitable Giving

Sergio Carvalho, University of Manitoba, Canada

## SESSION OVERVIEW

*Giving USA*, a yearbook of U.S. philanthropy, estimated charitable giving in 2005 at two hundred and sixty billion dollars—a growth of 6.1% over the previous year. While charitable assistance to those less fortunate than us is an undeniable part of the North American value system, the decision of *how much* and *who* to help is not an easy one. Monetary donations many times imply trade-offs between personal welfare, or the welfare of those close to us, and that of others. Faced with such dilemmas, factors that seemingly mitigate the need of others—for example, perceptions that a social cause is undeserving or does not warrant self-sacrifice—may act as added incentives for consumers to tip the balance in their own favor. Proliferating numbers of charitable organizations—*Internal Revenue Service* figures for 2004 put the number of public charities operating in the U.S. alone at 822,817—and the concomitant causes they campaign for, make it critical to understand how consumers make self-serving versus sacrifice decisions.

The objectives of the symposium were three-fold: (a) To encourage greater consumer research into charitable giving behaviors—a domain that remains under-examined despite its societal importance. While benevolent governments should ideally support deserving charitable causes, the escalating complexity of social needs and cutbacks in government funding have forced charities to rely more and more on corporate and individual level funding. Charities today must focus not only on alleviating social problems but also on competing with each other for finite resources. Well thought out promotional campaigns that are based on an understanding of how charitable decisions are made at the micro-level are essential to charitable organizations in meeting their goals; (b) To appeal to social marketers and the broader ACR community by bringing together research from the domains of philanthropic giving and consumer decision-making—an objective that was in line with the current conference theme of building bridges between diverse areas; and (c) To examine internal and external pressures that are potential facilitators as well as hindrances to consumers' charitable assistance. All papers within the symposium provided different perspectives within this framework and brought together a complement of topics on charitable decision-making. While the first two papers addressed potential facilitators to charitable donations, the final paper identified hindrances to philanthropy. Brief overviews of each paper, in the order of presentation, are as follows.

In the first paper, *Michal Strahilevitz* discussed the phenomenon of '*take-aversion*'—an aversion to taking patronage away from a charity over not participating at all—as an important facilitator of willingness to continue charitable donations by existing donors. The impact of external (peer awareness) and internal social stressors (guilt) on the take-aversion phenomenon were addressed—both in the context of private as well as publicly made decisions. *Sergio Carvalho* and *Namita Bhatnagar* discussed their research on the influence of internal group-categorizations and external signals of overall participation and group need on the decision to donate in the second paper. Best practices for charities that attempt to generate broad-based support for localized problems were suggested—specifically, by taking advantage of pre-existing in-group biases via re-classifications that place perceived out-group beneficiaries within all inclusive super-ordinate in-group

categories. The moderating effects of expected participation and group-need were then shown—added signals of high levels of participation will generate pressure to donate to campaigns targeting large super-ordinate groups only when the ability to make a perceptible difference is discerned. Finally, *Christine Bennett, Hakkyun Kim*, and *Barbara Loken* showed that disclosures of corporate sponsorship by a charity can be a hindrance to individual contributions—i.e., potential donors may perceive the charity as already well funded and a lack of personal ability to significantly contribute toward its goals. It also demonstrated that: (i) the greater the number of corporate sponsors, the lower the willingness to support a charity; and (ii) the lower the past giving behavior and prior non-profit expertise, the lower the likelihood of giving to charities supported by corporate donors.

## EXTENDED ABSTRACTS

### "Why Might One Feel Guilty for Giving a Homeless Guy a Dollar? The Effects of Endowment, Peer Awareness and Guilt on Charitable Giving"

*Michal Strahilevitz, Golden Gate University*

This paper explores the endowment effect in the context of charitable giving. Kahneman and Tversky (1979) demonstrated the phenomenon known as loss aversion–that losses loom larger than gains. In this research, a series of experiments are presented that demonstrate a phenomenon that can best be described as "take-aversion"—that taking away (from a charity) looms larger than not giving (to that same charity). The studies presented control for status-quo bias and charity preference. I also examine the effects of peer awareness (whether the decision to donate is made in the presence of fellow students) and guilt on the take-aversion.

Data is also presented that compares take aversion (with donations) to loss aversion (with various objects as well as with money). It is found that take-aversion can be even more powerful than loss aversion, regardless of whether the endowment in question is monetary, hedonic, or utilitarian. For example, even with a population that prefers receiving something (e.g., money, keychain, candy) over having money donated to a charity in a pure choice condition, subjects who are initially endowed with a donation to charity are less likely to trade that donation for a self endowment (e.g., money, keychain or candy) than subjects endowed with receiving something for themselves (e.g., money, keychain, candy) are to trading that in for a charitable donation. Although the relatively stronger aversion to undoing a donation than undoing a gain is stronger when others are aware of the subjects' donations, it occurs even when the decision of taking for oneself or giving to charity is made privately (i.e., not in the presence of one's peers).

Take-aversion is also observed in cases where subjects are endowed with a donation to one charity and given the option of moving that donation to another charity. For example, subjects endowed with a donation to March of Dimes tend to stick to that charity when given the option of switching to the World Wildlife fund, and subjects endowed with a donation to the World Wildlife Fund tend to prefer to keep the donation with the World Wildlife Fund rather than switch it over to the March of Dimes. Guilt is demonstrated to play a key mediating role in both switching from

charitable giving to getting something for oneself, and switching from donating to one charity to donating to another charity.

After presenting the results, as well as a theoretical explanation for the findings, I discussed how the guilt of taking (from a good cause), the pain of losing (one's own wealth), the joy of giving (to a good cause), and the fun of gaining or acquiring (for oneself) differ from one another in terms of both the nature and intensity of the emotions experienced. Implications to fund-raising that arise from having a better understanding of what take-aversion and loss aversion share in common, and how they differ, were also examined. Specifically, the phenomenon of "charity contracts" where donors sign long term commitments to sponsor a specific "unit of need" (be it a child, school, or stray animal) were discussed. This fund-raising tool allows charities to play on the negative emotions of undoing a charity commitment, and may lead donors to end up making larger contributions to a specific cause over time than they had originally intended.

### "The Role of Group-Categorizations within Charitable Campaigns: The Moderating Effects of Expected Participation and Group Need on Consumers' Willingness to Participate"

*Sergio Carvalho, University of Manitoba*
*Namita Bhatnagar, University of Manitoba*

Consumers in North America are generous in their support for social causes, and numerous charitable organizations routinely compete for donations of time and money. The manner in which people perceive the group-membership of beneficiaries is key in deciding charitable allocations. This is especially true given the targeted nature of most charitable campaigns that seek to address the needs of specific groups of people or specific problems (e.g., United Way's community-specific strategies; Red Cross' disaster relief for tsunami survivors in Asia). In this paper, we examine how group membership and the re-categorization of basic level out-groups within super-ordinate in-groups impact consumers' willingness to participate in targeted charity campaigns. We then look at the potential for variations in expectations of overall participation and group need in moderating these effects.

Recent evidence for positive biases in behaviors that help in-group members suggests that categorizing people as part of the in-group engenders perceptions of similarity and identification, and facilitates feelings of responsibility for their well being (Levine et. al, 2005). Such in-group categorizations are believed to decrease perceived costs of helping and increase the likelihood of providing assistance (Dovidio et. al, 1991). Along similar lines, Gaertner et al.'s (1993) Common In-group Identity model suggests that outsiders can reap the benefits of pro in-group biases via a re-categorization process that incorporates both the in- as well as out-group within an over-arching super-ordinate social category. Attitudes toward out-group members are enhanced when people are induced to view themselves as part of a common group (Dovidio et al, 1991). By this token, consumers should engage more willingly in charitable giving that benefits groups they already belong to—any re-classifications that place out- and in-groups within a single category should raise benevolence toward the former.

Consumers routinely face dilemmas hinged on trade-offs between helping others and helping themselves. Social Dilemma Theory posits that acting in the interest of the collective is strongly related to expectations of participation by others within the group (Sen, Gurhan-Canli, and Morwitz, 2001; Klandermans, 1992). Variations in overall participation levels act as signals of presence or absence of social norms surrounding participation, and give rise to attendant perceptions of normative pressure and felt obligation to

comply. Social dilemmas can also be resolved via perceptions of group need. Fisher and Ackerman (1998) believe that people feel a sense of obligation to assist when they see their group in need of help—a high value is put on incremental contributions made toward the attainment of group objectives. Expected participation and perceptions of group need should have similar normative effects within campaigns targeted toward in-group and out-group recipients as well as beneficiaries belonging to super-ordinate categories.

The effects of group categorization, expected participation and group need were tested within two laboratory experiments within the context of charitable donations for alleviating child poverty—a cause found to be important to the sample population. Undergraduate business students at a major mid-western university in Canada participated in the studies in exchange for course credit. In Study 1, we examined willingness to donate money for reducing child poverty within in-group versus out-group community contexts (i.e., within the home-province or an alternative province) and the effects of varying group participation (i.e., low or high), as well as the influence of re-categorizing out-groups and in-groups within one common over-arching category (i.e., by categorizing the home-province or the alternative province within Canada). The alternative community was chosen by pre-testing felt identification and belongingness to provinces using an independent sample from the same population. Results indicate that people exhibit greater generosity toward basic-level and super-ordinate in-groups as compared to out-group communities. Benevolence toward the out-group was enhanced upon re-classification within the super-ordinate country-level category. Rising expectations of group participation further increased willingness to participate—for the in-group target more so than the out-group—except in the case of the super-ordinate category (i.e., the overall Canadian category) and when the out-group was included within it (i.e., the alternative province within Canada category). It is possible that a priming of group size elicits free-rider effects where categories are perceived as large, as in the case of the latter two. Research into free-rider effects suggests that people within large groups significantly discount the extent of difference they have the ability to make in the provision of public good by the group. Thus, the bigger the group size, the smaller the relative share of contributions each group member tends to make (Albanese and Van Fleet 1985). A second study was conducted to investigate whether higher perceptions of group need and the extent of difference individuals are able to make would exacerbate willingness to participation within the super-ordinate group. ANOVA results of Study 2 show that willingness to participation in super-ordinate country-level campaigns rise with stronger expectations of group participation under conditions of high group need—for both predictive as well as normative participation willingness (measured via responses to the statements: "I will participate in the campaign;" and "I should participate in the campaign"). These results held for expected participation by others within the group as well. This suggests that consumers comply with normative pressure to abide by group participation norms when group need is high and it is felt that a perceptible contribution can be made toward attaining group objectives.

In a climate where charitable organizations routinely compete for funds, it is common practice to encourage support from individual donors by creating a sense of identification with causes being campaigned for. Social trade-offs that pit personal welfare against societal well-being make it difficult to generate broad-based support for problems faced by specific groups of people. This research provides managerial and theoretical insights into the effects of re-categorizations that frame outsiders and their problems as part of a common in-group and threats to collective welfare. Charitable

campaigns can also stimulate consumers' willingness to participate by sending signals of strong group participation as well as high group need when perceived group size is large.

### "Examining the Negative Impact of Corporate Sponsorship on Prospective Donors' Willingness to Support Nonprofit Organizations"

*Christine M. Bennett, University of Minnesota*
*Hakkyun Kim, University of Minnesota*
*Barbara Loken, University of Minnesota*

Effective fundraising is vital to the success of nonprofit organizations. These organizations require outside support often secured through grants, corporate donations (financial and in-kind) and individual donations in order to carry out their respective missions (e.g., to house the homeless or feed the needy). The Society for Nonprofit Organizations indicates that the fastest growing segment of nonprofit fundraising is corporate sponsorship, a strategy considered to be a "win-win" situation for both the sponsoring company and the nonprofit. Prior research suggests that consumers have favorable attitudes toward companies that support a cause and these attitudes can potentially impact purchase decisions and product evaluations in a positive way (Barone, Miyazaki and Taylor, 2000; Brown and Dacin, 1997; Sen and Bhattacharya, 2001).

Little research to date, however, has investigated the impact of corporate sponsorship on the nonprofit organization. In particular, little is known about the effects of corporate sponsorship on people's willingness to donate to a nonprofit when the nonprofit is the entity communicating the existence of the sponsorship to the public. The current research addresses this question. Specifically, we investigate how the disclosure of corporate sponsorship affects individual donations to the nonprofit. This issue is an important one because one technique widely used in the nonprofit sector is the public acknowledgement of corporate donors. Nonprofit organizations routinely and prominently disclose their major donors by noting their generosity in "thank you" advertisements in local newspapers with an appeal for readers to donate.

While the disclosure of corporate donors not only appeases sponsors, it may give the organization needed exposure and recognition which is important as many nonprofits have limited publicity budgets. However, this disclosure could potentially reduce an individual's willingness to support a nonprofit if having corporations on board increases the perception that the nonprofit is already well-funded or that an individual's contribution will have a minimal impact. Today, the general public is often bombarded with appeals to assist those less fortunate. While people are often ready to lend a hand, they are often troubled by the uncertainty of knowing whether or not an organization is deserving of their hard-earned money and will put it to good use. For example, when a new prospective donor is solicited for a monetary donation by a nonprofit organization to which they are unfamiliar, the prospective donor may not have a clear idea about whether the organization is actually in need of money. Huber and McCann (1982) and Jacard and Wood (1988) suggest that when relevant information is missing, people will infer values of the missing information from the information presented and will then adjust downward to reflect their uncertainty. Therefore, in order to reduce the uncertainty of whether or not a nonprofit is deserving of their donation, a prospective donor may infer the nature of the nonprofit from available cues. Specifically, the presence of corporate sponsors may indicate to prospective donors that nonprofit is already well-funded and that their own donations will have little impact.

Three experiments were conducted to test this premise. Specifically, we examine whether the disclosure of prominent donors influences individuals' willingness to support nonprofit organizations. In terms of the procedure, participants were first asked to read a message from a nonprofit organization helping at-risk and homeless teenagers and to indicate the extent to which they were willing to donate money to the nonprofit. In study 1, one factor was manipulated such that either prominent donors (i.e., corporations and foundations) were either listed or not on a nonprofit's annual appeal. A significant main effect of condition is observed such that participants that viewed a message with sponsors listed were less likely to donate money to the nonprofit than participants in the control condition ($M_{Control}=4.70$ vs. $M_{Sponsor}=4.32$; $F_{(1, 56)}=4.44$, $p<.05$). Study 2 was conducted to examine whether participants use sponsorship information as an informational cue. Specifically, we varied the number of sponsors listed (e.g., two corporate logos vs. nine corporate logos) and find that the greater the number of corporate sponsors listed, the less individuals are willing to support the nonprofit ($M_{Two}=4.15$ vs. $M_{Nine}=3.54$; $F_{(1, 91)}=5.02$, $p<.05$).

In study 3, we examine whether experience with nonprofits or past donating behavior impacts the use of corporate sponsors as informational cues. We relied on a 2 (control vs. sponsor) x 2 (nonprofit experience: high vs. low) between-subjects design. Results indicate a marginally significant interaction. Specifically, in the control condition, there is no difference in participants' willingness to donate to the nonprofit as a function of high or low prior experience with nonprofit organizations ($M=3.54$ vs. $M=3.83$). However, in the sponsorship condition, participants high in nonprofit experience were more likely to support the nonprofit and participants low in nonprofit experience were less likely to support the nonprofit ($M=4.50$ vs. $2.78$; $F_{(1, 24)}=3.78$, $p<.06$).

Altogether, these findings suggest that people who know that corporations are sponsoring a nonprofit organization are less likely to help the organization, compared to those who have no such information. Thus, these findings indicate that revealing corporate sponsors may negatively impact a prospective donor's willingness to support a nonprofit organization. It appears that people make inferences about the needs of an organization based on cues such as the advertisement of corporate sponsorship and such advertisement may unwittingly signal that the nonprofit is already sufficiently funded. This in turn lowers people's motivation to financially support to the nonprofit. Furthermore, our findings indicate that this phenomenon is particularly strong among people with little direct experience with nonprofits, probably because these individuals use the donor information as a peripheral cue, while those with prior experience with nonprofits may make judgments based on the focal message and are less affected by such cues.

## Symposia Summary

# Dazed and Confused by Choice: Antecedents and Consequences of Consumers' Desire for Choice Freedom

Simona Botti, London Business School, UK
Murat Usta, University of Alberta, Canada

## SESSION OVERVIEW

The objective of this symposium is to shed light on why consumers value freedom of choice, and on how perceived freedom of choice affects consumer decision processes. The research covered in this symposium proposes that the antecedents of consumers' desire for having freedom of choice are both cognitive and motivational in nature, and that this desire may lead to suboptimal decision outcomes.

The first paper, by Botti and Hsee, shows that consumers prefer making their own choices rather than having these choices externally imposed because they believe that choice leads to better performances and more positive affect. Three studies suggest that this belief is based on consumers' tendency to underestimate the emotional and cognitive costs of choosing. As a result, participants value the provision of choice even when its costs are higher than its benefits and choosing generates inferior outcomes than not choosing. The second paper, by Usta and Häubl, shows that consumers have a strong reluctance to relinquish their freedom to choose even if it is beneficial for them to do so. Evidence from three studies suggests that consumers' unwillingness to relinquish the control of their decisions to expert surrogates is based on their motivation to maintain an internal perceived locus of causality for their decisions. Reducing this desire to maintain an internal perceived locus of causality through manipulating motivational orientation eliminates the reluctance to relinquish decision control. The third paper, by Yuan and Dhar, shows that increasing consumers' perceived choice freedom can make them more susceptible to unsolicited persuasive messages. Results from three studies show that while people in forced choice situations with limited options are not much affected by store recommendation or popularity information, giving people greater choice freedom either by adding a no-choice option or by increasing the choice set size significantly increases the effectiveness of such persuasive information, even when their trustworthiness is questionable.

Prior research showed that consumers resist restrictions to their freedom of choice and engage in behaviors to reassert their feelings of autonomy. The three papers presented in this symposium share the premise that, although choice freedom is associated with both costs and benefits, it is harder for consumers to appreciate the costs of choosing and how they affect decision outcomes. This symposium therefore contributes to prior research by investigating the different psychological processes underlying consumers' desire for autonomy in decision making. Identifying such processes lays the foundation for developing a general theoretical framework that helps consumer researchers and marketers predict when, why, and how consumers prefer having the freedom to choose. Further, by showing the potentially negative consequences of perceived freedom of choice, this symposium alerts to the possibility that the mere provision of an opportunity to choose may increase consumers' perceived sense of control without increasing their objective welfare.

Consumers' preference for choosing can be accounted for by various theoretical perspectives. The papers presented in this session build a bridge between cognitive and motivational explanations for the phenomenon under investigation. Indeed, the motivation to feel autonomous in decision making can demonstrate itself through the use of a cognitive heuristic that underestimates the costs of being autonomous. In addition, these three papers build a bridge between the antecedents and the consequences of the phenomenon under study, namely consumers' quest for decision-making autonomy.

## EXTENDED ABSTRACTS

### "The Chooser's Curse: How Underestimating the Costs of Choosing Leads to Undesirable Outcomes"
*Simona Botti, London Business School*
*Christopher K. Hsee, University of Chicago*

Consumers are often willing to undergo extensive searches in order to enjoy the benefits of making optimal choices. For example, travelers shop around to find the most satisfactory tickets, investors wait for the best market conditions before picking their stocks, and singles engage in intensive dating when looking for the perfect spouse. Research has demonstrated that these search processes are associated with costs and benefits. Choosing allows to maximize satisfaction through the matching of personal preferences and available alternatives, and has beneficial psychological effects (Taylor and Brown 1988). Conversely, the cognitive effort required to evaluate the choice-set options and the emotional distress caused by decision conflicts may impair decision-making abilities and lower satisfaction (Iyengar and Lepper 2000; Luce 1998). Although optimal search models predict that rational consumers would stop searching if the costs of choosing outweighed its benefits, recent research has shown that consumers prefer choosing even when the provision of choice makes them worse off (Botti and Iyengar 2006). Consumers seem therefore to use a choice heuristic that causes them to systematically prefer choice in spite of its consequences on well-being. In this paper we examine this choice heuristic and its underlying psychological process. We propose that consumers want to choose because they tend to underestimate the cognitive and emotional costs of searching for the best option relative to its benefits. As a result of this cost underestimation consumers believe that the exercise of choice will necessarily make them better off, causing them to insist on choosing even in those circumstances in which choice leads to suboptimal outcomes. We tested our theory in three experiments.

Experiment 1 involved three groups of participants: Predictors, choosers, and non-choosers. Predictors were asked to imagine having $10,000 to invest in a 1-year CD. They were informed that there were numerous banks to choose from, each one offering a different interest rate ranging from 3.01% to 4%, and told to choose a bank using one of two online services. The first service initially charged $7 to show the interest rates of three randomly selected banks and allowed customers to decide whether to select one bank from this set or pay additional $7 to peruse other sets. The second service showed only three randomly selected banks for $7 from which customers could make their selection. Predictors were asked to indicate which of these two services they would prefer using and to predict which service would lead to a higher return and more positive affect during the decision process. The majority of predictors preferred the first service and expected this service to generate higher returns and more positive affect. Choosers and non-choosers

were given the same initial information about investing $10,000 in a CD; however, choosers were given the first service, which allowed them to search for the most satisfying rate, whereas non-choosers were given the second service, which provided them with only one set of banks from which to make their choice. Contrary to predictors' estimates, choosers obtained lower returns and reported lower positive affect than non-choosers.

It may be argued that predictors in Experiment 1 made erroneous forecasts simply because they did not directly make the decision. Hence, in Experiment 2 participants first experienced a decision process and then made their predictions. Participants were instructed to memorize as many randomly generated 7-digit phone numbers as possible within a 5-minute time frame and told that their final performance would depend on their ability to correctly memorize these numbers (they would gain 9 points for each correct number and lose 1 point for each incorrect number). Participants where then randomly assigned to one of the two experimental conditions: Choosers read that they would choose each number to memorize from a set of ten different randomly generated numbers whereas non-choosers were told that they would be presented each time with only one number to memorize. After taking the test, but before knowing their performance, participants were asked how they felt during the test. Next, they were informed of the two experimental conditions and asked in which condition they would prefer being if they had to take the test again, and which of the two conditions would generate a better performance and more positive affect. Consistent with the first study, the majority of participants preferred being in the choice condition and predicted choosers to experience more positive affect and perform better than non-choosers. In reality, choosers reported lower positive affect and performed worse because they misremembered more numbers and overall attempted fewer trials.

Experiment 3 used a similar paradigm as Experiment 2 but made the costs of choosing even more salient. Participants were asked to memorize three different 10-digit numbers. They were told that their performance depended on how many digits they would correctly and incorrectly remember (they would gain 0.9 points for each correct digit and lose 0.1 points for each incorrect digit) and the time spent taking the test (they would gain 0.5 points for each second saved from the 6-minute allotted time). Choosers were given a set of ten different randomly generated numbers from which to select the one number to memorize whereas non-choosers were told that they would be presented each time with one number to memorize. After taking the test but before knowing their performance participants reported their affective response to the test, were informed of the two experimental conditions, and asked to predict which condition would lead to higher performance and more positive affect. Consistent with previous results, the majority of participants preferred being in the choice condition and predicted higher performance and more positive affect for choosers. In actuality, choosers not only felt worse but also misremembered more digits, resulting in a lower performance than non-choosers.

Overall, these results support the hypothesis that consumers desire decision-making autonomy because they tend to underestimate the cognitive difficulties and emotional discomfort associated with the act of choosing even when these costs are made salient; as a result, they erroneously believe that choice provision will necessarily improve their well-being.

### "Self-Determination and the Relinquishment of Decision Control: Why Are Consumers Reluctant to Delegate their Decisions to Surrogates?"

*Murat Usta, University of Alberta*
*Gerald Häubl, University of Alberta*

When consumers use an expert as a surrogate to guide, direct, and/or transact marketplace activities on their behalf (e.g., a financial advisor), they relinquish some of the control of the decision process (Solomon 1986). It is remarkable, and also puzzling, that many consumers are reluctant to relinquish control to expert surrogates even when the benefits of doing so are known to be significant. Such reluctance is particularly evident in the domain of financial decision making where, for example, less than half of American equity investors rely on financial advisors for all of their stock market transactions (see ICI 2005). Individuals who make financial decisions without professional advice are more likely to make poor asset allocations (Benartzi and Thaler 2002), which results in tremendous welfare costs. The objective of this research is to investigate what underlies consumers' persistent reluctance to relinquish their decision making responsibilities to expert surrogates.

Self-determination theory (Deci and Ryan 2000) suggests that humans possess a basic need for autonomy, the desire to feel as the origin of one's actions. Individuals feel autonomous, as opposed to controlled, to the extent that they perceive an internal, as opposed to external, locus of causality for their actions. Some contextual factors are "autonomy supportive" (e.g., the opportunity to choose one's actions), while others are "controlling" in the sense that they undermine the need for autonomy (e.g., extrinsic rewards or surveillance). Autonomy-supportive contexts improve human functioning and well-being by bolstering an internal perceived locus of causality (Vansteenkiste et al. 2004). Based on self-determination theory, we propose that relinquishing the control of a decision shifts the perceived locus of causality (PLOC) for the decision from internal to external, which thwarts the need for autonomy. As a consequence, consumers' reluctance to relinquish the control of their decisions to expert surrogates is driven by their need to maintain an internal PLOC for their decisions.

In this paper, we report the results of three experiments that involved consequential investment decisions. For each investment decision, participants were first presented with ambiguous information about two stocks. They were then given a choice between making the investment decision on their own and obtaining the services of a financial advisor in connection with this decision. The nature of the advisor's service was manipulated such that it either (a) revealed a prediction as to which of the two stocks would yield a higher rate of return ("recommendation") or (b) made the decision on behalf of the participant ("delegation"). Decision makers who acquire a recommendation can retain an internal PLOC, because they are free to either comply with or reject the recommendation. By contrast, delegating a decision implies completely relinquishing the freedom to choose and induces an external PLOC. The results of a pretest also confirmed that delegating a decision results in an

external PLOC while obtaining a recommendation allows consumers to retain an internal PLOC.

Experiment 1 aimed to demonstrate consumers' reluctance to delegate their decisions to expert surrogates. The services of a financial advisor were either offered at a cost or for free. Normatively, reducing the cost of the advisor's services should increase consumers' likelihood of obtaining them. The results of this study show that providing the services for free rendered consumers significantly more likely to acquire the expert's recommendation about which option to choose. However, consumers' willingness to delegate their investment decision to the expert was low regardless of the cost of the expert's service.

The objective of Experiment 2 was to identify the motivational process that underlies this reluctance to delegate. To do so, we manipulated participants' motivational orientation. Prior to the investment decision, participants engaged in either a self-directed (i.e., autonomous motivation) or an other-directed (i.e., controlled motivation) card sorting task adapted from Nix et al. (1999). Autonomously motivated consumers who were acting with an internal PLOC were significantly less willing to delegate their decisions to the expert surrogate than they were to acquire the same surrogate's recommendation. On the contrary, consumers in controlled motivation who were acting with an external PLOC did not show such a tendency. Furthermore, consumers in controlled motivation were significantly more likely to delegate their decisions than those in autonomous motivation. Autonomously motivated participants approached the decision to retain or relinquish the control of their investment decision with an internal PLOC: They were threatened by a shift in their PLOC from internal to external caused by delegating their investment decisions. Thus, consumers' reluctance to relinquish their freedom to choose is based on their desire to maintain an internal PLOC for their decisions.

Experiment 3 aimed to investigate the influence of consumers' motivational orientation on their response to negative feedback about their competence in decision making. Receiving negative feedback made autonomy-oriented consumers (i.e., those predisposed to experience an internal PLOC) more likely to obtain the surrogate's recommendation, but not to delegate their decisions. By contrast, upon receiving negative feedback, controlled-oriented consumers (i.e., those predisposed to experience an external PLOC) became more likely to delegate their decisions, but not to take a recommendation. Receiving negative feedback about their competence in decision making made controlled oriented consumers more likely to relinquish their freedom to choose while it did not have such an effect on autonomy oriented consumers.

These results suggest that the unwillingness to relinquish the freedom to choose is based on the desire to experience an internal PLOC for one's decisions (i.e., one's reason to make the decision in a particular way should originate from one's self). This strong motivation inherent in consumers persists even in domains that require expertise, such as financial investments, and causes them to be reluctant to relinquish the control of their decisions to experts. Motivational orientation (autonomy or controlled) proves to be a predictor of whether or not consumers relinquish their freedom to choose (Experiment 2) and of whether or not consumers' likelihood to relinquish their freedom to choose increases upon receiving negative feedback about their competence in decision making (Experiment 3).

### "Perceived Choice Freedom and Consumers' Receptiveness to Persuasive Information"

*Wentao Yuan, New School for Social Research*
*Ravi Dhar, Yale University*

People in modern societies have a strong preference for choice freedom and autonomy. They usually prefer more to less choice options even though more options do not always lead to better decisions and greater happiness (Schwartz 2005). In this paper, we demonstrate that when consumers are given the impression of having greater choice freedom, they become less suspicious of potentially unreliable information. For example, they become more likely to follow, sometimes unwisely, store recommendations without convincing reasons. Ironically, the comfortable feeling of self control can make people more susceptible to external manipulations.

When consumers are shopping for products, a lot of information they learn is provided by the retail stores. Not only do stores routinely supply core product attributes such as price, features, and technical details, they sometimes also offer more normative information such as product popularity and subjective information such as expert recommendations and consumer reviews. On one hand, store-provided information, if accurate, can reduce decision difficulty and facilitate consumers in making sound choices. On the other hand, stores may provide selective or misleading information trying to sway consumers' decisions for the stores' own benefits. Generally consumers are aware of these possibilities. According to the Persuasion Knowledge Model (Friestad and Wright 1994), once consumers recognize an action as a tactic to influence their behaviors, they use their persuasion knowledge to cope with such an attempt. More intrusive persuasion attempts such as unsolicited recommendation may also induce psychological reactance (Brehm 1966) and result in negative consumer reactions (Fitzsimons and Lehmann 2003).

Reactance is usually considered as a response to threatened choice freedom. When a choice option is removed or threatened to be removed, people often try to reassert their freedom by increasing their liking for the threatened option. We argue that people would be most suspicious with store-provided information when they have limited choice freedom. If people's choice freedom is increased, the same persuasive information would have less impact on their perceived choice freedom. For example, if people have to choose between Products A and B, and they are told that A is

recommended by experts, their freedom to choose B over A will be threatened by this recommendation. However, if people also have the option to choose neither A nor B and explore other products instead, a recommendation for A may still threaten people's freedom to choose B over A, but it will not threaten people's freedom to choose neither product and explore other options. Therefore, we propose that when choice freedom is expanded by adding a no-choice option or by adding an extra product option, people will be less cautious with, and be more likely to be influenced by, store-provided information.

Study 1 examined how people responded to store recommendation in presence or absence of a no-choice option. Participants chose between two unfamiliar foreign DVD titles, one of which was described as being recommended by the rental store. In fact, the recommended alternative was manipulated and counterbalanced between participants. Half of the participants were also told that they had the option to rent neither DVD and search for other titles. The results showed that while participants who did not have the no-choice option were unaffected by the recommendation information, participants who had the no-choice option were significantly more likely to choose the recommended alternative. We ruled out the alternative explanation that people who preferred the non-recommended alternative were more likely to switch to the no-choice option. We also replicated the finding in Study 1 with a more familiar product (chocolate) and in a choice with potential real consequences (1/30 chance of winning the chosen chocolate box).

Like adding the no-choice option, increasing the number of available product options will also increase perceived choice freedom. Study 2 examined how people responded to popularity information when the size of choice set varied. Participants were provided with either two or three mixers to choose from. Of the two common alternatives that all participants saw, one was described by the store as being more popular than the other. The results showed that while participants who chose from only two alternatives were not significantly affected by popularity information, participants who chose from three alternatives were significantly more likely to choose the alternative that was claimed to be popular.

In Study 3, we showed a boundary condition of the choice freedom effect. Many consumers have the intuition that stores have higher incentive to sell expensive, as opposed to cheap, products. Therefore, store-provided information favoring a high-price product may elicit more suspicion, whereas information favoring a low-price product may be regarded as relatively reliable even when choice freedom is low. In Study 3, participants were asked to choose between two car tire models. Some were told the high-price model was more popular, some were told the low-price model was more popular, and the others were not given any popularity information. The results showed that if the low-price model was described as being popular, adding the no-choice option did not increase the effect of popularity information. On the contrary, if the high-price model was described as being popular, adding the no-choice option significantly increased the share of the high-price model.

Consumers cherish the freedom to choose, as well as the freedom to not choose. However, oftentimes they do not realize the costs associated with such freedom. The current research shows that possessing extra choice freedom could make consumers more susceptible to potentially unreliable information. In the studies we reported, recommendation and popularity information were not empirically derived but rather experimentally manipulated, and they were not accompanied by any supporting reasons. Therefore, by complying with such information, the participants in the high-freedom conditions may not have made the optimal choices. On the other hand, suspicion and reactance can be destructive in some situations. When persuasive information is reliable and unbiased, high choice freedom may also make consumers more receptive to valuable information. In either case, it is important for researchers to understand how choice freedom can influence consumer behaviors.

## SYMPOSIA SUMMARY
# "Do Unto Others…": The Influence of Others on Perceptions of Price (Un)Fairness
### A. Peter McGraw, University of Colorado, Boulder, USA

### SESSION OVERVIEW

The session examines factors influencing the perception of price (un)fairness. Prior research has examined many factors affecting fairness perceptions, such as the firm's motives for the price change (Campbell 1999) and the role of past prices, competitors' prices, and sellers' costs (Bolton, Warlop, & Alba 2003). Such research has tended to focus largely on factors directly related to the firm (e.g., costs, profits, motives). Yet, firms' pricing actions often result from other actions which may be beneficial or harmful to consumers. In addition, pricing actions may be perceived differently depending on what group of consumers is affected and how. The papers in this symposium focus on how the situation in which others affected, for better or for worse, by a price change influence perceptions of price unfairness.

In the first paper, Campbell develops a conceptual framework of the relationship between price and perceived (un)fairness, proposing that, symmetric to inferred motives, consumers may make inferences about the potential or realized harm to the consumer from the pricing action. Specifically, she explores how company characteristics and the identity of affected consumers affect price unfairness judgments. Her findings, across three studies, demonstrate that perceived harm to consumers of a price action can influence perceptions of the unfairness of the price action. Both the need for the product and the relative disadvantage of the consumer predicted perceived fairness of various price actions when costs of production were decreased. The results have implications for our understanding of perceptions of price unfairness and, more broadly, for understanding differences in consumers' perceptions of how markets do, and should, work. Consumers appear to be considering the relative affordability of products and to believe that fairness is implicated when consumers can be harmed by relatively high prices.

The second paper, by Varki, Miller, and Banerjee, builds on the notion that perceived inequities on "others" affect price perceptions. They examine situations in which prices are decreased (thus benefiting the consumer himself), but the decrease is accomplished through cost-cutting actions which negatively affect others (e.g., laying off workers), thus forcing an inherent trade-off between the self and others when it comes to price unfairness perceptions. Specifically, the paper examines whether the harm caused to others (such as employees) affects consumers' fairness perceptions of the reduced price, and whether consumers' ethical perspectives moderate their fairness perceptions. The findings demonstrate that price decreases can be perceived as unfair and that ethical perspective does affect perceptions of price unfairness. In addition, the findings indicate that the reason for the price decrease matters, and provide insight into the effect of various managerial cost-reducing actions on consumers' perceptions.

The third paper, by Schwartz and McGraw, also examines a situation in which consumers implicitly must make a trade-off between their own well-being and that of others. However, unlike in the second paper where consumers benefit by lower cost at the expense of others, in this paper, consumers are faced with a higher cost that benefits others. Specifically, Schwartz and McGraw investigate the effect of relationally reframing, or changing the perceived normative 'rules' at work within a trade-off, to undo the unsettling nature of the consumer exchange. They present results

from a series of studies showing people's perception of pricing fairness significantly varies depending on the nature of the good (e.g., medication vs. software) and the relational frame of the message. They show that communal-sharing messages (e.g., the price increase will help bring other safe, effective drugs to market), relative to market-pricing messages (e.g., the price increase is based on supply and demand in the marketplace), reduce distress over medication prices and ease perceptions of unfairness for price increases.

The discussant in this session is Lisa Bolton (Wharton) who has done influential work in the area of pricing, and fairness perceptions more specifically (e.g., Bolton et al. 2003).

By bringing together the three papers and discussant, the session improves our understanding of factors that affect perceptions of price unfairness and in particular, the influence of perceived harm (to consumers, employees, or unknown others) on such perceptions. Each paper in its own way examines the moral (and not just financial) aspect of price perceptions. The first paper focuses on consumer inferences about potential or realized harm to the consumer as a result of consumer need for the product (manipulated by type of product) and the relative disadvantage of the consumer (manipulated by type of consumer). The second paper also focuses on perceived harm, but examines the effect of harm to others (e.g., employees) rather than to consumers themselves. Moreover, it raises the question of how perceptions of price unfairness are perceived for price decreases and the role ethics play in such perceptions. The third paper considers the role of others but focuses on how justifications of higher prices which invoke others (e.g., benefits to society) change perceptions of price fairness by removing the need to make difficult moral trade-offs between money and well-being. Together, the papers provide insight into harm to consumers, employees, and society, that influence perceptions of price unfairness from an ethical standpoint. These factors are of particular importance considering current ethical concerns about company actions and current practices in the pharmaceutical industry. Finally, the papers serve to further our understanding of both perceptions of price unfairness and, more broadly, perceptions of how markets do, and should, work.

### EXTENDED ABSTRACTS

#### "The Role of Inferences of Impact on Perceptions of Price (Un)Fairness"
##### *Margaret C. Campbell, University of Colorado, Boulder*

Perceptions of price (un)fairness (PPU) encompass a consumer's subjective sense of a price as right, just, or legitimate versus wrong, unjust, or illegitimate. PPU influence multiple important marketplace factors such as willingness to pay, intentions to conduct business with a firm, and re-purchase intentions (Campbell

1999; Homburg et al. 2005; Kahneman, Knetsch, and Thaler 1986a & b). Importantly, perceptions of unfair prices can limit firm profits (e.g., Blinder 1991; Guth, Schmittberger, and Schwarze 1982).

Because of the importance of PPU, a growing body of research explores how perceptions of unfairness arise. Perceptions of price (un)fairness have been shown to rest on notions of dual entitlement (KKT 1986) whereby consumers and firms are seen as having rights to their reference prices and profits, respectively. A consumer may assess a given price relative to her reference price and react based on whether her entitlement expectations are violated. Violations of consumer reference prices that increase firm profits are perceived as unfair.

Recent research has expanded upon the classic dual entitlement framework. One stream has focused on understanding references consumers might use. For example, PPU can be influenced by reference points such as: past prices, competitor prices, firm costs, and type of product (e.g., Bolton and Alba 2006; Bolton et al. 2003; Ordonez, et al. 2000). A second line of research focuses on identifying variables, in addition to reference price and profit, that influence consumers' perceptions of (un)fairness. Research demonstrates that PPU are influenced by the inferences the consumer makes about the firm's motives for a price change (Campbell 1999), attributions for the price (Vaidyanathan and Aggarwal 2003; Xia et al. 2004), stimulus-based affect, and the source of the price (Campbell 2007).

Existent research provides evidence that characteristics of the firm influence PPU; the research presented here proposes that additionally, characteristics of the consumer can influence PPU. Specifically, we propose that, symmetric to inferences about the firm, such as inferred motives, consumers may make inferences about the potential harm to consumers from a pricing action and inferred harm can influence PPU. Thus, factors that affect inferred harm are expected to moderate the impact of pricing actions on PPU. Three experiments explore how several factors that influence perceived harm affect price (un)fairness judgments.

Consumers differ in relative advantage and disadvantage. The extent of disadvantage influences the degree of harm inferred from relatively high prices such that it was hypothesized that PPU would be higher when the consumer is relatively disadvantaged. Thus, Study 1 explored inferred harm from "consumer disadvantage" as an influence on PPU. Following KKT, we examine the effect of either decreasing or maintaining price when costs decrease. Inferred harm was manipulated by using two types of consumers. Study 1 had a 2 (price action: no change versus pass along half of a cost decrease) X 2 (consumer type: industrialized versus developing country). While there was no effect of the price action, consumer type significantly impacted PPU. Respondents indicated that it was more unfair to increase profits (by either not changing or only partially passing on the cost decrease) when the consumer was relatively disadvantaged (developing country: 3.96) than when the consumer was relatively advantaged (industrialized country: 4.90; $p<.03$).

Based on the idea that consumers will infer greater harm from relatively high prices for products for which consumers have a more critical need, study 2 explores the effects of "need criticality" on PPU. Inferences of potential consumer harm are manipulated by the criticality of a product. The 2 (price change: decrease vs. no change) X 2 (product: furniture vs. pharmaceuticals) design shows a marginal effect of the price change on PPU (different from KKT); respondents perceived it to be less fair to maintain prices in the face of a price decrease (4.55) than to decrease prices (5.11; $p<.07$). In addition, the company type had the expected effect such that price fairness was lower in the case of medicine (4.45) than furniture

(5.25; $p<.01$). Importantly, inferred harm was seen to mediate the effects of the product type on PPU.

Study 3 primes the concept of consumer need to further explore the role of perceived harm on PPU. The first two studies use different types of consumers (developing versus industrialized countries) and types of products (medicine versus furniture) that vary in terms of the harm of being unable to afford the product. However, while these vary as intended, they could also vary in unintended ways. Study 3 more directly examines the role of need/ harm by priming the concept for the same group of consumers and the same product. Further, this uses a non-essential good (a movie ticket) and a potential price decrease (a price discount for senior citizens). A 2 (prime: comfortably situated versus uncomfortably situated) X 2 (senior discount: present versus absent) shows the predicted interaction. When the idea that seniors have greater need is accessible, a senior discount is perceived to be fair and a lack of a discount is unfair, whereas when the idea of need is not primed, there is no effect of a senior discount on PPU.

This research indicates that inferences of harm to consumers can influence perceptions of the (un)fairness of a price action. Both the need for the product and the relative disadvantage of the consumer influenced the perceived fairness of maintaining or decreasing prices. Further, in study 2, inferred harm mediated the influence of the price on PPU. These findings have implications for our understanding of PPU and, more broadly, for understanding consumers' perceptions of how markets do, and should, work. The evidence suggests that consumers make inferences about the potential harm that could be caused to consumers by price actions. Consumers appear to consider relative affordability of products and to believe that fairness is implicated when consumers can be harmed by relatively high prices. It is important to take this into consideration in conceptualizations of PPU and, more broadly, of market mechanisms.

## "Understanding Fairness Perceptions for Price Decreases"

*Sajeev Varki, University of Rhode Island*
*Elizabeth G. Miller, Boston College*
*Syagnik Banerjee, University of Rhode Island*

Prior research on price unfairness perceptions has tended to focus on price increases and typically examines this issue based on the principle of dual entitlement (Kahneman, Knetch, and Thaler 1986). According to this principle, fairness perceptions are governed by a belief that firms are entitled to a reference profit and customers are entitled to a reference price. In the current research, we depart from this prior research in two ways. First, we focus on perceptions of price *decreases* rather than increases. Specifically, we explore how consumers respond to firms who lower prices at the expense of other constituents. Second, we expand on the traditional focus in price fairness research from the firm-consumer dyad to a triad which also includes the employee.

Our expanded perspective brings into focus an interesting dilemma for the individual consumer when confronted with a price decrease. With a price decrease, there is the potential for the individual to benefit at the cost of another, such as when a firm enables a price decrease through cost-cutting actions which harm employees. Numerous examples of such situations exist. For example, Walmart has been criticized for keeping costs down by not providing health benefits to its workers, though the ultimate beneficiary of lower prices is the consumer itself. Similarly, Nike has been criticized for its use of sweatshops and cheap foreign laborers. Thus, in determining the relative fairness of these actions and whether to patronize such firms, the consumer must inherently tradeoff their own good vs. that of an unknown other. Consequently, we expect that such decisions will be influenced by the consumer's ethicality or degree to which s/he is self-interested vs. other-focused.

Kohlberg (1969) suggested that individuals evolve along moral stages which relate to the degree to which people act to promote their self interests vs. selfless interests. Since individuals at higher levels of moral development are more likely to act to promote selfless interests, such individuals are more likely to perceive pricing practices which harm others (but benefit the self) as more objectionable than those at lower levels of moral development. Thus, in this paper, we examine how the ethical perspective of consumers (as measured by their cognitive moral development) affects their perceptions of price unfairness. In doing so, this paper integrates the relevant literature on ethics with the literature on price unfairness perceptions.

We examine the effects of price decreases and consumers' cognitive moral development (or ethical perspective) on price unfairness perceptions in two studies. The first study, which uses a 2 x 2 between-subjects design that crosses the existence of harm to others (harm: present, absent) with respondents' level of cognitive moral development (CMD: high, low), illustrates that price decreases can be perceived as unfair and that, consistent with expectations, cognitive moral development moderates these perceptions. Cost savings effected by harming others (e.g., by paying lower wages to employees or cutting employee benefits) led to the resulting price decrease being perceived as less fair than when the price decrease was effected through cost saving actions that did not harm others (e.g., acquiring new production facilities or savvy investments). However, only consumers with high levels of cognitive moral development actually perceived such decreases as unfair.

The second study delves more deeply into the process underlying consumers' price fairness judgments for price decreases. The study used a 2 x 2 x 3 x 2 between-subjects design, crossing firm reputation (high, low), reason for the price decrease (intention: to increase sales, to remain competitive), level of harm (none, low, high), and level of cognitive moral development (low, high). Findings indicate that consumers perceive price changes as being increasingly unfair as the degree of harm to others increases; however, the point at which consumers react to these changes depends on both the firm's intentions and the consumer's level of cognitive moral development. When (harmful) cost-cutting actions are undertaken to increase sales, actions are perceived as unfair regardless of the consumer's level of cognitive moral development. However, when these actions are undertaken to remain competitive, cognitive moral development does matter–any level of harm is viewed as unacceptable by those at high levels of cognitive moral development, while only high levels of harm negatively impact fairness perceptions for those with low levels of cognitive moral development. Despite these differences in fairness perceptions, consumers appeared to evaluate the relative benefits to self vs. others similarly regardless of their level of cognitive moral development.

As a whole, our findings demonstrate that price decreases can be perceived as unfair, but that such perceptions depend on the consumer's level of cognitive moral development, the manner in which the cost savings are realized, and company intentions. By expanding our focus beyond the traditional firm-consumer dyad to a triad which includes the employee, we identify a new class of factors–harm to others–which impact fairness perceptions. In addition, our work highlights the usefulness of cognitive moral development for understanding price fairness perceptions and for explaining individual differences in sensitivity to price fairness issues. Implications for modeling the fairness judgment process, using cognitive moral development as a segmentation variable, and managing consumers' reactions to price changes are discussed.

## "Justifying the High Price of Medication: How Relational Framing Reduces Consumer Distress"

*Janet Schwartz, Princeton University*
*A. Peter McGraw, University of Colorado, Boulder*

Over the last three decades advancements in medicine have lead to enormous gains for pharmaceutical companies. As the industry enjoys significant profits, health care costs have risen at

rates far outpacing inflation. And much of those costs are shared, in one form or another, by consumers. Although prescription drug costs are not the only contributor to rising prices, consumers and policymakers are becoming increasingly more educated and critical of the pharmaceutical industry. The industry has responded with increased public relations and marketing efforts to assuage concerns that medication prices are strictly profit-driven.

The current paper investigates marketing strategies that pharmaceutical companies use to justify the price of medication. In particular, we are interested in how the industry uses relational rhetoric to conceal a focus on profits– a focus that, incidentally, is required of all publicly traded companies. Consider for a moment a quote from Billy Tauzin, president of *PhRMA*, an industry lobbying organization:

"... truth is that we are-as an industry-focused on one thing: the patient. Granted, we're a business-a pretty darn big business. But we're a business OF people working FOR people. We make lives better through better health."

Tauzin's focus is clearly one of solidarity with the patient-consumer. This rationale is a common example of an industry pricing justification where consumers can comfortably believe that everyone is working together and are thus willing to accept higher prices to help reach the ultimate communal goal of improved public health and well-being.

Why might a focus on benefits to all people ease consumer tension? We argue that the message shifts attention away from market norms associated with pricing and refocuses attention on the norms that govern community membership. Fiske (1992) has proposed that people use four types of relationships and their norms to organize, evaluate, and coordinate most social interactions. Here we focus on two most relevant to our investigation:

*Communal sharing* (CS) splits the social world into emotionally charged classes that differentiate in-groups and out-groups without degree of distinction. Everyone in a community shares certain rights and incurs certain duties.

*Market pricing* (MP) makes possible ratio comparisons of the values of diverse entities through the use of a single value or utility metric. This structure underlies capitalism and monetary transactions from simple loans to complex financial instruments. Prototypical relations include most business to customer and business to business exchanges.

We propose that the pharmaceutical industry's strategy is effective because people find it difficult to confront explicit trade-offs between health and money. Put another way, people are reluctant to apply market-pricing rules to 'things,' like medicine, that they feel should be governed by communal-sharing rules (Fiske & Tetlock, 1997). Such taboo trade-offs are distressing to contemplate (see McGraw, Tetlock, & Kristel, 2003; Tetlock, et al. 2000) and people are thus motivated to avoid making such trade-off calculations. In addition, people are skeptical of those (e.g., pharmaceutical and insurance companies) who would make such trade-offs on their behalf.

In this paper, we investigate the effect of relationally *reframing*, or changing the perceived normative 'rules' at work within a trade-off, to obfuscate the unsettling nature of the exchange (see McGraw & Tetlock, 2005). We present the results of a series of studies showing people's perceptions of pricing fairness significantly varies depending on the nature of the good (e.g., medication versus software) and the relational frame of the message. We show that communal-sharing (CS) messages, relative to market-pricing (MP) messages, reduce distress over medication prices and ease perceptions of unfairness for price increases, in part because price increases benefit consumers in the future.

In Study 1 participants were randomly assigned to the role of either patient user or investor in a company that had just launched a successful new sleep aid. It was stated that the pharmaceutical company had been criticized for the medication's price and the participants were asked to evaluate a statement from the company's CEO. In one condition the CEO provided a CS justification (high R&D costs for beneficial medications, patient well-being) and in the other condition, an MP justification (competition, investor well-being). Regardless of their roles as users or investors the MP strategy was more aversive than the CS message. Investors, however, were less distressed by the MP justification than users.

In Study 2 participants were randomly assigned to review hypothetical statements from either a pharmaceutical or software company attempting to justify raising prices on a very successful product to make up for R&D losses on another product. This is a common defense in the pharmaceutical industry, but paradoxically one that previous research has identified as generally unacceptable (Kahneman, Knetsch, & Thaler, 1986). Half of the participants saw a CS rationale and the other half saw an MP rationale for the price increases. Both messages were judged equally fair for those reviewing the software company's statements. However, the MP rationale was judged more unfair than the CS rationale for the pharmaceutical company. That is, people were generally distressed at the price increase but particularly so when a pharmaceutical company's rationale was market driven.

Study 3 examined whether CS justifications were effective for any medication or medications necessary for health. Participants read statements from a pharmaceutical company attempting to justify raising prices on a successful medicine to compensate for R&D losses on another medicine. The product was varied so that participants considered either a cosmetic anti-wrinkle treatment or a cholesterol lowering medication. The CS and MP messages were judged equally fair for the anti-wrinkle treatment's price increase. However, the MP rationale was judged more unfair than the CS rationale for the cholesterol medication.

# Having vs. Doing: Materialism, Experientialism, and the Experience of Materiality

Michelle F. Weinberger, University of Arizona, USA

Melanie Wallendorf, University of Arizona, USA

## SESSION OVERVIEW

The overwhelming majority of consumer research literature focuses on consumers perceiving, choosing, purchasing, and using objects. While researchers often examine consumers' experiences with these objects, the consumption of experiences and activities that leave a low material trace such as vacationing, attending sporting events, and arts participation, remains under explored.

Philosophers and social scientists often present a moralizing dichotomy between the acquisition of the material and the acquisition of experiences, placing *'the doing'* of experiences on a higher moral and spiritual plane than *'the having'* (Belk 1985; Sartre 1956; Sirgy 1998; Van Boven 2005). This is reinforced in the materialism literature, which finds that materialism, the belief that the acquisition of objects can bring happiness, leads to negative psychological states such as dissatisfaction with life (Sirgy 1998), social anxiety (Schroeder and Dugal 1995), deficit disorder, conduct disorder and narcissism (Cohen and Cohen 1996). From Packard (1957) to Ewen (1976/2001), to Klein (2000), Ritzer (1993) and Schor (1998; 2004), a sociological cottage industry is devoted to the proposition that consumer materialism is a degrading outcome of untrammeled marketing power. Other research into the relationship between experientialism, materialism, and happiness has begun to emerge in psychology; however much theoretical work remains to be done on the types of people who value the experiential, the sociocultural impact of their valuation of the experiential, and the interrelationship between materialism and experientialism.

This session drew noted scholars together to explore the role that consumption experiences should play in our theoretical and empirical conceptualizations of materialism. Through retrospective examinations of research on experiences and revisiting the materialism scale with an eye towards experiences, a rich dialog surrounding this important and underdeveloped component of consumption emerged. The presentations were provocative rather than definitive reports in order to facilitate discourse on the topic during the third part of the session and throughout the conference.

The goals of the session were to increase thoughtful, scholarly investigation into the role of experiences in contemporary consumer culture, to further dimensionalize the materialism construct, and to begin the development of an organizing framework for the concepts presented. Each paper drew on the considerable expertise of the presenter(s), bringing together social psychologists, anthropologists, and sociologists to deeply reflect on how materialism and experientialism are similar and different, and the implications of experientialism for well-being.

In the first presentation, Marsha L. Richins discussed and reflected on the underlying data that led to the creation of her materialism scale (Richins and Dawson 1992). She began by explaining the creation of the object-centered materialism scale. In this presentation, for the first time she reflected on the original exclusion from the scale of experientially-oriented items. She further discussed the role that consumption of experiences might play in the materialism construct. As the developer of the most-widely used materialism scale and an expert on the materialism construct, Professor Richins' insights and reflections helped to provide a common base of understanding for discussion amongst session participants and attendants.

In the second presentation, Michelle F. Weinberger examined the centrality of material and experiential consumption in contemporary society, and identified cultural values undergirding this valuation. Weinberger's background in cultural sociology and her current research on consumption experiences provided another disciplinary perspective on the topic. Using data from depth interviews and ethnographic participant-observation, she discussed the role that experiences play for consumers of different social classes, and suggested that across status groups, consumers strategically collect experiences and objects in different ways to display cultural capital (Bourdieu 1984; Holt 1998). This perspective raises questions about differences between materialism and experientialism as currently conceived, and suggests new dimensions for evaluating the conceptual relationships among materialism, experientialism, social class, and well-being.

Finally, Eric J. Arnould and Linda L. Price put forward a new approach to considering materialism and experience. Professor Arnould's anthropological perspective and Professor Price's social psychology background as well as their research on extraordinary experiences provide substantial expertise for the session. Through examining the concept of well-being and consumers' use of marketplace resources for its creation, they presented a three dimensional matrix as an organizing framework for thinking about the interrelationships between well-being, materiality, and culture.

Taken together, the presentations provided a solid conceptual platform for discussion on the interrelationship between the experiential and the material and the implications of experiential acquisition for materialism research. During this last part of the session, the discussion was led by Professor Melanie Wallendorf whose own research into materialism (Wang and Wallendorf 2006) and consumption experiences (Belk, Wallendorf, and Sherry 1989; Wallendorf and Arnould 1991) uniquely suited her for this role. Rather than just discussing the papers, she facilitated a discussion and brainstorming session between participants and the audience on the belief that material possessions or experiences are essential in producing happiness.

## EXTENDED ABSTRACTS

### "The Nature of Materialism"

*Marsha L. Richins, University of Missouri*

This special session was intended to provide a dialog between scholars with interests in experientialism and those studying materialism. This portion of the session was intended to provide a selective overview of the construct and measurement of materialism, with a particular emphasis on those aspects most relevant to experientialism.

The presentation began with an overview of the nature of materialism as it has been studied in recent years in the field of consumer behavior and related social sciences. Materialism research in consumer behavior began with the pioneering work of Russ Belk, who carried out an extensive program of inquiry into the nature of materialism (e.g. Belk 1985; Ger and Belk 1996). His conceptualization of materialism treated it as a personality trait characterized by envy, nongenerosity, and possessiveness.

Building on Belk's (1985) work, Richins developed a slightly different characterization of materialism based in a person's values rather than one's personality. Her work in material values included the development of the Material Values Scale (Richins and Dawson 1992), which is widely used to measure materialism in consumer behavior and other fields. After briefly reviewing the early work on materialism in consumer behavior, this presentation explored in more detail the development of the Material Values Scale. Particular attention was paid to the reasoning and the qualitative research that informed the definition of materialism advanced by Richins and Dawson (1992) and the decision to exclude experiences from both the construct definition and the measurement scale.

The second part of this presentation explored the relationship between experience and materialism by examining the role of consumer goals or motivations. A central element of materialism is the belief that the acquisition of possessions is essential to life satisfaction and well-being; thus, the desire for happiness is the ultimate motivator for much acquisitive or otherwise materialistic behavior. Empirical evidence, however, consistently shows that materialists' beliefs in a causal linkage between acquisition and well-being are unfounded; a number of studies have shown that increases in income or the acquisition of desired objects rarely improves personal happiness for more than a brief period (e.g. Frederick and Loewenstein 1999). This portion of the presentation will highlight some of the current thinking about how specific motivations may influence the causal connection (or lack thereof) between materialism and well-being (e.g. Carver and Baird 1998; e.g. Srivastava, Locke, and Bartol 2001). It also explored the implications of these findings for experientialism and for possible relationships between experience and well-being.

### "Experiential and Material Consumption: A Cultural Perspective on Materialism Experientailism"
*Michelle F. Weinberger, University of Arizona*

The concept of materialism has fascinated scholars for hundreds of years, as possessions and objects have grown to occupy a focal position in both the process of social stratification and in the ideological conventions of developed nations (Belk 1985). Over the past twenty-five years, consumer research literature has paid significant attention to understanding both what materialism is (Belk 1985; Richins and Dawson 1992) and how a focus on objects influences individuals' lives and society as a whole (c.f. Belk 1985; Sirgy 1998). The term *materialism* has become negatively valenced and meaning laden as anti-materialism scholars have blamed an object orientation for feeding the capitalist system (Smelser 1973) to promoting spiritual vacancy.

The literature frequently conjures up the work of Sartre (1956) and Fromm (1976), by describing a moral ranking where the concepts of *having*, *doing*, and *being* are an ordered hierarchy (Belk 1985; Sirgy 1998; Van Boven 2005). These works describe *having* as the parent of materialism with its focus on accumulation, while *doing* is thought of as connected to experiences and lifestyle and is therefore deemed morally superior. The *doing* component includes consumption experiences that are less durable and less object-centric, such as dining out, traveling, and participating in activities.

While research within consumer behavior has associated materialism with *having*, research within psychology has begun to investigate experientialism, how people's valuation of *doing* rather than *having* impacts happiness and subjective well-being. In this stream, an experiential purchase involves the intention of acquiring a life experience and is contrasted with material purchases where one's intention is to acquire a material object (Smith and Lutz 1996; Van Boven 2005; Van Boven and Gilovich 2003). However, the experientialism research has not truly questioned the boundaries of

where materialism and experientialism crossover or the underlying reasons why people might value experiences and objects differently. Van Boven and Gilovich (2003) speculate that experiences make people happier because they are more open to positive reinterpretation, they are more central to one's identity, and experiences have greater social value. However, it is still unclear what about experiences makes people happier and if all experiences have the same effect.

This paper unpacks the centrality of experiences and objects in creating human happiness by conceptualizing them in terms of the economic and cultural capital that consumers gain through them. It provides a cultural explanation for the dichotomy and examines how different types of experiences and objects are mined by consumers.

Bourdieu's perspective on economic and cultural capital is employed to articulate the difference between material objects and experiences. Economic capital (expressed by converting money or assets into goods and services) can be exchanged monetarily in the market, but cultural capital (the knowledge, skills, and tastes that one tacitly develops) cannot be transferred directly (Bourdieu 1983). Certainly *what* people consume is important; but *how* they consume, the cultural capital they exhibit through their consumption, is what creates status groups and classification. Holt 's (1997) research on cultural capital finds that those with lower cultural capital value and consume with a taste for necessity, preferring items that are more practical, functional, and durable. Often, even when purchasing more expensive items, they consume widely accepted symbols of abundance, such as expensive cars and boats. On the other hand, those with high cultural capital can be more anti-materialist since material deprivation has never been as issue for them. As such, they reject an orientation towards abundance and instead exhibit a taste for the exotic, unique, and authentic. Their orientation is towards gaining a different type of cultural capital through the consumption of objects and experiences. These differences in taste mean that people with different levels of cultural capital purchase in different ways, and even when they are consuming the same things, the meanings behind their consumption is different.

Interestingly, the taste of those with lower cultural capital leads toward expenditures considered by Sartre (1956) and Van Boven (2005) as being in the realm of *having* associated with materialism. By way of contrast, the taste of those with higher cultural capital leads toward expenditures considered to be in the realm of *doing* or *being*. Such expenditures are elevated in a moral sense, exempt from the critique of materialism. Using data from depth interviews and ethnographic participant observation, this perspective raises questions about the scholarly vantage point from which a difference between materialism and experientialism is currently conceived, and suggests new dimensions for evaluating the conceptual relationships among materialism, experientialism, social class, and well-being.

### "Material, Experience, and Materiality"
*Eric J. Arnould, University of Wyoming*
*Linda L. Price, University of Arizona*

"Proper materialism…recognizes the irreducible relation of culture, which through production…creates persons in and through their materiality" (Miller 2005 p. 17). Implicit here is the idea that dividing consumption into goods-based consumption associated with materialism and a *having* orientation, and experience-based consumption associated with a *doing* orientation, may not be optimal for addressing issues of materialism and materiality in consumer research. In this presentation we consider the relationship between materialism, materiality and experience and introduce a

new conceptual model for understanding the interplay of materiality and experience.

Miller (1987) argues that society at a macro-level and consumers at an individual level are created in and through the material forms they project into the world through market mediated consumption activities. Everything from Klingon language and clothing, to river rafting adventures, to virtual financial instruments are forms humans create according to emergent strategies of action and knowledge and enacted through the dispositional order of the habitus (Miller 1987 p. 154). In turn, making, interacting with and consuming such forms produces consumers as "Klingons," Xtreme tourists, or on-line stock traders (Kozinets 2001; Zwick and Dholakia 2006a, 2006b).

Elaborating on Douglas (1992) and Vargo and Lusch (2004), market resources are fundamentally service vehicles. A critical service that both material objects and experiences provide is communication about the particular social position individuals occupy relative to the (narrative) self and socially relevant others. Thus well-being is determined by the capacity for self-creation that is enacted through the appropriation of market provided resources including goods, services and experiences (Miller 2005, p. 20). Lifestyle experiences and consumption practices that produce "authentic" selves or "authoritative" traditions (Arnould and Price 2000) may be viewed as practices of materiality, the consumption fuelled reappropriation of differentiated selves and social worlds, and not as mere vulgar materialism (Miller 1987 pp. 191-193). Moreover, objects, experiences and materialism are in a fundamentally unstable relationship; object and experiences move in an out of the focus of "materialistic" practices (Kopytoff 1986).

We posit a novel approach to materialism and experience via a 3 dimensional matrix which includes a material (object)-immaterial (experience) dimension, an elaborated-unelaborated dimension and an explicit-tactic cultural model dimension. All are envisioned as continuums without sharp boundaries and any example could move onto any space in the matrix depending on consumer action (Kopytoff 1986). The first dimension posits a conventional continuum between consumer goods and consumption experiences that is then problematized by the introduction of the other two dimensions.

The second dimension refers to the degree of imaginative consideration consumers devote to phenomena (Joy and Sherry Jr 2003; MacInnis and Price 1987). Examples include a household furnace (material) and everyday practices of frugality (immaterial), e.g., how people get the last drop of ketchup out of the bottle. Both are instances in which people tend not to provide elaborated accounts of their attitudes, feelings and experiences. The distinction between *having* and *doing* may be most persuasive in this unelaborated space where indexical and iconic meanings are not layered onto objects and experiences (Grayson and Shulman 2000). The concept of an assortment of objects or experiences whose value for happiness is available at market prices and may be highly substitutable with objects and experiences of similar value is consistent with this envisioned space. Research using the materialism construct might be adapted to examine experiences located in this unelaborated portion of the continuum.

In the elaborated space of this continuum, material objects and experiences contribute to happiness, but consumers' imaginative resources singularize and distance objects from commodity value. The heirloom table with knife marks put there by grandchildren is viewed as a source of happiness, but does not conform to conventional ideas of materialism (Curasi, Price, and Arnould 2004). The experience and immaterial value materialized in a wedding dress similarly varies from our ideas of materialism.

The third dimension refers to the nature of the cultural model in which the meaning of things and experiences are inscribed. We find informants who can tell us intricate, imaginative stories and can provide an explicit moral linked to a common set of cultural values (cultural model) associated with cherished possessions (material). River rafting (immaterial) guides provided both elaborate stories about nature, river magic and the like, and linked these stories to varied cultural models of nature and wilderness (Arnould, Price, and Tierney 1998). Many families practice elaborate Thanksgiving celebrations (immaterial) and often enact elaborate scripts and associated stories, but at the same time, rely on tacit cultural models in creating the annual feasts (e.g. we do and have the same thing as everybody else) (Wallendorf and Arnould 1991).

This matrix brings a number of issues into play. First, as suggested by the dashed arrow pyramid, consumer research has focused on some parts of the consumer-material interface, but not others. This raises questions about where and how current materialism constructs, measures, antecedents and consequences apply. Additional meaningful distinctions might center on the valuing of commodified versus singularized objects and experiences (Kopytoff 1986), on the extent to which the firm's value proposition is modified in consumer ownership and use, or other measures and constructs that capture the imaginative resources consumers layer onto objects and experiences (Arnould, Price, and Mahlshe 2005). The third dimension, tacit-explicit cultural models, has received little attention in terms of impact on materialism, experience and materiality. Nevertheless, the reflexivity of consumers in considering their possessions and experiences as against other cultural models may be central for interpreting the antecedents and consequences of materialism. This analysis could help us reconcile the consumer with a vast array of consumer objects and a low materialism score with the consumer who has few objects of value but a high score on materialism (Ger and Belk 1996).

Second, this matrix suggests we do not have theoretically elaborate models in consumer research for what drives movement along these axes. We know that expertise, memory and pleasure may drive consumers along the axis from unelaborated to elaborated, but many research questions remain. We also know that cultural contact, oppositional experiences, life transitions, unfamiliar experiences, and collision between social units (e.g., families with difference traditions) may drive consumers along the tacit to explicit cultural model axis. Researchers have argued that material surfeit drives consumers along the material immaterial axis, but this does not point to which consumers, and in which contexts, nor the plethora of possible consumption experiences consumers may adopt.

# Should Marketers Use Price Partitioning or Total Prices?

Silke Bambauer, University of Augsburg, Germany
Heribert Gierl, University of Augsburg, Germany

## ABSTRACT

Price partitioning means the division of a product's price into several components, provided that the components cannot be bought separately. Only some authors have analyzed the effects of price partitioning. They provide opposed recommendations on the question whether price partitioning is more advantageous than using total prices. In this paper we develop a theoretical background to explain the effects of price partitioning in more detail than it has been done in previous studies. Furthermore we present the results of a new empirical study according to which price partitioning leads to a less favorable product evaluation than does using total prices.

## INTRODUCTION

Some products and services are divided into several (often two) components which are charged single prices but can only be bought in combination (Bertini and Wathieu 2005; Lee and Han 2002), e.g., a fitness club membership and the joining fee. Morwitz, Greenleaf, and Johnson (1998) call this strategy partitioned pricing and they refer to the larger price component as the base price and to the smaller component as the surcharge. Surcharges are most often monetary surcharges, but in some cases the surcharge is a percentage of the base price. From a consumer research perspective it is interesting to examine how consumers react to this pricing technique.

Product or price bundles must be distinguished from partitioned prices because a consumer buying a product bundle pays one total price for several products which can also be bought as separate items. Thus, the difference between price partitioning and price bundling consists in the fact that in the case of price partitioning there is one product which is divided into several (price) components which cannot be bought separately, whereas in the case of price bundling, several products, which can be bought separately, are combined and sold for only one total price.

Some authors assume that price partitioning increases consumers' demand if applied appropriately (Chakravarti et al. 2002; Morwitz, Greenleaf, and Johnson 1998; Xia and Monroe 2004). Other authors argue that all kinds of hidden pricing are disadvantageous because consumers might avoid purchasing products with unclear prices (Ayres and Nalebuff 2003; Lee and Han 2002). Beyond the contradictious findings of a few existing studies, research in marketing has paid only little attention to effects of price partitioning on consumers' attitudes and behavior although partitioned prices are commonly used in marketing practice. Therefore, we discuss arguments in favor of and against price partitioning and explain why the existing literature offers contradictious recommendations. By analyzing additional mediating variables in the relation between price presentation and product evaluation, which have not been analyzed in previous studies, our paper provides new insights in the mechanisms which underlie price partitioning effects and thus is an important contribution to the existing consumer research. Furthermore our research enables marketers to plan their pricing strategies more carefully when choosing between using total prices and price partitioning or when deciding which type of price partitioning to apply.

## EMPIRICAL AND THEORETICAL BACKGROUND

We first sum up four previous studies on price partitioning. Then we present our theoretical research model which is supposed to explain effects of price partitioning in more detail than it has been done in the existing studies.

### Previous Research on the Effects of Price Partitioning

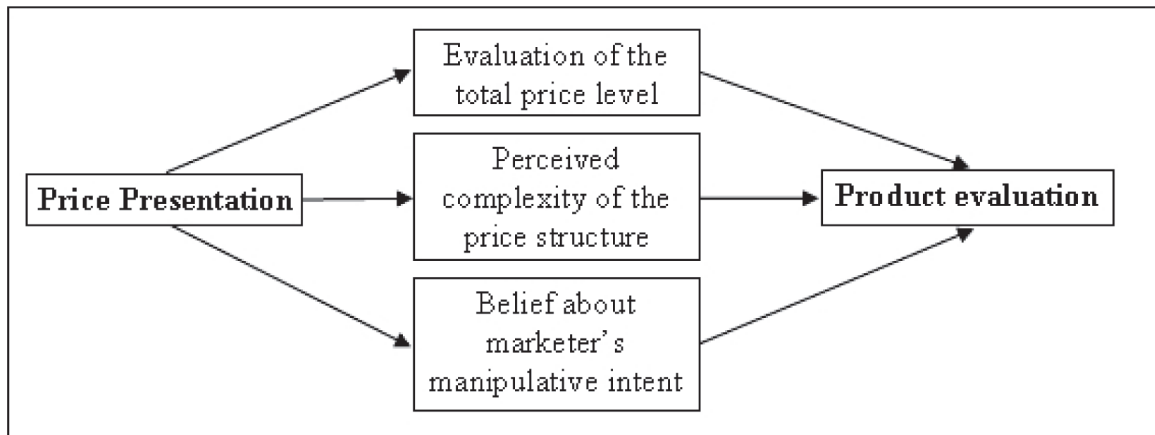
Morwitz, Greenleaf, and Johnson (1998) found that price partitioning increases consumers' demand compared to all-inclusive prices. Lee and Han (2002) report from their findings that using partitioned prices can cause negative consumer reactions, which leads to a negative change of brand attitude. Chakravarti et al. (2002) found that a product with a partitioned price for its components was evaluated more favorably and chosen more frequently than the same product with a total price. Xia and Monroe (2004) report that price partitioning has positive effects on both consumers' price satisfaction and their purchase intentions. As the authors of the cited studies came up with contradictious findings, based on these findings, it is not possible to derive a clear recommendation on whether marketers should use or avoid price partitioning. Therefore, we present theoretical approaches which can be applied to price partitioning and provide additional insights in effects of price partitioning (versus using total prices) on product evaluation, which can serve to explain the differing findings of the previous studies, and which enable us to derive clear recommendations on the appropriateness of price partitioning compared to using total prices.

### New Research Model

In order to analyze the effects of price partitioning versus using total prices on product evaluation we consider the effects of three mediating variables between price presentation and product evaluation which have been mentioned in research on price partitioning before. Consumers' evaluation of the total price level (i.e. their satisfaction with the price, their evaluation of a price as being comparatively low or high) and their perceived complexity (versus clarity) of the price structure are supposed to be relevant variables in the context of price partitioning effects (Xia and Monroe 2004). Since the marketer's intent also is often mentioned in the field of price research (Campbell 1995; Maxwell 1995), we argue that different types of price presentation also have effects on a consumer's belief about the intention the marketer pursues with using a certain pricing technique (e.g. mislead the customer by using partitioned prices) and thus include the consumers' belief about the marketer's manipulative intent in our research model. The resulting model is shown in figure 1.

Price presentation is a nominal variable with five values: total price and four types of partitioned prices. The types of price partitioning considered in this paper are combinations of surcharge amount relative to the base price (low, high) and surcharge presentation (monetary, percentage) for prices consisting of two components. We do not consider prices which consist of more than two components because over-partitioning (i.e. offering separate prices

**FIGURE 1**
EFFECTS OF PRICE PARTITIONING VERSUS USING TOTAL PRICES



for many product components) has been found to be disadvantageous (Xia and Monroe 2004). In the following sections we discuss theoretical approaches to found the relations assumed in figure 1.

**Effects of Price Presentation through Consumers' Evaluation of the Total Price Level on Product Evaluation**

Consumers' evaluation of the total price level as being comparatively low (positive evaluation) or high (negative evaluation) is supposed to have a positive effect on product evaluation. We now discuss possible effects of price partitioning versus using total prices on consumers' evaluation of the total price level. Morwitz, Greenleaf, and Johnson (1998) used the anchoring and adjustment heuristic to predict a positive effect of price partitioning on product evaluation. Applying 'anchoring and adjustment' to the processing of partitioned prices means that people are exposed to two components of a single stimulus (base price and surcharge). Their estimation task consists in calculating the total price. According to Yadav (1994) the base price is noticed first and the estimated total price is supposed to be biased toward the base price because the surcharge is insufficiently processed. Thus, if consumers use the anchoring and adjustment heuristic to process partitioned prices, they are supposed to evaluate the total price level as being comparatively low (positive evaluation) which leads to a positive overall effect on product evaluation.

'Averaging' might be another relevant strategy in the context of processing information about stimulus components. The studies of Troutman and Shanteau (1976) and Gaeth et al. (1990) show that people average bundle components so that minor components disproportionally contribute to the bundle's overall evaluation. Transferred to price partitioning the overestimation of the minor component (the surcharge) is supposed to lead to a higher estimate of the total price because both the valence of the components and the cognitive effort needed to determine the components' valence are considered. As the cognitive effort is not proportional to the price components' valence, the surcharge is ascribed a higher weight than it has in fact which results in 'averaging'. Using this processing strategy leads to an evaluation of the total price level as being comparatively high (negative evaluation) and thus to a negative overall effect on product evaluation.

Finally, the value function of the prospect theory (Tversky and Kahneman 1981) can also be used to explain the processing of stimulus components. Johnson, Herrmann, and Bauer (1999) report that total prices are more advantageous than partitioned prices because, based on the prospect theory argument, two single losses

subjectively weigh more heavily than one total loss which objectively corresponds to the sum of the single losses. Thus, based on this argument, consumers are supposed to evaluate the total price level of a partitioned priced product as being comparatively high (negative evaluation) which also leads to a negative overall effect on product evaluation.

Considering the three fields of research presented above which can be applied to gain further insights in possible mechanisms underlying the effects of price partitioning on product evaluation, we have conflicting assumptions on possible effects of price partitioning compared to using total prices because one theoretical approach suggests that partitioned prices are more beneficial than total prices whereas according to the other two approaches partitioned prices should not be used. The extent of difficulties in processing partitioned prices consumers perceive might explain why consumers unconsciously choose one of the three strategies to process price information and to evaluate the total price level (Morwitz, Greenleaf, and Johnson 1998). We assume that consumers use the anchoring and adjustment heuristic to process partitioned prices if they have considerable difficulties in processing the price components (i.e. in the case of a percentage surcharge). In this case they disregard the surcharge or only process it insufficiently which leads to the calculation of a low total price and thus to the evaluation of the total price level as being comparatively low (positive evaluation). However, if consumers do not perceive major difficulties in processing the surcharge (i.e. in the case of a monetary surcharge), they might try to process both components more accurately on the basis of 'averaging' or by applying the value function which results in the calculation of a comparatively high total price und thus in the evaluation of the total price level as being comparatively high (negative evaluation). These considerations lead to:

H1a: When using a percentage surcharge, price partitioning leads to a more favorable evaluation of the total price level than does using total prices.

H1b: When using a monetary surcharge, price partitioning leads to a less favorable evaluation of the total price level than does using total prices.

In order to explain effects of different surcharge amounts relative to the base price we cannot use the 'difficulty argument' because 'processing difficulty' is defined by the type of mathematical operation (addition versus multiplication) needed to execute

(Morwitz, Greenleaf, and Johnson 1998). Such effects can rather be explained by a cost-benefit approach. In the case of a low surcharge, the benefit of knowing the exact total price is low. Thus consumers might not be interested in processing the surcharge (Xia and Monroe 2004) and they might evaluate the total price level as being comparatively low. If the surcharge is high, consumers might judge the benefit of knowing the total price higher than the mental costs of processing the two price components (Xia and Monroe 2004) and consequently, they might calculate the total product price and thus evaluate the total price level as being comparatively high. Based on these considerations we derive:

H2: When using price partitioning, a low surcharge leads to a more positive evaluation of the total price level than a high surcharge (provided that the objective total price is the same in both cases).

With regard to the effect of the evaluation of the price level on product evaluation we assume:

H3: The more positive consumers' evaluation of the price level, the more positive is their product evaluation.

**Effects of Price Presentation through 'Perceived Complexity of the Price Structure' and 'Belief about Marketer's Manipulative Intent' on Product Evaluation**

The construct 'perceived complexity of the price structure' mirrors the fact the consumers perceive prices as being more or less transparent. As consumers expect marketers to use transparent prices, they might be dissatisfied when the price structure is more complex (less transparent) than they have expected (Lee/Han 2002). Presumably the price structure of a partitioned price is more complex than the one of a total price because in the first case there are at least two components which have to be processed. The dissatisfaction resulting from the unexpectedly high complexity will be transferred to the product and thus lead to a negative attitude toward the product. This argument might especially hold in the case of percentage surcharges (compared to monetary surcharges) because they make partitioned prices even less transparent. These considerations lead to:

H4: Generally, partitioned prices are perceived as being more complex than total prices. Consumers evaluate partitioned prices consisting of a base price and a percentage surcharge as being even more complex than prices consisting of a base price and a monetary surcharge.

With regard to the effect of perceived complexity of the price structure on product evaluation we assume:

H5: The more consumers perceive the price structure as being complex, the more negative is their product evaluation.

Moreover, consumers are supposed to think about the reasons a marketer has for applying partitioned prices instead of total prices (e.g., masking an excessive price). When faced with partitioned prices consumers are believed to ascribe a higher manipulative intent to the marketer than when faced with total prices because they might assume that the marketer tries to mislead them by using several price components. This assumption leads to a comparatively unfavorable evaluation of the product. This argument rather applies to percentage surcharges than to monetary surcharges because many consumers might neither be able nor willing to calculate the correct total price in the case of a percentage surcharge

and they might have the impression that the marketer tries to mislead his customers even more by using a percentage surcharge (Morwitz, Greenleaf, and Johnson 1998). Based on this argument we derive:

H6: Generally, in the case of partitioned prices, consumers feel more being manipulated than in the case of total prices. In the case of a percentage surcharge, consumers even ascribe a higher manipulative intent to the marketer than in the case of a monetary surcharge.

With regard to the effect of consumers' belief about the marketer's manipulative intent on product evaluation we assume:

H7: The more consumers feel being manipulated by the marketer, the more negative is their product evaluation.

Summarizing the theoretical considerations presented above, the effects of price partitioning compared to using total prices on product evaluation are supposed to be rather negative because the negative effects seem to outweigh the positive effects. The above derived hypotheses on the effects of price partitioning versus using total prices are tested in a new empirical study which is presented in the next section.

## NEW EMPIRICAL STUDY

**Experimental Design and Measures**

In our empirical study we used partitioned prices which consisted of two components and total prices. We chose test stimuli which were familiar to the respondents and which were regularly bought by them. Furthermore, the examples were chosen in compliance with the condition that both total and partitioned prices were realistic for these products or services. The authors of the previous studies on effects of price partitioning used surcharges ranging from 6 per cent to 43 per cent. Based on this specification we chose 5 and 40 per cent as low and high surcharges. We kept the total product prices approximately the same across conditions (i.e. line by line, the total prices are about the same, see table 1).

We created short scenarios containing product and price information to put the respondents in purchase situations which were as realistic as possible. The scenarios we used for the total price condition are shown in table 2 in a shortened version. All scenarios started with the words "Imagine, you would like to buy/ get …". The scenarios for the partitioned price conditions were the same but with single prices for the two components as listed in table 1.

The measures for the model variables and the correlations (for two items) as well as the Cronbach Alpha values (for three and more items) are shown in table 3.

In order to determine if the single items can be aggregated to the respective construct, we calculated Cronbach's Alpha if three or more items were used to measure one construct and bivariate correlations if two items were applied to measure a certain construct because Cronbach's Alpha is not appropriate for two item scales (Hulin and Cudeck 2001). The high correlation and Alpha values show that the construct values can be calculated as arithmetical means of the single indicators for each construct. These arithmetical means will be used in the analyses presented subsequently. In order to prove that the constructs can be clearly separated from each other, the correlations between the constructs are summarized in table 4.

The correlations between the constructs are moderate indicating that the constructs can be clearly separated from each other.

**TABLE 1**
EXPERIMENTAL DESIGN

| Product | Total product Price | Low surcharge (5 per cent) | | High surcharge (40 per cent) | |
|---|---|---|---|---|---|
| | | Monetary surcharge | Percentage surcharge | Monetary surcharge | Percentage surcharge |
| Mobile phone contract basic fee + price for minimum of call units (monthly) | € 20.00 | € 19.00 + € 1.005 | € 19.00 + 5% | € 14.30 + € 5.70 | € 14.30 + 40% |
| Sauna entrance + water park ticket | € 18.00 | € 17.20 + € 0.80 | € 17.20 + 5% | € 12.90 + € 5.10 | € 12.90 + 40% |
| Concert ticket + advance sale charge | € 50.00 | € 47.60 + € 2.40 | € 47.60 + 5% | € 35.70 + € 14.30 | € 35.70 + 40% |
| Hotel + visitors' tax | € 80.00 | € 76.20 + € 3.80 | € 76.20 + 5% | € 57.20 + € 22.80 | € 57.20 + 40% |
| Oil change service + car oil | € 150.00 | € 142.80 + € 7.20 | € 142.80 + 5% | € 107.10 + € 42.90 | € 107.10 + 40% |

**TABLE 2**
SCENARIOS

| Mobile phone Contract | Sauna entrance plus water park ticket | Concert ticket plus advance sale charge | Hotel plus visitors' tax | Oil change plus car oil |
|---|---|---|---|---|
| Buying a two-year mobile phone contract, monthly basic fee including a monthly minimum of required call units: € 20. | Using only the sauna area of a water park, but not the pools, pools are not separated from the sauna area, have to pay for both the pool and the sauna entrance, total price for 2 hours: € 18. | Visiting a concert, want to buy a ticket in advanced sale, ticket price including advance sale charge: € 50. | Planning a stay at a three-star hotel in Spain, bed and breakfast price per night including visitors' tax: € 80. | Car oil change, total price for oil change service including high-quality oil: € 150. |

**Procedure and Results**

175 respondents (86 men, 89 women) participated in our study in 2004 in Germany (35 participants per experimental group). Each participant evaluated all five test stimuli in the same manipulation condition, for example all five products with a partitioned price consisting of a base price and a low monetary surcharge. Using five examples per person served as a sample multiplier. The respondents read the first scenario, evaluated the first product, and indicated their evaluation of the total price level, of the complexity of the price structure and their belief about the marketer's manipulative intent (statements on 7-point scales). They then read the second scenario, completed the corresponding scales and so on. Finally, correspondents provided their involvement in the product categories which was needed to judge the comparability of the product categories, their age and gender. The order of the scenarios varied from person to person to control for order effects.

The five experimental groups were structurally equal with regard to age ($F=1.606$, $p>.10$) and gender (chi square=3.887, $p>.40$). In order to analyze the effects of price presentation on the mediator variables and on the target variable 'product evaluation', we used univariate models with 'price presentation' as independent variable and 'evaluation of the total price level', 'perceived complexity of the price structure', and 'belief about marketer's manipulative intent' as dependent variables in a first step. In a second step we applied a regression analysis to analyze the effects of the mediator variables on product evaluation. In a last step we conducted tests of mediation to prove that the assumed mediators indeed mediate the relation between 'price presentation' and 'product evaluation'. Using structural equation models instead of the three steps of analyses chosen here would have had the advantage that all effects could have been tested simultaneously. However, using structural equation models is not possible in the constellation

**TABLE 3**
MEASURES

| Model variable | Statement | Alpha/ Correlation |
|---|---|---|
| Evaluation of the total price level (P) | In general, this product is well-priced<br>Compared with similar products' prices, this price is well-priced.<br>This price is attractive. | .954 |
| Perceived complexity of price structure (C) | The presentation of the price is unclear.<br>I cannot notice this price at a glance. | .619 |
| Belief about marketer's manipulative intent (M) | My friends would judge this price as being an unfair price.<br>This supplier demands an unfair price. | .481 |
| Product evaluation (E) | This offer appeals to me.<br>This offer is attractive.<br>This offer is convincing.<br>This offer is worth the money. | .956 |
| Product category involvement (I) | Before buying … I gather a lot of product information.<br>When buying … I choose it very carefully. | .698 |

**TABLE 4**
CORRELATIONS

| Model variable | P | C | M | I |
|---|---|---|---|---|
| Evaluation of the total price level (P) | | | | .013 |
| Perceived complexity of the price structure (C) | -.347 | | | .123 |
| Belief about marketer's manipulative intent (M) | -.427 | .714 | | .077 |
| Product evaluation (E) | .741 | -.395 | -.635 | .111 |

considered here, because these models which are based on correlations or covariances require metric input data and the independent variable 'price presentation' (total price, four forms of price partitioning) is only nominal.

We now present the univariate analyses conducted in the first step. As the respondents proved to have different levels of involvement for the single product categories which had been intended to be used for sample multiplication, we integrated involvement as a metric covariate in the models to control for the involvement effect. The mean values and further results based on the pooled sample (across the five products) are shown in table 5.

The mean values show that consumers evaluate the total price level as being lower (favorable evaluation), but the complexity of the price structure and the marketer's manipulative intent as being higher when price partitioning is applied instead of using total prices. The overall effect of price partitioning compared to using total prices on product evaluation is negative because the mean value of product evaluation is highest in the case of a total price and is lower in all conditions of price partitioning considered here. In order to test the hypotheses H1, H2, H4, and H6 we applied $t$ statistics and we additionally report the results of Scheffé tests ($p_S$) to show that these are in line with the $t$ statistics ($p_t$).

We now look closer at the effects of price partitioning versus using total prices on the evaluation of the total price level. Using partitioned prices with percentage surcharges leads to a signifi-

cantly more positive evaluation of the price level than using total prices (low surcharge: 4.67-3.47: $t=6.53$, $p_t<.001$, $p_S<.001$; high surcharge: 4.38-3.47: $t=5.84$, $p_t<.001$, $p_S<.001$). Thus H1a is supported. However, H1b is not supported because contrarily to the assumption of H1b, the evaluation of the price level is more positive when using partitioned prices with monetary surcharges than when using total prices.

With regard to H2 the mean values of the evaluation of the total price level show that at least descriptively low surcharges lead to a more favorable evaluation of the total price level than do high surcharges. The difference of the mean values is highly significant for the case of monetary surcharges, but only significant at the .10 level for the case of percentage surcharges (monetary surcharge: 4.41-3.59: $t=5.26$, $p_t<.001$, $p_S<.001$; percentage surcharge: 4.67-4.38: $t=1.47$, $p_t<.10$, $p_S<.10$). Thus, H2 is widely supported.

The basic assumption of H4 was that partitioned prices are perceived as being more complex than total prices. This assumption is at least descriptively supported by the mean values and the pairwise differences are significant in three of four cases (3.51-2.97: $t=3.96$, $p_t<.001$, $p_S<.001$; 2.99-2.97: $t=.13$, $p_t>.10$, $p_S>.10$; 3.77-2.97: $t=4.96$, $p_t<.001$, $p_S<.01$; 5.11-2.97: $t=11.65$, $p_t<.001$, $p_S<.001$). The second part of H4 consisted in the assumption that, if only considering partitioned prices, consumers evaluate partitioned prices with a percentage surcharge as being even more complex than partitioned prices with a monetary surcharge. The

[1]: 1=very unfavorable evaluation, …, 7=very favorable evaluation
[2]: 1=low complexity, …, 7=high complexity
[3]: 1=low manipulative intent, …, 7=high manipulative intent

**TABLE 6**
RESULTS OF THE SOBEL TESTS OF MEDIATION

| Test of mediation for the dummy variable | Evaluation of the price level | Perceived complexity of the price structure | Belief about marketer's manipulative intent |
|---|---|---|---|
| total price | $z=5.24$, $p<.001$ | ($z=.69$, $p>.10$) | ($z=.05$, $p>.10$) |
| low monetary surcharge | $z=20.03$, $p<.001$ | ($z=.14$, $p>.10$) | $z=4.91$, $p<.001$ |
| high monetary surcharge | $z=4.28$, $p<.001$ | $z=7.70$, $p<.001$ | ($z=.90$, $p>.10$) |
| low percentage surcharge | $z=4.68$, $p<.001$ | $z=9.88$, $p<.001$ | $z=1.35$, $p<.10$ |
| high percentage surcharge | $z=18.75$, $p<.001$ | $z=10.66$, $p<.001$ | $z=10.99$, $p<.001$ |

mean values show that descriptively, percentage surcharges lead to the perception of a higher price structure complexity than do monetary surcharges, but the difference is only highly significant in the case of a high surcharge amount (low surcharge: 3.77-3.51: $t=1.45, p_t<.10, p_S<.10$; high surcharge: 5.11-2.99: $t=11.54, p_t<.001, p_S<.001$). Thus, taken together, H4 is widely supported.

The basic assumption of H6 again was that being confronted with partitioned prices, consumers generally feel more being manipulated than when being confronted with total prices. This first part of H6 is descriptively supported by the mean values and the pairwise differences are significant in three of four cases (3.05-3.03: $t=.14, p_t>.10, p_S>.10$; 3.39-3.03: $t=2.58, p_t<.01, p_S<.01$; 3.60-3.03: $t=3.58, p_t<.001, p_S<.001$; 4.50-3.03: $t=8.41, p_t<.001, p_S<.001$). With regard to the second part of H6 the mean values of the belief about the marketer's manipulative intent show that percentage surcharges lead to a higher perceived manipulative intent than do monetary surcharges (low surcharge: 3.60-3.05: $t=3.49$, $p_t<.05$, $p_S<.05$; high surcharge: 4.50-3.39: $t=6.35, p_t<.001, p_S<.001$). Thus, H6 is widely supported.

We now present the second step of our analyses which consisted in proving that all three mediator variables have significant effects on product evaluation. The results of a regression analysis ($R^2=.86$) show that the evaluation of price level has a strong and significantly positive effect on product evaluation ($\beta=.36$, $t=8.26$,

$p<.001$). Thus, consumers show a more positive evaluation of the product with an increasing positive evaluation of the price level and therefore, H3 is supported. Perceived complexity of the price structure has a significantly negative effect on product evaluation as assumed in H5 ($\beta=-.22$, $t=-6.27$, $p<.001$) which means that the more consumers perceive the price structure as being complex, the more negative is their product evaluation. The belief about the marketer's manipulative intent also influences product evaluation significantly negatively ($\beta=-.34, t=-8.31, p<.001$) which means that the more consumers feel being manipulated by the marketer, the more negative is their product evaluation supporting H7.

Finally we show that the variables which were assumed to be mediator variables are indeed mediator variables by conducting separate tests of mediation for each mediator variable following the recommendations of Baron and Kenny (1986). As regression analyses need to be conducted to test the mediating effects of the considered variables, the independent variable 'price presentation' (five nominal values: total price, low/high monetary/percentage surcharge) has to be transformed into five dummy variables to be appropriate for the regression analysis. Having five independent variables we consequently have to conduct five tests of mediation for each mediator variable. Using the Sobel test (Sobel 1982) leads to the results summarized in table 6.

Most of the tests lead to significant results indicating that the chosen variables indeed mediate the relation between price presentation and product evaluation.

Summarizing the findings of all conducted analyses, the results show that price partitioning has effects on product evaluation through different paths. The path through the evaluation of the price level has a positive sign, whereas the other two paths through perceived complexity of the price structure and belief about the marketer's manipulative intent have negative signs. The negative signs of the latter paths seem to outweigh the positive sign of the first path.

## CONCLUSION

The starting point of our investigation has been the fact that the authors of existing studies on effects of price partitioning came up with contradictious findings. Our study was intended to have a closer look at the mechanisms which underlie price partitioning effects. The results of our study show that price partitioning leads to a more favorable evaluation of the total price level, but to a higher perceived complexity of the price structure and to a higher perceived manipulative intent of the marketer than does using total prices. The overall effect of price partitioning on product evaluation proved to be negative compared to using total prices which is due to the fact that the negative effects of price partitioning through perceived complexity of the price structure and manipulative intent outweigh the positive effect through the evaluation of the total price level. The contradictious findings of previous studies might be traced back to the fact that the authors did not analyze all of these paths. Thus, summing up our results, we can say that marketers should not use partitioned prices because the disadvantages of this pricing technique outweigh the advantages. Provided that a marketer has to use partitioned prices for some reason (e.g. because partitioned prices are common or regulated by law in his industry), we can derive from our findings that monetary surcharges should be preferred over percentage surcharges because when applying monetary surcharges, prices are perceived as being less complex and the marketer is supposed to have a lower manipulative intent than in the case of percentage surcharges.

As starting points for further studies we suggest analyzing price partitioning effects in field experiments in retail stores because up to now, such effects have only been analyzed in simulated experiments. Using field experiments one could especially analyze how consumers decide between two comparable products with one product having a total price and the other product having a partitioned price. Moreover, it might be interesting to examine price partitioning effects for very low or very high priced products because the products considered in the study here are medium-priced. Furthermore, it might be helpful for practitioners to know whether there are special conditions under which using price partitioning might be beneficial, e.g., when a third party is responsible for one of the single price components.

# The Influence of Culture on Responses to the Globe Dimension of Performance Orientation in Advertising Messages – Results from the U.S., Germany, France, Spain, and Thailand

Sandra Diehl, Klagenfurt University, Austria
Ralf Terlutter, Klagenfurt University, Austria
Barbara Mueller, San Diego State University, USA

## INTRODUCTION

In many societies, individuals place a high level of importance upon performing well, for instance, in the workplace, in sports and in the marketplace. For both researchers and practitioners in the area of international advertising, it is of interest to know whether fashioning ads that incorporate performance-oriented appeals is likely to result in more favorable responses to such ads and whether local culture influences the perception and evaluation of these appeals.

The current paper proposes a conceptual model, which attempts to explain the impact of the cultural dimension of performance orientation on the perception and evaluation of a standardized advertisement. Little is known regarding factors which influence the success of standardized international campaigns (Zinkhan, 1994; Taylor, 2005) and research examining how standardized international campaigns are perceived and evaluated in different countries has been limited (for instance, Hudson, Hung, and Padley, 2002; Callow and Schiffman, 2004). The basic concept behind the model presented here is that a given standardized advertising stimulus is likely to be perceived and evaluated differently in various cultures, dependent upon the level of importance individuals place on performance orientation (individual level performance orientation) as well as the level of performance orientation in the environment surrounding that individual (societal level performance orientation). Hence, the model explicitly differentiates between cultural dimensions on an individual level versus cultural dimensions on a societal level.

By proposing a culturally-based conceptual model that explains the perception and evaluation of international advertising, the manuscript contributes to the development of a more general theory of culture's impact on advertising, which was identified as a key area for future research in international advertising (Taylor, 2005).

## THE CULTURAL DIMENSION OF PERFORMANCE ORIENTATION ACCORDING TO THE GLOBE FRAMEWORK

The conceptualisation of performance orientation in this investigation is based on a framework entitled GLOBE (Global Leadership and Organizational Behavior Effectiveness Research Program), which identified performance orientation as one of nine cultural dimensions capable of describing cultural variation among a large number of countries (House et al., 2004). As the GLOBE project provides data on societal performance orientation for a wide scope of nations–among them all major markets in terms of total global advertising expenditures–both academics and practitioners have access to a priori information on this cultural dimension. Terlutter, Mueller, and Diehl (2005) have applied GLOBE's cultural dimension of assertiveness to international advertising (see also Terlutter, Diehl, and Mueller, 2006).

GLOBE researcher Javidan (2004, 239) defines performance orientation as "the extent to which a community encourages and rewards innovation, high standards, and performance improvement." Performance orientation, as outlined by GLOBE researchers, has its roots in McClelland's (1961) concept of need for achievement, which is defined as the need to continually do better (McClelland, 1987). According to McClelland (1987), individuals with a high need for achievement tend to obtain pleasure from steady improvement. They prefer to work on tasks with moderate probabilities of success as these represent a challenge. Such individuals take personal responsibility for their actions and search out information on how to do things better. Performance orientation in the GLOBE study has also similarities to Schwartz and Bilsky's (1987) concept of achievement. They define achievement as "personal success through demonstrated competence" (p. 880).

GLOBE provides data on the societal level and explicitly differentiates between societal values and societal practices. The distinction between cultural values and cultural practices was incorporated to correspond with Schein's (2004) concepts of artifacts vs. espoused values as two unique levels of culture (House and Hanges, 2004). Artifacts are the visible products, processes and behaviors of a culture. They mainly reflect the "as is" and, therefore, the cultural practices. Espoused values are the individuals' or society's sense of what ought to be, as distinct from, what is. They primarily reflect the "should be" and, therefore, the cultural values.

Cross-cultural research has emphasized the importance of distinguishing between the influence of culture on an individual level, versus on a national or societal level (e.g., Schwartz, 1994; Triandis, 1995; Singelis and Brown, 1995; Malhotra, Agarwal, and Peterson, 1996; Kacen and Lee, 2002). As individuals are socialized through values that are held and behaviors that are practiced within their cultures, it is very likely that they adopt values and practices that are shared among members of their society (Markus and Kitayama, 1991). With regard to societal and individual performance orientation, culture-level data and individual level data on performance orientation can be expected to have similar, but not necessarily identical patterns. While GLOBE provides data on the societal level, i.e. culture-level, it does not do so on the individual level. This investigation collects data on performance orientation at the societal as well as the individual level.

## DEVELOPMENT OF THE CONCEPTUAL MODEL

Performance orientation is seen as desirable among members of many societies. Countries exhibiting high levels of performance orientation achieve–though typically within several decades time–an above average increase in economic wealth (McClelland, 1967). On an individual level, according to Schwartz and Bilsky (1987), performance orientation generally results in increased social acceptance and the admiration of others. Performance orientation also leads to increased status (Trompenaars, 1993). Hence, performance orientation is often viewed as something desirable at both the societal as well as the individual level. With regard to advertising, employing performance-oriented appeals may therefore be an effective means of enhancing the success of a commercial. It is thus expected that the level of perceived performance orientation in an advertisement leads to a more positive evaluation of the ad.

> *H1a: Perception of a higher level of performance orientation in an advertisement leads to a more positive evaluation of that advertisement.*

The relationship between the level of perceived performance orientation in an advertisement and the evaluation of the advertisement is expected to be positive in all countries, but its strength may vary depending on the importance that individuals in each country place upon performance orientation. If performance orientation is perceived as an important value by individuals of a given country, then the level of perceived performance orientation in an advertisement will have a stronger influence on the evaluation of the advertisement. The greater the importance of performance orientation, the more central it becomes in the individual's evaluation of an advertisement. On the other hand, if performance orientation is perceived as less important by individuals in a particular country, then the level of perceived performance orientation will likely play a less significant role in the judgment of that advertisement. Therefore, it is expected that in those nations in which individuals place greater importance on performance orientation, influence of the level of perceived performance orientation in an advertisement on the evaluation of that advertisement will be stronger, compared with those nations in which individuals place less importance on performance orientation. Hence, we hypothesize:

> *H1b: The influence of the level of perceived performance orientation in an advertisement on the evaluation of that advertisement will be stronger in those nations in which individuals place greater importance on performance orientation, compared with those nations in which individuals place less importance on performance orientation.*

One might expect that the country ranking highest in terms of performance orientation would most positively evaluate ads incorporating performance-oriented appeals. However, individuals' perceptions and evaluations of commercial messages are also based on the individual's frame of reference. Helson's (1948) adaptation-level theory and Parducci's (1965) range-frequency theory postulate that, based on previously encountered stimuli and the stimuli of a particular situation, the individual has a given adaptation-level, which serves as a comparison standard for subsequent perception and evaluation of stimuli.

In terms of advertising, both, adaptation-level theory as well as range-frequency theory suggest that the perception of performance orientation in commercial communications may be dependent upon the level of performance orientation surrounding the individual, which serves as a comparison standard for the perception of performance orientation in a given commercial. If the cultural environment, i.e. the society to which an individual belongs, is highly performance-oriented and places great importance on success, this level of performance is likely to serve as a frame of reference. This suggests that, in a culture with a high comparison standard regarding performance orientation, an ad designed to incorporate a performance-oriented appeal may be perceived as only mildly performance-oriented in nature. Conversely, in a cultural environment that is less performance-oriented, where individuals have a lower reference value regarding performance orientation, the very same ad may be viewed as highly performance-oriented in nature. In other words, a consumer socialized in a performance-oriented environment might perceive a given advertisement as significantly less performance-oriented than a consumer socialized in a relatively less performance-oriented environment would evaluate that very same ad.

It is expected that, given a standardized advertisement designed to incorporate a performance-oriented appeal, individuals in highly performance-oriented cultures will perceive a lower level of performance orientation in that advertisement than individuals in less performance-oriented cultures.

> *H2: Subjects from nations with lower performance orientation scores will perceive higher levels of performance orientation in a standardized advertisement incorporating a performance oriented appeal, compared with subjects from nations with higher performance orientation scores.*

Figure 1 displays the proposed conceptual framework of the analyses.

## RESEARCH DESIGN AND METHODS

To test the above stated hypotheses, a non-student survey was conducted in five countries, the U.S., Germany, France, Spain and Thailand. In-person interviews were conducted in each country. A full-page advertisement for a wrist-watch was developed. The ad portrayed a team on a sail boat, successfully manoeuvring through strong swells, thereby demonstrating performance-oriented behavior. In addition, the slogan in the ad read "Every performance counts." The ad was for a fictional brand of wrist-watches ("Schwartz"), in order to control for attitudes toward established or recognized brand names. The advertisement was designed in black/white to negate the influence of color preferences. The slogan was translated into the local language in the survey instruments for Germany, France, Spain and Thailand. Prior to conducting the investigation, this advertisement underwent a pre-test to ensure that it was indeed perceived as portraying performance-oriented behavior. Figure 2 shows the English version of the advertisement. The current analysis is based on 698 subjects from the five countries (US 180, Germany 142, France 100, Spain 100, and Thailand 176). Participants were between 18 and 74 years of age, with an average age of 32.9 years. The male/female ratio of participants was 50:50. A structured questionnaire was developed. Respondents either filled out the questionnaire independently or, it was administered by trained interviewers. To ensure comparable interviewing situations in all countries, all interviewers received extensive training and were provided with standardized text to employ in approaching subjects. The majority of respondents completed the questionnaire independently, minimizing interviewer influence. Interviewers explained to subjects that the investigation dealt with consumer responses to advertising. Subjects were informed that participation was completely voluntary and that all responses would remain anonymous. A translation/back-translation procedure was applied in the development of the questionnaires. Bi-lingual speakers translated the questionnaires and different bi-lingual speakers back-translated the questionnaires.

### Variables

*Perceived level of performance orientation in the ad* was measured via four items. The items were derived from descriptions of performance-oriented behavior found in the literature (McClelland, 1967; Trompenaars, 1993; Javidan, 2004). Subjects were first asked to assess the individuals portrayed in the ad. The questions read: "The persons in the advertisement seem to me …" (1) "performance-oriented", (2) "concerned only with performance", (3) "success-oriented" and (4) "as if success were the most important thing in life" (7-point-scale, 7=high). A one-factor model for the performance orientation measure was used. The four items were factor analyzed using confirmatory factor analysis and results indicate a high fit of the model. Alpha values (Cronbach, 1951) in the five countries were between .832 and .889. Given the high

internal consistency of the scale, based on the four items, mean values of the perceived level of performance orientation were computed for each country. Following the testing procedure proposed by Steenkamp and Baumgartner (1998), measurement invariance across the five countries regarding the perception of performance orientation in the ad is supported (full or partial configural, metric, scalar and factor-variance invariance). Meaningful comparisons of group means and of association measures can thus be carried out.

*Evaluation of the ad* was also measured via four items, adapted from MacKenzie and Lutz (1989). The questions read: (1) "Overall, I find the ad …" "not at all good" (=1) to "very good" (=7) (7-point-scale); "The ad is …" (2) "interesting", (3) "likeable" and (4) "pleasant" (7-point-scale, 7=high). Again, the items were analyzed using confirmatory factor analysis. Results showed a high fit of the model. Values of Cronbach's α in the five countries were between .898 and .920. Following the testing procedure proposed by Steenkamp and Baumgartner (1998), measurement invariance across the five countries regarding the evaluation of the ad is supported.

*Performance orientation* was conceptualized based on GLOBE. Scales were adjusted and extended for the current investigation. Participants were asked about their individual practices and values, as well as their societal practices and values. Questions for individual performance orientation practices read: (1) "I strive to continually improve my performance." (2) "To perform well in life is very important to me." (3) "'Performance is what counts' applies to me." (4) "I am performance-oriented." Questions for individual performance orientation values read: (1) "I should try harder to improve my performance." (2) "To perform well in life should be more important to me." (3) "Performance is what counts" should apply more strongly to me. (4) "I should be more performance-oriented." Questions for societal performance orientation practices read: "In country X people generally (1) "… strive to continually improve their performance." (2) "… reward those who strive for performance and innovation." (3) "… set challenging goals for themselves." (4) "… base rewards on effective performance." Questions for societal performance orientation values read: "In country X people should (1) "… strive to continually improve their performance." (2) "…more substantially reward those who strive to continually improve their performance." (3) "… set more challenging goals for themselves." (4) "…base rewards primarily on effective performance." Subjects were asked to indicate to what extent the statements were applicable on a seven-point scale. Alpha

Values in the five countries of the four subscales were all larger than .72. Given the high internal consistency of the subscales, mean values of the four subscales (individual value, individual practice, societal value, and societal practice) were computed. Table 1 displays GLOBE scores for societal values and practices for performance orientation as well as both individual and societal values and practices obtained from this investigation.

Societal values and practices of the current investigation match, in part, the country scores reported by GLOBE. Among the five countries, overall, the data on societal values and practices of the current study reveal that France and Spain lean toward lower performance orientation, Germany ranks in a middle, whereas the U.S. and Thailand score relatively high on societal performance orientation. When compared to the GLOBE scores, the most noticeable differences were found in the data on societal practices in Thailand. On an individual level, German and French subjects scored low on individual values, while once again, U.S. and Thai subjects, and even Spanish subjects, scored relatively high on individual values of performance orientation.

**RESULTS AND DISCUSSION**

Hypothesis H1a predicted that a higher perception of performance orientation in an ad would lead to a more positive evaluation of that ad. SEM estimations revealed that a higher perceived level of performance orientation in the ad indeed leads to a more positive evaluation of the ad for all countries. All standardized path coefficients were positive and significant (Table 2). Results Hypothesis H1a is thus confirmed by the data.

Hypothesis H1b addresses the strength of the relationship between perception of performance orientation in an advertisement and its evaluation. It was hypothesized that the influence of the level of perceived performance orientation in an advertisement on the evaluation of the advertisement will be stronger in those nations in which individuals place greater importance on performance orientation, compared with those nations in which individuals place less importance on performance orientation. As expected, multi-group structural equation modelling revealed that the influence of the perceived level of performance orientation on the evaluation of the advertisement is highest in Thailand, followed by Spain and the US and lowest in Germany and France. Multi-group structural equation modelling with Chi2-difference tests was used to analyze whether the relationship between variables differ significantly from one another in the five countries. Results indicate that the relationship

between the German and the French data set differs significantly from the dataset from Thailand, but that the relationship between the other datasets did not differ significantly. The rank order of the heights of path coefficients are as expected in the five countries, however, not all differences are significant. Thus, the results lend only partial support for hypothesis H1b. Figure 3 illustrates these findings.

Hypothesis H2 predicted, based on reference value theories, that subjects from nations with higher performance orientation scores will perceive lower levels of performance orientation in the advertisement, whereas subjects from nations with lower performance orientation scores will perceive higher levels of performance orientation in the ad. The study's country scores of societal practices suggest that Thailand and the U.S. are the nations with the highest level of performance orientation, whereas Germany, Spain, and in particular, France tend to have lower scores on societal

practices. Figure 4 shows that the perceived level of performance orientation in the ad indeed clearly differs between the five countries. In line with the stated hypotheses, U.S. subjects perceived the lowest level of performance orientation in the standardized ad, whereas the French, the Spanish and the German subjects perceived higher levels of performance orientation in the standardized ad. The results for Thailand, however, contradict our hypotheses. Thai subjects perceived a much higher level of performance orientation in the ad than was expected. While many Thai strive for higher performance and behave in a performance-oriented fashion, Thai society appears not to have caught up with this shift. One reason may be that as an emerging East Asian market (Aglionby, 2006), Thailand has only recently experienced a substantial economic success. Despite strong economic growth in 2006, and projected real GDP growth of 5% for 2007-2008 (EIU ViewsWire, 2007), Thailand still lags far behind the other four nations with regard to

numerous economic indicators, e.g., gross national income per capita (in US $, 2005, cf. World Bank): Thailand 2,750 versus US 43,740; France 34,810; Germany 34,580; and Spain 25,360). Thus, while Thai citizens value performance orientation, this cultural dimension is not yet omnipresent in Thai society.

Bonferroni tests revealed that differences between the U.S. and France, as well as between the U.S. and Thailand are significant (all p<.05). Though the differences in the perception of performance orientation in the ad are not significant between the subjects from Germany, Spain and France, the rankings are as expected.

These results suggest that an identical, i.e. standardized, ad is perceived differently in terms of the level of performance orientation reflected in the ad, dependent upon the subjects' country of origin and the level of performance orientation in those cultures (Figure 4). To summarize, the results lend partial support for hypothesis H2.

## SELECTED IMPLICATIONS

Overall, the proposed conceptual model was supported by the data. The results of this investigation suggest that, by incorporating a performance-oriented appeal in commercial messages, advertisers can positively influence the evaluation of those messages. As hypothesized, data revealed a significant relationship between the perceived level of performance orientation in an ad and the overall evaluation of the ad. This proved to be true for every country. Because performance orientation is a positively held value in many countries, it can therefore be seen as an appeal type suitable for cross-cultural standardized advertising campaigns. Results also revealed that, overall, a higher individual value of performance orientation increases the strength of the impact of perception of performance orientation and ad evaluation.

Results of this investigation suggest that a given, standardized ad incorporating a performance-oriented appeal may well be perceived quite differently in various markets. An important finding of

this study is that it is not consumers from the country with the highest performance orientation scores who perceived the highest level of performance orientation in a standardized advertisement. Instead, data suggest that countries with higher performance orientation in terms of societal practices perceive lower levels of performance orientation in the ad and vice versa. Advertisers employing a standardized approach in their international efforts must be aware that an ad incorporating performance-oriented appeals may well be perceived differently from one country to the next, dependent upon the role that performance orientation plays in that particular market. This also means that advertisers attempting to achieve a specific level of performance orientation in their campaigns will likely need to adapt the ads to various countries. For instance, if the general marketing strategy is to position a given brand with a performance oriented appeal, the execution in different countries will need to be adapted with regard to content and design of the commercial message. According to this investigation, in performance-oriented countries, stronger performance orientation cues may be needed if consumers are to perceive the ads as performance oriented in nature. In less performance-oriented countries, weaker cues may be sufficient to obtain the same level of perceived performance orientation.

Overall, the GLOBE framework has proven useful in this investigation. It guided the development of assumptions regarding the perceived level of performance orientation to be expected by consumers exposed to advertisements in the different countries. However, it is advisable researchers replicate cultural dimensions to be analyzed in future investigations. In assessing performance orientation in this investigation, based on GLOBE measures, major differences were found in societal practices in Thailand. While GLOBE reported relatively low scores of societal practices of performance orientation, the current study revealed relatively high values on that dimension. It appears that while many Thai strive for higher performance and behave in a performance-oriented fashion, performance orientation is not yet omnipresent in Thai society. This

might be explained by the fact that Thailand has only recently experienced a substantial economic success. This discrepancy in the results for Thailand need not be perceived as a weakness in the GLOBE data, but rather it underscores the importance of replicating the cultural dimensions in question for each specific country to be investigated.

## LIMITATIONS

There are several limitations to the above reported findings. Future examinations of performance orientation should include countries that differ even more significantly in their performance orientation scores, per the GLOBE data, than the five countries analyzed in this investigation. Performance orientation should be analyzed in the context of advertisements for additional product categories, as well as for services.

Further, in addition to the dimension of performance orientation, the GLOBE framework offers a number of other dimensions worthy of examination. For instance, humane orientation, future orientation, and gender egalitarianism may all prove fruitful. It would be of interest to explore whether the conceptual model proposed in this paper is applicable to the other GLOBE dimensions. Another particularly interesting question was not addressed in this investigation. It might well be that an overly strong performance-oriented appeal could negatively impact evaluation of an advertisement. The question arises whether there might be a threshold beyond which the positive influence of performance orientation on the evaluation of an advertisement turns into a negative influence. Future investigations may wish to examine whether this threshold can be identified, and how it differs between nations.

A final limitation addresses the general applicability of the GLOBE data reported by House et al. (2004). In some cases, the country scores of the current study differed from those reported by GLOBE. Additional empirical evidence on the validity and reliability of the GLOBE data on cultural dimensions would be of value.

# Unsuccessful Purchase Experiences and Future Consumer Decisions: Effects of Initial Goal Setting Processes and Counterfactual Thoughts

June-Hee Na, Chungju National University, Korea
Jongwon Park, Korea University, Korea
Kwanho Suk, Korea University, Korea

## ABSTRACT

It is hypothesized that a failure experience in the initial goal pursuit task might increase preparation for a subsequent future task and that the effect is moderated by the goal setting processes during the initial task. The results of two laboratory experiments support these predictions. In addition, the effect is mediated by the amount of upward (vs. downward) counterfactual thoughts generated in response to the failure. Finally, the effect is quite independent of the level of affect that participants experience after the failure.

## INTRODUCTION

When people experience a failure in their goal pursuit, they tend to imagine better or worse consequences that differ from the outcomes that have actually occurred. These imaginary thoughts, which are called *counterfactual thinking* (CFT), influence affect or feeling people experience after the failure. That is, people may feel better, if they mentally simulate even worse alternative outcomes that might also have happened (i.e., downward CFT), whereas they may feel even worse if they consider better outcomes that might also have occurred (i.e., upward CFT). The affective function has received extensive empirical support in the literature (e.g., Roese 1997 for a review).

Counterfactual thinking may provide another important function for individuals, namely a preparatory function, which is the central focus of the present research. That is, counterfactual thinking may provide preparatory functions such that upward CFT may stimulate people to prepare for the future. Further, the literature suggests that this function is likely to occur at the expense of immediate feelings of dissatisfaction. Thus, there might be a trade-off between the two functions. Nonetheless, little research on the relationship between CFT and preparation for future and on the factors governing the relationship has been conducted. The purpose of the present research is to investigate this matter. Specifically, over two experiments we demonstrate that initial goal setting processes determine the direction of counterfactual thinking in response to a goal failure, which in turn, influences the level of preparation for the future. Further, this effect occurs both in an anagram solving situation (experiment 1) and in a consumer purchase decision situation (experiment 2). In addition, the effect is shown to be mediated by the relative magnitude of upward versus downward CFT in response to a goal failure. Finally, the effect was quite independent of the level of affect that participants experienced after the failure.

## THEORETICAL BACKGROUND

### Counterfactuals, Affect, and Preparation

Counterfactual thinking (CFT) refers to mental simulations of alternative outcomes that might have occurred in response to the actual outcomes. Counterfactuals are typically in the form of conditional propositions, embracing both antecedents (e.g., "if-only") and consequents (e.g., "might have been"). Once in mind, these counterfactual thoughts influence a wide range of judgments and affective reactions, including self-inferences, regret, and happiness (Roese 1997 for a review).

Counterfactual thoughts may have an affective function (i.e., making people feel better) and a preparative function (i.e., making people better prepared for the future), for which the direction of CFT plays an important role. That is, a downward CFT (i.e., thoughts about alternative outcomes that are worse than actuality) rather than an upward CFT (i.e., thoughts about alternative outcomes that are better than actuality) is likely to produce an affective function, whereas the preparative function may be well served by upward rather than downward counterfactuals. For example, Roese (1994) manipulated the direction of counterfactuals that participants generated after recalling a negative episode in life. Participants who were asked to generate downward counterfactuals subsequently reported more positive affect than those asked to generate upward counterfactuals. However, the upward CFT participants showed more preparative intentions for a future episode than the downward CFT participants. These suggest that upward counterfactuals may prepare a person for the future at the expense of immediate feelings of dissatisfaction, whereas downward counterfactuals may enhance satisfaction at the expense of leaving a person unprepared for the future. Further, this trade-off has been advocated by other researchers (e.g., Boninger, Gleicher, and Strathman 1994; Markman et al. 1993).

### Goal Setting Processes, Counterfactuals, and Preparation

The existing literature has identified various factors that might determine the direction of counterfactual thinking (upward vs. downward). For example, the nature of the past outcome (e.g., failure vs. success; Markman et al. 1993), the mutability of past outcomes (e.g., Gilovich and Medvec 1994), individual differences (e.g., prevention vs. promotion focus in self regulation: Roese and Hur 1997), and contextual factors (e.g., priming of enjoyment vs. performance: Sanna, Meier, and Wegner 2001) were shown to influence the direction of counterfactuals.

Little attention has been directed to goal setting processes as a potential determinant of the direction of counterfactual thinking (except for Burrus and Roese 2006). According to the goal setting literature (e.g., Oettingen 2000, Oettingen, Pak, and Schnetter 2001) and the construal level theories (e.g., Burrus and Roese 2006), goal setting routes can vary in terms of how extensively people engage in higher construal level ('why') versus lower construal level ('how') features of a goal. The construal level theory (Trope and Liberman 2003) posits that the same object can be represented at multiple construal levels. Similarly the goal setting procedure can consider either *why* (i.e., the benefits of attaining a goal: high level construal) or *how* (i.e., ease or difficulty of achieving a goal: low level construal). The *why-only* route to goal setting concentrates on the positive consequence of goal attainment. For example, during the setting of a goal of losing weight, people may solely fantasize about better-looking appearance after a successful weight loss. In contrast, the *how-only* route is based on mere reflections on difficulties that must be overcome to attain a goal. Thus, people may focus primarily on the difficulty of performing daily exercise and keeping low-calorie diet program during setting a goal of losing weight.

Burrus and Roese (2006) examined the influence of the construal level of the goal setting on counterfactual judgment (i.e., the extent to which personal actions change the goal). They found insignificant (study 1) or marginally significant (study 2) difference in counterfactual judgment between the participants who concentrated on the thoughts related to why they should have achieved a goal and the participants who listed how they have achieved a goal. The results imply that the extent to which people generate counterfactual thoughts is not strongly influenced by whether the goal setting is done at a higher construal level or at a lower construal level.

However, the literature on the goal setting procedure presents a third way of setting a goal (Oettingen et al. 2001). The third, *balanced* route to goal setting rests on simultaneous consideration of high and low construal levels of goal attainment. In this case, people might consider both better-looking appearance and difficulty of keeping low-calorie diet. Considering both construal levels tends to strengthen goal commitment when the goal is perceived to be attainable since mental contrasting transforms the higher level features into something to be achieved and the lower level features into something to be done (Oettingen 2000; Oettingen et al. 2001). As a result, the increased level of goal commitment might serve as a basis for generating counterfactuals after experiencing a failure in goal pursuit.

Based on this, we contend that goal setting processes should influence counterfactual thinking in response to a failure of goal pursuit, thereby affecting the level of preparation for the future. Specifically, we expect that after experiencing a failure, one is more likely to generate upward counterfactual thinking when both the high and low construal level features of a goal are simultaneously considered (i.e., 'balanced' goal setting) rather than when one considers only either high or low construal level features of goal attainment. Since the literature suggests that upward CFT leads to a higher level of future preparation (e.g., Roese 1997), we further expected that the balanced goal setting processes would lead to a higher level of preparation for the future than either why-only or how-only goal setting processes. These hypotheses were tested and confirmed in anagram solving task situation (experiment 1) and in an online shopping task situation (experiment 2).

## EXPERIMENT 1

Experiment 1 tests the effect of the goal setting type on future preparation after experiencing a failure to achieve a goal. We hypothesize that the levels of counterfactual thinking and preparation are higher when one considers both why and how rather than only one feature. Another goal of experiment 1 is to test the mediating role of upward (vs. downward) counterfactual thinking in the effect of goal setting type on preparation. To do so, two types of instructions for CFT generation (unrestricted CFT vs. restricted CFT) were employed crossed over the goal-setting conditions (why-only vs. how-only vs. balanced). Participants were either allowed to freely imagine and write down counterfactual thoughts that came to mind (i.e., unrestricted CFT) or asked to imagine and write down only one CFT (i.e., restricted CFT). If the effect of goal setting processes on future preparation is mediated by their influence on the relative magnitude of upward (vs. downward) CFT, as hypothesized, the influence of the goal setting type on the future preparation will be significantly greater for the balanced condition than the other conditions in the unrestricted-CFT conditions, but the effects will be eliminated in the restricted-CFT conditions. These predictions were tested in a situation in which participants in three goal setting processes set initial goals, solved anagrams as a target task, and received negative feedback about their performance.

## Method

*Participants and Design.* A total of 156 undergraduate students from a large university participated in the experiment. They received a pen as a gift for participation. Participants were randomly assigned to each combination of 3 (goal setting type: why-only vs. how-only vs. balanced) x 2 (CFT generation: unrestricted vs. restricted CFT) conditions.

*Stimuli and Procedure.* The experiment was conducted in classrooms. Upon arrival, participants were told that they would participate in an anagram test and that if they solved seven or more out of 10 anagrams, they would receive a prize valued at about $10. Then, they were given a booklet which contained instructions and anagrams. The cover page presented a brief overview of the study. The second page presented sample anagram tests. The manipulation of the type of goal setting process was achieved on the third page. Participants in the why-only conditions were first asked to imagine and write down the positive consequences of winning $10 by solving at least seven anagrams. Participants in the how-only conditions were asked to write down difficulties and obstacles to overcome to attain the cash prize. In the balanced conditions, participates were instructed to write down both benefits and costs of attaining the goal. The thoughts written down by the participants in each condition were later classified into why-related and how-related thoughts, and served as a manipulation check for the goal setting processes.

The test anagrams were presented on the next page. Participants were presented with ten moderately difficult anagrams: FARCS (scarf), WOMNA (woman), RACMAIE (America), RCNOTEC (concert), ARESMEU (measure), EOPYALM (Maypole), UPRETTM (trumpet), TLPHSOAI (hospital), TORVALEE (elevator), and TMGRNAIKE (marketing). Participants were allowed to take as much time as they wanted to solve the anagrams, but actually took no longer than 15 minutes. This task was followed by a short break during which participants' correct answers were counted. Then, when the session resumed, participants were informed their anagram test scores. No one solved more than six anagrams correctly (average anagram solved=2.28, *SD*=1.42) and there was no significant influence of experimental variables on the number of correct answers (*p*'s>.10). Thus, all participants were informed that they had failed to correctly solve at least seven anagrams.

Then, participants were asked to open the second booklet that included measures for counterfactual thinking, affect, and preparation. First, counterfactual thinking in response to the negative feedback was measured by asking participants to write down their current thoughts and feelings about the anagram test in an "if—then" format. In the restricted CFT conditions, the participants were asked to imagine and write down only one counterfactual thought that came to mind, whereas there was no restriction on the number of listed thoughts in the unrestricted CFT conditions. These thoughts were later classified into upward CFT and downward CFT. After this, the affect that participants experienced after the feedback was assessed along four 9-point scales (1=strongly disagree, 9=strongly agree) that captured satisfaction, happiness, sadness, and gloominess. The four ratings were averaged to form a composite index of affect (α=.87). Finally, participants' future preparation was assessed by asking participants to indicate their agreement with two statements along scales ranging from 1 (strongly disagree) to 9 (strongly agree): "I am willing to participate in the next anagram test" and "I am ready to participate in another anagram test." These ratings were averaged to form a composite index of future preparation (α=.94). After completing the measures, participants were debriefed and dismissed.

**TABLE 1**
Results: Experiment 1

| | Unrestricted CFT | | | Restricted CFT | | |
|---|---|---|---|---|---|---|
| | Why-only (*n*=24) | How-only (*n*=25) | Balanced (*n*=27) | Why-only (*n*=27) | How-only (*n*=27) | Balanced (*n*=26) |
| CFT | | | | | | |
| Upward CFT (1) | 1.88 | 1.16 | 3.15 | 0.96 | 1.00 | 1.00 |
| Downward CFT (2) | 0.08 | 0.04 | 0.07 | 0.04 | 0.00 | 0.00 |
| Difference: (1)–(2) | 1.79 | 1.12 | 3.07 | 0.93 | 1.00 | 1.00 |
| Preparation | 5.00 | 4.36 | 6.00 | 4.89 | 4.54 | 4.64 |
| Affect | 2.32 | 2.61 | 2.69 | 2.51 | 2.61 | 2.60 |

**Results**

*Manipulation Checks.* To check if the manipulation of goal setting process (why-only vs. how-only vs. balanced) was successful, the thoughts that participants had generated during the goal setting stage were classified into why-related thoughts (i.e., thought related to the benefits of attaining the goal) and how-related thoughts (i.e., things to do to achieve the goal) by two independent judges (inter-judge reliability=.88). Then, the frequency of these thoughts were analyzed by a 3 (goal setting type) x 2 (CFT generation) x 2 (type of goal-related thoughts: benefit vs. cost) mixed ANOVA. As expected, participants generated more why-related thoughts than how-related thoughts in why-only conditions (*M*=2.72 vs. *M*=0.63), fewer why-related thoughts than how-related thoughts in how-only conditions (*M*=0.70 vs. *M*=2.15), and both thoughts quite equally in the balanced condition (*M*=1.69 vs. *M*=1.48). These results indicate that the experimental variables were successfully manipulated.

*Counterfactual Thinking.* We predicted that the direction of counterfactual thinking (i.e., upward vs. downward CFT) would be affected by the process through which one initially sets a goal. To test this prediction, two independent judges coded counterfactual thoughts into upward CFT if the thoughts mentioned imagined outcomes that were better than what had actually happened, and into downward CFT if they were about worse outcomes than what had actually occurred (inter-judge reliability=.89). Disagreements between the two judges were resolved through discussion.

Table 1 shows the numbers of upward CFT and downward CFT and the difference between the two scores as a function of goal setting conditions and CFT generation. Overall, participants generated more upward CFT than downward CFT (96% vs. 4% of 164 CFT in the unrestricted CFT condition). This is consistent with the existing research suggesting that people tend to generate upward CFT than downward CFT when they experience a negative outcome (e.g., Sanna 1997).

Our prediction was tested by a 3 (goal setting type) x 2 (CFT generation) ANOVA on the relative magnitude of upward and downward CFT generated after the negative feedback. In the unrestricted CFT conditions, a larger number of upward CFT (vs. downward CFT) was generated in the balanced conditions (*M*=3.07) than either in the why-only conditions (*M*=1.79; $F(1, 150)$=32.38, $p$<.01) or in the how-only conditions (*M*=1.12; $F(1, 150)$=72.72, $p$<.01). The difference in the latter two conditions was also significant ($F(1, 150)$=8.90, $p$<.01). Under the restricted CFT conditions, however, the difference between the upward and downward CFT was virtually identical over goal setting conditions ($F$<1.0). This pattern was confirmed by a significant interaction of goal setting

and CFT generation on the relative magnitude of upward versus downward CFT ($F(2, 150)$=55.06, $p$<01).

*Preparation.* It was hypothesized that the level of preparation would be higher in the balanced conditions than in the why-only or how-only conditions, when participants were allowed to freely generate CFT, but that the effect would be eliminated if participants were restricted to generate only one CFT. This prediction was confirmed by an analysis of preparation ratings as a function of goal setting and CFT-generation. As shown in table 1, when CFT generation was restricted, the preparation level did not significantly vary over the three goal setting conditions ($F$<1.0). When CFT was freely generated, however, the level of preparation was higher in the balanced condition (*M*=6.00) than in the why-only condition (*M*=5.00; $F(1, 150)$=6.54, $p$<.05) or in the how-only condition (*M*=4.36; $F(1, 150)$=18.66, $p$<.01). The latter two conditions did not significantly differ from each other ($F(1, 150)$=2.78, $p$>.10). This pattern was confirmed by a significant interaction effect in an omnibus ANOVA test ($F(2, 150)$=4.72, $p$<.05).

*Mediating Role of CFT.* The mediating role of CFT in the effect of goal setting on preparation was further tested in the unrestricted CFT conditions using the procedure suggested by Baron and Kenny (1986). Goal setting processes significantly influenced both the level of future preparation ($F(2, 73)$=13.66, $p$<.01) and the relative magnitude of upward CFT (vs. downward CFT) generated after the negative feedback ($F(2, 73)$=13.66, $p$ <.01). To examine the mediating role of CFT between goal setting and preparation, an ANCOVA was conducted with the relative magnitude of upward versus downward CFT being a covariate. The effect of goal setting on preparation, which was originally significant ($F$=13.66), was substantially reduced to only a marginal significance when the relative magnitude of CFT was co-varied ($F(2, 72)$=2.69, $p$=.08). These results indicated that the effect of goal setting processes on preparation was mediated by their influence on the relative magnitude of upward (vs. downward) CFT, as hypothesized.

*Affect.* The affect that participants experienced upon receiving the failure feedback was also analyzed as a function of the goal setting conditions. A two-way ANOVA on the affect yielded a marginally significant effect of the goal setting type ($F(2, 150)$=2.86, $p$<.10). Planned contrasts indicated that affect in the why-only conditions (*M*=2.42) was less positive than either in the how-only conditions (*M*=2.67; $F(1, 150)$=4.65, $p$<.05) or in the balanced conditions (*M*=2.65; $F(1, 150)$=3.95, $p$ <.05), with the difference between the latter two conditions being insignificant ($F$<1.0). The main effect of CFT generation and its interaction with goal setting type were not significant ($F$'s<1.0). Thus, a negative relationship

between affect and preparation was not supported since the pattern of the effect of goal setting on affect was inconsistent with the effect on preparation.

## Discussion

The results from experiment 1 were generally consistent with our proposition that the balanced goal setting process, compared to either why-only or how-only processes, would lead to a higher level of preparation for the future, and that the effect would be accounted for by the mediating role of the CFT relative magnitude of upward CFT. In addition, the increased preparation set for the future in the balanced conditions was *not* at the expense of immediate feelings of dissatisfaction, contrary to the previous research. The next experiment attempted to find evidence showing the influence of goal setting on CFT and preparation in an online shopping context.

## EXPERIMENT 2

Experiment 2 was conducted to replicate the results from experiment 1 in a consumer behavior domain. Participants in the experiment were invited to a computer-simulated online shopping for an MP3 player, in which they were led to experience an unsuccessful purchase episode, and then asked to indicate the level of preparation for a next online shopping. As in the previous Experiment, the initial goal setting process was experimentally manipulated, and its impact on CFT, affect, and preparation was investigated.

## Method

*Participants and Design.* A total of 90 undergraduate students from a large university participated in the experiment for extra course credit. Participants were randomly assigned to one of the three goal-setting conditions (why-only vs. how-only vs. balanced), as explained below.

*Stimuli and Procedure.* We simulated an online shopping episode in which participants were asked to make a purchase decision for an MP3 player after browsing product information at online stores. The experiment was conducted in a computer lab. Several sessions of 10 to 15 participants were run. Upon arrival, participants were seated in front of a PC, which was programmed to display instructions, stimuli, and questions on the screen. Participants moved to a next screen by clicking their mouse when they finished the current screen page. However, the experimenter controlled the pace of this proceeding by asking participants to click the mouse to move to the next screen only after all participants finished the task on the current screen page

The first screen displayed an overview of the study. Participants were informed that the study intended to explore consumers' online shopping behavior. The second screen displayed some key attributes to consider when purchasing an MP3 player (e.g., easy to carry, file storage, etc.) and benefits of online shopping. With this preamble, the next screen manipulated the type of goal setting processes. First, all participants were given the same goal of purchasing an MP3 player online at a good price. However, they were asked to first consider either only higher or lower construal level features of the goal or both, depending on the assigned experimental conditions. Specifically, participants in the why-only condition were asked to imagine and type in positive consequences of successfully purchasing an MP3 player at an online store (e.g., "good quality product at a less expensive price"). Participants in the how-only condition were asked to consider the obstacles and difficulties in purchasing an MP3 player online (e.g., "too many products to compare across online stores"). In the balanced condition, participants were asked to imagine both benefits and costs of successful online shopping.

After this, participants were given a task of searching product information online to select the MP3 player model to purchase and provided with nine online shopping store names on a screen. A click on a particular store name popped up a window for the online shopping mall carrying a variety of products including MP3 players. Participants were allowed to browse stores on the list at their own pace and to stop search whenever they wished. They completed the shopping task by clicking an icon for the selected MP3 player.

All listed stores except for the one named "Happy Dream Mall" were hyperlinked to corresponding websites such that clicking a name led participants to the shopping mall website. However, Happy Dream Mall was a hypothetical one that was created for the experiment. Thus, the computer screen displayed a sign of "connecting…" indefinitely when participants clicked the name. This was necessary to operationalize a negative feedback on the shopping task, as explained shortly.

*Negative Feedback.* After completing the search and making a purchase decision for the MP3 model, participants were then asked to move to the next screen on which a post-purchase scenario was presented. Specifically, participants were instructed to imagine that they had received the MP3 player model that they had ordered. In addition, they were told that the same model was on sale in "Happy Dream Mall" and that the price was the lowest among the all shopping malls. This information was deemed effective in eliciting participants' counterfactual thinking, "I should have waited longer until the website was accessed..."

*Dependent Measures.* The next two screens asked participants to write down their counterfactual thoughts upon receiving the negative feedback on an empty sheet separately provided by the experimenter, and measured participants' level of affect along the same scales as employed in experiment 1. After this, participants' preparation level for the next online shopping was assessed on two 9-point scales that measured their willingness and readiness to shop online again ($\alpha$=.72). Finally, participants were debriefed, thanked, and dismissed.

## Results

*Manipulation Checks.* The manipulation of goal setting processes was successful. An analysis of thoughts generated during the goal setting stage indicated that participants in the why-only conditions generated more why-related thoughts than how-related thoughts (*M*=5.20 vs. *M*=.10), whereas the reverse was true in the how-only condition (*M*=.25 vs. *M*=4.89). In the balanced condition, however, participants generated both types of thoughts quite equally (*M*=3.04 vs. *M*=2.64). This pattern was confirmed by a significant two-way interaction of goal setting processes (why-only vs. how-only vs. balanced) and type of thoughts ($F(2, 83)=92.54, p<.01$), as expected.

*Counterfactual Thinking.* Participants generated more upward (vs. downward) CFT in the balanced conditions (*M*=2.75) than either in the why-only conditions (*M*=1.93; $F(1, 83)=11.37, p<.01$) or in the how-only conditions (*M*=1.04; $F(1, 83)=49.09, p<.01$), as expected (table 2). The difference between the latter two conditions was also significant ($F(1, 83)=13.71, p<.01$). This pattern was confirmed by the significant main effect of goal setting conditions in an omnibus ANOVA ($F(2, 83)=27.53, p<.01$).

*Preparation.* The extent to which participants felt prepared for a future online shopping was analyzed as a function of goal setting conditions (Table 2). As expected, the overall effect of goal setting was significant ($F(2, 83)=12.73, p<.01$). The preparation level was significantly higher in the balanced condition (*M*=6.30) than either in the why-only condition (*M*=5.15; $F(1, 83)=16.26, p<.01$) or in the how-only condition (*M*=4.95; $F(1, 83)=20.54, p<.01$). The

## TABLE 2
### Results: Experiment 2

| | Why-only (n=30) | How-only (n=28) | Balanced (n=28) |
|---|---|---|---|
| CFT | | | |
| Upward CFT (1) | 2.40 | 1.39 | 2.86 |
| Downward CFT (2) | 0.47 | 0.36 | 0.11 |
| Difference: (1)–(2) | 1.93 | 1.04 | 2.75 |
| Preparation | 5.15 | 4.95 | 6.30 |
| Affect | 2.33 | 2.96 | 2.60 |

latter two conditions did not differ significantly ($F<1.0$). These results replicated the findings of experiment 1 and confirmed our hypothesis.

*Mediating Role of CFT.* As shown earlier, goal setting processes significantly influenced both future preparation ($F(2, 83)=12.73$, $p<.01$) and the relative magnitude of upward CFT ($F(2, 83)=27.53$, $p<.01$). The results of an ANCOVA with the magnitude of upward (vs. downward) CFG as a covariate indicated that the effect of goal setting on preparation, which was originally significant ($F=12.73$), was reduced but still remained significant ($F(2, 82)=10.44$, $p<.01$). Therefore, the mediating role of CFT was not confirmed in experiment 2.

*Affect.* Not surprisingly, participants felt quite unhappy ($M=2.62$) when they received the negative feedback. This unhappiness did not significantly vary over the goal setting conditions ($F(2, 83)=2.26$, $p>.10$).

## GENERAL DISCUSSION

This research extends Burrus and Roese (2006), who found insignificant or weak influence of the construal level (high vs. low) of goal setting on counterfactual thinking, and examines how counterfactual thoughts and the preparation level for the future after experiencing a failure in goal pursuit is affected by the process through which one initially sets a goal. The results of the present research provides strong support for our prediction that consideration of both positive consequences and difficulties of attaining a goal during the goal setting, compared to consideration of only one, leads to better preparation for the future after experiencing a failure in the current goal pursuit. The results of two experiments consistently demonstrated that goal setting processes significantly influenced both preparation level and the relative magnitude of upward versus downward of CFT in the hypothesized direction. Further, this effect was true regardless of whether the task involved an anagram solving (experiments 1) or a consumer decision (experiment 2).

The present research also identifies these effects. That is, the mediating role of upward versus downward counterfactual thinking was confirmed by covariance analyses showing that the effect was reduced to non-significance when the relative number of upward versus downward CFT was co-varied in experiments 1. This mediation was further confirmed when the extent to which counterfactual thinking was experimentally manipulated. That is, experiment 1 has shown that the effect of goal setting processes on preparations was substantial when the generation of CFT was freely allowed, but eliminated if it is experimentally restricted. These results seem to provide strong support for the mediating role of CFT.

The existing literature suggests that upward counterfactuals may prepare a person for the future at the expense of immediate feelings of dissatisfaction, whereas downward counterfactuals may enhance satisfaction at the expense of leaving a person unprepared for the future (e.g., Boninger et al. 1994; Markman et al. 1993). Our results suggest that such a trade-off is not always the case. That is, our goal setting manipulation had a significant effect on participants' upward CFT after experiencing a failure, which in turn influenced the level of future preparation. However, the manipulation had no effect on the level of affect participants experienced after the failure. This seems consistent with previous research that demonstrated self-efficacy as moderator of the affective consequences of upward and downward counterfactual thinking (Sanna 1997). Thus, counterfactual direction may not be so closely linked to affect.

Studies on regulatory focus in self regulation often experimentally manipulate the regulatory focus variably by asking participants in the promotion focus conditions to consider things that they want to happen and how to achieve them, but those in the prevention focus conditions to consider how to avoid things that they do not want to happen in their lives (e.g., Liberman et al. 2001). To reiterate, we manipulated the initial goal setting processes by varying focus of consideration during the goal setting stage (i.e., focusing on positive consequences, difficulties and obstacles, vs. both). Thus, this procedure can be seen as somewhat analogous to that of regulatory focus manipulation. To this extent, one may explain the differences we observed in preparations among goal setting conditions in terms of differences in regulatory focus. This explanation can not be entirely dismissed because we didn't measure participants' level of regulatory focus. However, it is unlikely to be the case for at least for two reasons. First, if this explanation is valid, one should expect the highest preparation level in the why-only conditions. However, our results consistently showed the highest level in the balanced conditions, not in the why-only conditions. Second, the alternative explanation is based on research suggesting that promotion focused individuals tend to generate upward CFT than prevention focused individuals (e.g., Roese and Hur 1999). However, our results indicate that the relative magnitude of upward (vs. downward) CFT was largest in the balanced, not in the why-only conditions.

# Effect of Goal Salience and Goal Conflict on Typicality: The Case of "Health Food"

Hiba El Dahr, IAM, UMR-MOISA Montpellier, France
Fatiha Fort, SupAgro, UMR-MOISA Montpellier, France

## ABSTRACT

The aim of this article is to highlight the role of consumer's goals, in this case the "health" goal, in the cognitive representations and perception of food products, in particular "health foods." On the basis of the goal theories used in a categorical approach in information processing, we show that the salience of health goals has a significant influence on the perceived typicality of the products in the health food category. The consumption context and the overall hierarchy of the goals sought constitute moderating variables.

## INTRODUCTION

For several years, following a trend already seen in North America and Japan, "health" argument has provided an opportunity to develop products on the French food market. The increasing number of product launches claiming to be "healthy" illustrates consumers' interest in "alicaments" (medicated foods) and a growing awareness of better nutrition. Treating the question of diet as an integral part of a general public health policy, awareness campaigns are undertaken by the authorities to promote among the consumers products with high nutritional value. Whether it is a matter of individual worries (as a result of food safety crisis) or firms' marketing concerns, the socio-economic context thus appears to favour products with a strong health image. However, faced with the profusion of supply on the one hand, and the diversity of consumers' expectations on the other (health, pleasure, well-being, ethics, ecological concerns etc.), consumer's choice is becoming more and more complex. The increasing number of views on nutrition provided by media, the medical profession and authorities reinforce this trend, while messages concerning products "health" value are often contradictory.

Therefore, it is worth examining how the consumer perceives "health foods" according to his own motivations and personal expectations. We should therefore pay particular attention to personal goals as individual determinants of food choices linked with health. The interest in goals is justified not only by their cognitive dimension directed towards action, but also by their motivational and affective content whose role is supported by theoretical models of health behaviour (Self-Regulation Models of Carver & Scheier, 1982; Cognitive Social Theory of Bandura, 2004).

In this article, we are concerned with the role of goals in mental representations and in the organization of information about products (specifically health foods) in a category-based framework of information processing. We propose therefore to define the mechanisms whereby personal goals (i.e. health goals) affect products' perception within cognitive categories called "goal-derived categories" (Barsalou, 1983, 1991) depending on goals organization and on goal salience. We will use the concept of typicality as a key construct in categorization theory. Our purpose is to show that, in the "health food" category:

– the perception of product typicality is significantly influenced by health goals salience and by other competing goals pursued by the consumer,
– the influence of health goals salience on product typicality varies according to the consumption context (Figure 1).

Goal theories will be explored in order to highlight the hierarchical organization of goals in memory and their instrumental links with concrete products and behaviour. Within the theoretical accounts of categorization, typicality concept will be used in order to introduce health goals salience as an antecedent of typicality in the health food category (defined as a goal-derived category).

The results of a quantitative survey will then be presented in order to test the research hypotheses.

## THEORETICAL BACKGROUNDS

Goal theories assume that goals are organized within a hierarchical structure (Carver & Scheier, 1982) based on instrumentality links. Goals of lower order, closely linked to action levels, constitute concrete means for reaching higher, more abstract and more stable goals (Gutman, 1982). The closeness between goals and behaviour appears at three levels: through goal structure; goal accessibility and goal content.

In fact, the hierarchical structure defines different goal's levels of abstraction: abstract, central and operational (Bagozzi & Dabholkar, 1994), which exert a driving role on behaviour by guiding towards actions or towards concrete products which conform with goals.

Goal accessibility (Higgins & King, 1981; Wyer & Srull, 1981; Förster et al., 2005) or goal "salience" (Ratneshwar et al., 2001) refers to the "level of awareness of the goal" through levels of attention and intention of working memory (Austin and Vancouver, 1996). Acting in a significant way on perception and cognitive representations (Ratneshwar et al., 2001), goal salience is a necessary condition for the commitment to behaviour, notably as regards health. Previous studies show that goal salience depends on motivation (Förster et al., 2005), on situation (Vallacher & Wegner, 1985; Ratneshwar et al., 2001), and on frequency and recency of prior activations (Förster et al., 2005). The notion of content of goals refers to classifications of outcomes or states that individuals approach or avoid in their behaviour according to the origin of these states (internal or external), their nature, or to their meaning. Although the number of goals that an individual is able to pursue is relatively limited (Austin & Vancouver, 1996), studies show that the pursuit of multiple goals may lead to goals conflict when these are of a contradictory or incompatible nature, which may have many consequences on behaviour. Two possibilities may therefore be envisaged as regards the use of goal theories in the field of consumer behaviour:

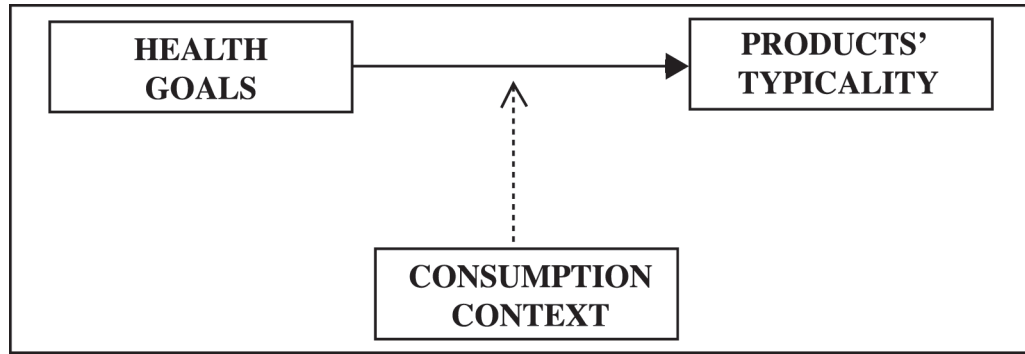
– one is focused on motivation and its effect on behaviour,
– the other corresponds to knowledge about products organization in memory. This aspect has been particularly developed by Barsalou (1991) who has shown that goals influence products' cognitive representations and form "goal-derived categories" (example: category of products to eat when dieting).

Goals will therefore be involved in categorization process and thus in consumers' choice.

## RESEARCH HYPOTHESES

Typicality is a central concept in categorization theory. Cognitive psychology shows that, apart from its role in determining object membership and positioning within a category (Mervis & Rosch, 1981), there is a strong positive relationship between

**FIGURE 1**
The role of health goals in the health food category



typicality and attitude (Loken & Ward, 1987; Nedungadi & Hutchinson, 1985), preferences, and the product choice within a category (Changeur & Chandon, 1995). Typicality judgments are very useful in understanding consumer's choice. Much research has been carried out on variables determining the level of perceived typicality. Among these variables, the literature gives the following determinants: familiarity (Loken & Ward, 1990), frequency of instantiation (Barsalou, 1985), family resemblance, attributes structure (Loken & Ward, 1990), ideal (Barsalou, 1985) and coherence.

Behind of these determinants of typicality, we postulate in this research that, in the case of goal-derived categories (Barsalou, 1991):

H1:  Pursued goals salience, which represents the ideal of the category determines products' typicality.

Thus, in the "health food" categories, products' level of typicality is determined by the salience (and activation level) of health goals. In fact, according to Barsalou (1991), the ideal of the category influences both the category's membership and its members' typicality. Moreover, Förster *et al*. (2005) suggest that great accessibility of goals and the constructs related to them make it possible to detect the most effective environmental stimuli in the pursuit of these goals, thus improving the probability of their attainment. According to this point of view, goal salience seems to be correlated with typicality, insofar as the most typical members are, according to Barsalou (1983, 1991), those which best serve to reach the goal sought.

In addition, cognitive psychology and marketing show that for each consumption situation, there are corresponding goals sought by the individual. The activation of situational goals occurs, according to Förster *et al*. (2005) under the effect of environmental variables which automatically trigger the process of their pursuit (Schwarz *et al*., 2003). Goals salience is thus influenced by the context, which can make certain goals more accessible and more prioritized than others. Furthermore, Ratneshwar *et al*. (1991; 1997) have shown that for each situational goal there are corresponding specific benefits which are rendered salient by situational factors, for which specific products can be used in order to attain fixed goals. Starting from the principle that, in a categorization context, products which best satisfy the category goal are the most typical, this suggests that typical products should correspond best with the consumption context in order to respond to the category objective. We therefore postulate that:

H2:  The influence of goal salience on products' typicality in goal-derived categories is moderated by the appropriateness level of these products for the context.

However typicality does not depend only on personal goal salience but also on the accessibility of the other goals in the hierarchy. Decision theories postulate that the individual gives more attention and subjective value to products capable to satisfy a need or a given goal as long as this need is active (Lewin, 1935; Klinger, 1975; Förster *et al*., 2005). From this point of view, attention to and usefulness of products vary according to the intensity or the importance of goals, which they serve (Brendl *et al*., 2003).

Studies have focused on the influence of active goals on the attractiveness of products or behaviour related to these goals (Klinger, 1975; Brendl & Higgins, 1996; Ratneshwar *et al*., 1997; Ratneshwar *et al*., 2000; Brendl *et al*., 2000). Theses works suggest that the level of goal salience has an influence on product preference, and that a "devaluation effect" may be driven by products that are perceived as irrelevant as regards active goal (Brendl *et al*., 2003; Förster, *et al*., 2005). Moreover, the effect of active goals is reinforced by their protection against environmental stimuli which do not compete with their attainment (Brendl *et al*., 2000; Brendl *et al*., 2003; Förster, *et al*., 2005). Among these factors, we suggest that competing goals could affect main goal's effect in the evaluation of products according to their level of importance or intensity.

If we assume that, in goal-derived categories typicality is influenced by goal salience level, and by taking into account that a given individual is able to pursue several consumption goals simultaneously, we assume that:

H3.a:  The effect of goal salience on typicality is significant when competing goals are not highly rated
H3.b:  The effect of goal salience on typicality is not significant when at least one of the competing goals is highly rated

If we take the case of health goals as an example, their effect (assumed to be significant) on typicality can be seen as follows (Figure 2).

## METHODOLOGY

To test these hypotheses, we have chosen the health food category. The interest in food products is justified by their close link

**FIGURE 2**
Conceptual model and research hypothesis

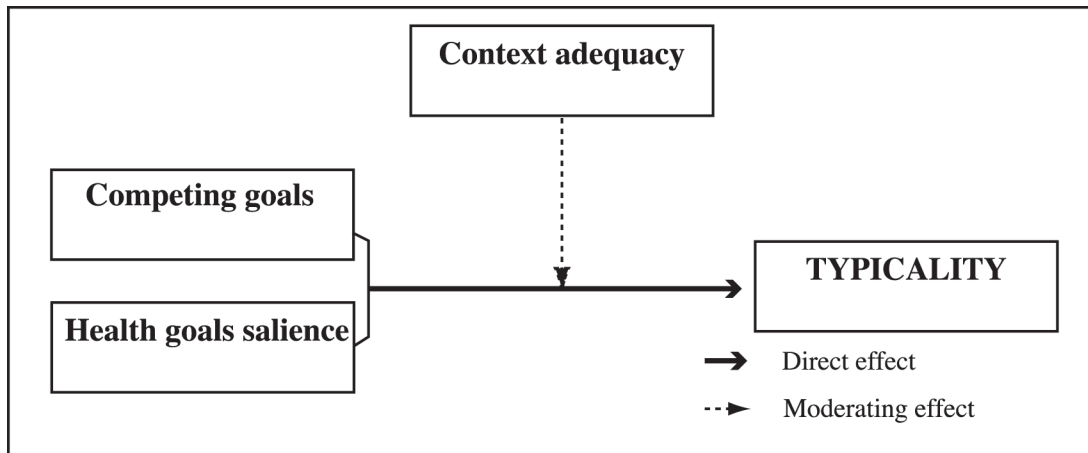


**TABLE 1**
Products retained for the final experiment

| BREAKFAST | SPORT | SNACKING |
|-----------|-------|----------|

with health goals and by the diversity of objectives, which underlie their consumption (biological, cultural, economic, social and psychological).

An exploratory qualitative study was made as a first step among 22 individuals in order to identify perceptions of health foods. A lexical analysis showed that health goal could be broken down into three main subordinates goals: the need for a balanced diet, the prevention of illness and the desire for food security (in terms of health risks). The analysis also revealed 3 consumption contexts in which health goals were particularly salient: breakfast, sport and snacking context. Associated with these 3 situations, a list of 145 products was submitted to 3 judges to select products belonging to the health food category. 44 products were selected unanimously by the 3 judges to be used in a quantitative study in order to test our research hypotheses. 15 out of these products (Table 1) were retained for the final experiment (5 products per situation).

404 participants took part in the 2nd phase of the survey (the quantitative phase), spread uniformly over 3 experimental groups according to the usual socio-demographic criteria (sex, age, educational level and size of housing area).

As a first step, the salience of health goals was evaluated in order to understand how this variable could influence food perception and product classification into categories. Thus, we submitted the participants to a product categorization task based on the work of Murphy and his colleagues (1999, 2001, 2003) and Berger & Bonthoux (2000) in cognitive psychology. This task succeeded in defining the nature of associations made among the products and in distinguishing the nutritional and health links (e.g. calcium and milk) of the taxonomic categorizations (e.g. milk and cheese). Another task, suggested by the work of Ratneshwar *et al.* (2001),

was given to the participants in order to evaluate the degree of similarity between products pairs (on a 7-point scale (from "*very different*" to "*very similar*"). The authors had checked that perceived similarity between health-related products were correlated with health goal salience. Thus, when products sharing few common traits were judged similar as regards a given goal, this shows a high level of goal salience in the consumer's cognitive representations.

We also included in the measurement of health goals salience a motivational dimension which, according to Higgins *et al.* (1981), is an important determinant of goal accessibility which has been excluded from earlier research. We evaluated motivation in the tasks linked to health foods by way of a 7-point scale adapted from Maheswaran (1994), also used by Odou (2000), ranging from "*don't agree at all*" to "*agree completely*":

> "*When I choose health foods:*
> *I read carefully the information on the pack*
> *I am keen to read the product description*
> *I am keen to find out more about the product*"

Finally, a score for health goals salience is obtained by the average of the measurements of motivation, similarity and associations between products.

The suitability of products in the consumption context was measured on a scale adapted from Jean (2000) going from 1 (*not at all suitable*) to 7 (*completely suitable*) in response to the following question: "*Please indicate to what extent each of the following products seems to you suitable for [context]'.*

In order to measure the hierarchy of goals pursued by consumers, we have made use of goal theories where objects and concrete

**TABLE 2**
Results of linear regressions of health goals salience as antecedent of the typicality in different contexts

|  | $R^2$ | t | β |
|---|---|---|---|
| **Breakfast** | 55.44 % | 1.97 | 0.209* |

\* *significant at 5% level*

goals represent means of reaching abstract goals. So we have used some criteria sought in food products consumption in general, which reflect higher pursued goals, including "health", namely: *price, taste, freshness, origin, packaging, respect for the environment, ease of preparation, label* and *health*. For each of the 3 studied contexts, we established a classification of these criteria according to their perceived importance by the participants. This variable (importance) was measured using an Osgood scale with 7 points, ranging from "*not at all important*" to "*very important*" in response to the following question: "*Can you indicate to what extent you attach importance to each of the following criteria in your choice of foods?*"

Typicality was evaluated by the way of the representativeness of products as regards health food category. A 7-point scale ranging from 1 (*not at all representative*) to 7 (*completely representative*) was used in response to the following question: "*In your opinion, to what extent is each of these products representative of the health food category?*"

### RESULTS AND DISCUSSION

Table 2 shows results of linear regressions of health goals salience as an antecedent of typicality in the 3 studied contexts. The regression model was as follows:

Typicality=constant+salience+conformity+coherence+attributes structure+sharing of attributes+subjective expertise[1]+E

where "salience" is the variable which describes the salience of health goals; "conformity" is the conformity of the products with the ideal of the category (Barsalou, 1985) or the degree to which products permit health goals attainment; "coherence" describes perceived coherence between products and category (Dawar & Anderson, 1994); "attributes structure" describes the degree to which products possess the category attributes (Odou, 2000); "sharing of attributes" describes the difference between products and category in the degree of possession of these attributes; "subjective expertise" refers to the perception that the individual has of his level of competence in the health food category.

Although the prediction quality is lower in sport and snacking than in breakfast situation (where $R^2$=55.68 %), a large part of typicality is correctly predicted by health goals salience.

[1]According to our results expertise variable has no significant influence on typicality. The other variables used in the regression model are the classical typicality determinants in marketing and psychological literature.

Regression coefficients are all positive but not significant in all contexts, notably in sport context (p=0.605). Hence, we find that health goal salience is not a significant determinant of typicality in every situation. Consequently, (H1) is only partially supported by theses findings.

To test the moderating effect of products adequacy for the context, we first tested the distribution normality of this variable before dividing observations into two groups. Actually, it is assumed that normally distributed variables can be transformed into nominal variables with a threshold effect around the mean (obtained for the variable *context adequacy*). ANOVA analysis is then used to compare typicality effects in the two groups (Group 1, has considered products as inappropriate for the situation, and Group 2 as appropriate). ANOVA results (Table 3) show that the differences in typicality evaluation in the two groups were significant at the 5% level threshold in the 3 situations (p=0.05; 0.007 et 0.000 respectively). This result confirms that context adequacy of products has a moderating effect on their typicality in health food category, which partly explains the variability in the effect of health goal salience on typicality.

In order to analyze the influence of goals conflict in the hierarchy, we established a classification of the different product criteria sought by participants in the 3 studied contexts (Table 4). We selected health competing factors according to their "perceived importance" ratings. Thus, we assumed as competing with health factors those that obtained a greater "importance" rating.

According to this classification, we notice that, in breakfast situation, "taste" and "freshness" get better ratings (first and second position respectively) and thus seem to be more valued than health considerations (3rd position). They are therefore considered as competing with health concerns. By introducing "taste" and "freshness" concerns with health in the regression model, we were able to study the combined effects of all these factors on typicality.

Table 5 shows that, in breakfast situation, "taste" and "freshness" variables has not a statistically significant influence on product typicality. However, health factor has a significant influence at the 5% threshold (p=0.030). Therefore, our (H3.a) hypothesis is consistently supported.

Actually, sport situation allows us to analyze the influence of health criterion with interaction with highly valued competing criteria which have significant influence on the dependent variable (typicality). Table 5 shows that in this situation (sport), taste, freshness, environmental aspects and price are more valued than health goals (more highly rated by participants). Whereas health contribution is not significant in sport situation (p=0.881), taste variable (p=0.050) and respect for the environment (p=0.002) are significant at the 5% threshold. Freshness and price variables have

**TABLE 3**
Differences in typicality ratings according to context adequacy (on 7-point scale)

|  | Adequacy Mean | | Typicality Mean | | ANOVA | | |

*\* significant at 5% level*

no significant influence on typicality. These findings show that taste and respect for the environment factors may have an inhibitory effect on health considerations. Introduced into the regression model, they contribute significantly to explain typicality variance. The hypothesis (H3.b) is supported by these results. In snacking situation, table 5 shows that health dimension influences typicality (p=0.006) whereas the competing criteria, i.e. taste and freshness, do not contribute in the same way. Their influence on typicality is in fact not significant (p=0.240 and 0.739 respectively).

Considered as a whole, we have therefore validated the hypothesis (H1) and shown that salient health goals influence perceived typicality in health food category in certain situations. Theses findings are particularly relevant when goal-related products are assumed to match the consumption context (H2). This

influence of health goal salience is more important as health competing goals are less influential. (H3.a). Once other goals of the hierarchy are valued compared with health criteria (when the individual considers other criteria in his food choice), health goals influence on typicality becomes less important (H3.b).

## CONCLUSION

The main conclusion of this research offers evidence and insights on how goals impact categorization process and health food evaluation by way of two dimensions: goal hierarchy and goal salience.

Our findings offer additional evidence that the consumer does not pursue a health goal alone, but that there may be interactions between different goals according to individual priorities and context. These goals interferences may influence product judgments. Our findings are consistent with psychological literature (Abraham & Sheeran, 2003), which suggests that goal theories consider the possibility of goals conflicts, and the influence of salient goals. Moreover, the theory of action identification (Vallacher and Wegner, 1985) emphasizes that context is able to alter the salience of certain goals in a given situation. Ratneshwar and his colleagues (1997, 2001) support these findings and show that, according to situational factors, different goals may take priority, thus affecting products perception and representations. Our results are congruent with these assumptions in the sense that, for each situation there is a different hierarchy of goals and a different perception of products typicality in health food category. These results may have important implications in consumer behaviour research.

First, by manipulating health situational factors (by means of ads for example) it is possible to activate (or inhibit) other goals, which would lead to different product evaluations according to health competing goals. On the operational level, notably that of product management, typicality concept could be used to respond to consumer needs. To improve a product "health" image, it is possible to reinforce its perceived typicality as regards health food category or specific goals sought by the consumer. This could be done for example by devaluating its perceived typicality as regards goals that compete with health. Such a strategy favours a better positioning, especially when products serve double needs: nutrition and pleasure, health and "terroir", health and naturality etc. This research accentuates the need to consider different consumer concerns specially those to which he gives priority. Since, for example, for one consumer pleasure is the main motive in food consumption, to lessen products typicality as regards health goals seems to be a prudent strategy by reinforcing enjoyment image, taste and flavour instead of product medicinal aspects.

Finally, although analyzing consumer behaviour using goal theories may appear a deterministic and functionalist approach, this study shows that it is possible to guide consumer choice through marketing by using the concept of "goal salience". By encouraging a suitable nutritional discourse and by controlling the actual "food cacophony", the consumer can be guided towards a balanced diet, favorable both to his health and to his various expectations.

Some limits can be drawn at the end of this research and open doors to further investigations:

Analyzing food behaviors as being determined by goals can rise some interrogations as for the rigidity of this deterministic and functionalist approach. In order to understand the reality of food consumption and the consumer as a socialized individual, it would be interesting to include into the model the ecological variables underlining the role of the agents of influence, the culture or the social environment which can have as much influence on perceptions and choices (Steptoe *et al*., 1995; Pliner & Mann, 2004) as personal motivations.

Another limit concerns the experimental procedure and the categorization task in particular which, in our case, requires reasoning in terms of products and " health food " rather than of "healthy eating". However, healthy behavior analysis requires to think food not only in terms of combinations of products but in terms of balance, preparation process and consumption, which could make difficult the task of products evaluation in our experimentation and limit the external validity of the results. It would be useful, in a future research, to associate with the categorization tasks, others aspects, as for example, the origin of the products, their mode of preparation or their consumption.

In our research, we focused on the intrinsic attributes of the products related to their functionality and their degree of conformity to health goals. While being conscious that other extrinsic attributes can influence the evaluation of the products, it would be interesting to study the categorization schemes privileged by the consumer that can be related to the goal, the brand, the product category or the area of origin.

# Verticalization: The Impact of Channel Strategy on Product Brand Loyalty and the Role of Involvement in the Fashion Industry

Hanna Schramm-Klein, Saarland University, Germany
Dirk Morschett, University of Fribourg, Switzerland
Bernhard Swoboda, University of Trier, Germany

## ABSTRACT

Our study contributes to the knowledge on how manufacturers' distribution channel strategy impact brand loyalty. Using PLS regression, we demonstrate that in the fashion industry, characteristics of the retail channel contribute higher to product brand loyalty in vertically integrated channels while the impact of product brand characteristics on brand loyalty is higher in conventional channels. We also show that consumers' involvement has a stronger effect for verticals. Our results imply that strong product brands are less reliant on verticalization to be successful, whereas weaker brands can benefit from support from the retail environment and this can be achieved more effectively in vertically integrated channels.

## INTRODUCTION

Vertical marketing systems such as corporate channels (e.g. manufacturer owned retail outlets) or contractual channels (e.g. franchise systems, retailer cooperatives, concessions) have grown dramatically during the past decade. For example, verticals such as Zara, H&M, or Mango range among the most successful retailers in the fashion industry. We define verticalization as manufacturers' forward integration: "Manufacturers' own retail sales branches and own mail-order operations are the chief examples of producer-led vertically integrated channels; while franchisees and agents are instances of intermediaries in vertically co-ordinated producer-led channels" (Guirdham 1972, 68). Vertically integrated channels provide companies with greater control over their business processes, products and profits (Heide 1994). From the perspective of brand management, the main objective of verticalization is that the distribution concept can be focused solely on the manufacturer's (product) brand. Thus, the distribution concept can be controlled in terms of the manufacturer's objectives. Conflicts, that in traditional channels for example can result from contradictory objectives of manufacturers and retailers (Corsten and Kumar 2005), can be avoided. The design and management of distribution channels thus is important for building brand equity. For example, Srivastava, Shervani, and Fahey (1998) classify the distribution channel as the firm's "relational market-based assets", and Keller (2003b) emphasizes that channel strategy is an important means to build brand awareness and to improve strength, favorability, and uniqueness of brand associations.

The establishment of vertically integrated marketing channels is not only an important phenomenon in practice but academic literature on vertical integration has also grown considerably over the last few decades. While the main focus of this stream of research focuses on internal aspects of vertical channel relationships such as power, dependence, trust, conflict or coordination and cooperation between the companies on the different stages of the value chain (Gundlach, Achrol, and Mentzer 1995; Morgan and Hunt 1994; Vinhas and Anderson 2005), only few studies have–somewhat astonishingly–analyzed the impact of vertically integrated channels on consumer behavior. In addition, a review of brand equity literature (Yoo, Donthu, and Lee 2000) shows that despite the high interest in the concept of brand equity, as stated by Shocker, Srivastava and Ruekert (1994, 157), "more attention is needed in

[…] the development of more of a 'systems view' of brands and products to include how intangibles created by pricing, promotional, service, and distribution decisions of the brand manager combine with the product itself to create brand equity and effect decision making". Hoeffler and Keller (2003) emphasize in this context that the most neglected research area is the effect of various channel strategies on brand equity.

Therefore, in this article we address the question how forward verticalization of manufacturers impacts consumer reactions towards the brand. According to the formerly described gaps in empirical research, we mainly focus on the influence of the distribution channel on the manufacturer's product brand. Our main interest is if vertically integrated marketing channel systems and the related distribution channel characteristics lead to superior consumer reactions to the brand compared to non-vertical marketing channel systems. In this context, we also address the issue if the impact of channel strategy is related to consumers' involvement, as there exists almost no research on this question.

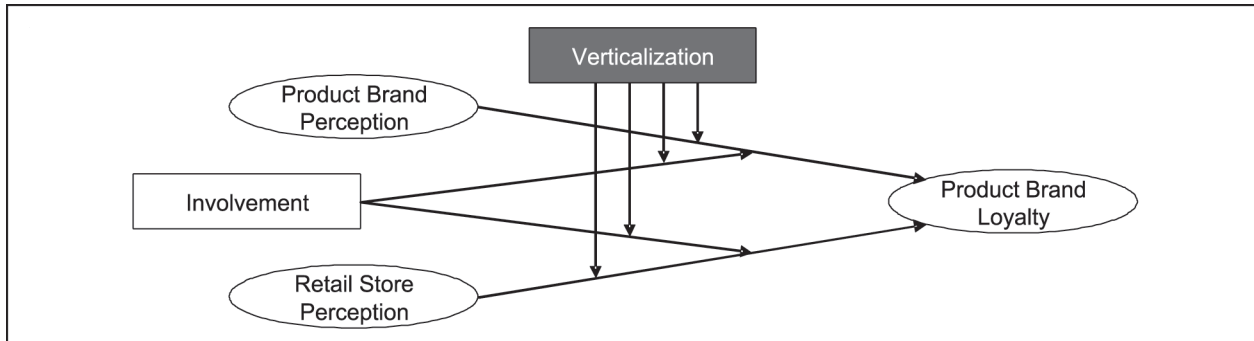
## THEORETICAL BACKGROUND AND RESEARCH HYPOTHESES

Relationship marketing literature suggests that brand loyalty is of strategic importance for companies to obtain a sustainable competitive advantage (Sirdeshmukh, Singh, and Sabol 2002). Loyalty is understood to be a long-term attachment to a firm (Dick and Basu 1994) and it is considered to be intimately linked to consumer based brand equity (Johnson, Herrmann, and Huber 2006). We consider brand loyalty as an adequate concept to analyze the outcome of manufacturers' distribution policy. Our conceptual framework (see figure 1) is mainly based on theories from cognitive and environmental psychology. Our basic assumption is that product brand loyalty is not only influenced by characteristics of the product itself but also by the retail environment in which it is sold. Besides these main effects, we suppose that verticalization and involvement play an important role in moderating these relationships.

*Product Brand Loyalty*. The main theoretical foundations to examine loyalty formation are found in cognitive dissonance theory, learning theory and risk theory (Sheth and Parvatiyar 1995). Several conceptualizations of loyalty have been described in the literature (Gounaris and Stathakopoulos 2004). Generally, the main components of customer loyalty are considered to be repurchase, recommendation and supplementary purchases (Mittal, Kumar, and Tsiros 1999).

*Product Brand Perception*. Regarding the antecedents of brand loyalty, the vast amount of literature on customer based brand equity (Keller 2003b) suggests that consumers' evaluations of brand characteristics are of major importance. The outcome of such evaluation processes determines the value individuals derive from a brand (Sirdeshmukh et. al. 2002). In this context, two main dimensions of product evaluation have to be considered: the utilitarian dimension which relates to the functions performed by a product and the hedonic dimension which results from emotional aspects derived from the experience of buying and using the product

**FIGURE 1**
Conceptual Model



(Chaudhuri and Holbrook 2001). When an evaluation is positive, the utility and the benefits of the product brand dominate. We therefore propose:

H1: The better the evaluation of the utilitarian and the hedonic dimensions of the product brand is, the higher is product brand loyalty.

*Retail Store Perception*. Loyalty intentions towards the product brand also are influenced by the environment, in which the products are presented and sold (Keller 2003a). Therefore the influence of the retail store has to be considered. According to retailing research literature, consumers' perception of the store can be regarded as being closely related to the construct "store image". In an early and typical definition, Martineau (1958, 47), characterizes store image as "the way in which a store is defined in the shopper's mind, partly by its functional qualities and partly by an aura of psychological attributes." As store image research has identified the major facets of store image, this study will draw on those studies (Lindquist 1974; Mazursky and Jacoby 1986; Mitchell 2001) to capture the evaluation of major store attributes which correspond to the consumers' perception of the elements of the retail marketing mix instruments (Bloemer and de Ruyter 1998). Three store image facets that appear in almost every store image study are assortment and price, service and store atmosphere. As environmental psychology suggests, environmental stimuli such as characteristics of the retail store influence product evaluations (Bitner 1992). Several studies have shown that consumers' reactions to the products are affected by diverse elements of the store (see Turley and Miliman 2000 for a review on 60 studies). While these studies often only focus on single or few characteristics of the retail environment, Baker et al. (2002) use an integrative approach and show for multiple store environment cues (social, design, and ambient factors) how they influence consumers' perception of the merchandise value. Based on previous research we propose:

H2: The better the evaluation of the retail store is, the higher is product brand loyalty.

*Verticalization*. Following McCammon (1970), we include corporate vertical marketing systems (e.g. manufacturer-owned retail stores) and contractual vertical marketing systems (e.g. franchisees) in our conceptualization of verticalization. Verticalization of manufacturers into the retail channel can be interpreted similar to a brand extension. As branding literature suggests, not only context effects in general are important for consumer evaluations of the brand, but that a consistent brand environment is also critical to

generate brand loyalty (Lynch Jr., Chakravarti, and Mitra 1991). Similar to what has been analyzed mainly in the context of product branding strategies as "ingredient branding", which deals with situations in which a component of a total product is carrying its own brand label (Desai and Keller 2002), the product brand can be interpreted as an "ingredient brand" of the retail channel (Ailawadi and Keller 2004). Thus, aspects of image transfer between retail brand and the product brand are important (Park, Milberg, and Lawson 1991). According to this stream of literature, we propose that the product brand perception and retail store perception are intimately linked. Of major significance is consistency between product image and store image (Park et. al. 1991). Several empirical studies have shown the importance of retail store image for product brand image (Dodds, Monroe, and Grewal 1991; Yoo et. al. 2000). In vertically integrated channels the channel strategy, and thus, the retail marketing mix elements applied are aligned according to the manufacturers' brand strategy. Therefore, a high degree of fit between product brand image and channel image should be the rule. As brand extension literature suggests, this should result in a more consistent brand image (Ailawadi and Keller 2004). For our analysis of the impact of vertical strategy, we refer mainly to inference theory and schema theory. Inference theory suggests that consumers make their judgments about the product based on the information they receive from the cues that are available to them (Baker et. al. 2002). According to schema theory, consumers are guided by schemas, that is cognitive structures of organized prior knowledge, when making judgments about products (Fiske 1982). Vertical channels should deliver more consistent cues. We therefore suppose that the related effects such as halo-effects or irradiation are more important in vertically integrated than in conventional channels. This is also in line with implications from the literature on contextual correction or assimilation and contrast effects (Martin 1986), which implies that the level of congruence between cues (e.g. the retail store characteristics) and the product brand is important because consumers assess the correctness of their reaction to a product by elaborating on differences or similarities between the cues and the target. Thus, we propose a moderating effect:

H3: The relationships between product brand perception and product brand loyalty and between the retail store perception and product brand loyalty are moderated positively by verticalization.

*Involvement*. Consumer behavior research has shown that personal characteristics of the consumers impact their choice and buying behavior (Sheth 1983). In this context, numerous variables

such as demographics (e.g. age, gender) or psychographics of the consumers (e.g. personality, shopping motives, lifestyle, and experiences) have been analyzed. Out of these, involvement is considered as one of the most important factors of influence on consumer evaluation processes of products and retail stores and on the development of brand loyalty (Johnson et. al. 2006). Involvement has been conceptualized and measured in a variety of ways (see Bienstock and Stafford 2006 and Zaichkowsky 1985 for an overview). Following Zaichkowsky (1985, 342), we define involvement as "A person's perceived relevance of the object based on inherent needs, values, and interests" and relate to product category involvement. In previous research, numerous theories and studies point to the importance of involvement and state a significant influence of involvement on consumers' cognitive, affective and behavioral responses such as attention, processing, search, satisfaction or brand commitment (Laaksonen 1994 provides an overview). One of the most influential models to explain the effect of involvement is Petty and Cacioppo's (1984) Elaboration Likelihood Model (ELM). Transferring these insights from previous research to our research questions, we assume that the evaluation processes of higher involved consumers should be more pronounced and more elaborate than those of lower involved consumers. They therefore should lead to more pronounced product brand loyalty (Bloemer and Kasper 1995; Olsen 2007). We consequently suppose:

*H4*:   The relationships between product brand perception and product brand loyalty and between retail store perception and product brand loyalty are moderated positively by consumers' involvement.

Although consumers' involvement has been studied extensively in the field of consumer research, only few studies addressed the relationship between involvement and types of retail stores (King and Ring 1980 or Lockshin, Spawton, and Macintosh 1997), and, more specifically, only few studies have analyzed the significance of involvement in the context of manufacturers' vertical channel strategy. One of the few examples is Csipak, Chebat, and Venkatesan's (1995) study on the relationship between type of channel (direct versus indirect) and involvement in the service industry. Drawing from brand extension and involvement research, we suppose that in vertical channels where product brand and retail image are aligned, higher involvement should lead to even more manifest and enduring loyalty intentions than in conventional channels. This is also in line with cue utilization theory (Olson and Jacoby 1972), which suggests that consumers try to reduce risk by using cues (e.g. brand, price, or store characteristics) as indicators of product quality and that in the low involvement case, consumers apply simple decision rules in arriving at attitudinal judgments. Under high involvement conditions, the interaction between consumer and stimuli is an ongoing process and information is processed in a more detailed and thoughtful manner (Hansen 2005). This is also suggested by contextual correction literature, which implies that consumers need to be motivated to elaborate on differences or similarities between environmental cues and the product brand to form long-term attitudes (Bosmans 2006). Congruity between product brand and distribution channel, which should be the rule in vertical channels, therefore, should lead to even more pronounced and more long-term positive reactions towards the product brand (Park et. al. 1991). We consequently propose a moderating effect of verticalization:

*H5*:   The moderating effect of involvement on the relationships between product brand perception, retail store

perception and product brand loyalty in vertical channels is stronger than in conventional channels.

## METHODOLOGY

To test our hypotheses, we chose product brands as stimuli that are distributed both in vertical and in conventional channels. We selected four different product brands (Esprit, s.Oliver, Tom Tailor, Street One) based on market share ("share of closet", see Du, Kamakura, and Mela 2007) and the number of vertically integrated outlets of the manufacturers in Germany. We conducted our empirical study in two German cities and included twelve different retail stores in which these products are sold in our study. We chose these stores based on market share and included seven vertical outlets and five conventional retail stores (in which all four product brands were available) into our study. To collect our data, interviews were conducted in the pedestrian area of both cities. Therefore, a random sample could not be achieved. To obtain a representative sample, respondents were selected based on a quota plan (age and gender according to German fashion shopper characteristics). Each respondent was asked about one product and the store in which he shops most often for this brand. Respondents were allocated almost equally to the product brands and the retail stores (795 respondents, vertically integrated: m=389, conventional retail channels: n=406), taking into account quotas for age and gender for each sub-group.

Measure validation and model testing were conducted using SmartPLS (Partial Least Squares), a structural equation modeling tool that utilizes a component-based approach to estimation. We chose PLS because it allows representing both formative and reflective latent constructs (Jarvis, MacKenzie, and Podsakoff 2003) and avoids the problem of underidentification that can occur under covariance-based analysis (e.g. LISREL) (Bollen 1989). Product brand and retail store perception are often captured with multiattribute models. Despite the great amount of literature on these topics both for product brand and retail store perception no commonly agreed upon scales exist. Product brand perception and retail store perception each reflect a composite of individual characteristics of the product and the channel and therefore are operationalized effectively in a formative rather than reflective way. Considering content specification and indicator specification, we sought to capture the facets of product and retail store perception in a comprehensive manner. As the choice of indicators is critical for the design of formative constructs (Diamantopoulos and Winklhofer 2001), we developed our scales based on a broad literature review and managerial interviews. We extracted 16 items to describe product brand perception (see Birtwistle and Tsim 2005 for an overview) and 21 items to describe retail store perception in the fashion industry (see Lindquist 1974 and Mitchell 2001 for an overview). Because our intention was to capture all salient characteristics of the product and the store, we conducted a pretest. The main purpose of this pretest was (1) to analyze if all relevant attributes were included in our scale and (2) to eliminate irrelevant items from the scale. After this pretest, we reduced the item battery for product brand perception to 12 items (utilitarian dimension: 7 items, hedonic dimension: 5 items) and the item battery for retail store perception to 16 items (assortment/price: 7 items, service: 6 items, store atmosphere: 3 items). Substantial collinearity among indicators would affect the stability of indicator coefficients in formative measurement models because they are based on linear equation systems. In our study, none of the indicators revealed multicollinearity problems (none of the variance inflation factors exceeded 2.76). All product brand perception dimensions have been compared across the different retail settings and didn't show significant differences. Thus, product brand perception captures

**EQUATION 1**

$$t = \frac{path_{sample1} - path_{sample2}}{\left[\sqrt{\frac{(m-1)^2}{(m+n-2)} * S.E._{sample1}^2 + \frac{(n-1)^2}{(m+n-2)} * S.E._{sample2}^2}\right] * \left[\sqrt{\frac{1}{m} + \frac{1}{n}}\right]}$$

perceptions that are distinct from informants' perceptions of the associated retail stores.

In formative measurement models it is critical to pay attention to nomological validity as internal consistency reliability is not an appropriate standard for evaluating the adequacy of the measures (Bollen and Lennox 1991; Jarvis, MacKenzie, and Podsakoff 2003). We therefore included 3 additional items in our survey that captured general assessments of the product brand and the retail store, respectively (overall assessment of product brand/retail store; trust towards product brand/retail store; judgment, whether product brand/retail store serves to satisfy consumer's needs). According to branding literature and according to our theoretical assumptions, the constructs we included in our model should show a positive relationship towards these constructs. We estimated bivariate correlations between the formative constructs (results from PLS regression) and the general evaluative constructs. All correlations were positive and significant (range from .30 to .60, p<.01). As the constructs behave as expected with respect to other construct to which they are theoretically related (Churchill 1995), we assume that nomological validity is satisfactory with respect to all the relevant variables.

Involvement was measured with reflective indicators. We used Tigert, Ring, and King's (1976) fashion involvement index which captures fashion innovativeness, fashion interpersonal communication, fashion interest, fashion knowledgeability and fashion awareness as dimensions of fashion involvement (also see King and Ring Lawrence 1980). To conceptualize brand loyalty we also chose a reflective measurement approach. Following Zeithaml, Berry, and Parasuraman (1996) and Aaker (1996), loyalty was captured using four items measuring the intention to recommend, the likelihood of repurchases, the cross-buying-intention and the willingness to pay a price premium for the brand. The measurement model of the reflective indicators was assessed for internal consistency. For involvement, the average variance extracted (AVE) of .41 was considered as acceptable because Cronbach's Alpha of .76 was satisfactory and composite reliability was as high as .76 (Bagozzi and Baumgartner 1994). The brand loyalty scale also shows a high level of internal consistency with regard to Cronbach's Alpha of .77, AVE of .62 and composite reliability of .86. In addition, we assessed discriminant validity for the reflective constructs with Fornell and Larcker's (1981) criterion. The square root of the average variance extracted for involvement and for loyalty was greater than the correlation between involvement and loyalty and any other construct. The discriminant validity, thus, was satisfactory.

## HYPOTHESES TESTING AND DISCUSSION

To test our hypotheses, we conducted PLS regression. To analyze the moderating effect of involvement, interaction terms were calculated by multiplying construct values for the diverse dimensions of product brand perception and of retail store perception (all formative constructs) which were calculated in a separate, non-moderated path model, and the indicator values of the reflec-

tive measurement model of involvement (all values were standardized before calculating the product terms; see Chin, Marcolin, and Newsted (2003) for this procedure to model interaction effects). Verticalization was measured as a binary construct (coded as a dummy variable) based on company information. Therefore, to assess moderating effects of verticalization we conducted multigroup analysis. We calculated separate PLS regression models for vertically integrated channels and for conventional channels, respectively. We then calculated the significance level of the observed differences between both models assuming that path coefficient variances in both groups are approximately equal using t-test. To calculate t-test, we used standard errors from bootstrapping. These values are mean adjusted reflecting standard deviation of the sampling distribution opposed to the sample standard deviation. Therefore, to calculate t-test, this has to be corrected by multiplying the standard errors from the bootstrapping procedure with the square root of the sample size (Chin 2000) (Equation 1).

The results of the moderated PLS model and the t-test are displayed in table 1. While it is not possible to report an overall goodness of fit for the model, because the objective of PLS is prediction versus fit (Fornell and Cha 1994), the $r^2$ values of brand loyalty as well as the Stone-Geisser-Criterion which assesses the predictive quality of the model ($Q^2$ values) indicate an adequate model specification for each of the models (Chin 1998).

In hypothesis 1 we proposed a positive effect of product brand evaluation on brand loyalty. Our results show a positive significant effect which is higher for the utilitarian dimension of the product brand than for the hedonic dimension. This result was interesting as it indicates that also in the fashion industry, where one could argue that emotional aspects of the product should be of high importance, functional aspects seem to dominate in terms of influence on long-term brand loyalty. Hypothesis 2 that relates to the impact of the evaluation of the retail store on product brand loyalty is only partly supported by our empirical results. The impact of assortment/price perception and of service perception on product brand loyalty in model 3 (all respondents) is positive and significant, whereas, contrary to our expectations, no significant effect can be shown for the perception of store atmosphere. This result was interesting as we supposed that especially in the fashion industry such aspects should be important.

Hypothesis 3 posited a moderating effect of verticalization. The results show that four of the relationships we examined in our analysis are moderated by verticalization, but the empirical data supports hypothesis 3 only partly because only two of these moderating effects are in the postulated direction. According to our assumptions, the perception of assortment and price exerts a higher influence on product brand loyalty in vertically integrated channels. Also, the impact of store atmosphere, which shows a positive and significant influence in model 1 (vertically-integrated channel subsample) but no significant influence in model 2 (conventional channel sub-sample), seems to be moderated positively by verticalization. However, the perception of services seems to be negatively moderated by verticalization. This could be interpreted

**TABLE 1**

Results of partial least squares

as an indication that in conventional channels service aspects that do not relate specifically to the product brand seem to exert a positive influence. This seems plausible as it could point to the availability of a higher variety of service dimensions in conventional channels, for example due to a broader possible range of services which go beyond product brand specific services. Regarding product brand perceptions, the influence of the utilitarian dimension of product brand evaluation on product brand loyalty is moderated negatively by verticalization. Thus, in vertically integrated channels, as the evaluation of the retail store becomes more important, characteristics of the product brand become less important.

In hypothesis 4 we supposed a moderating effect of involvement. The results of model 3 show that only one out of five relationships under review is moderated by involvement: only the relationship between the perception of the hedonic product dimension and product brand loyalty shows the significant and positive effect we proposed in our hypothesis. This points to a high importance of emotional aspects of the products for higher involved customers which seems plausible for the fashion industry. All in all, we only find little support for hypothesis 4 in our data.

The analysis of the impact of verticalization on these moderating effects (hypothesis 5) shows three significant moderating effects of which only two are positive and one, however, is negative. According to our assumptions, the moderating effect of involvement on the relationship between the perception of hedonic dimension of the product and product brand loyalty is higher in vertically integrated channels. Whereas service dimensions of the retail store did not show a significant impact on product brand loyalty in vertically integrated channels, there seems to be positive and significant interaction between service perception and involvement in vertical channels while no significant interaction effect can be shown for conventional channels. The relationship between store atmosphere and product brand loyalty is moderated negatively by

verticalization. Interestingly, the impact of the store atmosphere perception on product brand loyalty in vertically integrated channels is moderated negatively by involvement. This seems to indicate that–in vertically integrated channels–the higher involved customers are, the more important are product oriented dimensions. Store atmosphere aspects in this situation probably are perceived as distracting customers from the product brand. Taking these results into account, hypothesis 5 is only partly supported.

As a general intention of our study was to analyze if vertically integrated channels are more successful than conventional channels, we conducted ANOVA (using the latent variable scores from the PLS regression) to analyze the differences in product brand loyalty between vertically integrated and conventional channels. The results (mean value vertically integrated channels: .19; mean value conventional channels: -.18; F=29.32; p=.000) show that indeed, as a result of the moderating effects on the relationships analyzed in our model, brand loyalty in vertically integrated channels is higher and thus, verticals seem to be more successful.

**CONCLUSIONS AND IMPLICATIONS**

With the results of our study, we can add to the knowledge on the sources of success of vertically integrated channel systems. Consonant with empirical observations on the continuously growing market share of verticals such as H&M, Zara, or Mango, our study shows an advantage of verticals in terms of consumers' loyalty. We were able to show that characteristics of the retail channel are important to build product brand loyalty and that the contribution of the retail store perception to product brand loyalty is significantly higher in vertically integrated channels. With our study, we also are able to show that the higher involved consumers are, the more important are hedonic aspects of the product for product brand loyalty creation. Our study also adds to the knowledge on the significance of involvement in the context of verticalization. The results show that verticalization moderates the

impact of involvement of the effects of product and retail store perception on product brand loyalty.

This study reinforces the commonly agreed upon assumption that for manufacturers a careful selection of distribution channels is of key importance to generate product brand loyalty. But our results also imply that verticalization seems to be more important for weaker brands. According to our results and contrary to what we expected, in conventional channels, the product brand seems to be less contingent on its retail channel environment (which is not as "tailor-made" as it is in vertically integrated channels) and the product characteristics themselves exert a higher influence on brand loyalty than in vertical channels. The product brand has to compete with other product brands in the assortment and single product brands receive less support from the channel environment. Thus, if the manufacturer has a strong product brand, verticalization is not necessarily required to be successful, whereas, on the other hand, weaker brands can benefit from the support of a favorable retail channel environment and this can be achieved more effectively in vertically integrated channels. In channel design, manufacturers also should care for consumers' involvement. Our study shows that with an increase in consumers' involvement, in vertical channels the impact of service aspects becomes more important, while, however, with higher involvement the impact of the store atmosphere is alleviated.

As with all research, our study is constrained by certain limitations, thus implying areas for further research. The limitations mainly refer to the focus of the analysis on the impact of retail channel characteristics. In future research, other factors of influence such as situational variables, additional personal characteristics, etc. should be analyzed. We also focused our analysis on brick-and-mortar outlets. We suggest that future analysis should investigate other channels such as remote ordering or the Internet and should take into consideration that some manufacturers use multichannel distribution systems. Also, we conducted our empirical study in the fashion industry. Future research should analyze if our results can be transferred to other categories in the consumer goods industry. A possible limitation of our study also could result from the retail context (fashion retailing in Germany) in which our study was conducted. Thus, in future research, the relationships should be tested in other countries and other retail sectors.

# APPENDIX
Measures

| A. Measures of Product Brand Perception<br>(anchors: 1=totally agree; 5=do not agree at all) |
| --- |
| Products of Brand X… |
| … have a good value for money. |
| … are of high quality in terms of fabrics, durability, wear resistance. |
| … are easy to clean. |
| … fit well. |
| … are comfortable to wear. |
| … are well-cut. |
| … match well within the product range of Brand X and can be combined in various ways (e.g. color patterns within the range). |
| … are aesthetic and tasteful. |
| … are expressive. |
| … are up-to-date / fashionable. |
| … are fancy / creative. |
| … are elegant. |
| B. Measures of Retail Store Perception<br>(anchors: 1=totally agree; 5=do not agree at all) |
| Store Y… |
| … provides a good value for money. |
| … offers high quality merchandise. |
| … offers a wide selection of merchandise. |
| … offers up-to-date / trendy merchandise. |
| … has a high in-store availability of products that I want to buy. |
| … offers exclusive products that are not available elsewhere. |
| … offers matching outfits (e.g. in terms of color concepts). |
| … always has enough sales people in the store. |
| … has sales people that are very customer-oriented (e.g. friendly, offer support). |
| … has sales people that are very competent (e.g. fashion know how). |
| … has an attractive in-store design. |
| … has an appealing exterior store design. |
| … has a clientele that I feel comfortable with. |
| … is clean, fair and tidy. |
| … offers good general services (e.g. payment methods, guarantees, return policy, changing rooms). |
| … allows efficient and quick shopping. |
| C. Fashion Involvement Index (Tigert, King, and Ring 1976)<br>(semantic differentials; 5-point scale, anchors: + 2 …-2) |
| I buy new clothing fashions earlier in the season than most others. -----<br>I buy new clothing fashions later in the season than most others. |
| I give a great deal of information about new clothing fashions to my friends. -----<br>I give very little information about new clothing fashions to my friends. |
| I am more interested in clothing fashions than most others. -----<br>I am less interested in clothing fashions than most others. |
| I am more likely to be asked for advice about new clothing fashions than most others. -----<br> am less likely to be asked for advice about new clothing fashions than most others. |
| I read the fashion news regularly and try to keep my wardrobe up-to-date with the fashion trends. -----<br>I am not at all interested in fashion trends. |
| D. Measures of Product Brand Loyalty<br>(anchors: 1=totally agree; 5=do not agree at all) |
| I would recommend to relatives and friends to buy products of Brand X. |
| The likelihood that I will buy products from Brand X in the next years is very high. |
| The likelihood that I will buy more products from Brand X in the next years is very high. |
| I am willing to pay a higher price for products from Brand x than for products from other fashion brands. |

# The Influence of In-Store Experiential Events on Shopping Value Perceptions and Shopping Behavior

Sean Sands, Monash University, Australia
Harmen Oppewal, Monash University, Australia
Micheal Beverland, The University of Melbourne, Australia

## ABSTRACT

This paper investigates the potential for experience enhancing in-store retail events to impact consumer value perceptions and behavior. We report findings from a survey where the presence and type of in-store experiential event was varied by shopping scenario descriptions with regard to DIY category shopping. ANOVA and mediation tests are conducted and indicate that the presence of an in-store event significantly increases consumer value perceptions and reported shopping behavior intentions. We find no significant differences among the types of in-store event presented for either perceived shopping value or shopping behavior intention. We do, however, find event specific effects for consumers perceived shopping enjoyment.

## INTRODUCTION

Since Kotler (1973-1974) coined the term atmospherics a plethora of research has investigated the impact of visual, aural, olfactory, and tactile dimensions of the retail environment on a variety of behavioral factors (Turley and Milliman 2000). Studies have investigated the impact of these variables in isolation (i.e., the effect of music only), or in some combination (i.e. the effects of music and lighting). However, in all these studies the effects of the holistically experienced retail environment have remained somewhat unexplored. Indeed, although the individual atmospheric variables are important in the development of a retail experience (Machleit and Eroglu 2000; Morrison and Beverland 2003; Pine and Gilmore 1999), their final effects may be dependent upon the consumer's affective evaluation of the environment (Snodgrass, Russell, and Ward 1988). We therefore suggest that the literature on atmospherics and retail experience would be enhanced by empirical research examining the impact of in-store experiential events on consumers.

A holistic perspective on retail experience is provided by Pine and Gilmore (1999) and Schmitt (1999), who both propose that there are unique dimensions that encompass the multiple aspects of atmospheric variables forming retail experiences. We adopt the typology of Pine and Gilmore (1999) as the basis for formulating experiential in-store event dimensions. These dimensions are the (i) aesthetic, which includes the visual, aural, olfactory, and tactile dimensions, (ii) educational, (iii) entertaining, and (iv) escapist, which at its extreme may allow consumers to experience an alternate reality. In this paper, we study the effects of these four types of retail experience on consumer value perceptions and behavioral intentions. We in particular investigate if value perceptions mediate the effects of the types of retail experience on behavioral responses. Overall, we hypothesize that as atmospheric variables have been shown to positively impact consumer value perceptions and behavioral responses, so too may the presence of in-store experiential events. Essentially we propose that these events positively impact consumer perceived shopping value perceptions and, consequently, also consumers' intended shopping behavior.

We test this notion in a survey among a sample of shoppers in a DIY category using an experimental approach. The survey presented respondents with different descriptions of in-store events based on the typology by Pine and Gilmore (1999). Results indicate

that the presence of an in-store event significantly increases value perceptions, in particular expected shopping enjoyment, and reported shopping behavior intentions. We find limited effects for the type of event presented. The type of in-store event presented influences the level of perceived shopping enjoyment but not the other value components, convenience and risk. Before discussing the further details of our hypotheses and findings we provide a summary of the pertinent literature in the section below, followed by a description of the method of our study. Finally, we discuss the implications of the main findings and provide recommendations for future research.

## RELEVANT LITERATURE

Most literature on retail environments draws its theoretical foundations from either environmental psychology and the S-O-R paradigm or the perceived value framework. As comprehensively summarised by Turley and Milliman (2000), this S-O-R paradigm assumes that environments contain stimuli (S) that cause changes to a consumer's organismic (or internal) state (O), which in turn cause approach or avoidance responses (R) (Mehrabian and Russell 1974). The S-O-R paradigm explains and presents evidence pertaining to numerous environmental cues, such as visual, aural, olfactory and tactile cues, and their related effects on consumer responses. For example, Mehrabian and Russell (1974) assert that shoppers react to retail environments with approach (e.g. desire to stay in the environment, or actively explore) or avoidance (e.g. desire to leave) behaviors. These studies have typically investigated the effects of either singular (i.e., music) or some combination (i.e., music and lighting) of atmospheric independent variables on a number of dependent variables.

Although atmospheric variables in isolation can have positive effects, as highlighted in Turley and Milliman's (2000) review, in practice these variables produce their effects in combination with other in-store variables. Little seems to be known about how combinations of atmospheric variables, in terms of retail experience, impact consumer behavior (Baker et al. 2002; Beverland et al. 2006; Wakefield and Baker 1998) and current perspectives provide mixed results. In general, pleasant environments have resulted in positive effects, however arousing environments have resulted in mixed findings (Kaltcheva and Weitz 2006). Baker et al. (2002) suggest that stores which engage high shopping experience costs may encourage consumers to avoid the store.

The perceived value paradigm has also been influential in the study of retail environments (Day and Crask 2000; Sweeney and Soutar 2001; Woodruff 1997). Zeithaml (1988, 14) defined perceived value as "…the consumer's overall assessment of the utility of a product based on perceptions". To date, studies have attempted to correlate perceived shopping value to retail variables such as satisfaction (Babin, Darden, and Griffin 1994; Babin et al. 2005), customer share (Babin and Attaway 2000), and repatronage intentions (Stoel, Wickliffe, and Lee 2004). Some have included a focus on retail variables, such as satisfaction, word-of-mouth, loyalty, repatronage intentions and repatronage anticipation (Jones, Reynolds, and Arnold 2006). In addition, previous research has shown that shopping environments can impact consumer percep-

tions, potentially impacting a variety of behavioral variables from enjoyment to behavioral intention (Turley and Milliman, 2000). There has been however little research investigating the impact of experience enhancing retail events on value perceptions.

Within the shopping value literature two types of value are often identified, being utilitarian and hedonic value (Babin et al. 1994; Childers et al. 2001). Utilitarian shopping value can be related to the consumer's need to obtain some utilitarian consequences from visiting a store (i.e., obtaining product information, acquiring a product) and incorporates aspects such as shopping convenience and perceived risk. Hedonic shopping value can be related to the consumer's need to obtain fun and pleasure and relates to the perceived level of shopping enjoyment. These dimensions of perceived shopping value refer to consumers' perceived utility on utilitarian and hedonic dimensions. However, there have been mixed results from studies investigating the effects of retail environments on shopping behavior (Kaltcheva and Weitz, 2006).

Two things seem to have remained unexplored in this literature. Firstly, the two paradigms have not been brought together to investigate how retail experiences can potentially increase value perceptions (Jones et al. 2006), referred to as perceived shopping value in this paper. Secondly, there has been limited empirical investigation if, and when, retail experiences impact behavioral variables, for example shopping behavior intentions. Both Pine and Gilmore (1999) and Schmitt (1999) develop operational typologies of retail experience, both proposing that there are unique dimensions encompassing the multiple aspects comprising retail experience. Thompson and Arsel (2004) note that both of these typologies offer consumers distinctively themed servicescapes, designed to facilitate the experience.

Schmitt (1999) develops a typology of experience based on five key dimensions, sense, feel, think, act, and relate. These dimensions provide a framework by which companies and brands can engage consumers in an experiential manner. Alternatively Pine and Gilmore (1999) developed a fairly operationally defined view of retail experience. In their view, retail experience can comprise of four experience realms: the aesthetic, educational, entertaining and escapist realm. Whilst both typologies provide potentially fruitful avenues for empirical investigation, we adopt the Pine and Gilmore (1999) typology in this paper. One reason for this adoption is that the Schmitt (1999) typology seems particularly well suited to the creation of brand experiences. For instance, Schmitt (1999) proposes that consumers be engaged to sense, feel, think, act, and relate. The Pine and Gilmore (1999) typology provides four distinct experience designs particularly well suited to retail settings, aesthetic, education, entertainment, and escapism. Furthermore, these four realms are well suited to form the basis of distinct offerings in an experimental setting.

Based on this typology, we define an in-store experiential event as an event that encompasses the multiple aspects of retail atmospherics (i.e., the aesthetic environmental attributes) and engages the individual in either, an aesthetic experience, an educational experience, an entertainment experience, or some form of escapist experience. A key component in defining an in-store experiential event is that these events can vary along the dimensions of participation and immersion. Educational and escapist events allow the consumer to actively participate where entertaining and aesthetic events are passive.In addition, escapist and aesthetic events allow the consumer to be immersed in the environment, whereas an entertaining or educational event allow for the consumer to absorb some form of knowledge or information. Hence, an in-store experiential event differs from an atmospheric variable in terms of the way in which a consumer is immersed and participates within the store setting.

## HYPOTHESES

Based on the theoretical ascertains in the previous section we develop several testable hypotheses. First, given that previous research has shown store environments can positively impact consumer behavior we predict that in-store experiential events will impact consumers in a similar manner. Consequently, we predict that the presence of experience enhancing in-store events will positively influence our dependent variables, increasing (*H1*) consumer shopping value perceptions and (*H2*) consumer shopping behavior intentions. Furthermore, and drawing from both the S-O-R and the value framework we propose that in-store experiential events (S) cause changes to consumers' perceived shopping value (O), which in turn impact consumer shopping behavior intentions (R). Hence we predict that (*H3*) the relationship between the presence of such in-store events and shopping behavior intention is mediated by perceived shopping value, with higher levels of perceived shopping value resulting in higher levels of shopping behavior intention. Finally, given that we adopt the Pine and Gilmore (1999) typology, experimentally manipulating the type of in-store event we predict that (*H4*) events generating different types of experience will have different effects on the value generated. Specifically, given that the educational and escapist events allow consumers to learn and engage with the products (active participation) we expect these events to differ from the aesthetic and entertaining events as these events are purely passive in participation. On the dimensions of perceived shopping value, we predict that active events (education, escapist) will reduce consumer levels of perceived risk, increase their perceived convenience, and not differ across expected enjoyment levels. In a similar vein, we predict that the active events will significantly increase shopping behavior intentions.

## METHOD

### Sample

Telephone recruitment was used to approach a random sample of households in a large Metropolitan area for participation in a mail-back survey about shopping for DIY products. Of 488 questionnaires distributed, a total of 312 (64%) was returned. The sample consisted of 58.8% females. In terms of age, a wide range of age groups was represented.

### Experimental procedure and design

The questionnaire first asked respondents about their most recent visit to a DIY store. They were then presented with a hypothetical scenario in which they were supposed to revisit this store but the store would be hosting a special event. Asking to imagine a store that they were familiar with allowed for a point of reference for consumers (Starmer 2000). The event descriptions that followed manipulated the in-store event along the four Pine and Gilmore (1999) event dimensions. For example, with the educational scenario the description was as follows:

When you reach the store you find out that the store has an in-store event running, this event is based on the concept of education. Within this store you are presented with the ability to seek professional advice by way of in-store presentations and/ or one-on-one interaction with specialists.

The remaining scenarios were described in a similar manner. The manipulation of store environments in order to measure consumer responses has proven successful in previous research (Koelemeijer and Oppewal 1999). In addition to the experimental conditions a separate control version was created in which no event

was described to respondents. The control scenario provided no information about an in-store event to the respondents. This resulted in a between-subjects design with five questionnaire versions for the four event types and one control. Each respondent was randomly allocated into one of the five scenario conditions. . Of the 312 questionnaires received, 64 were from the aesthetic event scenario, 74 from the educational scenario, 70 from the entertaining scenario, 69 from the escapist scenario, and 35 from the control condition.

### Dependent variables

There were two key behavioral dependent variables measured in the study, perceived shopping value and shopping behavior intentions. The dependent variable of perceived shopping value relates to the "consumer's overall assessment …based on perceptions of what is received and what is given" (Zeithaml, 1988, 14). Whilst the most common trade-off is between quality and price (Monroe 1990), Sweeney and Soutar (2001) suggest that this is often an overly simplistic definition. To measure perceived shopping value in relation to retail experience we adapt measures for three sub-dimensions, perceived shopping risk (Jacoby and Kaplan 1972, Sweeney, Soutar, and Johnson 1999), perceived shopping convenience (Seiders et al. 2005), and perceived shopping enjoyment (Childers et al. 2001). The second dependent variable was shopping behavior intention. This was a six-item scale based on Donovan and Rossiter's (1982) scale and its later refinement by Kaltcheva and Weitz (2006). All items were scored on a seven-point Likert scale, anchored by 'strongly disagree' and 'strongly agree'.

### Manipulation check

Following the description of the in-store experiential events, respondents were asked to write one thing that they liked (and one that they disliked) about the event described to them. Analysis of the open-response comments formed the basis for the manipulation checks. The open-responses were coded in terms of 5 categories, aesthetic-based, education-based, entertaining-based, escapist-based, and other for responses outside this classification. The percentage responses coded in correspondence with the manipulations were .39 for aesthetic, .63 for educational, .33 for entertaining, and .52 for escapist. All these percentages are significantly higher than the chance rate of .20. Hence, the open-ended responses indicate that the manipulation of the events was comprehended in the intended manner.

## RESULTS

### Perceived shopping value

The first dependent variable of interest was perceived shopping value. The measure of perceived shopping value comprised a summation of the three separate measures on the dimensions of hedonic and utilitarian value: perceived shopping convenience, perceived shopping risk, and perceived shopping enjoyment. These three constructs had Coefficient Alpha reliabilities of: .82, .83, and .89, respectively. For analysis purposes, respondents were divided into two groups (Group 1: The experiential condition; Group 2: The control condition) in order to test for difference in behavior depending on the presence or absence of an in-store event. A one-way between groups analysis of variance was conducted to explore the impact of experiential events on levels of overall perceived shopping value and the three individual components of the perceived shopping value.

There was a statistically significant difference in overall perceived shopping value scores between the experiential event condition and the control condition [$F(1, 290)=18.16$, $p \leq .001$]. The actual difference in mean scores between groups was medium according to Cohen's (1988) criteria. The size of the effect can be assessed by calculating partial eta squared, which provides an estimate of the strength of association available for ANOVA. When there are two levels of the independent variable eta squared is the point biserial correlation between the continuous (dependent) variable and the dichotomous variable (Tabachnick and Fidell 2001). In this instance, the effect size was .06.

Further analysis of the individual components of overall perceived shopping value was conducted. There was a statistically significant difference in perceived shopping enjoyment scores between the experiential conditions and the control condition [$F(1, 299)=23.61$, $p \leq .001$]. The actual difference in mean scores between groups was medium according to Cohen's (1988) criteria. This effect size, calculated using eta squared, was .07. The remaining components, perceived shopping convenience and perceived shopping risk, did not differ significantly between any of the groups. In summary, hypothesis 1 is supported as the in-store experiential event did influence overall perceived shopping value. The event specifically affected the perceived shopping enjoyment component and not the convenience or risk dimensions of perceived shopping value.

### Shopping behavior intention

For testing the influence of in-store events on shopping behavior intention, a similar ANOVA was conducted with shopping intention as the dependent variable. $H_2$ predicts that the in-store experiential events will result in overall higher levels of shopping behavior intention. Again, for analysis purposes, respondents were divided into the same two groups as previously. A one-way between groups analysis of variance was conducted to explore the impact of experiential events on levels of shopping behavior intention.

There was a statistically significant difference in overall shopping behavior intention scores between the experiential condition and the control condition [$F(1, 293)=10.49$, $p \leq .01$]. The actual difference in mean scores between groups was small according to Cohen's (1988) criteria. This effect size, calculated using eta squared, was .03. These results suggest that when respondents were presented with a condition in which an experiential event was present their overall shopping behavior intention increased. In summary, hypothesis 2 is supported as the in-store experiential event did influence consumers reported shopping intentions.

### Mediation tests

$H_3$ predicts that the relationship between in-store experiential events and shopping behavior intention is mediated by perceived shopping value. It is anticipated that the mediation will work such that the announcement of the event will result in increased levels of perceived shopping value which in turn will enhance shopping behavior intention. We followed Baron and Kenny's (1986) criteria for mediation. These authors recommend a 3-stage, sequential procedure whereby: i) each mediating variable is estimated as a function of the independent variable, ii) the dependent variable is estimated as a function of the independent variable, and iii) the dependent variable is estimated as a function of the mediating variable as well as the independent variable. For mediation to exist, the beta coefficient for the independent variable must be non-significant in the presence of the mediating variable. If this beta coefficient is reduced but is still significant, then it can be concluded that the effect of the independent variable on the dependent variable is only partially mediated.

The results reveal that the direct path from in-store event to shopping behavior intention was significant (beta=4.03, $t=3.2$, $p \leq$

.001). Respondents who had been exposed to an experiential event indicated higher levels of shopping behavior intention than those who had not been exposed to an experiential event. The effect of the independent variable on the proposed mediator was also statistically different from zero (beta=6.06, $t$=4.23, $p \leq .001$), hence respondents who were exposed to an experiential event indicated higher levels of perceived value. Finally, for mediation to exist, the beta coefficient for the independent variable must be non-significant in the presence of the mediating variable. The direct effect of the independent variable on the dependent variable, controlling for the mediator was not statistically different from zero (beta=1.97, $t$=1.64 $p >$·.05), indicating no relationship between the event and shopping behavior intention when controlling for perceived shopping value. Thus, all of Baron and Kenny's (1986) criteria for mediation are established, which confirms mediation and provides support for hypothesis 3. This result indicates that the level of perceived shopping value does mediate the relationship between experiential events and shopping behavior intention.

**Differences between events**

There was a statistically significant difference [$F(4, 287)$=5.06, $p \leq .001$] in overall perceived shopping value scores between each of the four experimental groups [aesthetic ($M$=55.02, SD=7.84), education ($M$=53.39, SD=8.32), entertaining ($M$=53.70, SD=7.51), and escapist ($M$=53.16, SD=7.48)] and the control group ($M$=47.83, SD=7.54). In this instance, the effect size was .07. Planned comparisons revealed no significant difference amongst the event types. Further analysis of the individual components of overall perceived shopping value revealed a statistically significant difference in perceived shopping enjoyment scores between each of the in-store event conditions and the control condition [$F(4, 296)$=7.22, $p \leq .001$]. The actual difference in mean scores between groups was medium according to Cohen's (1988) criteria. This effect size, calculated using eta squared, was .09. Planned comparisons revealed a significant difference [$F(1, 296)$=3.91, $p \leq .05$] in the mean score between the aesthetic event ($M$=18.73, SD=5.01) and each of the remaining event types. There were no further differences between the event types.

There was a statistically significant difference [$F(4, 290)$=3.33, $p \leq .05$] in overall shopping behavior intention scores between the event conditions and the control condition. The actual difference in mean scores between groups was small according to Cohen's (1988) criteria. This effect size, calculated using eta squared, was .04. Planned comparisons revealed no significant difference among the four in-store event types. In summary, hypothesis 4 can not be supported as there were no significant differences amongst the four event types in either perceived shopping value of shopping behavior intentions. There was, however a significant difference in perceived shopping enjoyment for the aesthetic event.

## DISCUSSION

The experiment presented here investigated the impact of in-store experiential events on consumers' perceived shopping value and shopping behavior intentions. In addition, we investigated if there were any differences on these dependent variables among the four event types used in the hypothetical scenarios. The experiment was conducted among a sample of potential real shoppers in a large metropolitan area and involved the manipulation of store descriptions presented in a survey. The S-O-R and value frameworks provided useful foundation to investigate the impact of in-store experiential events (S) on perceived shopping value (O) and shopping behavior intentions (R). In the present study, it was found that in-store experiential events are significantly associated with both perceived shopping value and shopping behavior intentions. Furthermore, perceived shopping value acted as a mediator variable between the in-store event and the consumers shopping behavior intentions.

With regard to perceived shopping value, our results found evidence for differentiated influences of the experimental condition, the in-store event, especially for perceived shopping enjoyment. Our findings suggest that when a retailer has an in-store experiential event, overall consumer expectations of the shopping experience increased. This increase is driven in particular by the hedonic value dimension, measured as perceived shopping enjoyment, and not by the utilitarian value dimensions, which were operationalised as convenience and risk. Regarding the latter, apparently, in the category studied (DIY) the presence of an in-store experiential event is not seen as a component of the retail environment that will make shopping more risky or difficult.

With regard to consumers' shopping behavior intentions, we found support for differences in overall shopping behavior intention scores between respondents in the experiential conditions and the control condition. In general, respondents reported behavioral intentions (i.e., approach, purchase intention) increased when a store had an experiential event present. We also found a direct mediating effect of perceived shopping value between in-store retail events and shopping behavior intention. The results fulfilled the mediation criteria set by Baron and Kenny (1986).

In this study we found no significant differences between the in-store experiential event types based on the active and passive scenarios. On both of the dependent variables, perceived shopping value and shopping behavior intentions, all four event types were significantly different to the control. We found a difference between the aesthetic event and all other event types on the value dimension of expected shopping enjoyment. Overall, our respondents reported significantly higher anticipated enjoyment for the aesthetic event. There were no other differences amongst the event types. In some respects this conforms to previous findings which have found conflicting results in highly arousing environments (i.e., active) and more consistent, and positive, effects in pleasant (i.e., passive) environments (Kaltcheva and Weitz, 2006). There are two potential explanations for this lack of differentiation between the event types. First, whilst the Pine and Gilmore (1999) typology provides an attractive framework, perhaps the dimensions are undifferentiated and consumers do not clearly see the difference between an entertaining and an educational event. Furthermore, there may be heterogeneity within the sample, such that certain consumer segments may prefer certain event types, however this was not the focus of this study.

There are some limitations to this study. The most important is that it has relied on written descriptions of the retail environment and events. This is however a limitation that is shared with the majority of research into retail atmospherics (Erogul and Machleit 1990; Gardner and Siomkos 1986). Further research should be conducted in real retail store settings, preferably using experimental manipulations of in-store experiential events, to further investigate aspects of consumer expectations, shopping goals, and behavioral outcomes.

Keeping these limitations in mind, we are able to make a number of recommendations. Our findings suggest that consumers exhibit different behavioral intentions towards retailers depending on the retail environment and the consumer's level of perceived shopping value, in particular their level of perceived shopping enjoyment. The results empirically confirm that in-store experiential events can positively influence consumer behavior in terms of both their subjective value perceptions prior to the consumption

experience and their anticipated behavioral responses. From the findings presented in this paper, we conclude that experiential events can be a determinant of how consumers evaluate a retail encounter. Our findings build on previous research that has shown the impact of atmospheric variables to show that retail experiences can positively impact consumer behavior. Designing experiments within retail environments to study the actual impact on consumers and retailer outcomes would be a logical next step in this area.

# Consuming $30-a-Pound Cheese: The Role of the Retail Cheesemonger as *CICERONE*

Scott D. Roberts, St. Edward's University, USA
W. Brett McKenzie, Roger Williams University, USA
Kathleen Shirley Micken, Roger Williams University, USA

## ABSTRACT

To get artisan cheese from producer to consumer requires a uniquely different channel than for most agricultural products, with a cheesemonger playing a central role. Artisan cheese making, distribution and sale in the northeastern United States are both sufficiently established and rich in regional variation to support examining the cheesemonger/cheese consumer interaction. Through traditional qualitative methods of observation, interview, and immersion, we identify and document the important rituals that accompany the cheese buying process. We explain the pivotal roles of narrative and story and of store atmospherics and staging to the process of making meaning in the cheesemaker to cheesemonger to cheese consumer channel.

*"What we need," a woman said, "is more skilled cheesemongers."*
*Adam Gopnik, 1990 American Cheese Society Meeting, NYC.*

## INTRODUCTION

Cheese is the central object, frequent passion and oftentimes obsession of the cheesemaker, cheesemonger and devoted cheese consumer. The central figure in the commercialization of artisanal cheese is the cheesemonger, who performs an evangelist-like role for great cheese. S/He serves the artisanal producer by consulting on the product, working with the media to present and highlight the novel, and serving as a guide, or *cicerone*, for purchasers looking for new experiences.

The definitions for categories/types of cheeses among cheesemakers and cheesemongers in the United States are not codified in regulatory language, as they are in the European Union. Some terms, however, are common and important for the cheesemaker, monger, and connoisseur. *Farmstead* cheese is made of milk from animals owned and husbanded by the cheesemaker. *Artisan* (or sometimes *farmstand*) cheese is made from the milk of local animals, hand-crafted in small batches, usually via traditional methods. *Specialty* cheeses are often made by a cooperative, yet are still of high quality. *Industrial* cheese is made in a factory, with the aim of producing a cheese with minimal variation in taste or texture from one batch to the next. In the progression from the farmstead through industrial, the proximity of animals, the amount of handwork, and the scale of production all change. Animal presence decreases, handwork is replaced by machinery, and scale rises from community output measured in pounds to industrial output measured in tons. Similarly, regional and seasonal variation diminishes from the farmstead to the industrial and experimentation in process and finishing is wrung from the mechanized, industrial cheese.

Cheese is a more complex product than many other specialty goods because it is a "living thing." First, if not shipped correctly, the cheese may be destroyed. Second, many cheeses require aging, a component of the process to produce the cheese itself. Aging requires not only a controlled environment—correct temperature and humidity—but also an ecology that allows for the correct molds, such as *Geotrichum candidum* which gives the bloomy, white, skin of many notable French cheeses (*The Cheese Nun 2006*). Finally, the aging process may be coupled with a curing process. These curing processes can range from storing the cheese on cedar boughs, wrapping the cheese in grape or chestnut leaves, to washing the cheese in salt, beer, or liqueurs, and turning, brushing, wrapping, waxing or thumping. Part of the art of the cheesemonger is knowing when the cheese is at its perfect state for eating. The role of aging is so critical to preparing the cheese for market that its role has been formalized as *affinage*.

The cheese revival in America is of recent origin. There is some evidence of American artisan cheeses made prior to World War II, such as the New York State Poona, a type of Brie, along with the hard cheeses of Vermont, Wisconsin, and California (Roueche 1949). Following World War II, industrial food production accelerated, substituting notions of "nutrition" for food (Mintz 1996) and culminating in products such as General Foods' Tang or Pillsbury's Space Food Sticks, emblematic of a future world of food divorced from agriculture. The rise in interest in cheese has followed on the heels of the success of American wines. The development of traditional, agricultural markets seems to have been part of backlash against the futuristic Jetson lifestyle and the mechanization of life's pleasures that accompanies it (Ritzer 2004). This reaction has included the successes of microbreweries and the ongoing attempts to nurture profitable markets for artisan breads, heirloom vegetables, and specialty livestock (Honoré 2004).

The cheese making revival seems to have begun with goats in the late seventies in California with Laura Chennel (*Saveur 2005*). Cheese making has since incorporated other animals, especially cows—for "back to the farm" types who have rediscovered the need to exploit the added value of cheese making to complement selling milk (Sullivan 2005). Artisan cheesemakers are found in almost all states, with large concentrations in New England, especially Vermont, in the upper Midwest, and in California, notably north of San Francisco.

## LITERATURE REVIEW

An artisan cheese producer has four primary options for selling cheese: a retail outlet at the point of production, a farmers' market, a website, or a retail store owned by someone else. While specialty food retailers seem not to have been much studied, farmers' markets have.

Farmers' markets are a growing phenomenon in the US and elsewhere. In 2005 US consumers spent $1 billion shopping at 4,400 farmers' markets across the country (USDA 2006). In the UK, 30% of consumers report having shopped at a farmers' market (IGD 2002). Some (c.f., Hinrichs et al. 1998) have characterized this preference for local production as "Jeffersonian idealism," and argue that the perception of locally produced food being better, both ecologically and socially, is inaccurate (c.f., Born and Purcell 2006). Nevertheless, it is a growing movement.

While the original motivations for shopping at farmers' markets centered around price and food quality (Walton et al. 2002), today consumers purchase from farmers' markets for nutritional, social (Kalcik 1984), and personal reasons. Consumers seem to make the assumption that food sold at these markets is organic, that it has been raised in an agriculturally responsible manner, and therefore is better tasting and fresher than what they can purchase from a supermarket (Holloway and Kneafsey 2000; Lev and Stephenson 2001a, 2001b; Szmigin, Maddock and Carrigan 2003).

Social factors also come into play. Consumers report enjoying the interaction with producers and other consumers (Lev, Brewer and Stephenson 2003). They get to know the farmers and learn about how and where the food was produced. Consumers also interact with other consumers and may discover different uses for the produce (Archer et al. 2003). At the same time, consumers are acquiring stories about the food and about the producers that they can, in turn, tell to their families and friends (Greenberg 2006). These stories become part of the discourse and part of the consumption of the food stuffs. Finally, consumers come away from these interactions with their own positive feelings about supporting local producers (Youngs and Holden 2002). In all these ways, shopping at a farmers' market becomes a reflection of a consumer's own identity and an expression of one's values (Schaefer and Crane 2001).

Farmers' markets, however, tend to be a warm weather phenomenon. Because the products are fresh, the markets are inextricably tied to the agricultural cycles specific to a given region. There are some notable exceptions such as the Green Markets in New York City; but even there, the scope is much reduced in the colder months. Store-front retail outlets for artisan products, on the other hand, provide both producers and consumers a more permanent location. For producers, these retailers offer an opportunity to achieve wider exposure as well as assistance with the marketing efforts. For consumers, specialty retailers provide an outlet for satisfying the same set of needs and for having a similar set of experiences as otherwise provided by the farmers' markets. The primary difference is that instead of interacting with the producer of the products, the consumer is interacting with the retailer. The retailer, thus, becomes the surrogate for the farmer. And, in order to provide the desired experience, the retailer and the surrounding atmosphere must take on the critical elements of the farmers' market shopping experience, such as product quality and authenticity, product stories, social interactions and personal value affirmation. As noted in the introduction, the cheesemonger is a true intermediary as he or she mediates the exchange between the cheesemaker and the cheese consumer. Previous research suggests three ways in which the cheesemonger serves as a coach or trusted advisor.

First, the cheesemonger helps artisan cheese producers understand the realities of the market and also helps cheese consumers understand the realities of artisan production, such as seasonality. Goats, for example do not produce milk year-round; when cows are grazing in the pasture, their milk will take on a different color and flavor than in the winter when they are eating hay in the barn. The cheesemonger also works with cheesemakers to understand the importance of scale—in this case, of not over-producing and becoming too industrialized—and working with the cheese consumer to understand the value of variability in cheese—that variation from wheel to wheel is a desirable quality.

Second, the cheesemonger authenticates and guarantees the product (McCracken 2005). This is an important role, because artisan cheesemakers do not have the national marketing muscle of industrial cheese brands. Accordingly, cheese consumers need help in assessing the options: which ones are truly artisanal and which are counterfeit. In this way, the cheesemonger influences the "perceived genuineness" (Rose and Wood 2005) of the offerings. As Lewis and Bridger (2000) explain, "One cannot mass produce authenticity. Rather, it has to be introduced on an almost person-to-person basis, with individual needs, desires, expectations and interests being fully accounted for." (p. 198). In Beverland's work on perceived authenticity in high-end wines (2006), heritage and relationship to place were deemed strong indicators of products being the "real thing." A major role for the cheesemonger is to convey the pedigree and place of cheese for the consumer.

The claim of authenticity also requires trust. Morgan and Hunt (1994) advocated for the importance of trust in marketing relationships; the cheesemonger must likewise develop the trust of his/her customers. The consumer is no longer purchasing directly from the cheese producer, but rather from the producer's agent. The cheesemonger also takes on the traditional retail roles of assortment, merchandising, and the like. In performing each of these functions, s/he is making choices for the consumer and the consumer has to trust those decisions. Trust also comes into play when consumers try new and different cheeses at the monger's recommendation. The personal touch from a trusted advisor gives consumers the courage to try something new.

Third, the cheesemonger orchestrates the consumer's cheese experiences. Store décor, atmosphere, and layout, as well as the rituals between consumer and cheesemonger are all important. As Molotch (2003) explains, "The artistic–including the subtleties of detail–creates markets. …, the sensual makes people want things" (p. 62). Thus the way in which the cheeses are displayed and presented, the non-cheese products that also are offered, the signage, and even the store location all are critical elements under the cheesemonger's control. Creating the right setting enhances the consumer's willingness to try something new (King et al. 2007).

Further, artisan cheese is a high involvement product (Kupiec and Revell 2001) purchased by consumers who are on a quest for unique products and unique experiences (TASTE Council 2004) that help express their individuality (McCarthy, O'Reilly and Cronin 2001). At least initially, consumers are not familiar with the different artisan cheeses and depend on the cheesemonger and his/her staff for recommendations. Thus the level of individualized service also is an important component of the shopping experience.

Sampling is another important aspect of the cheese buying process (Reed 2003). Important, too, is the environment in which the sampling takes place: unhurried, friendly, low-pressure. Consumers are sampling not only the cheese itself but also the narratives about how and where the cheeses are made and by whom. This knowledge (about the maker, the process, and the origin of the cheese) leads to a perception of superior quality as well as to a higher level of satisfaction. Stefani, Romano and Cavicchi (2006) conclude that when consumers know the place or origin of food, they are willing to pay more for the product, but only if they can be assured that the product is authentic/genuine and that it is of high quality. The former attribute is provided by the cheesemonger and his/her retail store; the latter attribute is co-provided by the cheesemonger and customer via the rituals of tasting and storytelling.

These narratives and rituals also facilitate the movement of meaning from the cheese to the cheese consumer (McCracken 1991). As the cheesemonger tells stories about the cheese, s/he is transferring specialized knowledge to the consumer–who, in turn, may use this knowledge to convey insider status to friends and family via the retelling of the stories. The importance of telling the "cheese story" is an oft-repeated admonition in the literature about artisan cheese (c.f., Gloy and Stephenson 2006).

With these ideas as background, we set out to investigate further the cheese consumer-retailer interaction.

## METHODS

While the data gathering process was inextricably linked to the data analysis process, we have separated their respective descriptions for the readers' convenience.

### Data Gathering

Data gathering is ongoing for the project, but the data collection associated with this report took place from the fall of 2004

through early 2007. We began with a curiosity about why consumers would pay up to five times the price for this cheese versus more standard, mass-market cheeses (we observed that some cheeses approached $30 per pound). From there we quickly moved to a goal of developing expertise about artisan cheese making and consumption. Two of the authors had previously studied non-mass-market cheeses in France (Roberts and Micken 1996), so there was some initial familiarity with the category. We started this project by reading deeply from fictional and nonfictional accounts of high-end food sales and consumption, including regular food sections in newspapers (the *New York Times* Wednesday Food section, for example), specialty food trade publications, cheese-focused publications, and bulletins from state extension services. Then we began visiting and interviewing owners and managers of several cheese specialty stores in northeastern United States cities, including Boston, New York City, Philadelphia, and Providence. The visits included participant and nonparticipant observation of the buyer-seller interactions. We also took note of store layouts, décor, ambiance cues, staff, customer mix, and in particular, the cheeses (merchandise mix and merchandise layouts) offered for sale. If the stores had storage caves for *affinage*, or aging, we toured those.

Additionally, we also visited a prominent farmers' market in New York City, which featured ten artisan cheese vendors. We also visited several more casual summer markets that featured a number of regional producers. We visited and interviewed three cheesemakers onsite, two of whom had a small retail space as a part of their operations. We ate at cheese-themed restaurants and interviewed waiters and *maitre d's*. One of the authors attended a class on cheese and beer pairings. We videotaped many of these encounters, though not all of them. We took pictures of shops, consumers, retail staff, farm animals, the cheese making process, and the context of all things cheese as we made these data gathering visits. A prior paper reports our efforts at understanding online cheese retailers (Roberts, Micken and McKenzie 2006), and those findings informed this study as well. Less formally, we have become more self-conscious of our own cheese purchases and become more aware of cheese offerings in restaurants and in grocery stores.

Together, these exercises have yielded many hours of videotape, as well as some audio files, and several notebooks full of handwritten and word-processed field notes from our encounters. Additionally, we have a file full of artifacts, such as brand-imprinted serving napkins, business cards, cheese guidebooks purchased at the stores, and the like.

The following is a list of retailer settings we have analyzed for this study.

Data gathering trips to three artisan cheesemakers (Connecticut, Massachusetts, Utah), two of whom sold to consumers at their locations. Each of these visits lasted over two hours.

Data gathering trips to seven cheese specialty shops: Cambridge/Boston, NYC-3, Philadelphia-2, Providence, and Tiverton (RI). The Providence owner has become a "key informant," defined by Tremblay (1957, p 688) as one who is "interviewed intensively over an extensive period of time for the purpose of providing a relatively complete ethnographical description of the social and cultural patterns of their group." He has been nice enough to let us visit him on at least a half-dozen occasions. These shop trips have lasted from one-half hour to nearly three hours, depending on the investigational climate and the busyness of the store.

Data gathered at a cheese-pairing seminar.

Data gathered at two cheese-themed restaurants, including interviews of staff.

Data gathered at farmers' markets.

**Data Analysis**

Data gathering and analysis have been ongoing and iterative since the very beginning of the project. As the data set grew to include new types of data, or additional data of the same type, we incorporated that material into our understanding of artisan cheese. As one author would read something new or interesting related to expensive or interesting cheese or other foods, that reference was shared with the other authors. As our files grew fatter, we developed a working bibliography, with 31 pages of annotated entries. We took these early ideas with us as semi-structured questions to ask our first two retailer informants.

An early attempt at an empirical study was to content analyze a set of cheesemaker websites/online retailers published in *Saveur* magazine (2005). In that analysis, we employed traditional qualitative methods in addition to two computer programs (NVivo and Tinderbox), comparing and contrasting the results from the different analytical approaches. This yielded some early insight and competing models for how sellers make their cheeses more valuable, but did not help us with the consumer side of the equation.

As we delved more deeply into data about cheese consumption and marketing processes, and as the meanings in the data began to unfold, it occurred to us that the cheese retailer, and more particularly, the highly knowledgeable cheesemonger, holds the key to the mystique and the value of these artisan cheeses in the eyes and the wallets of the consumers. Our next round of analysis, then, included more data gathering specific to the model of the retailer as *cicerone*, or guide. In other words, our analysis led to another iteration–we sought to confirm an emerging model of the central role of the retailer/cheesemonger by conducting additional data gathering trips to retail outlets and through additional interviews. It is part of this data-derived model that we report on in the following sections.

## FINDINGS: CHEESEMONGER AS *CICERONE*

*Cicerone*: (ci·ce·ro·ne) 1 : a guide who conducts sightseers 2 : MENTOR, TUTOR *(Webster's American Dictionary)*.

The *Oxford English Dictionary* (2nd Edition, 1989) provides the following explanatory note for the origins of *cicerone*: "A guide who shows and explains the antiquities or curiosities of a place to strangers. (Apparently originally given to learned Italian antiquarians, whose services were sought by visitors seeking information about the antiquities of a place; subsequently usurped by the ordinary professional 'guide'.)"

Just as the oenophile learns the practices of the wine connoisseur's world with its swirl, sip, and spit activities, and its specialized vocabulary of "nose," "legs," or "mouth feel," and its heightened descriptions of "plumy," "oaky," or "undertones of cinnamon," the cheese aficionado inhabits a specialized world. The cheesemonger is often the guide to this world. This role is more crucial as a cheese provides more immediate gratification and it cannot be forgotten in one's basement with the expectation of reaching a peak some years in the future. What follows is a discussion of the many different examples of cheesemongers taking on the *cicerone* role that we encountered in the investigations and observations described in the Methods section above. We present these as our own "cheese narratives," and hope that the readers enjoy this tasting,

The leading cheese stores, at least in the Northeast, are located in traditional neighborhoods. They may have secondary stores in the more upscale, urban neighborhoods, as Murray's Cheese (NYC) has its Grand Central stand, DiBruno Brothers (Philadelphia) its Rittenhouse Square store, and Formaggio Kitchen, its South Boston expansion. The original stores, Murray's on the edge of Greenwhich Village, DiBrunos in the Italian Market, and Formaggio in Cambridge, are located in areas where many older families still live. Rent control in New York allows the remaining members of the World War II generation to continue to shop for their familiar items. The triple deckers and two family residences surrounding Formaggio allow the academic community walking access to the store. Even though Farmstead, in Providence, is a more recently founded store, it is located in a traditional shopping area, close by a residential apartment complex for the elderly. Farmstead still caters to the customer who comes once a week for "a half-pound of Black Diamond" (Cheddar) that she has purchased weekly in the neighborhood prior to Farmstead's replacing the previous "Cheese Shop," a store that stocked English food stuffs.

The significant departure from store bought cheeses is that artisan cheese shops will always cut cheese to order. While there might be some prewrapped smaller sections of a cheese, unless the cheese is a small wheel and the wrapping is integral to the cheese, the cheese buyer is never dissuaded from requesting a slice from a larger wheel. Many cheese shops will also wrap the fresh cut cheese for purchase in a more natural wrapping, such as butcher paper or waxed paper, rather than plastic. This is explained by the cheese needing to breathe; a plastic wrap suffocates the cheese. The cheese is also almost always cut as a single piece, with slices being rare, although some of the Wisconsin and Pennsylvania cheeses from square molds may be sliced.

A primary practice of cheese lovers is tasting cheese prior to a purchase. This is the cheese equivalent of wine tasting at a vineyard. To outsiders, it appears to be a ritual of the buying process. To the initiated, however, it is central to the experience. Unlike wine, where consistency from one bottle to the next of the same vintage is expected, cheeses by artisan manufacturers can vary from wheel to wheel. For many, this variation is celebrated because it often reflects the season of production, with the summer cheeses having a richer color and more grassy flavor for example. With some cheese, especially those with mixed milk of cows, goats, and sheep, the cheese will vary by the production cycles of the ruminant being milked. Tasting a cheese is so essential, that *Saveur* (April 2005, p. 75) notes: "Signs of a Good Cheese Shop #2–You can sample cheeses before you buy them."

Tasting cheese follows a similar pattern in most cheese shops. A small slice of cheese is presented on a knife or piece of paper. Sometimes, the cheesemonger will share in the tasting, remarking on the flavors. It is also not unusual for a tasting to be offered to another customer at the same time, although that is less frequent in the larger stores. One cheese store has a variation on the tasting presentation where the cheese is scrubbed with a dull knife, like a butter knife, to draw up a small ball on the knife end, which is then scraped against the buyer's finger. This process warms the cheese, thereby enhancing its flavors. It also increases the intimacy with the cheesemonger because the cheesemonger in this instance comes from behind the counter, bearing the wheel of cheese, and displays it more fully than if the consumer were watching the process from across a countertop.

Tasting a cheese usually involves a conversation with the cheesemonger. This is the chance for the cheesemonger to guide the buyer. (As one cheesemonger said, "You have to help people learn to love the things you love.") S/He may suggest a more pungent cheese, or a cheese with a different finish. The conversation may also develop into the expected uses for the cheese, either as a cheese board for a dinner, with different recommendations to follow a beef dinner as opposed to something lighter. Increasingly, cheesemongers are recommending accompaniments for the cheese itself, beyond wines or beers. Formaggio Kitchen is noted as much for its *confettura*, *mostarda* and *cotognata* which are different fruit based jams or paste condiments for cheese. A regional cheese maker has specifically marketed its cheese in combination with regional condiments and suggested means to serve and present the cheese.

The cheese cutting process is in full view of the customer. If one tastes the cheese, and approves, one generally purchases from the wheel one has tasted. Like the cheese tasting, cutting the cheese is often a collaboration between the purchaser and the cheesemonger. Commonly, the knife is laid against the cheese, with words "Is that it?" so that the purchaser approves the quantity.

While the cheese purchasing process develops as a conversation between the cheesemonger and the buyer, the cheese buyer's interactions with the cheesemonger begin prior to approaching the counter. The tradition in New England seems to be to present the "cheese wall" (see Figure 1). This is an edifice of cheese built on top of the cooler cases where other cheeses are kept. The cheese wall can extend well above the heads of the counter staff, obscuring them from direct view. The cheese wall not only allows more cheese to be displayed, but allows the harder cheeses to stay closer to room temperature, the better to judge them in a tasting.

The dizzying heights of some cheese walls does not end with the cheese itself, but is often surmounted by identifying tags. Unlike the simple tags of a botanical garden that would list a common name and Latin specification, these cards are stories in themselves. Most often, they are handwritten, sometimes ornamented with little sketches or perhaps a flag (see Figure 2). The text usually names the cheese, describes a more familiar family of cheeses, then identifies the cheese uniquely, often employing story-like vignettes that tell of the cheesemaker and his/her methods. Usually only the cheesemonger or a trusted employee is allowed to write these tags. Our key informant told us that, "I still do most of the signs. I'm kinda anal about this. I want to keep the hand-crafted look."

## DISCUSSION

Consumers can now draw upon a dizzying range of considerations, as ethical, ecological and health issues are brought to bear upon product choices. Is this product safe? How was it produced, and who by? And, of course, these questions complicate a more fundamental one–what does buying this say about me? Signifiers of social status and personal identity are more complex and nuanced ... and more almost universally considered in everyday consumption (Willmott and Nelson 2005, p. 105).

In the end, it is clear that the cheesemonger, in explaining the processes, characteristics, and potential uses of specialized cheeses, is performing an essential function for both the cheese producer and the cheese consumer. The cheesemonger's *cicerone* role is an especially important one in an economy teeming with choices and in a society of consumers seeking to fulfill not only functional needs but hedonic ones as well. The cheesemonger and his/her shop are repositories of specialized information and stories that seem ideally suited for twenty-first century "foodies," who tend to be both variety seekers and information junkies (Becker and Wright 2006). The telling of cheese stories accompanied by personalized tasting rituals conducted by the trusted cheesemonger in a carefully staged setting combine to make the cheese buying experience nigh irresistible to the consumer.

There is an interesting parallel in another specialty agricultural product: wine. Oenophiles have publications such as the *Wine Enthusiast* and critics such as Robert M. Parker, Jr. (and his own

FIGURE 1

FIGURE 2

newsletter the *Wine Advocate*) to serve as guides. Parker has been particularly influential. His role has been to demystify wine for a public unsure of trusting their local liquor salesman or other writers suspected of being industry insiders. Through telling stories about vintners and their wineries and by providing his own opinions, he has influenced wine preferences and production on a global scale. In fact, his ratings are now suspected of driving the wine industry to adapt their products to match his palate (McCoy 2006). The cheesemonger, who operates on a much smaller scale with a more fragile product, provides a similar mediating role between the consumer and producer. The cheesemonger explains the cheese to the consumer and the provides consumer's response to the cheesemaker, possibly influencing future production.

McCracken (2005) suggests that marketers are just beginning to understand the full extent of the retailer's role in making meaning. Perhaps the close relationship between the cheese producer and the cheesemonger as well as the cheesemonger's role as *cicerone*–guide, raconteur, and authenticator–may make for an analytical scheme that helps uncover the ways in which consumer-retailer interactions co-create meaning in other specialty food areas as well. Understanding the deeper relationship between the retailer and the producer and the feedback loop may also help uncover the growth of the network around artisanal and authentic foodstuffs.

# Drunk and (Dis) Orderly: The Role of Alcohol in Supporting Liminality

Emma N. Banister, Lancaster University, UK
Maria G. Piacenitini, Lancaster University, UK

## ABSTRACT

This paper examines the use of alcohol consumption to provide support for students during transitions at a key liminal stage. We explore some of the positive experiences and rituals surrounding alcohol consumption via student-led focus groups. Our findings suggest that this extended period of liminality is often experienced positively, lending students 'permission' to behave in ways they might otherwise consider unacceptable. Liminality helps us to understand this context of students 'betwixt and between' different important life stages, whereby alcohol assumes an important facilitating role enabling them to play with their identity.

## INTRODUCTION

This paper examines the use of alcohol consumption by young people to provide support during transitions at a key liminal stage. We explore some of the positive experiences and outcomes that young people associate with alcohol, seeking to understand why many younger consumers continue to drink heavily, despite widespread publicity regarding the detrimental effects of alcohol consumption. Specifically we examine the rituals that surround the consumption of alcohol, to help forge an understanding of young peoples' relationship with alcohol. After some initial background and a review of the literature we develop our conceptualization, which focuses on alcohol's role in supporting the liminal transition experienced by higher education students.

## BACKGROUND

Excessive alcohol consumption, or 'binge drinking' is identified as a worrying trend in Britain (Plant and Plant, 2006), and the tendency to drink excessively is an accepted (and even expected) norm within student culture in some parts of the world (see for example Webb et al 1996 and Piacentini and Banister, 2006; [UK]; Wechsler et al 1994 and Treise et al, 1999 [US]). A plethora of studies have considered the circumstances around, and motivations for, excessive alcohol consumption. These studies tend to focus on two distinct sets of motivations driving alcohol consumption. Firstly, the extent to which alcohol facilitates socialization and enjoyment, particularly for young people (Darian, 1993; Lui and Kaplan, 1996; Pavis et al., 1997) and the contribution of rituals to these social effects (Beccaria and Sande 2003). Secondly, studies focus on the personal benefits associated with drinking, such as asserting gender identity, mood alteration, coping with personal problems, dealing with stress and relieving boredom (Darian, 1993; Lui and Kaplan, 1996; Pavis et al., 1997; Thom and Francome, 2001). A recent focus has been the attempt to more successfully 'enter' the social worlds of young people and students and identify the role that alcohol plays in constructing these social worlds (see for example Treise et al., 1999; Measham, 2004a; Banister and Piacentini, 2006).

Our study focuses on the alcohol consumption of Higher Education students. As part of our effort to identify why alcohol consumption is so high within this group, and is perceived as playing such a significant role in the student experience, we seek to identify what it is about the Higher Education experience (in the UK) that makes it a different, even unique, life stage. Taking our starting point from Noble and Walker (1997) who explored the liminal experience of the transition from high school to college, and

the facilitating role of symbolic consumption, we argue that university undergraduate students occupy an ambiguous transitional position. This paper focuses on the role that alcohol (and its surrounding rituals) plays in supporting this position/transition and experience.

## CONCEPTUAL FOUNDATIONS

### Transitions to early adulthood

According to George (1993: 360), entry to early adulthood is characterized by the three key transitions of: leaving school, first full-time job and first marriage/establishing a family. For students, the exit transition represented by 'leaving school' often accompanies the entry role of 'becoming a student', the corollary of which, for many, is leaving the parental or family home.[1] 'Becoming a student' is therefore a point at which many assume the responsibilities associated with setting up their own home. In addition, most arrive at university aged 18, and are legally adults, with rights to vote, drink alcohol, have sex and smoke cigarettes.

Although many young people experience a similar transitional period of being neither viewed by society as a child nor regarded as a fully-fledged adult (Arnett, 2007), it can be argued that the Higher Education system elongates this transitional period. Students experience the 'freedoms' of adulthood yet within a protected environment, receiving guidance from more experienced adults as authority figures (such as university housing and administrative staff). Societal and cultural expectations about student life compound this effect, where students play to expectations about typical student behavior (Banister and Piacentini, 2006). The position of students is ambiguous, they occupy a space 'betwixt and between' childhood and adulthood. Although transitions are by definition discrete and bounded in duration (George 1993, p.358), this paper will develop the point that many students see this time as an elongated liminal period of 'delayed adulthood', and alcohol assumes a key role.

### Alcohol consumption as ritualistic behavior

Past research identifies the extent to which drinking alcohol can be located as a ritualistic behavior. Rook (1985) identifies four ritual components that are normally associated with rituals and Treise et al (1999) apply these to the context of alcohol consumption, as follows: "Drinking requires an artifact (the alcohol itself), a script (rules about who can and cannot drink legally, when and where the drinking will occur, agreements about transportation to and from the places where drinking occurs), a performance role (how to drink, how many drinks to consume, how to behave while drinking), and an audience (peers, bartenders, campus personnel)" (p. 19). Breaking down rituals into their component parts can encourage a broader view of the consumption of alcohol, a view that incorporates an exploration of the behaviors and contexts that accompany its consumption.

Another approach to understanding rituals is provided by Driver (1991), who views rituals as 'social gifts', serving three main

---

[1] In the UK, many UG students choose to live away from the family home, and for the vast majority this is the first time they have done so.

functions. Firstly, Driver sees *reinforcement* and in some cases the *creation* of social order as one of the more obvious functions of rituals. He suggests rituals function as a means by which to mark times and spaces, symbolizing realities, to represent a structured world. In the context of alcohol, Measham (2004a, p.319) describes "calculated hedonism" as operating within the boundaries of time (typically the weekend), space (club, bar etc), company (supportive friends) and intensity. Banister and Piacentini (2006) argue these boundaries become temporarily blurred or alternative in the case of Higher Education students. Students have different requirements on their time (which cannot be as neatly compartmentalized as for many other sectors of the population), a range of (social) spaces specifically targeting their leisure time (mostly involving alcohol), and are surrounded by other young people.

The other aspect to the provision of order is in a more utilitarian or factitive way, whereby the product (in this case alcohol) can cause things to happen, representing "leisure time out" (Measham and Brain 2005, p.267) from the busy lives of modern day consumers, essentially a "controlled loss of control" (Measham 2004b, p.338). In contrast to any potential ordering functions of rituals, Driver (1991) argues that rituals can also have an opposite effect in that they can *disorder* and refashion the way in which life is lived. For university students, a significant proportion of their time is very structured and ordered around academic and, increasingly, part time paid work. In contrast, their 'own' time perhaps allows them the opportunity to lead more disordered lives, representing a break from the norm, and this is where alcohol could play an important role.

The second social gift Driver suggests draws on Turner's (1969) work on communitas and liminality. He develops the theme that rituals are important for the experience of community. In the student context, liminality is characterized by destructuring in relation to what Turner calls the social structure. So, while ritualized liminality structures are employed, they are different from the usual structures of society and "are often utilized to emphasize homogeneity, equality, anonymity and foolishness" providing an alternative sense of social order, resulting in 'disordered order'. The third social gift identified by Driver is that of transformation which assists in the dynamic of social change through the ritual processes of transformation. Alcohol clearly has an innate transformative power (you may get drunk) but it also offers a mechanism or opportunity for change. The transformative power of rituals, the idea of changing 'states' and the extent to which the enactment of rituals can place participants in new social situations, is central to our understanding of students' alcohol consumption.

Tucker (2005) further argues that traditionally the ritual of alcohol consumption served to establish social order in a community, via the symbolic meanings associated with pubs and alcohol and associated culturally approved patterns of behavior. However, the contemporary "unrestrained drinking" of the type primarily associated with the young does not fit well with this model, Tucker (2005) instead suggests a ritual model based on liminality as more appropriate. Liminality, in the sense of freedom from 'normal codes of behavior', is fitting from both the consumer (student) side but also from the industry angle in terms of the style of drinking it facilitates. The liminal drinking place is valued as an escape; its very attraction is its position as *"an escape from the pressures and constraints of normal life"* (Tucker 2005: 11).

**Conceptualization: Alcohol's role in supporting students in liminal transition**

Our conceptualization draws on Van Gennep's (1960 [1909]) framework of rites of passage, involving three stages: separation; transition (liminal period); and aggregation or (re)incorporation. We focus on the liminal phase, where individuals find themselves between two different role statuses, but not firmly grounded in either; that is, they are "betwixt and between stages" (Van Gennep 1960) and their identity is suspended. At such times, consumers undergo intense experiences with different norms and characteristics from their regular (prior) pattern of social organization, often creating personal rites of passage facilitating the transformation to their new concept of self. The liminal period is therefore characterized by role ambiguity whilst individuals attempt to refashion themselves into new roles.

Noble and Walker (1997) examine the transition from high school to college student and develop a framework which provides a useful organizing structure for our context (see Figure 1). According to Noble and Walker (1997), the liminal transition begins with the separation stage, triggered by some external event, and resulting in detachment from a prior role. Following this, the person enters an ambiguous stage where they begin the search for a new self or new role. Finally, the tension between old and new roles becomes reduced and the person settles into a state of improved well-being. Noble and Walker (1997) identify the way in which symbolic forms of consumption support the process of change and the relative emerging stability.

The concept of liminal transitions has already been successfully applied to an alcohol consumption setting. Research in social anthropology focuses on the role of alcohol (and intoxication) in the Norwegian Russefeiring celebration, a 17-day transition ritual marking the passage from high school student to adulthood (Sande 2002). Developing this further, Beccaria and Sande (2003) suggest that alcohol and intoxication can reflect a separation from previous identity, social structures and categories: "An intoxicated person is a liminal person in the process of transformation and transition outside the normal order of the society" (p.102). Building on these Norwegian studies it can be argued that alcohol can be relevant throughout what is a fairly long and drawn out period as young people take on a new, yet temporary, position (studenthood) on their path to 'adulthood proper'. We can call this period of transition 'delayed adulthood', with liminality marking *separation* from the old role (school student) and the assumption of a new temporary role (studenthood), which exists outside the 'normal order of society' (see Figure 1). We therefore argue that during this *prolonged* period of liminality (cf. Sande 2002), many university students use alcohol as a principle means by which to detach from their old role (as school pupil). Studenthood itself represents a period of liminality, with students occupying an ambiguous phase–'betwixt and between' childhood and adulthood. For many students, their final year of study marks the onset of preparations for aggregation (reflecting 'adulthood proper') as their lives become increasingly focused on academic and career goals.

## RESEARCH DESIGN

Our research was based in a campus university in the North West of England. We employed researchers from the students' immediate peer group in order to get closer to their culture, and to minimize the effect of academic researchers being experienced as authority figures, a particular issue for this research given the central issue of 'delayed adulthood'. Five undergraduate second year student researchers were recruited on the basis of their competence on a marketing research module. Second year student researchers were recruited, specifically, as they themselves are in the midst of the liminal period (in contrast with first years who are perhaps still experiencing separation and final year students moving towards aggregation).

All participants were second year undergraduates except where indicated (i.e. 1 student).

The student researchers were invited to a training session, where an iterative approach (initiated by the authors but involving the students) was employed to design the focus group guide. The student researchers were asked to recruit participants from their friendship groups for a discussion about alcohol consumption and students' social lives whilst at university. Selection was solely on the basis of friendship groups, irrespective of gender, age or alcohol behavior. The discussions lasted between 1 and 1.5 hours. The researchers received a payment for their part in the research (including transcription costs). Consent forms were issued and retained by our researchers in order to grant anonymity to participants. Participants' names were changed within the transcripts. Table 1 provides key participant information.

Our student-led focus groups undoubtedly broadened the scope of our findings—i.e. with discussion of subject matter that might otherwise be considered illicit and unwise to discuss with academic staff. However, there were limitations associated with this method of data collection and recruitment for the study. Firstly while our student researchers collected data that was ultimately deemed useful, there were times when a more experienced re-

searcher could (and would) have delved deeper into certain issues. Our researchers did not always possess the relevant techniques or were not always as familiar with the (potential) research foci to fully appreciate the importance of some lines of discussion. In addition we should identify the possible negative effects of the method of recruitment–the student researchers' friendship groups. Again this was likely to widen the scope of findings in the sense that the context would have seemed more natural and therefore conducive to discussion. However, any situation like this—and in particular when participants are 'known' to each other—introduces the likelihood of elements of social desirability. At times the moderator (i.e. the student researcher) provided a check on this, but it is clear that this would also have affected the quality of the data.

The data was analyzed inductively, by the two academic researchers, through a process of initially reading and rereading all the transcripts. Our starting point was to attempt understanding of what it was about the student context that encouraged high levels of alcohol consumption. Despite this primarily inductive approach our analysis was also, of course, informed by academic literature with which we were familiar. The two authors independently

identified the key themes and patterns, which emerged from the data. Insights were then compared and alternative explanations sought, and these informed the development of our conceptualization, as well as the more detailed discussion that follows.

## FINDINGS

The concept of liminality as an overall (dis)organizing structure, as presented in Figure 1, provides the starting point for the presentation of our findings. Our empirical data highlights the extent to which alcohol consumption and the associated intoxication can provide a means for students to assume and cement their new student role and attain the social and psychological benefits that alcohol consumption can bring (as described in Darian 1993; Pavis et al 1997; Webb et al 1996). Alcohol consumption provides many of our participants with a means to accept and revel in the ambiguity associated with their position as students or 'delayed adults'. Central to this is the implicit understanding that engaging in excessive alcohol consumption is a temporary state, which will necessarily end on reaching 'adulthood proper' with the assumption of additional responsibilities this entails. Our overall finding is therefore in keeping with previous research-that alcohol functions as a tool of social facilitation for young people (e.g. Pavis et al 1997; Webb et al 1996). However, through gaining a more refined understanding of the unique context in which young people find themselves, we develop analysis themes that facilitate understanding of why this is so, and in turn explain why it has been so difficult for parents, teachers, government, health and support workers to suggest alternative means of social facilitation to discourage the excessive consumption of alcohol.

### Liminality–betwixt and between…. delayed adulthood

Our first theme focuses on the concept of liminality itself. Students occupy a unique position as 'betwixt and between' childhood and adulthood, reflecting a status which we suggest represents a form of delayed adulthood. While being allowed a degree of autonomy, students still exist within a context where considerable authority is exerted by 'adults' (lecturers, university support staff, porters, landlords etc). Students are expected to conform to certain ideals—attending lectures, submitting coursework, performing at an 'acceptable' level in their studies—and behave in a manner that fits with the organizing structure. The two sides to university life are identified by Vicky, *"I think uni is split into two, you have your friends and stuff and you have your academic stuff."* This immediately suggests a dual purpose of university that is widely held, this sense that you go to university to be educated and to achieve a degree but that it also serves a very important social function: *"your friends and stuff"*.

Participants recognize their unique 'not yet adult' status and there is very much a feeling of the need to make the most of it–to enjoy what is left of their youth. Much discussion suggests that heavy drinking will cease once students graduate and leave university (aggregation), with one participant even referring to his liminal status.

> *Dennis: When I grow up I know I won't be [drinking heavily], uni is the time now for me to be drinking*
> *Suzy: I think it's an important part of uni.*
> *Melanie: And I'm sure we'll slow down when we are older*
> *Penny: I don't know, to me drinking is an important part of uni but I think when I'm older it will be just as important.*
> *Rick: Yeah! I think so too…*
> *Penny: I can't see myself going out and getting drunk.*
> *Suzy: It's expected of you almost at uni. You are expected to be drunk!*

Here Penny and Rick disagree with the original suggestion that alcohol consumption will slow down with age. (Penny: *"…when I'm older it will be just as important"*). However, she then backtracks slightly suggesting that although she will drink, the role of alcohol will have changed considerably. Many of our participants in other discussions suggest that on leaving university they will be more likely to drink alcohol in the manner of their parents–for example with meals and in lesser quantities. This suggests that they consider the responsibilities of university (e.g. developing their academic knowledge and perhaps a part time job) can be more easily combined with alcohol consumption than the demands of a full time *career* job, which they hope for post-university.

We find that alcohol provides a means for students to 'let off steam' and demonstrate the autonomy they enjoy once they leave the confines of the lecture theatre, i.e. with alcohol effectively marking time and (social) space (Driver 1991). At its most obvious, this is demonstrated by a wish to get as drunk as possible. On the occasions our participants drink alcohol, it is usually with the sole intention of getting drunk.

> *Justin: I don't see the point personally of going out and [only] having a couple of drinks*
> *Ryan: Yeah, see all or nothing*
> *Justin: Yeah I wouldn't go out and have two or three pints and come home and go to bed*

This *"all or nothing"* type attitude is common amongst our participants. The sense is given that having just a few drinks is a 'waste' you wouldn't have achieved anything (i.e. got drunk or achieved liminality in the sense discussed by Beccaria and Sande 2003) so why would you bother to drink at all. This could partly be explained by the extent to which cost is clearly a consideration for our participants. Limited financial resources is not a characteristic unique to students in Higher Education but it marks them out from many other young people living away from home. Participants continuously discuss the cost of drinks, and the challenge seems to be that of maximizing expenditure in order to achieve the 'best' result. This represents a kind of cost-benefit analysis, where limited funds are used to achieve the best tangible results (drunkenness). The units per bottle are used not to moderate drinking but to help our participants achieve their 'purpose' of getting drunk. Some participants went as far as to remark that if intoxication is not the aim, there is little point in drinking anything.

> *Rhys: If you don't want to drink, then you shouldn't drink at all. If you think about it, you go into a pub, you drink three pints, that's six quid on average, and unless you're Ben, three pints isn't going to get you pissed, so there's no point in drinking. Then you just need a wee….*

Our participants use (excessive) alcohol consumption to build ties within their own particular communitas, which consist of other undergraduate students. This contrasts with Noble and Walker's (1996) findings whereby symbolic possessions fill the void of communitas as opposed to helping create and develop them. At the same time, excessive alcohol consumption serves to build, maintain and accentuate students' separateness from other populations, for example older people or other young non-student adults.

### Alcohol rituals to support liminality

It is our intention to locate our participants' drinking behavior within their own shared-culture. It might be more accurate to speak of shared culture*s* as it became evident that each (focus) group of friends has their own key ritual scripts and performances that

involve alcohol. For some, these provide rites of passage, marking entrance (initiation) into particular friendship groups. These ritualistic activities were sometimes explained 'to the tape', recognition of the need to offer explanations of their behavior and rituals to outsiders of the group. This demonstrates the extent to which our participants (including the student researchers) see themselves as a somewhat exclusive group, utilizing unique practices and rituals, which could be unfamiliar to 'outsiders' of their sub-group within the student culture

For many of these rituals, alcohol provides the key ritual artifact as Treise et al, (1999) suggest-particularly in the case of drinking games and initiation rituals. However, in other cases alcohol provides an organizing ritual in the sense that without alcohol there would be no ritual, but it is certainly not an end in itself, a point that we shall return to. Ritualistic drinking games are discussed whereby the forfeit typically involves drinking copious amounts of alcohol. Sometimes this would revolve around a particular drink, such as absinthe (because of its very high alcohol content), or a mixture of sprits:

> Rhys: ... a 'dirty pint' is where you have a pint full of spirits. Think about downing a pint of spirits, you aren't going to be well afterwards.
> Harry: The alcohol is worth about £25. Literally you've got to accept that you will be sick when you do a dirty pint. You drink it, raise your glass to the crowd then go to the bathroom and then just vomit like a bastard

Other participants discuss 'initiation' practices that are specific to their social group.

> Brian: We were playing a drinking game of darts and it involved pretty much everyone every few minutes downing either a shot of absinthe or whisky. And we were drinking beer at the same time. We drank a lot. And a few days afterwards my head felt genuinely not right, I was genuinely worried and other people that were there said the same thing. For a few days my head really wasn't in the right place

The discussions suggest these practices to be a fairly masculine activity. While the female members of the groups seem to be knowledgeable about the particulars of these practices, they do not acknowledge participating. It seems these rituals are something to participate in and endure, but not necessarily something to enjoy. One of our groups revealed they had built a piece of equipment (the Beer Bong) and written a song, which were key artifacts for their ritual practices, adding to the mystique associated with the ritual (and also perhaps the separateness it helped achieve). These particular rituals not only set friendship groups apart from non-students but also apart from other students who are not part of the group and therefore not party to these particular rituals. For these activities, alcohol is clearly an essential element–without the alcohol there would be no ritual.

> Carl: What kind of part does alcohol usually play in these types of situations?
> Ryan: Erm every part really
> Justin: Yeah
> Dennis: It is the part (laughs)
